Advanced Load Management
Controlled Load Switch with Low R_{ON}

The NCP4552x series of load switches provide a component and area-reducing solution for efficient power domain switching with inrush current limit via soft start. In addition to integrated control functionality with ultra low on−resistance, these devices offer system safeguards and monitoring via fault protection and power good signaling. This cost effective solution is ideal for power management and hot-swap applications requiring low power consumption in a small footprint.

Features

- Advanced Controller with Charge Pump
- Integrated N-Channel MOSFET with Low R_{ON}
- Input Voltage Range 0.5 V to 13.5 V
- Soft-Start via Controlled Slew Rate
- Adjustable Slew Rate Control (NCP45521)
- Power Good Signal (NCP45520)
- Thermal Shutdown
- Undervoltage Lockout
- Short-Circuit Protection
- Extremely Low Standby Current
- Load Bleed (Quick Discharge)
- This is a Pb−Free Device

Typical Applications

- Portable Electronics and Systems
- Notebook and Tablet Computers
- Telecom, Networking, Medical, and Industrial Equipment
- Set−Top Boxes, Servers, and Gateways
- Hot Swap Devices and Peripheral Ports

Table 1. PIN DESCRIPTION

Pin	Name	Function
1, 9	V_{IN}	Drain of MOSFET (0.5 V – 13.5 V), Pin 1 must be connected to Pin 9
2	EN	NCP45520−H & NCP45521−H – Active−high digital input used to turn on the MOSFET, pin has an internal pull down resistor to GND
		NCP45520−L & NCP45521−L – Active−low digital input used to turn on the MOSFET, pin has an internal pull up resistor to V_{CC}
3	V_{CC}	Supply voltage to controller (3.0 V – 5.5 V)
4	GND	Controller ground
5	BLEED	Load bleed connection, must be tied to V_{OUT} either directly or through a resistor ≤ 1 kΩ
6	PG	NCP45520 – Active−high, open−drain output that indicates when the gate of the MOSFET is fully charged, external pull up resistor ≥ 1 kΩ to an external voltage source required; tie to GND if not used
	SR	NCP45521 – Slew rate adjustment; float if not used
7, 8	V_{OUT}	Source of MOSFET connected to load

Stresses exceeding Maximum Ratings may damage the device. Maximum Ratings are stress ratings only. Functional operation above the Recommended Operating Conditions is not implied. Extended exposure to stresses above the Recommended Operating Conditions may affect device reliability.

1. NCP45520 only. PG is an open−drain output that requires an external pull up resistor ≥ 1 kΩ to an external voltage source.
2. Surface−mounted on FR4 board using 1 sq−in pad, 1 oz Cu.
3. Surface−mounted on FR4 board using the minimum recommended pad size, 1 oz Cu.
4. Ensure that the expected operating MOSFET current will not cause the Short−Circuit Protection to turn the MOSFET off undesirably.
5. Tested by the following methods @ T_A = 25°C:
   ESD Human Body Model tested per JESD22−A114
   ESD Machine Model tested per JESD22−A115
   ESD Charged Device Model tested per JESD22−C101
   Latch−up Current tested per JESD78
6. Rating is for all pins except for V_{IN} and V_{OUT} which are tied to the internal MOSFET's Drain and Source. Typical MOSFET ESD performance for V_{IN} and V_{OUT} should be expected and these devices should be treated as ESD sensitive.

APPLICATIONS INFORMATION

Enable Control

Both the NCP45520 and the NCP45521 have two part numbers, NCP4552x-H and NCP4552x-L, that only differ in the polarity of the enable control.

The NCP4552x-H devices allow for enabling the MOSFET in an active-high configuration. When the V_{CC} supply pin has an adequate voltage applied and the EN pin is at a logic high level, the MOSFET will be enabled. Similarly, when the EN pin is at a logic low level, the MOSFET will be disabled. An internal pull down resistor to ground on the EN pin ensures that the MOSFET will be disabled when not being driven.

The NCP4552x-L devices allow for enabling the MOSFET in an active-low configuration. When the V_{CC} supply pin has an adequate voltage applied and the EN pin is at a logic low level, the MOSFET will be enabled. Similarly, when the EN pin is at a logic high level, the MOSFET will be disabled. An internal pull up resistor to V_{CC} on the EN pin ensures that the MOSFET will be disabled when not being driven.

Power Sequencing

The NCP4552x devices will function with any power sequence, but the output turn−on delay performance may vary from what is specified. To achieve the specified performance, there are two recommended power sequences:

1) $V_{CC} \rightarrow V_{IN} \rightarrow V_{EN}$
2) $V_{IN} \rightarrow V_{CC} \rightarrow V_{EN}$

Load Bleed (Quick Discharge)

The NCP4552x devices have an internal bleed resistor, R_{BLEED}, which is used to bleed the charge off of the load to ground after the MOSFET has been disabled. In series with the bleed resistor is a bleed switch that is enabled whenever the MOSFET is disabled. The MOSFET and the bleed switch are never concurrently active.

It is required that the BLEED pin be connected to V_{OUT} either directly (as shown in Figures 4 and 7) or through an external resistor, R_{EXT} (as shown in Figures 3 and 6). R_{EXT} should not exceed 1 kΩ and can be used to increase the total bleed resistance.

Care must be taken to ensure that the power dissipated across R_{BLEED} is kept at a safe level. R_{EXT} can be used to decrease the amount of power dissipated across R_{BLEED}.

Power Good

The NCP45520 devices have a power good output (PG) that can be used to indicate when the gate of the MOSFET is fully charged. The PG pin is an active-high, open-drain output that requires an external pull up resistor, R_{PG}, greater than or equal to 1 kΩ to an external voltage source, V_{TERM}, that is compatible with input levels of all devices connected to this pin (as shown in Figures 3 and 4).

The power good output can be used as the enable signal for other active−high devices in the system (as shown in Figure 5). This allows for guaranteed by design power sequencing and reduces the number of enable signals needed from the system controller. If the power good feature is not used in the application, the PG pin should be tied to GND.

Slew Rate Control

The NCP4552x devices are equipped with controlled output slew rate which provides soft start functionality. This limits the inrush current caused by capacitor charging and enables these devices to be used in hot swap applications.

The slew rate of the NCP45521 can be decreased with an external capacitor added between the SR pin and ground (as shown in Figures 6 and 7). With an external capacitor present, the slew rate can be determined by the following equation:

$$\text{Slew Rate} = \frac{K_{SR}}{C_{SR}} \text{ [V/s]} \qquad \text{(eq. 1)}$$

where K_{SR} is the specified slew rate control constant, found in Table 4, and C_{SR} is the slew rate control capacitor added between the SR pin and ground. The slew rate of the device will always be the lower of the default slew rate and the adjusted slew rate. Therefore, if the C_{SR} is not large enough to decrease the slew rate more than the specified default value, the slew rate of the device will be the default value. The SR pin can be left floating if the slew rate does not need to be decreased.

Short−Circuit Protection

The NCP4552x devices are equipped with short−circuit protection that is used to help protect the part and the system from a sudden high−current event, such as the output, V_{OUT}, being shorted to ground. This circuitry is only active when the gate of the MOSFET is fully charged.

Once active, the circuitry monitors the difference in the voltage on the V_{IN} pin and the voltage on the BLEED pin. In order for the V_{OUT} voltage to be monitored through the BLEED pin, it is required that the BLEED pin be connected to V_{OUT} either directly (as shown in Figures 4 and 7) or through a resistor, R_{EXT} (as shown in Figures 3 and 6), which should not exceed 1 kΩ. With the BLEED pin connected to V_{OUT}, the short−circuit protection is able to monitor the voltage drop across the MOSFET.

If the voltage drop across the MOSFET is greater than or equal to the short−circuit protection threshold voltage, the MOSFET is immediately turned off and the load bleed is activated. The part remains latched in this off state until EN is toggled or V_{CC} supply voltage is cycled, at which point the MOSFET will be turned on in a controlled fashion with the normal output turn−on delay and slew rate. The current through the MOSFET that will cause a short−circuit event can be calculated by dividing the short−circuit protection threshold by the expected on−resistance of the MOSFET.

Thermal Shutdown

The thermal shutdown of the NCP4552x devices protects the part from internally or externally generated excessive

temperatures. This circuitry is disabled when EN is not active to reduce standby current. When an over-temperature condition is detected, the MOSFET is immediately turned off and the load bleed is activated.

The part comes out of thermal shutdown when the junction temperature decreases to a safe operating temperature as dictated by the thermal hysteresis. Upon exiting a thermal shutdown state, and if EN remains active, the MOSFET will be turned on in a controlled fashion with the normal output turn-on delay and slew rate.

Undervoltage Lockout

The undervoltage lockout of the NCP4552x devices turns the MOSFET off and activates the load bleed when the input voltage, V_{IN}, is less than or equal to the undervoltage lockout threshold. This circuitry is disabled when EN is not active to reduce standby current.

If the V_{IN} voltage rises above the undervoltage lockout threshold, and EN remains active, the MOSFET will be turned on in a controlled fashion with the normal output turn-on delay and slew rate.
