GENERAL DESCRIPTION

The K4S161622H is 16,777,216 bits synchronous high data rate Dynamic RAM organized as 2 x 524,288 words by 16 bits, fabricated with SAMSUNG's high performance CMOS technology. Synchronous design allows precise cycle control with the use of system clock I/O transactions are possible on every clock cycle. PIN FUNCTION DESCRIPTION

| Pin | Name | Input Function |
|-------------------------------------|---|---|
| CLK | <i>System Clock</i> | Active on the positive going edge to sample all inputs. |
| \overline{CS} | <i>Chip Select</i> | Disables or enables device operation by masking or enabling all inputs except CLK, CKE and L(U)DQM |
| CKE | <i>Clock Enable</i> | Masks system clock to freeze operation from the next clock cycle. CKE should be enabled at least one cycle prior to new command. Disable input buffers for power down in standby. |
| A ₀ ~ A _{10/AP} | <i>Address</i> | Row / column addresses are multiplexed on the same pins. Row address : RA ₀ ~ RA ₁₀ , column address : CA ₀ ~ CA ₇ |
| BA | <i>Bank Select Address</i> | Selects bank to be activated during row address latch time. Selects bank for read/write during column address latch time. |
| \overline{RAS} | <i>Row Address Strobe</i> | Latches row addresses on the positive going edge of the CLK with \overline{RAS} low. Enables row access & precharge. |
| \overline{CAS} | <i>Column Address Strobe</i> | Latches column addresses on the positive going edge of the CLK with \overline{CAS} low. Enables column access. |

- Notes :**
1. The minimum number of clock cycles is determined by dividing the minimum time required with clock cycle time and then rounding off to the next higher integer. Refer to the following clock unit based AC conversion table
 2. Minimum delay is required to complete write.
 3. All parts allow every cycle column address change.
 4. In case of row precharge interrupt, auto precharge and read burst stop.
 5. Parameters depend on programmed CAS latency.
 6. If clock rising time is longer than 1ns, $(tr/2-0.5)ns$ should be added to the parameter.
 7. Assumed input rise and fall time $(tr \ \& \ tf)=1ns$.
If $tr \ \& \ tf$ is longer than 1ns, transient time compensation should be considered, i.e., $[(tr + tf)/2-1]ns$ should be added to the parameter.
 8. In 100MHz and below 100MHz operating conditions, $tRDL=1CLK$ and $tDAL=1CLK + 20ns$ is also supported. SAMSUNG recommends $tRDL=2CLK$ and $tDAL=2CLK + tRP$.

(V=Valid, X=Don't Care, H=Logic High, L=Logic Low)

Note : 1. OP Code : Operand Code

A0 ~ A10/AP, BA : Program keys. (@MRS)

2. MRS can be issued only at both banks precharge state.

A new command can be issued after 2 clock cycle of MRS.

3. Auto refresh functions are as same as CBR refresh of DRAM.

The automatical precharge without row precharge command is meant by "Auto".

Auto/self refresh can be issued only at both banks precharge state.

4. BA : Bank select address.

If "Low" at read, write, row active and precharge, bank A is selected.

If "High" at read, write, row active and precharge, bank B is selected.

If A10/AP is "High" at row precharge, BA is ignored and both banks are selected.

5. During burst read or write with auto precharge, new read/write command can not be issued.

Another bank read/write command can be issued after the end of burst.

New row active of the associated bank can be issued at tRP after the end of burst.

6. Burst stop command is valid at every burst length.

7. DQM sampled at positive going edge of a CLK masks the data-in at the very CLK (Write DQM latency is 0),

but makes Hi-Z state the data-out of 2 CLK cycles after. (Read DQM latency is 2)
