

DC MOTOR PULSE WIDTH MODULATOR

DESCRIPTION

The SG1731 is a pulse width modulator circuit designed specifically for DC motor control. It provides a bi-directional pulse train output in response to the magnitude and polarity of an analog error signal input. The device is useful as the control element in motor-driven servo systems for precision positioning and speed control, as well as in audio modulators and amplifiers using carrier frequencies to 350 KHz.

The circuit contains a triangle waveform oscillator, a wideband operational amplifier for error voltage generation, a summing/scaling network for level-shifting the triangle waveform, externally programmable PWM comparators and dual $\pm 100\text{mA}$, $\pm 22\text{V}$ totem pole drivers with commutation diodes for full bridge output. A SHUTDOWN terminal forces the drivers into a floating high-impedance state when driven LOW. Supply voltage to the control circuitry and to the output drivers may be from either dual positive and negative supplies, or single-ended.

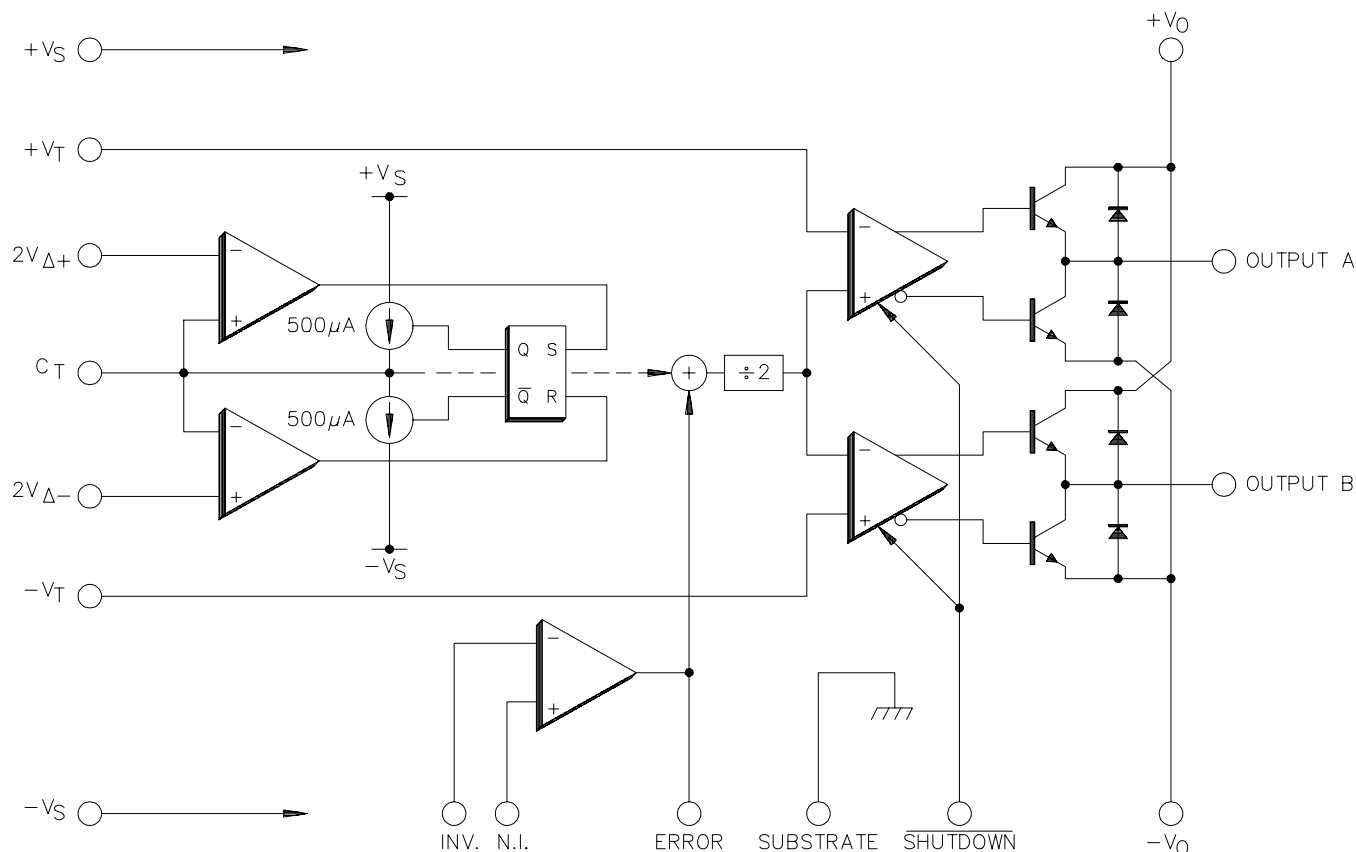

FEATURES

- $\pm 3.5\text{V}$ to $\pm 15\text{V}$ control supply
- $\pm 2.5\text{V}$ to $\pm 22\text{V}$ driver supply
- Dual 100mA source/sink output drivers
- 5KHz to 350KHz oscillator range
- High slew rate error amplifier
- Adjustable deadband operation
- Digital SHUTDOWN input

HIGH RELIABILITY FEATURES - SG1731

- ◆ Available to MIL-STD-883
- ◆ LMI level "S" processing available

APPLICATION INFORMATION

SUPPLY VOLTAGE

The SG1731 requires a supply voltage for the control circuitry (V_S) and for the power output drivers (V_O). Each supply may be either balanced positive and negative with respect to ground, or single-ended. The only restrictions are:

1. The voltage between $+V_S$ and $-V_S$ must be at least 7.0V; but no more than 44V.
2. The voltage between $+V_O$ and $-V_O$ must be at least 5.0V; but no more than 44V.
3. $+V_O$ must be at least 5V more positive than $-V_S$. This eliminates the combination of a single-ended positive control supply with a single-ended negative driver supply.

SUBSTRATE CONNECTION

The substrate connection (Pin 10) must always be connected to either $-V_S$ or $-V_O$, whichever is more negative. The substrate must also be well bypassed to ground with a high quality capacitor.

OSCILLATOR

The triangle oscillator consists of two voltage comparators, a set/reset flip-flop, a bi-directional 500 μA current source, and an external timing capacitor C_T . A positive reference voltage ($2V_{\Delta+}$) applied to Pin 2 determines the positive peak value of the triangle, and a negative reference voltage ($2V_{\Delta-}$) at Pin 7 sets the negative peak value of the triangle waveform.

Since the value of the internal current source is fixed at a nominal $\pm 500\mu A$, the oscillator period is a function of the selected peak-to-peak voltage excursion and the value of C_T . The theoretical expression for the oscillator period is:

$$T_{OSC} = \frac{2C_T dV}{5 \times 10^{-4}} \quad (Eq.1)$$

where C_T is the timing capacitor in Farads and dV is V_{OSC} in Volts peak-to-peak.

As a design aid, the solutions to Equation 1 over the recommended range of T_{OSC} and V_{OSC} are given in graphic form in Figure 1. The lower limit on T_{OSC} is 1.85 μs , corresponding to a maximum frequency of 350 KHz. The maximum value of V_{OSC} , ($2V_{\Delta+}$) - ($2V_{\Delta-}$), is 10V peak-to-peak for linear waveforms.

ERROR AMPLIFIER

The error amplifier of the SG1731 is a conventional internally-compensated operational amplifier with low output impedance. All of the usual feedback and frequency compensation techniques may be used to control the closed-loop gain characteristics. The control supply voltage $\pm V_S$ will determine the input common mode range and output voltage swing; both will extend to within 3V of the V_S supply.

PULSE WIDTH MODULATION

Pulse width modulation occurs by comparing the triangle waveform to a fixed upper ($+V_T$) and lower ($-V_T$) threshold voltage. A crossing above the upper threshold causes Output A to switch to the HIGH state, and a crossing below

APPLICATION INFORMATION (continued)

the lower threshold causes Output B to switch to the HIGH state. If $\pm V_s$ is less than $\pm 8V$ then $\pm V_T$ can be obtained with resistors from $\pm V_s$. If $\pm V_s$ is greater than $\pm 8V$ use zeners.

Threshold crossings are generated by shifting the triangle waveform up and down with the error voltage (Pin 5). A positive error voltage will result in a pulse width modulated output at Driver A (Pin 13). Similarly, a negative error voltage produces a pulse train at Driver B (Pin 12). Figure 2 illustrates this process for the case where $V_{\Delta+}$ is greater than V_T .

It is important to note that the triangle shifting circuit also attenuates the waveform seen at C_T by a factor of 2. This results in a waveform at the PWM comparators with a positive peak of $V_{\Delta+}$ and a negative peak of $V_{\Delta-}$, and must be taken into account when selecting the values for $+V_T$ and $-V_T$.
