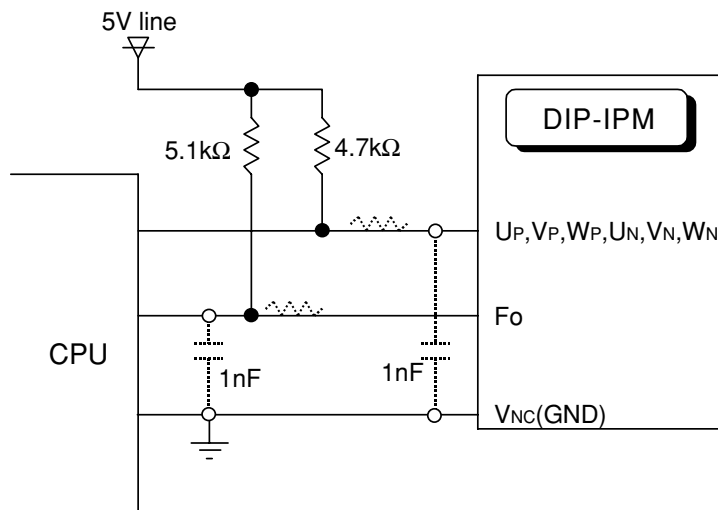

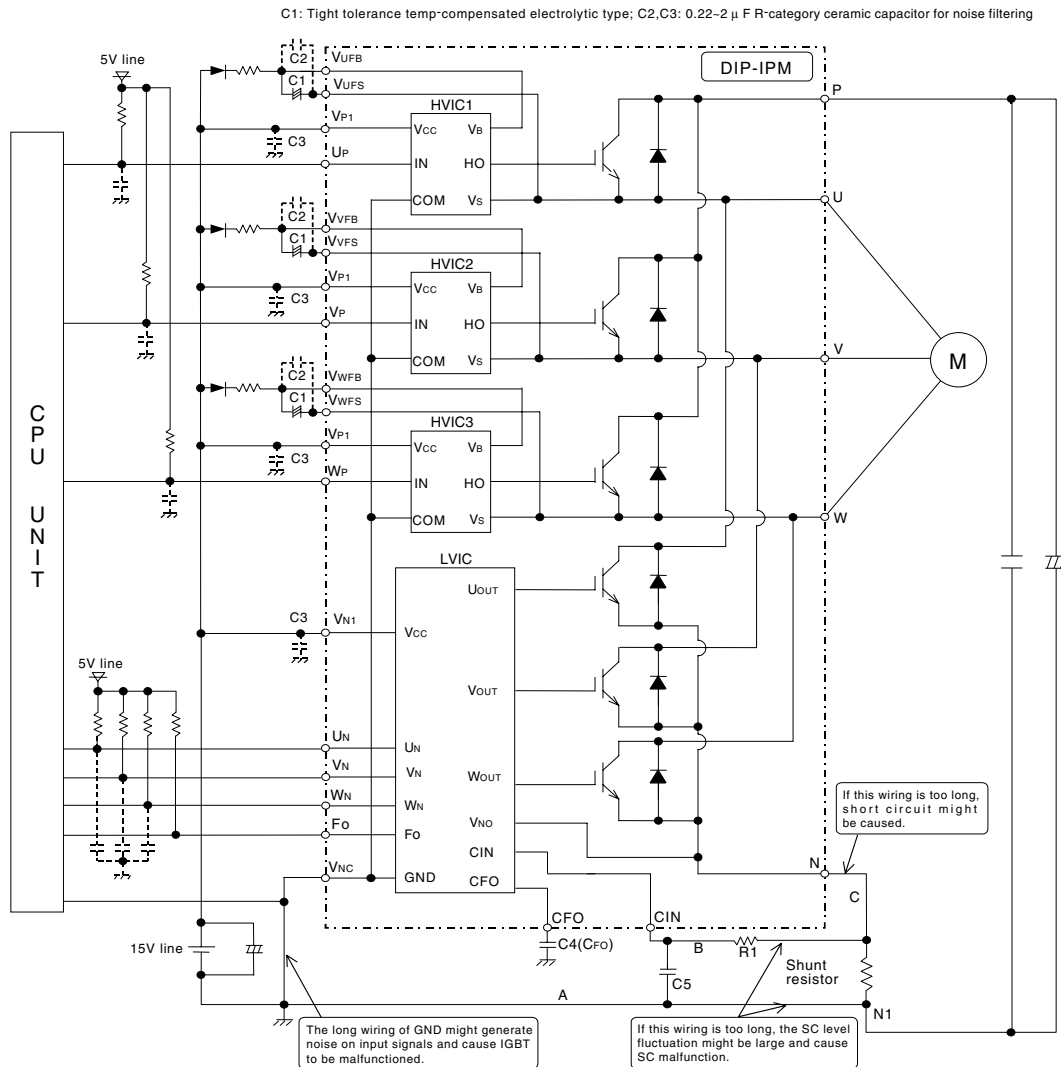

Fig. 6 RECOMMENDED CPU I/O INTERFACE CIRCUIT

Note : RC coupling at each input (parts shown dotted) may change depending on the PWM control scheme used in the application and on the wiring impedance of the application's printed circuit board.

Fig. 7 TYPICAL DIP-IPM APPLICATION CIRCUIT EXAMPLE

- Note 1:** To prevent the input signals oscillation, an RC coupling at each input is recommended, and the wiring of each input should be as short as possible (less than 2cm).
- 2:** By virtue of integrating an application specific type HVIC inside the module, direct coupling to CPU terminals without any opto-coupler or transformer isolation is possible.
- 3:** Fo output is open collector type. This signal line should be pulled up to the positive side of the 5V power supply with approximately 5.1k Ω resistance.
- 4:** Fo output pulse width should be decided by connecting an external capacitor between Cfo and Vnc terminals (Cfo). (Example : Cfo = 22 nF \rightarrow tfo = 1.8 ms (typ.))
- 5:** Each input signal line should be pulled up to the positive side of the 5V power supply with approximately 4.7k Ω resistance (other RC coupling circuits at each input may be needed depending on the PWM control scheme used and on the wiring impedances of the system's printed circuit board). Approximately a 0.22-2 μ F by-pass capacitor should be used across each power supply connection terminals.
- 6:** To prevent errors of the protection function, the wiring of A, B, C should be as short as possible.
- 7:** In the recommended protection circuit, please select the R1C5 time constant in the range of 1.5-2 μ s.
- 8:** Each capacitor should be put as nearby the terminals of the DIP-IPM as possible.
- 9:** To prevent surge destruction, the wiring between the smoothing capacitor and the P&N1 terminals should be as short as possible. Approximately a 0.1-0.22 μ F snubber capacitor between the P&N1 terminals is recommended.
