

DS55107/DS75107/DS75108/DS75208 Dual Line Receivers

General Description

The products described herein are TTL compatible dual high speed circuits intended for sensing in a broad range of system applications. While the primary usage will be for line receivers of MOS sensing, any of the products may effectively be used as voltage comparators, level translators, window detectors, transducer preamplifiers, and in other sensing applications. As digital line receivers the products are applicable with the SN55109/SN75109 and μ A75110/DS75110 companion drivers, or may be used in other balanced or unbalanced party-line data transmission systems. The improved input sensitivity and delay specifications of the DS75208 make it ideal for sensing high performance MOS memories as well as high sensitivity line receivers and voltage comparators.

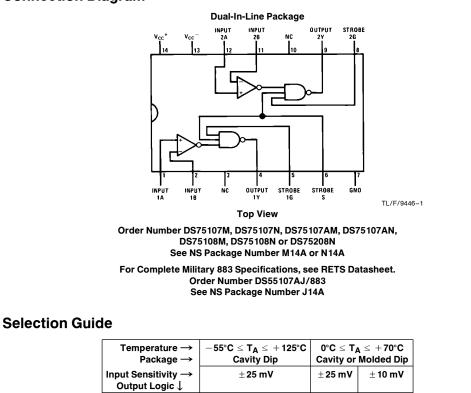

Input protection diodes are incorporated in series with the collectors of the differential input stage. These diodes are

Connection Diagram

useful in certain applications that have multiple $V_{CC}+$ supplies or $V_{CC}+$ supplies that are turned off.

Features

- Diode protected input stage for power "OFF" condition
- 17 ns typ high speed
- TTL compatible
- \pm 10 mV or \pm 25 mV input sensitivity
- ±3V input common-mode range
- \blacksquare High input impedance with normal V_{CC}, or V_{CC} = 0V
- Strobes for channel selection
- Dual circuits
- Sensitivity gntd. over full common-mode range
- Logic input clamp diodes—meets both "A" and "B" version specifications
- ±5V standard supply voltages

Absolute Maximum Ratings (Note 1)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.	Strobe Input Voltage 5.5V Storage Temperature Range -65°C to +150°C Maximum Power Dissipation* at 25°C
Supply Voltage, V _{CC} + 7V Supply Voltage, V _{CC} 7V	Cavity Package 1308 mW Molded Package 1207 mW
Differential Input Voltage ±6V	Lead Temperature (Soldering, 4 sec) 260°C
Common Mode Input Voltage ±5V	*Derate cavity package 8.7 mW/°C above 25°C; derate molded package 9.7 mW/°C above 25°C.

Operating Conditions

	DS55107 DS75107, DS75108, DS75208				208	
	Min	Nom	Max	Min	Nom	Max
Supply Voltage V _{CC} $^+$	4.5V	5V	5.5V	4.75V	5V	5.25V
Supply Voltage V _{CC} -	-4.5V	-5V	-5.5V	-4.75V	-5V	-5.25V
Operating Temperature Range	-55°C	to	+ 125°C	0°C	to	+ 70°C

Note 1: "Absolute Maximum Ratings" are those values beyond which the safety of the device cannot be guaranteed. Except for "Operating Temperature Range" they are not meant to imply that the devices should be operated at these limits. The table of "Electrical Characteristics" provides conditions for actual device operation.

Note 2. Unless otherwise specified min/max limits apply across the -55°C to +125°C temperature range for the DS55107 and across the 0°C to +70°C range for the DS75107, DS75108 and DS75208. All typical values are for T_{A} = 25°C and V_{CC} = 5V.

Note 3: All currents into device pins shown as positive, out of device pins as negative, all voltages referenced to ground unless otherwise noted. All values shown as max or min on absolute value basis.

Note 1: Differential input is +10 mV to -30 mV pulse. Delays read from 0 mV on input to 1.5V on output.

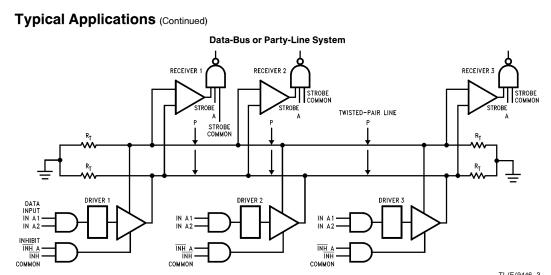

Basic Balanced-Line Transmission System

APPLICATION

The DS55107, DS75107 dual line circuits are designed specifically for use in high speed data transmission systems that utilize balanced, terminated transmission lines such as twisted-pair lines. The system operates in the balanced mode, so that noise induced on one line is also induced on the other. The noise appears common mode at the receiver input terminals where it is rejected. The ground connection between the line driver and receiver is not part of the signal circuit so that system performance is not affected by circulating ground currents.

The unique driver output circuit allows terminated transmission lines to be driven at normal line impedances. High speed system operation is ensured since line reflections are virtually eliminated when terminated lines are used. Crosstalk is minimized by low signal amplitudes and low line impedances.

The typical data delay in a system is approximately (30 $\,+\,$ 1.3L) ns, where L is the distance in feet separating the driver and receiver. This delay includes one gate delay in both the driver and receiver.

Data is impressed on the balanced-line system by unbalancing the line voltages with the driver output current. The driven line is selected by appropriate driver input logic levels. The voltage difference is approximately:

$$V_{\text{DIFF}} \simeq \frac{1}{2} I_{\text{O(on)}} \times R_{\text{T}}$$
(1)

High series line resistance will cause degradation of the signal. The receivers, however, will detect signals as low as TL/F/9446-3

(2)

25 mV (or less). For normal line resistances, data may be recovered from lines of several thousand feet in length

Line termination resistors (RT) are required only at the extreme ends of the line. For short lines, termination resistors at the receiver only may prove adequate. The signal amplitude will then be approximately:

The strobe feature of the receivers and the inhibit feature of the drivers allow the DS55107, DS75107 dual line circuits to be used in data-bus or party-line systems. In these applications, several drivers and receivers may share a common transmission line. An enabled driver transmits data to all enabled receivers on the line while other drivers and receivers are disabled. Data is thus time multiplexed on the transmission line. The DS55107. DS75107 device specifications allow widely varying thermal and electrical environments at the various driver and receiver locations. The data-bus system offers maximum performance at minimum cost.

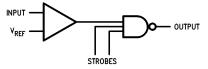

The DS55107, DS75107 dual line circuits may also be used in unbalanced or single line systems. Although these systems do not offer the same performance as balanced systems for long lines, they are adequate for very short lines where environment noise is not severe.

The receiver threshold level is established by applying a DC reference voltage to one receiver input terminal. The signal from the transmission line is applied to the remaining input. The reference voltage should be optimized so that signal

Typical Applications (Continued)

swing is symmetrical about it for maximum noise margin. The reference voltage should be in the range of -3.0V to +3.0V. It can be provided by a voltage supply or by a voltage divider from an available supply voltage.

Unbalanced or Single-Line Systems

Precautions in the Use of DS1603, DS3603, DS55107, DS75107, DS75108 and DS75208 Dual Line Receivers

The following precaution should be observed when using or testing DS55107, DS75107 line circuits.

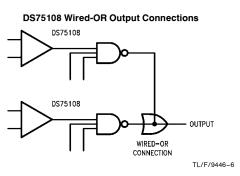

When only one receiver in a package is being used, at least one of the differential inputs of the unused receiver should be terminated at some voltage between -3.0V and +3.0V, preferably at ground. Failure to do so will cause improper operation of the unit being used because of common bias circuitry for the current sources of the two receivers.

The DS55107, DS75107 and DS75108 line receivers feature a common mode input voltage range of ± 3.0 V. This satisfies the requirements for all but the noisiest system applications. For these severe noise environments, the common mode range can be extended by the use of external input attenuators. Common mode input voltages can in this way be reduced to ± 3.0 V at the receiver input terminals. Differential data signals will be reduced proportionately. Input sensitivity, input impedance and delay times will be adversely affected.

The DS75108 line receivers feature an open-collector-output circuit that can be connected in the DOT-OR logic configuration with other DS75108 outputs. This allows a level of logic to be implemented without additional logic delay.

Circuit Differences Between "A" and Standard Devices

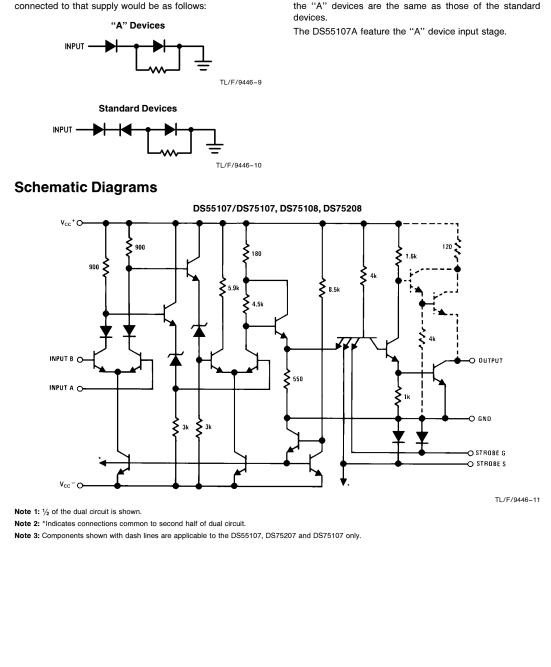

The difference between the "A" and standard devices is shown in the following schematics of the input stage.

Downloaded from Elcodis.com electronic components distributor

Typical Applications (Continued)

The input protection diodes are useful in certain party-line systems which may have multiple V+ power supplies and, in which case, may be operated with some of the V+ supplies turned off. In such a system, if a supply is turned off and allowed to go to ground, the equivalent input circuit connected to that supply would be as follows:

This would be a problem in specific systems which might

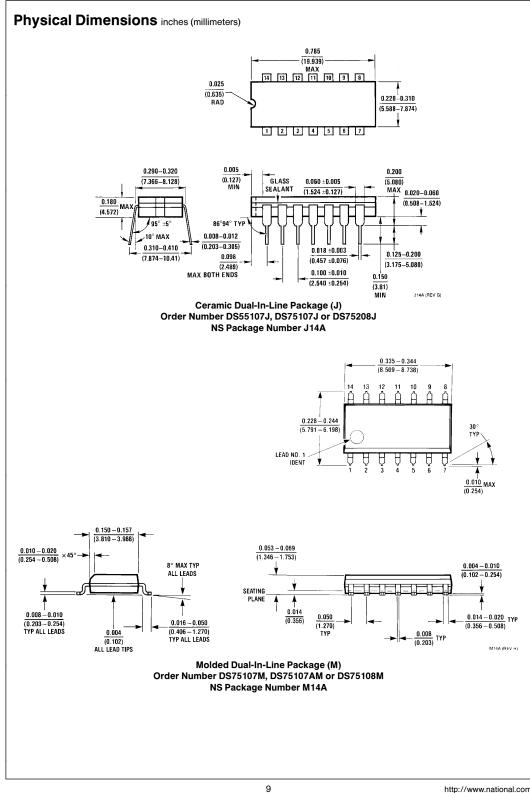

possibly have the transmission lines biased to some poten-

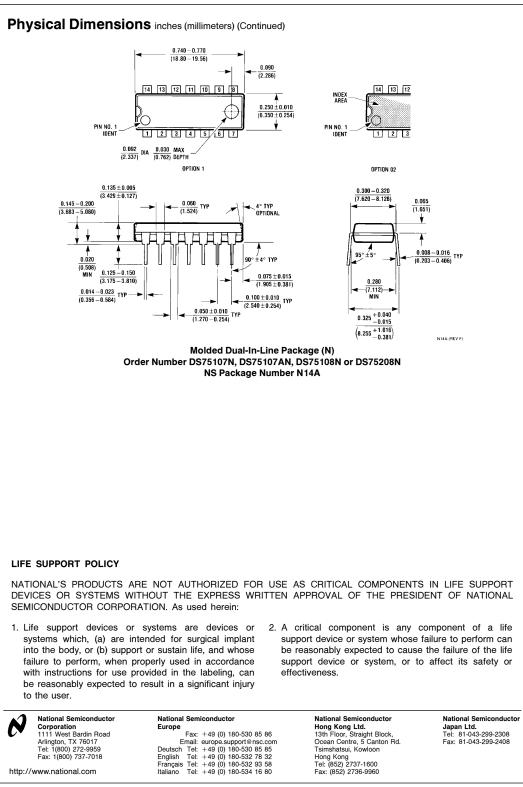

tial greater than 1.4V. Since this is not a widespread application problem, both the "A" and standard devices will be

available. The ratings and characteristic specifications of
