Section 1. General Description

1.1 Contents

1.2	Features	21
1.3	Programmable Options	22
1.4	Structure	23

1.2 Features

Features of the MC68HC705P9 include:

- Four peripheral modules
 - 16-bit input capture/output compare timer
 - Synchronous serial I/O port (SIOP)
 - 4-channel, 8-bit analog-to-digital converter (ADC)
 - Computer operating properly (COP) watchdog
- 20 bidirectional input/output (I/O) port pins and one input-only port pin
- On-chip oscillator with connections for:
 - Crystal
 - Ceramic resonator
 - External clock
- 2104 bytes of EPROM/OTEPROM
 - 48 bytes of page zero EPROM/OTEPROM
 - Eight locations for user vectors

- 128 bytes of user RAM
- Bootloader ROM
- Memory-mapped I/O registers
- Fully static operation with no minimum clock speed
- Power-saving stop, wait, and data-retention modes
- Available packages:
 - 28-pin plastic dual in-line package (PDIP)
 - 28-pin small outline integrated circuit (SOIC)
 - 28-pin ceramic dual in-line package (CERDIP)

1.3 Programmable Options

The options in [Table 1-1](#) are programmable in the mask option register.

Table 1-1. Programmable Options

Feature	Option
COP watchdog	Enabled or Disabled
External interrupt pin triggering	Negative-edge triggering only or Negative-edge and low-level triggering
SIOPI data format	MSB first or LSB first

2.3.9	TCMP	29

Pin Descriptions

2.2 Pin Assignments

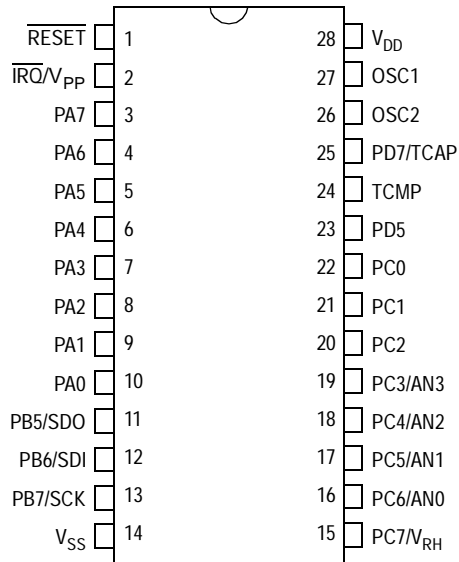

Figure 2-1. Pin Assignments

2.3 Pin Functions

2.3.1 V_{DD} and V_{SS}

V_{DD} and V_{SS} are the power supply and ground pins. The MCU operates from a single 5-V power supply.

Very fast signal transitions occur on the MCU pins, placing high short-duration current demands on the power supply. To prevent noise problems, take special care to provide good power supply bypassing at the MCU as

Figure 2-2 shows. Place the bypass capacitors as close as possible to the MCU. C2 is an optional bulk current bypass capacitor for use in applications that require the port pins to source high current levels.

Figure 2-2. Bypassing Recommendation

2.3.2 OSC1 and OSC2

The OSC1 and OSC2 pins are the connections for the on-chip oscillator. The oscillator can be driven by any of the following:

- Crystal
- Ceramic resonator
- External clock signal

The frequency of the on-chip oscillator is f_{OSC} . The MCU divides the internal oscillator output by two to produce the internal clock with a frequency of f_{OP} .

2.3.2.1 Crystal Connections

The circuit in **Figure 2-3** shows a typical crystal oscillator circuit for an AT-cut, parallel resonant crystal. Follow the crystal supplier's recommendations, as the crystal parameters determine the external component values required to provide reliable startup and maximum stability. The load capacitance values used in the oscillator circuit design should include all stray layout capacitances. To minimize output distortion, mount the crystal and capacitors as close as possible to the pins.

Figure 2-3. Crystal Connections

NOTE: Use an AT-cut crystal. Do not use a strip or tuning fork crystal. The MCU may overdrive or have the incorrect characteristic impedance for a strip or tuning fork crystal.

2.3.2.2 Ceramic Resonator Connections

To reduce cost, use a ceramic resonator in place of the crystal. **Figure 2-4** shows a ceramic resonator circuit. For the values of any external components, follow the recommendations of the resonator manufacturer. The load capacitance values used in the oscillator circuit design should include all stray layout capacitances. To minimize output distortion, mount the resonator and capacitors as close as possible to the pins.

Figure 2-4. Ceramic Resonator Connections

NOTE: Because the frequency stability of ceramic resonators is not as high as that of crystal oscillators, using a ceramic resonator may degrade the performance of the ADC.

2.3.2.3 External Clock Connections

An external clock from another CMOS-compatible device can drive the OSC1 input, with the OSC2 pin unconnected, as **Figure 2-5** shows.

Figure 2-5. External Clock Connections

2.3.3 $\overline{\text{RESET}}$

A logic zero on the $\overline{\text{RESET}}$ pin forces the MCU to a known startup state. The $\overline{\text{RESET}}$ pin input circuit contains an internal Schmitt trigger to improve noise immunity.

2.3.4 $\overline{\text{IRQ}}/V_{\text{PP}}$

The $\overline{\text{IRQ}}/V_{\text{PP}}$ pin has the following functions:

- Applying asynchronous external interrupt signals
- Applying V_{PP} , the EPROM/OTPROM programming voltage

2.3.5 PA7–PA0

PA7–PA0 are general-purpose bidirectional I/O port pins. Use data direction register A to configure port A pins as inputs or outputs.

2.3.6 PB7/SCK–PB5/SDO

Port B is a 3-pin bidirectional I/O port that shares its pins with the SIOP. Use data direction register B to configure port B pins as inputs or outputs.

2.3.7 PC7/ V_{RH} –PC0

Port C is an 8-pin bidirectional I/O port that shares five of its pins with the ADC. Use data direction register C to configure port C pins as inputs or outputs.

2.3.8 PD7/TCAP and PD5

Port D is a 2-pin I/O port that shares one of its pins with the capture/compare timer. Use data direction register D to configure port D pins as inputs or outputs.

2.3.9 TCMP

The TCMP pin is the output compare pin for the capture/compare timer.

Figure 3-2. I/O Register Summary (Sheet 4 of 4)

3.5 RAM

The 128 addresses from \$0080–\$00FF are RAM locations. The CPU uses the top 64 RAM addresses, \$00C0–\$00FF, as the stack. Before processing an interrupt, the CPU uses five bytes of the stack to save the contents of the CPU registers. During a subroutine call, the CPU uses two bytes of the stack to store the return address. The stack pointer decrements when the CPU stores a byte on the stack and increments when the CPU retrieves a byte from the stack.

NOTE: *Be careful when using nested subroutines or multiple interrupt levels. The CPU may overwrite data in the RAM during a subroutine or during the interrupt stacking operation.*

3.6 EPROM/OTPROM

An MCU with a quartz window has 2104 bytes of erasable, programmable ROM (EPROM). The quartz window allows EPROM erasure with ultraviolet light.

NOTE: *Keep the quartz window covered with an opaque material except when programming the MCU. Ambient light may affect MCU operation.*

In an MCU without the quartz window, the EPROM cannot be erased and serves as 2104 bytes of one-time programmable ROM (OTPROM). The following addresses are user EPROM/OTPROM locations:

- \$0020–\$004F
- \$0100–\$08FF
- \$1FF8–\$1FFF (reserved for user-defined interrupt and reset vectors)

The mask option register (MOR) is an EPROM/OTPROM location at address \$0900.

3.6.1 EPROM/OTPROM Programming

The two ways to program the EPROM/OTPROM are:

- Manipulating the control bits in the EPROM programming register to program the EPROM/OTPROM on a byte-by-byte basis
- Activating the bootloader ROM to download the contents of an external memory device to the on-chip EPROM/OTPROM

3.6.1.1 EPROM Programming Register

The EPROM programming register contains the control bits for programming the EPROM/OTPROM.

\$001C	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	0	0	0	0	LATCH	0	EPGM
Write:	R	R	R	R	R		R	
Reset:	0	0	0	0	0	0	0	0

R = Reserved

Figure 3-3. EPROM Programming Register (EPROG)

LATCH — EPROM Bus Latch

This read/write bit latches the address and data buses for EPROM/OTPROM programming. Clearing the LATCH bit automatically clears the EPGM bit. EPROM/OTPROM data cannot be read while the LATCH bit is set. Resets clear the LATCH bit.

- 1 = Address and data buses configured for EPROM/OTPROM programming
- 0 = Address and data buses configured for normal operation

EPGM bit— EPROM Programming

This read/write bit applies the voltage from the \overline{IRQ}/V_{PP} pin to the EPROM/OTPROM. To write the EPGM bit, the LATCH bit must already be set. Clearing the LATCH bit also clears the EPGM bit. Resets clear the EPGM bit.

- 1 = EPROM/OTPROM programming power switched on
- 0 = EPROM/OTPROM programming power switched off

NOTE: *Writing logic ones to both the LATCH and EPGM bits with a single instruction sets LATCH and clears EPGM. LATCH must be set first by a separate instruction.*

Bits 7–3 and Bit 1— Reserved

Bits 7–3 and bit 1 are factory test bits that always read as logic zeros.

Take the following steps to program a byte of EPROM/OTPROM:

1. Apply 16.5 V to the $\overline{\text{IRQ}}/V_{\text{PP}}$ pin.
2. Set the LATCH bit.
3. Write to any EPROM/OTPROM address.
4. Set the EPGM bit for a time, t_{EPGM} , to apply the programming voltage.
5. Clear the LATCH bit.

3.6.1.2 Bootloader ROM

The bootloader ROM, located at addresses \$1F00–\$1FEF, contains routines for copying an external EPROM to the on-chip EPROM/OTPROM.

The bootloader copies to the following EPROM/OTPROM addresses:

- \$0020–\$004F
- \$0100–\$0900
- \$1FF0–\$1FFF

The addresses of the code in the external EPROM must match the MC68HC705P9 addresses. The bootloader ignores all other addresses.

Figure 3-4 shows the circuit for downloading to the on-chip EPROM/OTPROM from a 2764 EPROM. The bootloader circuit includes an external 12-bit counter to address the external EPROM. Operation is fastest when unused external EPROM addresses contain \$00. The bootloader function begins when a rising edge occurs on the $\overline{\text{RESET}}$ pin while the V_{PP} voltage is on the $\overline{\text{IRQ}}/V_{\text{PP}}$ pin, and the PD7/TCAP pin is at logic one.

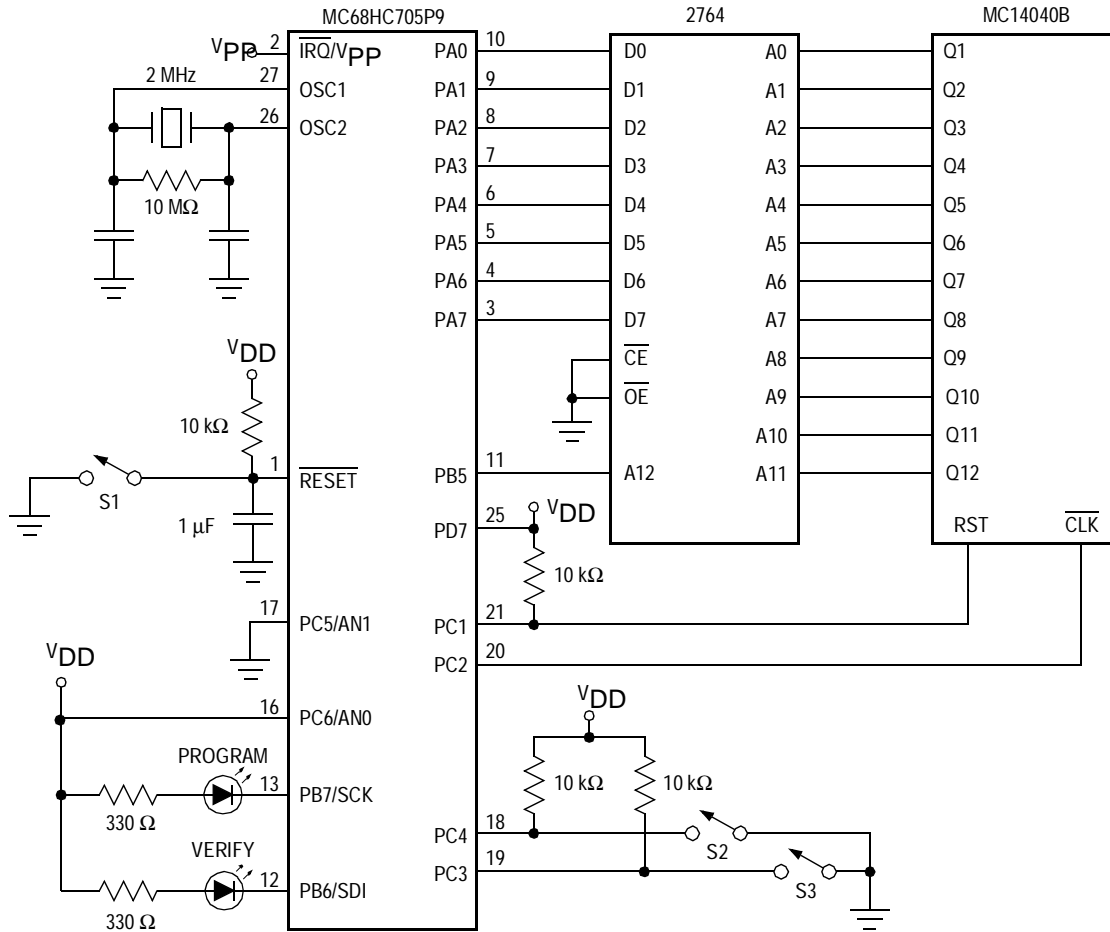

Figure 3-4. Bootloader Circuit

The logical states of the PC4/AN2 and PC3/AN3 pins select the boot loader function, as [Table 3-1](#) shows.

Table 3-1. Bootloader Function Selection

PC4/AN2	PC3/AN3	Function
1	1	Program and verify
1	0	Verify only

Complete the following steps to bootload the MCU:

1. Turn off all power to the circuit.
2. Install the EPROM containing the code to be downloaded.
3. Install the MCU.
4. Select the bootloader function:
 - a. Open switches S2 and S3 to select the program and verify function.
 - b. Open only switch S2 to select only the verify function.
5. Close switch S1.
6. Turn on the V_{DD} power supply.

CAUTION: Turn on the V_{DD} power supply **before** turning on the V_{PP} power supply.

7. Turn on the V_{PP} power supply.
8. Open switch S1. The bootloader code begins to execute. If the PROGRAM function is selected, the PROGRAM LED turns on during programming. If the VERIFY function is selected, the VERIFY LED turns on when verification is successful. The PROGRAM and VERIFY functions take about 10 seconds.
9. Close switch S1.
10. Turn off the V_{PP} power supply.

CAUTION: Turn off the V_{PP} power supply **before** turning off the V_{DD} power supply.

11. Turn off the V_{DD} power supply.

3.6.2 EPROM Erasing

The erased state of an EPROM bit is zero. Erase the EPROM by exposing it to 15 Ws/cm^2 of ultraviolet light with a wavelength of 2537 angstroms. Position the ultraviolet light source one inch from the EPROM. Do not use a shortwave filter.

Cerdip packages have a transparent window for erasing the EPROM with ultraviolet light. In the windowless PDIP and SOIC packages, the 2104 EPROM bytes function as one-time programmable ROM (OTPROM).

3.7 Mask Option Register

The mask option register (MOR) is an EPROM/OTEPROM byte that is programmable only with the bootloader function. The MOR controls:

- LSB first or MSB first SIOP data transfer
- Edge-triggered or edge- and level-triggered external interrupt pin
- Enabled or disabled COP watchdog

To program the MOR, use the 5-step procedure given in [3.6.1.1 EPROM Programming Register](#). Write to address \$0900 in step 3.

\$0900	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	0	0	0	0	SIOP	IRQ	COPE
Write:								
Reset:	Unaffected by reset							
Erased:	0	0	0	0	0	0	0	0

 = Unimplemented

Figure 3-5. Mask Option Register (MOR)

SIOP — Serial I/O Port

The SIOP bit controls the shift direction into and out of the SIOP shift register.

- 1 = SIOP data transferred LSB first (bit 0 first)
- 0 = SIOP data transferred MSB first (bit 7 first)

IRQ — Interrupt Request

The IRQ bit makes the external interrupt function of the $\overline{\text{IRQ}}/\text{V}_{\text{PP}}$ pin level-triggered as well as edge-triggered.

- 1 = $\overline{\text{IRQ}}/\text{V}_{\text{PP}}$ pin negative-edge triggered and low-level triggered
- 0 = $\overline{\text{IRQ}}/\text{V}_{\text{PP}}$ pin negative-edge triggered only

COPE — COP Enable

COPE enables the COP watchdog. In applications that have wait cycles longer than the COP watchdog timeout period, the COP watchdog can be disabled by not programming the COPE bit to logic one.

- 1 = COP watchdog enabled
- 0 = COP watchdog disabled

4.2 Features

Features include:

- 2.1-MHz bus frequency
- 8-bit accumulator
- 8-bit index register
- 13-bit program counter
- 6-bit stack pointer
- Condition code register with five status flags
- 62 instructions
- Eight addressing modes
- Power-saving stop, wait, and data-retention modes

4.3 Introduction

The central processor unit (CPU) consists of a CPU control unit, an arithmetic/logic unit (ALU), and five CPU registers. The CPU control unit fetches and decodes instructions. The ALU executes the instructions. The CPU registers contain data, addresses, and status bits that reflect the results of CPU operations.

4.4 CPU Control Unit

The CPU control unit fetches and decodes instructions during program operation. The control unit selects the memory locations to read and write and coordinates the timing of all CPU operations.

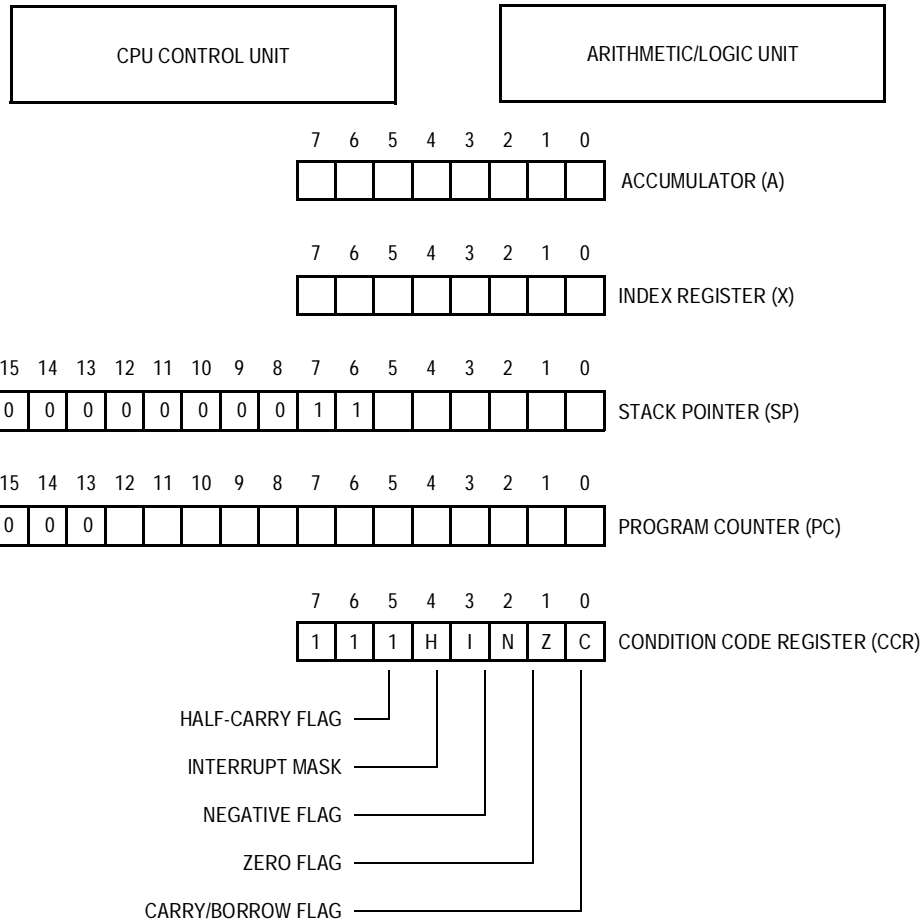

Figure 4-1. CPU Programming Model

4.5 Arithmetic/Logic Unit

The arithmetic/logic unit (ALU) performs the arithmetic, logic, and manipulation operations decoded from the instruction set by the CPU control unit. The ALU produces the results called for by the program and sets or clears status and control bits in the condition code register (CCR).

4.6 CPU Registers

The M68HC05 CPU contains five registers that control and monitor MCU operation:

- Accumulator
- Index register
- Stack pointer
- Program counter
- Condition code register

CPU registers are not memory mapped.

4.6.1 Accumulator

The accumulator is a general-purpose 8-bit register. The CPU uses the accumulator to hold operands and the results of arithmetic and logic operations.

Figure 4-2. Accumulator (A)

4.6.2 Index Register

The index register can be used for data storage or as a counter. In the indexed addressing modes, the CPU uses the byte in the index register to determine the effective address of the operand.

Figure 4-3. Index Register (X)

4.6.3 Stack Pointer

The stack pointer is a 16-bit register that contains the address of the next stack location to be used. During a reset or after the reset stack pointer instruction (RSP), the stack pointer is preset to \$00FF. The address in the stack pointer decrements after a byte is stacked and increments before a byte is unstacked.

Figure 4-4. Stack Pointer (SP)

The 10 most significant bits of the stack pointer are permanently fixed at 0000000011, so the stack pointer produces addresses from \$00C0 to \$00FF. If subroutines and interrupts use more than 64 stack locations, the stack pointer wraps around to address \$00FF and begins writing over the previously stored data. A subroutine uses two stack locations; an interrupt uses five locations.

Freescale Semiconductor, Inc.

Central Processor Unit (CPU)

4.6.4 Program Counter

The program counter is a 16-bit register that contains the address of the next instruction or operand to be fetched. The three most significant bits of the program counter are ignored internally and appear as 000.

Normally, the address in the program counter automatically increments to the next sequential memory location every time an instruction or operand is fetched. Jump, branch, and interrupt operations load the program counter with an address other than that of the next sequential location.

Figure 4-5. Program Counter (PC)

4.6.5 Condition Code Register

The condition code register is an 8-bit register whose three most significant bits are permanently fixed at 111. The condition code register contains the interrupt mask and four flags that indicate the results of the instruction just executed.

Figure 4-6. Condition Code Register (CCR)

H — Half-Carry Flag

The CPU sets the half-carry flag when a carry occurs between bits 3 and 4 of the accumulator during an ADD or ADC operation. The half-carry flag is required for binary-coded decimal (BCD) arithmetic operations.

I — Interrupt Mask

Setting the interrupt mask disables interrupts. If an interrupt request occurs while the interrupt mask is logic zero, the CPU saves the CPU registers on the stack, sets the interrupt mask, and then fetches the interrupt vector. If an interrupt request occurs while the interrupt mask is set, the interrupt request is latched. Normally, the CPU processes the latched interrupt as soon as the interrupt mask is cleared again.

A return from interrupt (RTI) instruction pulls the CPU registers from the stack, restoring the interrupt mask to its cleared state. After any reset, the interrupt mask is set and can be cleared only by a software instruction.

N — Negative Flag

The CPU sets the negative flag when an arithmetic operation, logical operation, or data manipulation produces a negative result.

Z — Zero Flag

The CPU sets the zero flag when an arithmetic operation, logical operation, or data manipulation produces a result of \$00.

C — Carry/Borrow Flag

The CPU sets the carry/borrow flag when an addition operation produces a carry out of bit 7 of the accumulator or when a subtraction operation requires a borrow. Some logical operations and data manipulation instructions also clear or set the carry/borrow flag.

4.7 Instruction Set

The MCU instruction set has 62 instructions and uses eight addressing modes. The instructions include all those of the M146805 CMOS Family plus one more: the unsigned multiply (MUL) instruction. The MUL instruction allows unsigned multiplication of the contents of the accumulator (A) and the index register (X). The high-order product is stored in the index register, and the low-order product is stored in the accumulator.

4.7.1 Addressing Modes

The CPU uses eight addressing modes for flexibility in accessing data. The addressing modes provide eight different ways for the CPU to find the data required to execute an instruction. The eight addressing modes are:

- Inherent
- Immediate
- Direct
- Extended
- Indexed, no offset
- Indexed, 8-bit offset
- Indexed, 16-bit offset
- Relative

4.7.1.1 *Inherent*

Inherent instructions are those that have no operand, such as return from interrupt (RTI) and stop (STOP). Some of the inherent instructions act on data in the CPU registers, such as set carry flag (SEC) and increment accumulator (INCA). Inherent instructions require no operand address and are one byte long.

4.7.1.2 *Immediate*

Immediate instructions are those that contain a value to be used in an operation with the value in the accumulator or index register. Immediate instructions require no operand address and are two bytes long. The opcode is the first byte, and the immediate data value is the second byte.

4.7.1.3 *Direct*

Direct instructions can access any of the first 256 memory locations with two bytes. The first byte is the opcode, and the second is the low byte of the operand address. In direct addressing, the CPU automatically uses \$00 as the high byte of the operand address.

4.7.1.4 *Extended*

Extended instructions use three bytes and can access any address in memory. The first byte is the opcode; the second and third bytes are the high and low bytes of the operand address.

When using the Motorola assembler, the programmer does not need to specify whether an instruction is direct or extended. The assembler automatically selects the shortest form of the instruction.

4.7.1.5 *Indexed, No Offset*

Indexed instructions with no offset are 1-byte instructions that can access data with variable addresses within the first 256 memory locations. The index register contains the low byte of the effective address of the operand. The CPU automatically uses \$00 as the high byte, so these instructions can address locations \$0000–\$00FF.

Indexed, no offset instructions are often used to move a pointer through a table or to hold the address of a frequently used RAM or I/O location.

4.7.1.6 *Indexed, 8-Bit Offset*

Indexed, 8-bit offset instructions are 2-byte instructions that can access data with variable addresses within the first 511 memory locations. The CPU adds the unsigned byte in the index register to the unsigned byte following the opcode. The sum is the effective address of the operand. These instructions can access locations \$0000–\$01FE.

Indexed 8-bit offset instructions are useful for selecting the kth element in an n-element table. The table can begin anywhere within the first 256 memory locations and could extend as far as location 510 (\$01FE). The k value is typically in the index register, and the address of the beginning of the table is in the byte following the opcode.

4.7.1.7 Indexed, 16-Bit Offset

Indexed, 16-bit offset instructions are 3-byte instructions that can access data with variable addresses at any location in memory. The CPU adds the unsigned byte in the index register to the two unsigned bytes following the opcode. The sum is the effective address of the operand. The first byte after the opcode is the high byte of the 16-bit offset; the second byte is the low byte of the offset.

Indexed, 16-bit offset instructions are useful for selecting the kth element in an n-element table anywhere in memory.

As with direct and extended addressing, the Motorola assembler determines the shortest form of indexed addressing.

4.7.1.8 Relative

Relative addressing is only for branch instructions. If the branch condition is true, the CPU finds the effective branch destination by adding the signed byte following the opcode to the contents of the program counter. If the branch condition is not true, the CPU goes to the next instruction. The offset is a signed, two's complement byte that gives a branching range of -128 to $+127$ bytes from the address of the next location after the branch instruction.

When using the Motorola assembler, the programmer does not need to calculate the offset, because the assembler determines the proper offset and verifies that it is within the span of the branch.

4.7.2 Instruction Types

The MCU instructions fall into the following five categories:

- Register/Memory Instructions
- Read-Modify-Write Instructions
- Jump/Branch Instructions
- Bit Manipulation Instructions
- Control Instructions

4.7.2.1 Register/Memory Instructions

These instructions operate on CPU registers and memory locations. Most of them use two operands. One operand is in either the accumulator or the index register. The CPU finds the other operand in memory.

Table 4-1. Register/Memory Instructions

Instruction	Mnemonic
Add Memory Byte and Carry Bit to Accumulator	ADC
Add Memory Byte to Accumulator	ADD
AND Memory Byte with Accumulator	AND
Bit Test Accumulator	BIT
Compare Accumulator	CMP
Compare Index Register with Memory Byte	CPX
EXCLUSIVE OR Accumulator with Memory Byte	EOR
Load Accumulator with Memory Byte	LDA
Load Index Register with Memory Byte	LDX
Multiply	MUL
OR Accumulator with Memory Byte	ORA
Subtract Memory Byte and Carry Bit from Accumulator	SBC
Store Accumulator in Memory	STA
Store Index Register in Memory	STX
Subtract Memory Byte from Accumulator	SUB

4.7.2.2 Read-Modify-Write Instructions

These instructions read a memory location or a register, modify its contents, and write the modified value back to the memory location or to the register.

NOTE: Do not use read-modify-write operations on write-only registers.

Table 4-2. Read-Modify-Write Instructions

Instruction	Mnemonic
Arithmetic Shift Left (Same as LSL)	ASL
Arithmetic Shift Right	ASR
Bit Clear	BCLR ⁽¹⁾
Bit Set	BSET ⁽¹⁾
Clear Register	CLR
Complement (One's Complement)	COM
Decrement	DEC
Increment	INC
Logical Shift Left (Same as ASL)	LSL
Logical Shift Right	LSR
Negate (Two's Complement)	NEG
Rotate Left through Carry Bit	ROL
Rotate Right through Carry Bit	ROR
Test for Negative or Zero	TST ⁽²⁾

1. Unlike other read-modify-write instructions, BCLR and BSET use only direct addressing.
2. TST is an exception to the read-modify-write sequence because it does not write a replacement value.

4.7.2.3 *Jump/Branch Instructions*

Jump instructions allow the CPU to interrupt the normal sequence of the program counter. The unconditional jump instruction (JMP) and the jump-to-subroutine instruction (JSR) have no register operand. Branch instructions allow the CPU to interrupt the normal sequence of the program counter when a test condition is met. If the test condition is not met, the branch is not performed.

The BRCLR and BRSET instructions cause a branch based on the state of any readable bit in the first 256 memory locations. These 3-byte instructions use a combination of direct addressing and relative addressing. The direct address of the byte to be tested is in the byte following the opcode. The third byte is the signed offset byte. The CPU finds the effective branch destination by adding the third byte to the program counter if the specified bit tests true. The bit to be tested and its condition (set or clear) is part of the opcode. The span of branching is from -128 to +127 from the address of the next location after the branch instruction. The CPU also transfers the tested bit to the carry/borrow bit of the condition code register.

Table 4-3. Jump and Branch Instructions

Instruction	Mnemonic
Branch if Carry Bit Clear	BCC
Branch if Carry Bit Set	BCS
Branch if Equal	BEQ
Branch if Half-Carry Bit Clear	BHCC
Branch if Half-Carry Bit Set	BHCS
Branch if Higher	BHI
Branch if Higher or Same	BHS
Branch if $\overline{\text{IRQ}}$ Pin High	BIH
Branch if $\overline{\text{IRQ}}$ Pin Low	BIL
Branch if Lower	BLO
Branch if Lower or Same	BLS

Continued on next page

Table 4-3. Jump and Branch Instructions (Continued)

Instruction	Mnemonic
Branch if Interrupt Mask Clear	BMC
Branch if Minus	BMI
Branch if Interrupt Mask Set	BMS
Branch if Not Equal	BNE
Branch if Plus	BPL
Branch Always	BRA
Branch if Bit Clear	BRCLR
Branch Never	BRN
Branch if Bit Set	BRSET
Branch to Subroutine	BSR
Unconditional Jump	JMP
Jump to Subroutine	JSR

4.7.2.4 Bit Manipulation Instructions

The CPU can set or clear any writable bit in the first 256 bytes of memory, which includes I/O registers and on-chip RAM locations. The CPU can also test and branch based on the state of any bit in any of the first 256 memory locations.

Table 4-4. Bit Manipulation Instructions

Instruction	Mnemonic
Bit Clear	BCLR
Branch if Bit Clear	BRCLR
Branch if Bit Set	BRSET
Bit Set	BSET

4.7.2.5 Control Instructions

These instructions act on CPU registers and control CPU operation during program execution.

Table 4-5. Control Instructions

Instruction	Mnemonic
Clear Carry Bit	CLC
Clear Interrupt Mask	CLI
No Operation	NOP
Reset Stack Pointer	RSP
Return from Interrupt	RTI
Return from Subroutine	RTS
Set Carry Bit	SEC
Set Interrupt Mask	SEI
Stop Oscillator and Enable $\overline{\text{IRQ}}$ Pin	STOP
Software Interrupt	SWI
Transfer Accumulator to Index Register	TAX
Transfer Index Register to Accumulator	TXA
Stop CPU Clock and Enable Interrupts	WAIT

Central Processor Unit (CPU)

Section 5. Resets and Interrupts

5.1 Contents

5.2	Resets.	66
5.2.1	Power-On Reset.	66
5.2.2	External Reset	67
5.2.3	COP Watchdog Reset	68
5.3	Low-Voltage Protection.	68
5.4	Interrupts.	68
5.4.1	Software Interrupt.	69
5.4.2	External Interrupt	69
5.4.3	Timer Interrupts	71
5.4.3.1	Input Capture Interrupt.	71
5.4.3.2	Output Compare Interrupt	71
5.4.3.3	Timer Overflow Interrupt	71
5.4.4	Interrupt Processing	72

5.2 Resets

A reset immediately stops the operation of the instruction being executed, initializes certain control bits, and loads the program counter with a user-defined reset vector address. The following sources can generate resets:

- Power-on reset (POR) circuit
- $\overline{\text{RESET}}$ pin
- COP watchdog

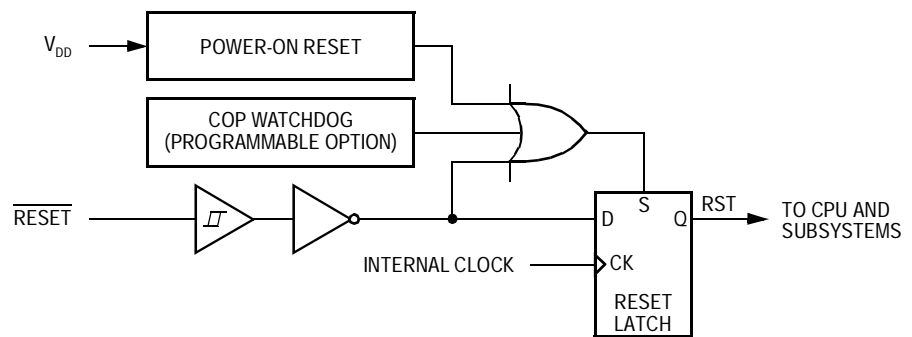

Figure 5-1. Reset Sources

5.2.1 Power-On Reset

A positive transition on the V_{DD} pin generates a power-on reset.

NOTE: *The power-on reset is strictly for power-up conditions and cannot be used to detect drops in power supply voltage.*

A $4064 t_{CYC}$ (internal clock cycle) delay after the oscillator becomes active allows the clock generator to stabilize. If the $\overline{\text{RESET}}$ pin is at logic zero at the end of $4064 t_{CYC}$, the MCU remains in the reset condition until the signal on the $\overline{\text{RESET}}$ pin goes to logic one.

Notes:

1. Power-on reset threshold is typically between 1 V and 2 V.
2. Internal clock, internal address bus, and internal data bus are not available externally.

Figure 5-2. Power-On Reset Timing

5.2.2 External Reset

A logic zero applied to the $\overline{\text{RESET}}$ pin for one and one-half t_{CYC} generates an external reset. A Schmitt trigger senses the logic level at the $\overline{\text{RESET}}$ pin.

Notes:

1. Internal clock, internal address bus, and internal data bus are not available externally.
2. The next rising edge of the internal clock after the rising edge of $\overline{\text{RESET}}$ initiates the reset sequence.

Figure 5-3. External Reset Timing

Table 5-1. External Reset Timing

Characteristic	Symbol	Min	Max	Unit
$\overline{\text{RESET}}$ Pulse Width	t_{RL}	1.5	—	t_{CYC}

5.2.3 COP Watchdog Reset

A timeout of the COP watchdog generates a COP reset. The COP watchdog is part of a software error detection system and must be cleared periodically to start a new timeout period. To clear the COP watchdog and prevent a COP reset, write a logic zero to bit 0 (COPC) of the COP register at location \$1FF0.

5.3 Low-Voltage Protection

A drop in power supply voltage below the minimum operating V_{DD} voltage is called a brownout condition. A brownout while the MCU is in a non-reset state can corrupt MCU operation and necessitate a power-on reset to resume operation.

The best protection against brownout is an undervoltage sensing circuit that pulls the $\overline{\text{RESET}}$ pin low when it detects a low-power supply voltage. The undervoltage sensing circuit may be made of discrete components or an integrated circuit can be used.

For information about brownout and the COP watchdog, see [Section 8. Computer Operating Properly Watchdog \(COP\)](#).

5.4 Interrupts

The following sources can generate interrupts:

- SWI instruction
- $\overline{\text{IRQ/V}_{PP}}$ pin
- Capture/compare timer

An interrupt temporarily stops normal program execution to process a particular event. An interrupt does not stop the operation of the instruction being executed, but takes effect when the current instruction completes its execution. Interrupt processing automatically saves the CPU registers on the stack and loads the program counter with a user-defined interrupt vector address.

5.4.1 Software Interrupt

The software interrupt (SWI) instruction causes a non-maskable interrupt.

5.4.2 External Interrupt

An interrupt signal on the $\overline{\text{IRQ}}/\text{V}_{\text{PP}}$ pin latches an external interrupt request. When the CPU completes its current instruction, it tests the IRQ latch. If the IRQ latch is set, the CPU then tests the I bit in the condition code register. If the I bit is clear, the CPU then begins the interrupt sequence.

The CPU clears the IRQ latch during interrupt processing, so that another interrupt signal on the $\overline{\text{IRQ}}/\text{V}_{\text{PP}}$ pin can latch another interrupt request during the interrupt service routine. As soon as the I bit is cleared during the return from interrupt, the CPU can recognize the new interrupt request. **Figure 5-4** shows the $\overline{\text{IRQ}}/\text{V}_{\text{PP}}$ pin interrupt logic.

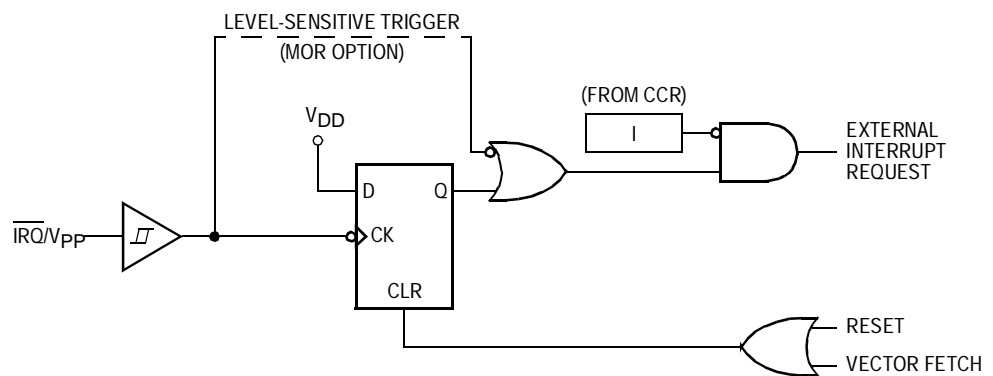

Figure 5-4. External Interrupt Logic

Setting the I bit in the condition code register disables external interrupts.

Interrupt triggering sensitivity of the $\overline{\text{IRQ}}/\text{V}_{\text{PP}}$ pin is a programmable option. The $\overline{\text{IRQ}}/\text{V}_{\text{PP}}$ pin can be negative-edge triggered or negative-edge- and low-level triggered. The level-sensitive triggering option allows multiple external interrupt sources to be wire-ORed to the

$\overline{\text{IRQ}}/\text{V}_{\text{PP}}$ pin. An external interrupt request, shown in **Figure 5-5**, is latched as long as any source is holding the $\overline{\text{IRQ}}/\text{V}_{\text{PP}}$ pin low.

Figure 5-5. External Interrupt Timing

Table 5-2. External Interrupt Timing ($V_{\text{DD}} = 5.0 \text{ Vdc}$)⁽¹⁾

Characteristic	Symbol	Min	Max	Unit
Interrupt Pulse Width Low (Edge-Triggered)	t_{ILIH}	125	—	ns
Interrupt Pulse Period	t_{ILIL}	Note ⁽²⁾	—	t_{CYC}

- $V_{\text{DD}} = 5.0 \text{ Vdc} \pm 10\%$, $V_{\text{SS}} = 0 \text{ Vdc}$, $T_{\text{A}} = T_{\text{L}}$ to T_{H}
- The minimum t_{ILIL} should not be less than the number of interrupt service routine cycles plus $19 t_{\text{CYC}}$.

Table 5-3. External Interrupt Timing ($V_{\text{DD}} = 3.3 \text{ Vdc}$)⁽¹⁾

Characteristic	Symbol	Min	Max	Unit
Interrupt Pulse Width Low (Edge-Triggered)	t_{ILIH}	250	—	ns
Interrupt Pulse Period	t_{ILIL}	Note ⁽²⁾	—	t_{CYC}

- $V_{\text{DD}} = 3.3 \text{ Vdc} \pm 10\%$, $V_{\text{SS}} = 0 \text{ Vdc}$, $T_{\text{A}} = T_{\text{L}}$ to T_{H}
- The minimum t_{ILIL} should not be less than the number of interrupt service routine cycles plus $19 t_{\text{CYC}}$.

5.4.3 Timer Interrupts

The capture/compare timer can generate the following interrupts:

- Input capture interrupt
- Output compare interrupt
- Timer overflow interrupt

Setting the I bit in the condition code register disables timer interrupts.

5.4.3.1 Input Capture Interrupt

An input capture interrupt request occurs if the input capture flag, ICF, becomes set while the input capture interrupt enable bit, ICIE, is also set. ICF is in the timer status register, and ICIE is in the timer control register.

5.4.3.2 Output Compare Interrupt

An output compare interrupt request occurs if the output compare flag, OCF, becomes set while the output compare interrupt enable bit, OCIE, is also set. OCF is in the timer status register, and OCIE is in the timer control register.

5.4.3.3 Timer Overflow Interrupt

A timer overflow interrupt request occurs if the timer overflow flag, TOF, becomes set while the timer overflow interrupt enable bit, TOIE, is also set. TOF is in the timer status register, and TOIE is in the timer control register.

Resets and Interrupts

5.4.4 Interrupt Processing

The CPU takes the following actions to begin servicing an interrupt:

- Stores the CPU registers on the stack in the order shown in **Figure 5-6**
- Sets the I bit in the condition code register to prevent further interrupts
- Loads the program counter with the contents of the appropriate interrupt vector locations:
 - \$1FFC and \$1FFD (software interrupt vector)
 - \$1FFA and \$1FFB (external interrupt vector)
 - \$1FF8 and \$1FF9 (timer interrupt vector)

The return from interrupt (RTI) instruction causes the CPU to recover the CPU registers from the stack as shown in **Figure 5-6**.

Figure 5-6. Interrupt Stacking Order

Table 5-4. Reset/Interrupt Vector Addresses

Function	Source	Local Mask	Global Mask	Priority (1 = Highest)	Vector Address
Reset	Power-On RESET Pin	None	None	1	\$1FFE-\$1FFF
	COP Watchdog ⁽¹⁾		None	1	
			None	1	
Software Interrupt (SWI)	User Code	None	None	Same Priority as Instruction	\$1FFC-\$1FFD
External Interrupt	IRQ/V _{PP} Pin	None	I Bit	2	\$1FFA-\$1FFB
Timer Interrupts	ICF Bit OCF Bit TOF Bit	ICIE Bit OCIE Bit TOIE Bit	I Bit	3	\$1FF8-\$1FF9

1. The COP watchdog is programmable in the mask option register.

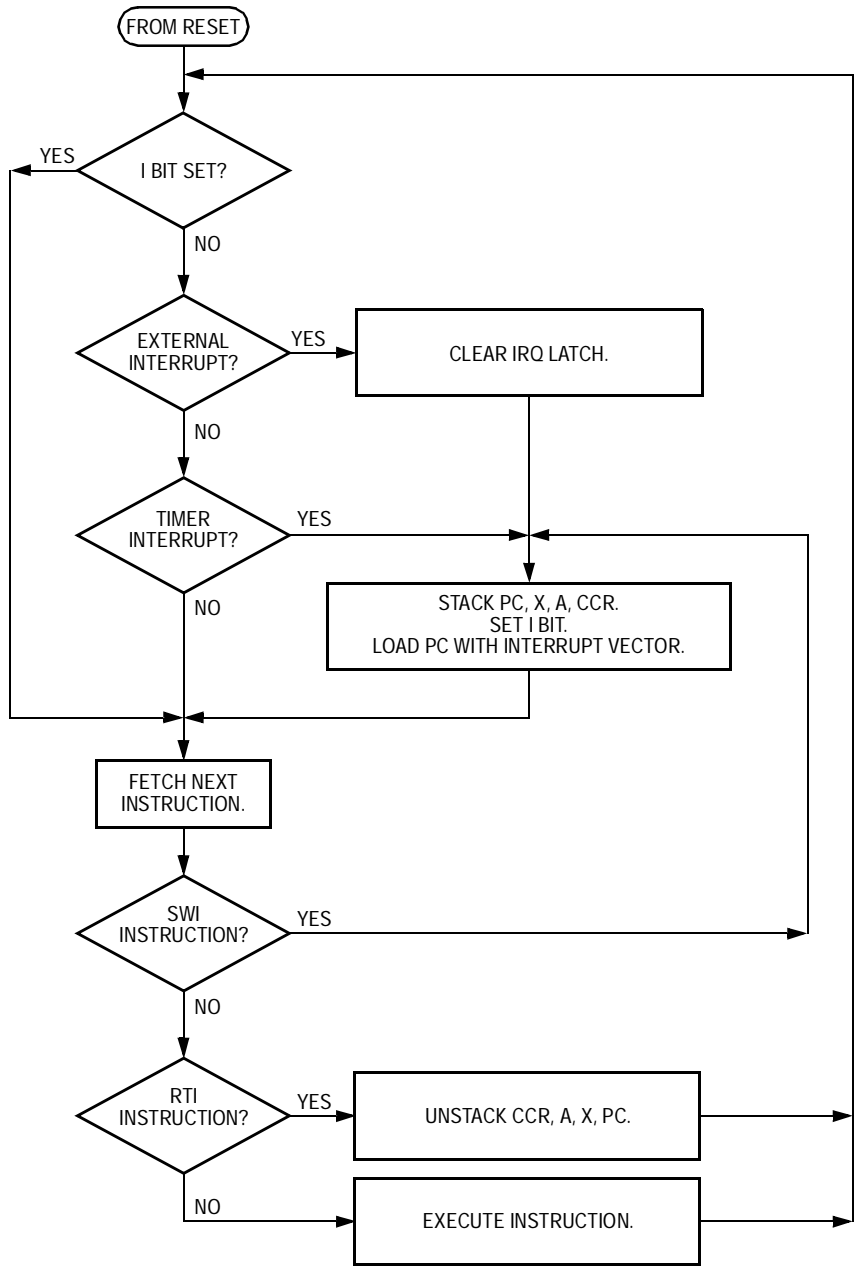

Figure 5-7. Interrupt Flowchart

Section 6. Low Power Modes

6.1 Contents

6.2	Stop Mode	75
6.3	Wait Mode	78
6.4	Data-Retention Mode	80

6.2 Stop Mode

The STOP instruction puts the MCU in its lowest power-consumption mode and has the following effects on the MCU:

- Stops the internal oscillator, the CPU clock, and the internal clock, turning off the capture/compare timer, the COP watchdog, the SIOF, and the ADC
- Clears the I bit in the condition code register, enabling external interrupts
- Clears the ICIE, OCIE, and TOIE bits in the timer control register, disabling further timer interrupts

The STOP instruction does not affect any other registers or any I/O lines.

The following events bring the MCU out of stop mode:

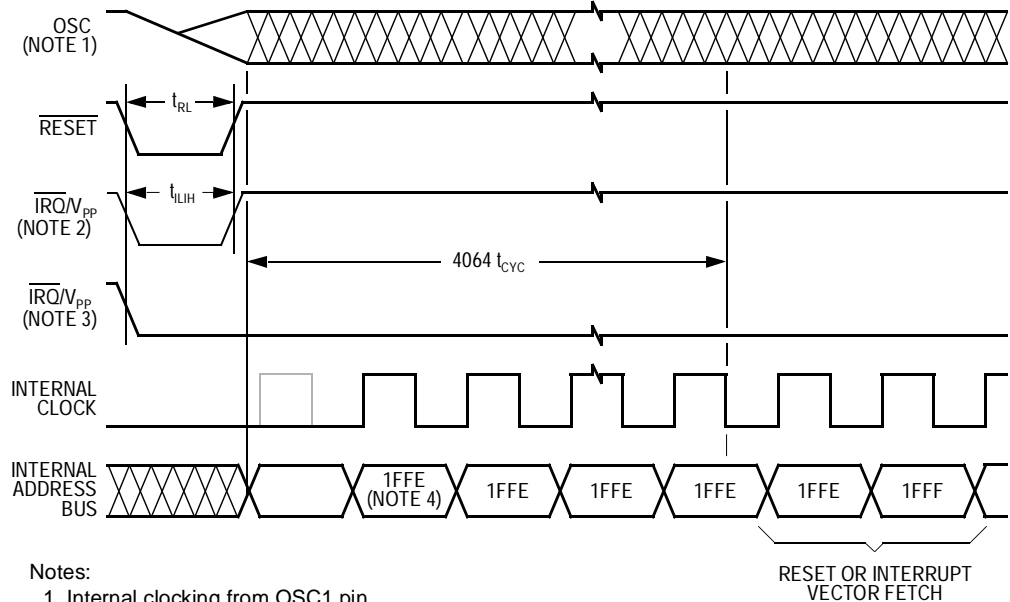

- An external interrupt signal on the \overline{IRQ}/V_{PP} pin — A high-to-low transition on the \overline{IRQ}/V_{PP} pin loads the program counter with the contents of locations \$1FFA and \$1FFB. The timer resumes counting from the last value before the STOP instruction.
- External reset — A logic zero on the \overline{RESET} pin resets the MCU and loads the program counter with the contents of locations \$1FFE and \$1FFF. The timer begins counting from \$FFFC.

When the MCU exits stop mode, processing resumes after a stabilization delay of 4064 oscillator cycles.

An active edge on the PD7/TCAP pin during stop mode sets the ICF flag when an external interrupt brings the MCU out of stop mode. An external interrupt also latches the value in the timer registers into the input capture registers.

If a reset brings the MCU out of stop mode, then an active edge on the PD7/TCAP pin during stop mode has no effect on the ICF flag or the input capture registers.

See [Figure 6-1](#) for stop recovery timing information.

- Notes:
1. Internal clocking from OSC1 pin
 2. Edge-triggered external interrupt mask option
 3. Edge- and level-triggered external interrupt mask option
 4. Reset vector shown as example

Figure 6-1. Stop Recovery Timing

Figure 6-2 shows the sequence of events caused by the STOP instruction.

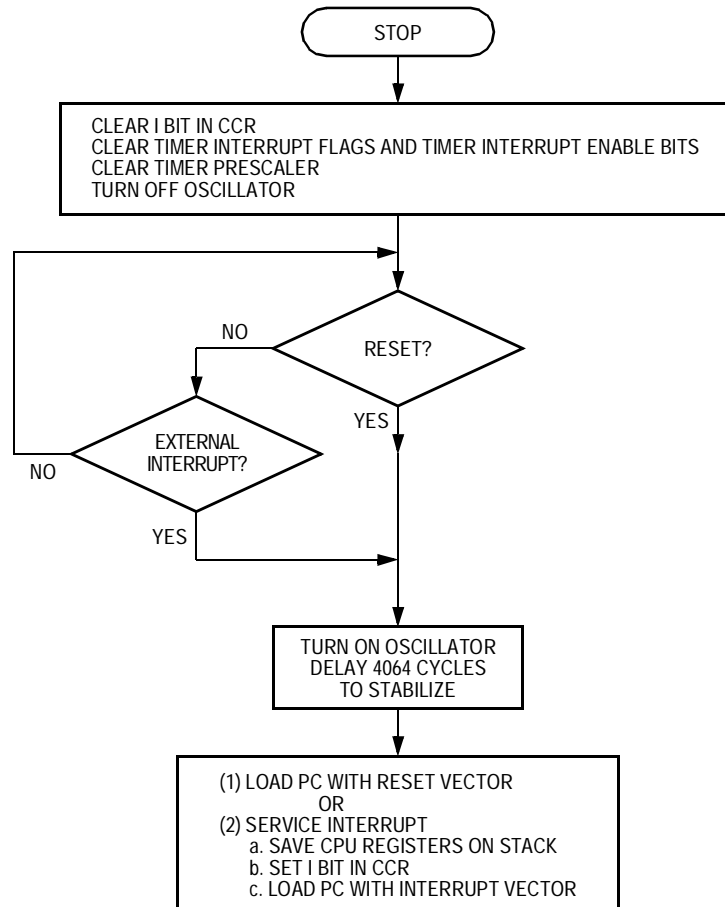

Figure 6-2. STOP Instruction Flowchart

6.3 Wait Mode

The WAIT instruction puts the MCU in an intermediate power-consumption mode and has the following effects on the MCU:

- Clears the I bit in the condition code register, enabling interrupts
- Stops the CPU clock, but allows the internal clock to drive the capture/compare timer, the COP watchdog, and the ADC

The WAIT instruction does not affect any other registers or any I/O lines.

The following conditions restart the CPU clock and bring the MCU out of wait mode:

- External interrupt — A high-to-low transition on the $\overline{\text{IRQ}}/\text{V}_{\text{PP}}$ pin loads the program counter with the contents of locations \$1FFA and \$1FFB.
- Timer interrupt — Input capture, output compare, and timer overflow interrupt requests load the program counter with the contents of locations \$1FF8 and \$1FF9.
- COP watchdog reset — A timeout of the COP watchdog resets the MCU and loads the program counter with the contents of locations \$1FFE and \$1FFF. Software can enable timer interrupts so that the MCU can periodically exit wait mode to reset the COP watchdog.
- External reset — A logic zero on the $\overline{\text{RESET}}$ pin resets the MCU and loads the program counter with the contents of locations \$1FFE and \$1FFF.

Figure 6-3 shows the sequence of events caused by the WAIT instruction.

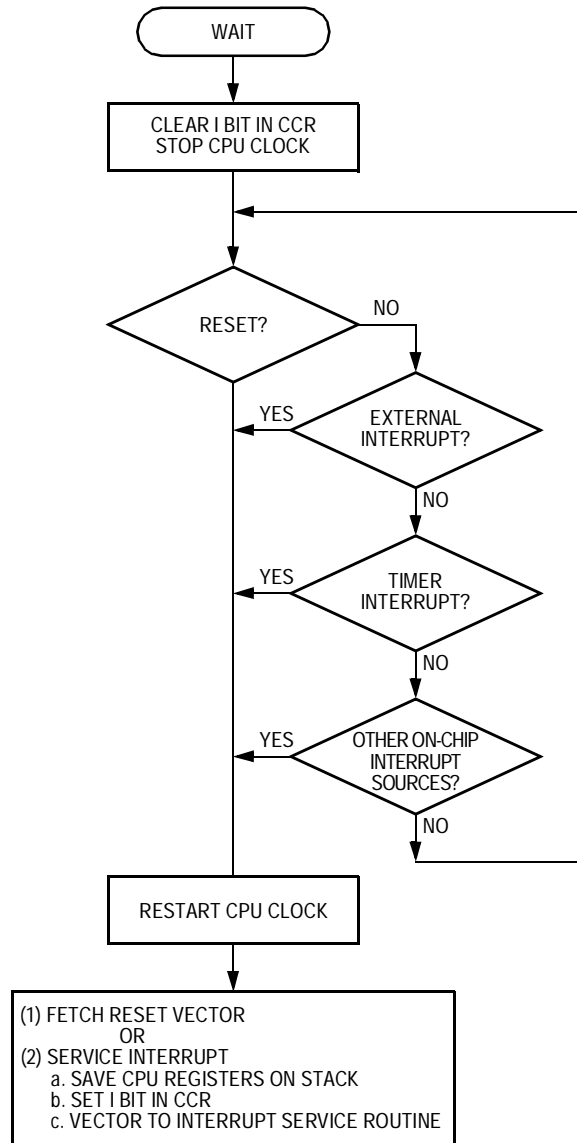

Figure 6-3. WAIT Instruction Flowchart

Figure 6-4 shows the effect of the STOP and WAIT instructions on the CPU clock and the timer clock.

Figure 6-4. STOP/WAIT Clock Logic

6.4 Data-Retention Mode

In data-retention mode, the MCU retains RAM contents and CPU register contents at V_{DD} voltages as low as 2.0 Vdc. The data-retention feature allows the MCU to remain in a low-power consumption state during which it retains data, but the CPU cannot execute instructions.

To put the MCU in data-retention mode:

1. Drive the $\overline{\text{RESET}}$ pin to logic zero.
2. Lower the V_{DD} voltage. The $\overline{\text{RESET}}$ pin must remain low continuously during data-retention mode.

To take the MCU out of data-retention mode:

1. Return V_{DD} to normal operating voltage.
2. Return the $\overline{\text{RESET}}$ pin to logic one.

7.2 Introduction

Twenty bidirectional pins and one input-only pin form four parallel input/output (I/O) ports. All the bidirectional port pins are programmable as inputs or outputs.

NOTE: *Connect any unused I/O pins to an appropriate logic level, either V_{DD} or V_{SS} . Although the I/O ports do not require termination for proper operation, termination reduces excess current consumption and the possibility of electrostatic damage.*

Figure 7-1. Parallel I/O Port Register Summary

7.3 Port A

Port A is an 8-bit general-purpose I/O port.

7.3.1 Port A Data Register (PORTA)

The port A data register contains a latch for each of the eight port A pins.

\$0000	Bit 7	6	5	4	3	2	1	Bit 0
Read:	PA7	PA6	PA5	PA4	PA3	PA2	PA1	PA0
Write:								
Reset:	Unaffected by reset							

Figure 7-2. Port A Data Register (PORTA)

PA[7:0] — Port A Data Bits

These read/write bits are software programmable. Data direction of each port A pin is under the control of the corresponding bit in data direction register A. Reset has no effect on port A data.

7.3.2 Data Direction Register A (DDRA)

Data direction register A determines whether each port A pin is an input or an output.

\$0004	Bit 7	6	5	4	3	2	1	Bit 0
Read:	DDRA7	DDRA6	DDRA5	DDRA4	DDRA3	DDRA2	DDRA1	DDRA0
Write:								
Reset:	0	0	0	0	0	0	0	0

Figure 7-3. Data Direction Register A (DDRA)

DDRA[7:0] — Data Direction Register A Bits

These read/write bits control port A data direction. Reset clears DDRA[7:0], configuring all eight port A pins as inputs.

- 1 = Corresponding port A pin configured as output
- 0 = Corresponding port A pin configured as input

Parallel Input/Output (I/O) Ports

NOTE: Avoid glitches on port A pins by writing to the port A data register before changing data direction register A bits from 0 to 1.

Figure 7-4 shows the I/O logic of port A.

Figure 7-4. Port A I/O Circuit

Writing a logic one to a DDRA bit enables the output buffer for the corresponding port A pin; a logic zero disables the output buffer.

When bit DDRAx is a logic one, reading address \$0000 reads the PAx data latch. When bit DDRAx is a logic zero, reading address \$0000 reads the voltage level on the pin. The data latch can always be written, regardless of the state of its data direction bit. Table 7-1 summarizes the operation of the port A pins.

Table 7-1. Port A Pin Operation

Data Direction Bit	I/O Pin Mode	Accesses to Data Bit	
		Read	Write
0	Input, Hi-Z ⁽¹⁾	Pin	Latch ⁽²⁾
1	Output	Latch	Latch

- 1. Hi-Z = high impedance
- 2. Writing affects data register, but does not affect input.

7.4 Port B

Port B is a 3-bit I/O port that shares its pins with the serial I/O port (SIOP).

NOTE: Do not use port B for general-purpose I/O while the SIOP is enabled.

7.4.1 Port B Data Register (PORTB)

The port B data register contains a latch for each of the three port B pins.

Figure 7-5. Port B Data Register (PORTB)

PB[7:5] — Port B Data Bits

These read/write bits are software programmable bits. Data direction of each port B pin is under the control of the corresponding bit in data direction register B. Reset has no effect on port B data.

NOTE: Writing to data direction register B does not affect the data direction of port B pins that are being used by the SIOP. However, data direction register B always determines whether reading port B returns the states of the latches or the states of the pins.

SCK — Serial Clock

When the SIOP is enabled, SCK is the SIOP clock output (in master mode) or the SIOP clock input (in slave mode).

Parallel Input/Output (I/O) Ports

SDI — Serial Data Input

When the SIOP is enabled, SDI is the SIOP data input.

SDO — Serial Data Output

When the SIOP is enabled, SDO is the SIOP data output.

7.4.2 Data Direction Register B (DDRB)

Data direction register B determines whether each port B pin is an input or an output.

NOTE: Enabling and then disabling the SIOP configures data direction register B for SIOP operation and can also change the port B data register. After disabling the SIOP, initialize data direction register B and the port B data register as your application requires.

\$0005	Bit 7	6	5	4	3	2	1	Bit 0
Read:	DDRB7	DDRB6	DDRB5	0	0	0	0	0
Write:								
Reset:	0	0	0	0	0	0	0	0

= Unimplemented

Figure 7-6. Data Direction Register B (DDRB)

DDRB[7:5] — Data Direction Register B Bits

These read/write bits control port B data direction. Reset clears DDRB[7:5], configuring all three port B pins as inputs.

- 1 = Corresponding port B pin configured as output
- 0 = Corresponding port B pin configured as input

NOTE: Avoid glitches on port B pins by writing to the port B data register before changing data direction register B bits from 0 to 1.

Figure 7-7 shows the I/O logic of port B.

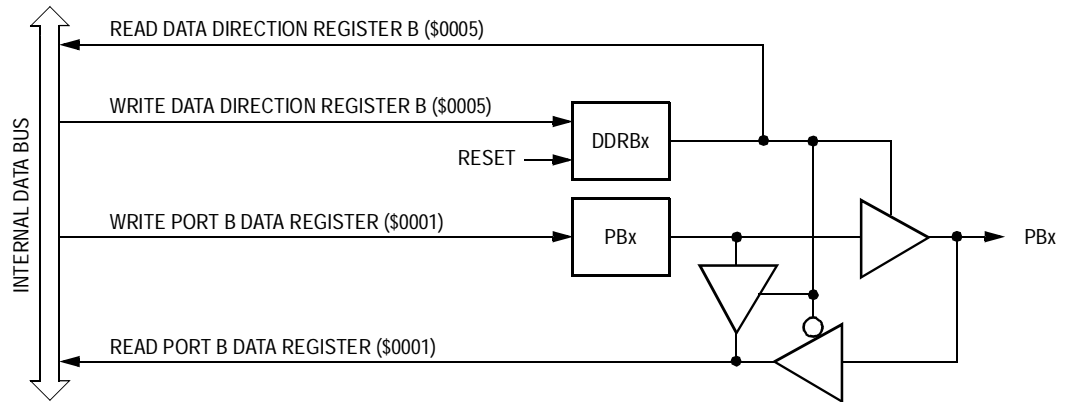

Figure 7-7. Port B I/O Logic

Writing a logic one to a DDRB bit enables the output buffer for the corresponding port B pin; a logic zero disables the output buffer.

When bit DDRBx is a logic one, reading address \$0001 reads the PBx data latch. When bit DDRBx is a logic zero, reading address \$0001 reads the voltage level on the pin. The data latch can always be written, regardless of the state of its data direction bit. [Table 7-2](#) summarizes the operation of the port B pins.

Table 7-2. Port B Pin Operation

Data Direction Bit	I/O Pin Mode	Accesses to Data Bit	
		Read	Write
0	Input, Hi-Z ⁽¹⁾	Pin	Latch ⁽²⁾
1	Output	Latch	Latch

1. Hi-Z = high impedance
2. Writing affects data register, but does not affect input.

7.5 Port C

Port C is an 8-bit I/O port that shares five of its pins with the A/D converter (ADC). The five shared pins are available for general-purpose I/O functions when the ADC is disabled.

Parallel Input/Output (I/O) Ports

7.5.1 Port C Data Register (PORTC)

The port C data register contains a latch for each of the eight port C pins.

Figure 7-8. Port C Data Register (PORTC)

PC[7:0] — Port C Data Bits

These read/write bits are software programmable. Data direction of each port C pin is under the control of the corresponding bit in data direction register C. Reset has no effect on port C data.

V_{RH} — Voltage Reference High Bit

When the ADC is turned on, the PC7/ V_{RH} pin is the positive ADC reference voltage.

AN[3:0] — Analog Input Bits

When the ADC is turned on, the AN0–AN3 pins are software-selectable analog inputs. Unused analog inputs can be used as digital inputs, but pins PC3/AN3, PC4/AN2, PC5/AN1, and PC6/AN0 cannot be used as digital outputs while the ADC is on. Only pins PC0, PC1, and PC2 can be used as digital outputs when the ADC is on.

The port C data register reads normally while the ADC is on, except that the bit corresponding to the currently selected ADC input pin reads as logic zero.

Writing to bits PC7–PC3 while the ADC is on can produce unpredictable ADC results.

7.5.2 Data Direction Register C (DDRC)

Data direction register C determines whether each port C pin is an input or an output.

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	DDRC7	DDRC6	DDRC5	DDRC4	DDRC3	DDRC2	DDRC1	DDRC0
Write:								
Reset:	0	0	0	0	0	0	0	0

Figure 7-9. Data Direction Register C (DDRC)

DDRC[7:0] — Data Direction Register C Bits

These read/write bits control port C data direction. Reset clears DDRC[7:0], configuring all port C pins as inputs.

- 1 = Corresponding port C pin configured as output
- 0 = Corresponding port C pin configured as input

NOTE: Avoid glitches on port C pins by writing to the port C data register before changing data direction register C bits from 0 to 1.

Writing to bits DDRC7–DDRC3 while the ADC is on can produce unpredictable ADC results.

Figure 7-10 shows the I/O logic of port C.

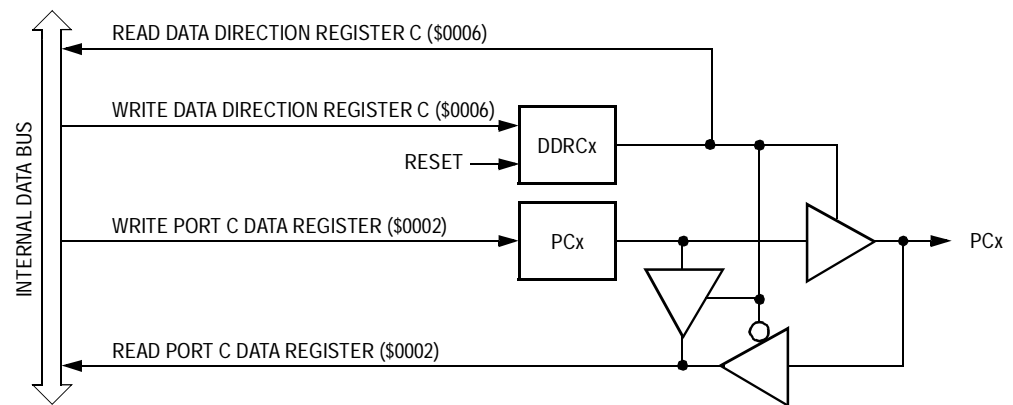

Figure 7-10. Port C I/O Logic

Writing a logic one to a DDRC bit enables the output buffer for the corresponding port C pin; a logic zero disables the output buffer.

When bit DDRCx is a logic one, reading address \$0002 reads the PCx data latch. When bit DDRCx is a logic zero, reading address \$0002 reads the voltage level on the pin. The data latch can always be written, regardless of the state of its data direction bit. [Table 7-3](#) summarizes the operation of the port C pins.

Table 7-3. Port C Pin Operation

Data Direction Bit	I/O Pin Mode	Accesses to Data Bit	
		Read	Write
0	Input, Hi-Z ⁽¹⁾	Pin	Latch ⁽²⁾
1	Output	Latch	Latch

- 1. Hi-Z = high impedance
- 2. Writing affects data register, but does not affect input.

7.6 Port D

Port D is a 2-bit port with one I/O pin and one input-only pin. Port D shares the input-only pin, PD7/TCAP, with the capture/compare timer. PD7/TCAP is the timer input capture pin. The PD7/TCAP pin can always be a general-purpose input, even if input capture interrupts are enabled.

7.6.1 Port D Data Register (PORTD)

The port D data register contains a latch for each of the two port D pins.

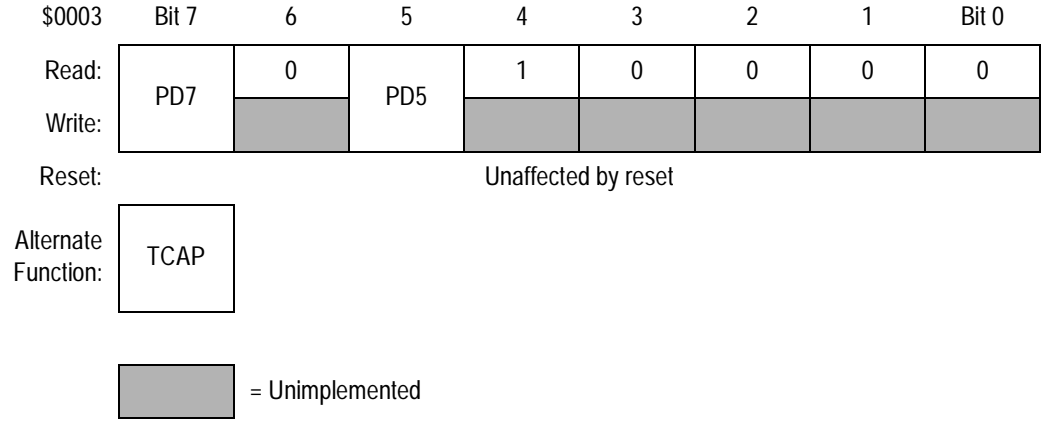

Figure 7-11. Port D Data Register (PORTD)

PD7 and PD5 — Port D Data Bits

These read/write bits are software programmable. Data direction of each port D pin is under the control of the corresponding bit in data direction register D. Reset has no effect on port D data.

TCAP — Timer Capture

TCAP is the input capture pin for the timer.

Freescale Semiconductor, Inc.

Parallel Input/Output (I/O) Ports

7.6.2 Data Direction Register D (DDRD)

Data direction register D determines whether each port D pin is an input or an output.

\$0007	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	0	DDRD5	0	0	0	0	0
Write:								
Reset:	0	0	0	0	0	0	0	0

 = Unimplemented

Figure 7-12. Data Direction Register D (DDRD)

DDRD5 — Data Direction Register D Bit

This read/write bit controls the data direction of pin PD5. Reset clears DDRD5, configuring PD5 as an input.

- 1 = PD5 configured as output
- 0 = PD5 configured as input

NOTE: Avoid glitches on port D pins by writing to the port D data register before changing data direction register D bits from 0 to 1.

Figure 7-13 shows the I/O logic of port D.

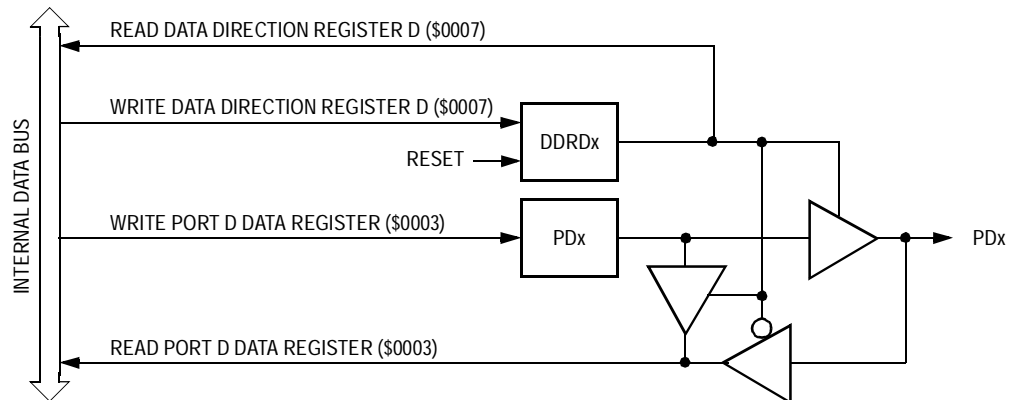

Figure 7-13. Port D I/O Logic

Writing a logic one to a DDRD bit enables the output buffer for the corresponding port D pin; a logic zero disables the output buffer.

When bit DDRDx is a logic one, reading address \$0003 reads the PDx data latch. When bit DDRDx is a logic zero, reading address \$0003 reads the voltage level on the pin. The data latch can always be written, regardless of the state of its data direction bit. **Table 7-4** summarizes the operation of the port D pins.

Table 7-4. Port D Pin Operation

Data Direction Bit	I/O Pin Mode	Accesses to Data Bit	
		Read	Write
0	Input, Hi-Z ⁽¹⁾	Pin	Latch ⁽²⁾
1	Output	Latch	Latch

- 1. Hi-Z = high impedance
- 2. Writing affects data register, but does not affect input.

8.2 Features

Features include:

- Protection from runaway software
- 65.5-ms timeout period (with 2-MHz bus frequency)
- Wait mode operation

Computer Operating Properly Watchdog (COP)

8.3 Introduction

The purpose of the computer operating properly (COP) watchdog is to reset the MCU in case of software failure. Software that is operating properly periodically services the COP watchdog and prevents the reset from occurring. The COP watchdog function is programmable in the mask option register.

8.4 Operation

8.4.1 COP Watchdog Timeout

The COP watchdog is a 16-bit counter that generates a reset if allowed to time out. Periodically clearing the counter starts a new timeout period and prevents the COP from resetting the MCU. A COP watchdog timeout indicates that the software is not executing instructions in the correct sequence.

NOTE: *The internal clock drives the COP watchdog. Therefore, the COP watchdog cannot generate a reset for errors that cause the internal clock to stop.*

The COP watchdog also depends on a power supply voltage at or above a minimum specification and is not guaranteed to protect against brownout. For information about brownout protection, see [Section 5. Resets and Interrupts](#).

8.4.2 COP Watchdog Timeout Period

Use the following formula to calculate the COP timeout period:

$$\text{COP timeout period} = \frac{131,072 \text{ cycles}}{f_{\text{BUS}}}$$

where

$$f_{\text{BUS}} = \frac{\text{crystal frequency}}{2}$$

8.4.3 Clearing the COP Watchdog

To clear the COP watchdog and prevent a COP reset, write a logic zero to bit 0 (COPC) of the COP register at location \$1FF0.

If the main program executes within the COP timeout period, the clearing routine needs to be executed only once. If the main program takes longer than the COP timeout period, the clearing routine must be executed more than once.

NOTE: Place the clearing routine in the main program and not in an interrupt routine. Clearing the COP watchdog in an interrupt routine might prevent COP watchdog timeouts even though the main program is not operating properly.

8.5 Interrupts

The COP watchdog does not generate interrupts.

8.6 COP Register

The COP register is a write-only register that returns the contents of EPROM location \$1FF0 when read.

\$1FF0	Bit 7	6	5	4	3	2	1	Bit 0
Read:	D7	D6	D5	D4	D3	D2	D1	D0
Write:								COPC
Reset:	U	U	U	U	U	U	U	0

= Unimplemented
 U = Unaffected

Figure 8-1. COP Register (COPR)

COPC — COP Clear

COPC is a write-only bit. Periodically writing a logic zero to COPC prevents the COP watchdog from resetting the MCU. Reset clears the COPC bit.

8.7 Low-Power Modes

The STOP and WAIT instructions put the MCU in low-power consumption standby modes.

8.7.1 Stop Mode

The STOP instruction clears the COP watchdog counter. Upon exit from stop mode by external reset:

- The counter begins counting from \$0000.
- The counter is cleared again after the 4064-cycle oscillator stabilization delay.

Upon exit from stop mode by external interrupt:

- The counter begins counting from \$0000.
- The counter is *not* cleared again after the oscillator stabilization delay and has a count of 4064 when the program resumes.

8.7.2 Wait Mode

The COP watchdog continues to operate normally after a WAIT instruction. Software should periodically take the MCU out of wait mode and write to the COPC bit to prevent a COP watchdog timeout.

Section 9. Timer

- Programmable polarity of input capture edge
- Programmable polarity of output compare signal
- Alternate counter registers
- 16-bit counter
- Interrupt-driven operation with three maskable interrupt flags:
 - Input capture
 - Output compare
 - Timer overflow

9.3 Introduction

The timer provides a timing reference for MCU operations. The input capture and output compare functions provide a means to latch the times at which external events occur, to measure input waveforms, and to generate output waveforms and timing delays. [Figure 9-1](#) shows the structure of the timer module.

Figure 9-1. Timer Block Diagram

9.4 Operation

The timing reference for the input capture and output compare functions is a 16-bit free-running counter. The counter is preceded by a divide-by-four prescaler and rolls over every 2^{18} cycles. Timer resolution with a 4-MHz crystal is 2 μ s. Software can read the value in the counter at any time without affecting the counter sequence.

Because of the 16-bit timer architecture, the I/O registers for the input capture and output compare functions are pairs of 8-bit registers.

Figure 9-2. Timer I/O Register Summary

9.4.1 Pin Functions

The timer uses two pins.

9.4.1.1 PD7/TCAP

PD7/TCAP is the input capture pin. When an active edge occurs on PD7/TCAP, the timer transfers the current counter value to the input capture registers. PD7/TCAP is also an I/O port pin.

9.4.1.2 TCMP

TCMP is the output-only output compare pin. When the counter value matches the value written in the output compare registers, the timer transfers the output level bit, OLVL, to the TCMP pin.

9.4.2 Input Capture

The input capture function is a means to record the time at which an external event occurs. When the input capture circuitry detects an active edge on the PD7/TCAP pin, it latches the contents of the timer registers into the input capture registers. The polarity of the active edge is programmable.

Latching values into the input capture registers at successive edges of the same polarity measures the period of the input signal on the PD7/TCAP pin. Latching the counter values at successive edges of opposite polarity measures the pulse width of the signal. **Figure 9-3** shows the logic of the input capture function.

Figure 9-3. Input Capture Operation

9.4.3 Output Compare

The output compare function is a means of generating an output signal when the 16-bit counter reaches a selected value. Software writes the selected value into the output compare registers. On every fourth internal clock cycle the output compare circuitry compares the value of the counter to the value written in the output compare registers. When a match occurs, the timer transfers the programmable output level bit (OLVL) from the timer control register to the TCMP pin.

Software can use the output compare register to measure time periods, to generate timing delays, or to generate a pulse of specific duration or a pulse train of specific frequency and duty cycle on the TCMP pin.

Figure 9-4 shows the logic of the output compare function.

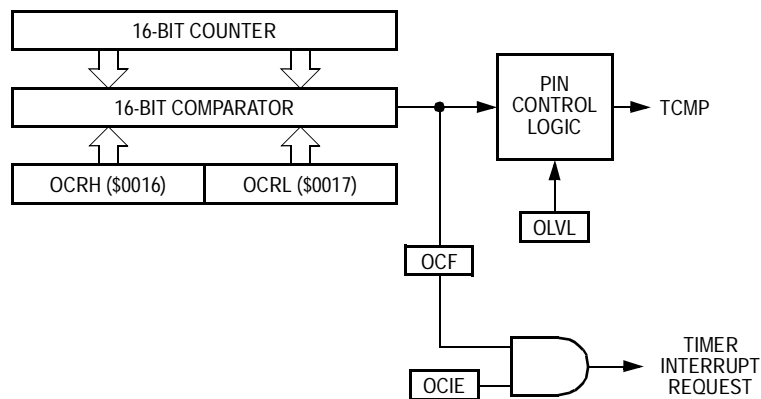

Figure 9-4. Output Compare Operation

9.5 Timing

Table 9-1. Timer Characteristics ($V_{DD} = 5.0 \text{ Vdc}$)⁽¹⁾

Characteristic	Symbol	Min	Max	Unit
Timer Resolution ⁽²⁾	t_{RESL}	4.0	—	t_{CYC}
Input Capture Pulse Width	t_H, t_L	125	—	ns
Input Capture Pulse Period	t_{TLTL}	Note (3)	—	t_{CYC}

- $V_{DD} = 5.0 \text{ Vdc} \pm 10\%$, $T_A = T_L$ to T_H unless otherwise noted.
- A 2-bit prescaler in the timer is the limiting factor as it counts 4 t_{CYC} .
- The minimum t_{TLTL} should not be less than the number of interrupt service routine cycles plus 19 t_{CYC} .

Table 9-2. Timer Characteristics ($V_{DD} = 3.3 \text{ Vdc}$)⁽¹⁾

Characteristic	Symbol	Min	Max	Unit
Timer Resolution ⁽²⁾	t_{RESL}	4.0	—	t_{CYC}
Input Capture Pulse Width	t_H, t_L	250	—	ns
Input Capture Pulse Period	t_{TLTL}	Note (3)	—	t_{CYC}

- $V_{DD} = 3.3 \text{ Vdc} \pm 10\%$, $T_A = T_L$ to T_H unless otherwise noted.
- A 2-bit prescaler in the timer is the limiting factor as it counts 4 t_{CYC} .
- The minimum t_{TLTL} should not be less than the number of interrupt service routine cycles plus 19 t_{CYC} .

Figure 9-5. Input Capture Characteristics

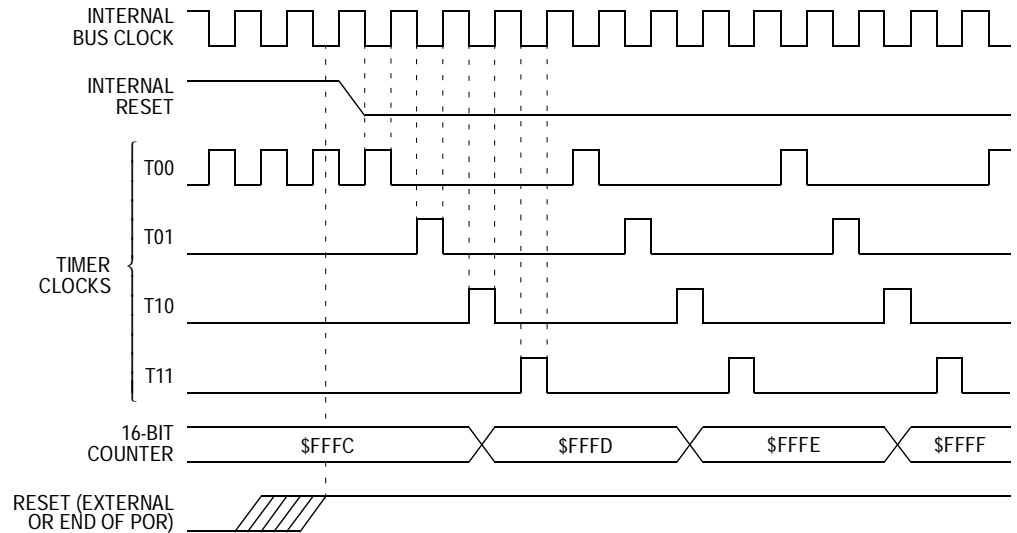

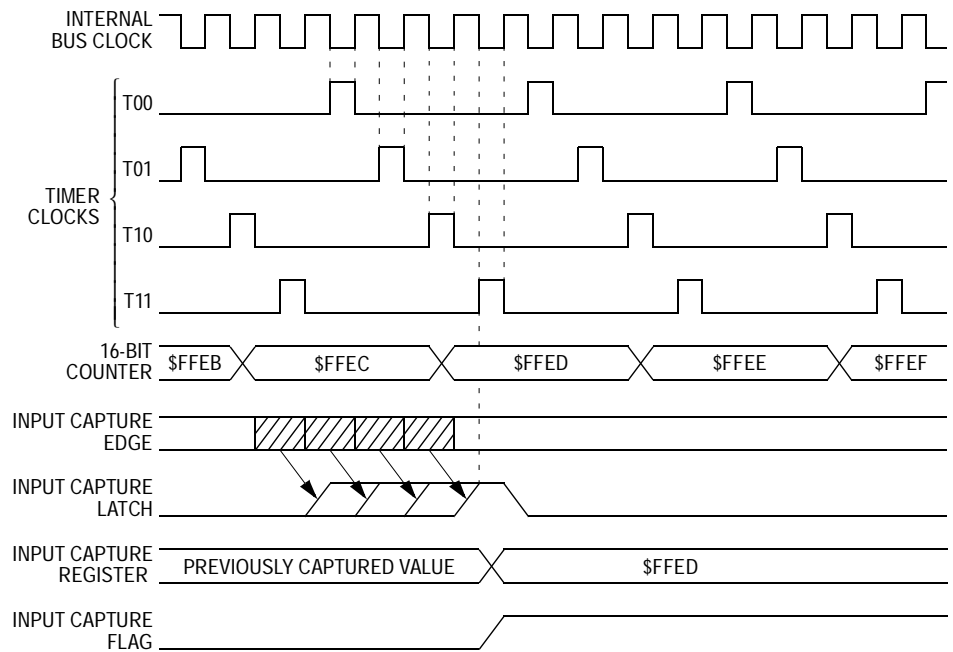

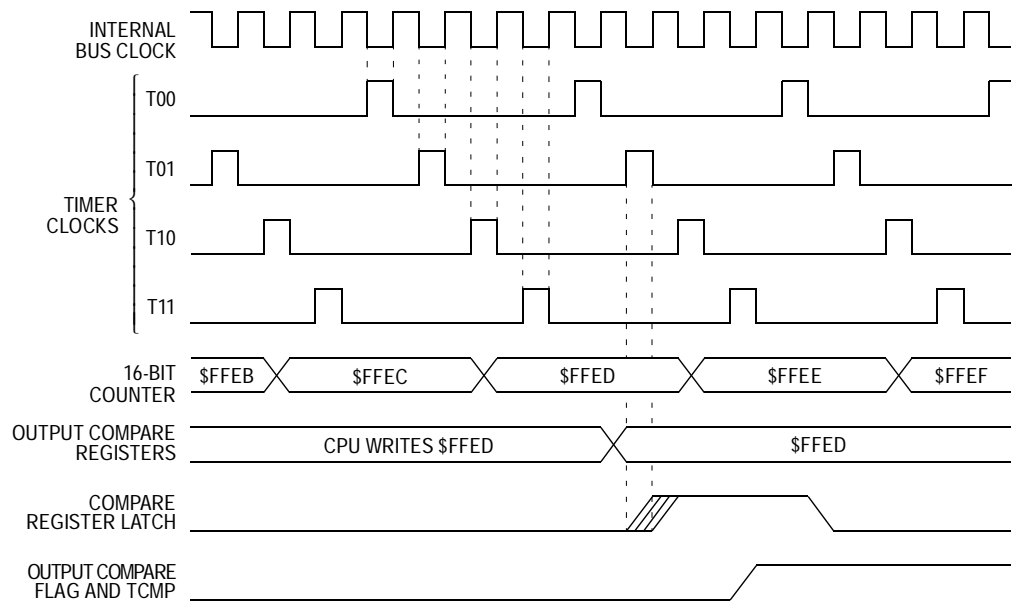

Figure 9-6. Timer Reset Timing

Note:

If the input capture edge occurs in the shaded area between T10 states, then the input capture flag becomes set during the next T11 state.

Figure 9-7. Input Capture Timing

NOTES:

1. A write to the output compare registers may occur at any time, but a compare only occurs at timer state T01. Therefore, the compare may follow the write by up to four cycles.
2. The output compare flag is set at the timer state T11 that follows the comparison latch.

Figure 9-8. Output Compare Timing

Figure 9-9. Timer Overflow Timing

9.6 Interrupts

The following timer sources can generate interrupts:

- Input capture flag (ICF) — The ICF bit is set when an edge of the selected polarity occurs on the input capture pin. The input capture interrupt enable bit, ICIE, enables ICF interrupt requests.
- Output compare flag (OCF) — The OCF bit is set when the counter value matches the value written in the output compare registers. The output compare interrupt enable bit, OCIE, enables OCF interrupt requests.
- Timer overflow flag (TOF) — The TOF bit is set when the counter value rolls over from \$FFFF to \$0000. The timer overflow enable bit (TOIE) enables timer overflow interrupt requests.

Table 9-3 summarizes the timer interrupt sources.

Table 9-3. Timer Interrupt Sources

Source	Local Mask	Global Mask	Priority (1 = Highest)
ICF Bit OCF Bit TOF Bit	ICIE Bit OCIE Bit TOIE Bit	I Bit	3

9.7 I/O Registers

The following registers control and monitor the operation of the timer:

- Timer control register (TCR)
- Timer status register (TSR)
- Timer registers (TRH and TRL)
- Alternate timer registers (ATRH and ATRL)
- Input capture registers (ICRH and ICRL)
- Output compare registers (OCRH and OCRL)

9.7.1 Timer Control Register

The timer control register (TCR) performs the following functions:

- Enables input capture interrupts
- Enables output compare interrupts
- Enables timer overflow interrupts
- Controls the active edge polarity of the TCAP signal
- Controls the active level of the TCMP output

\$0012	Bit 7	6	5	4	3	2	1	Bit 0
Read:	ICIE	OCIE	TOIE	0	0	0	IEDG	OLVL
Write:								
Reset:	0	0	0	0	0	0	U	0

U = Unaffected

Figure 9-10. Timer Control Register (TCR)

ICIE — Input Capture Interrupt Enable

This read/write bit enables interrupts caused by an active signal on the PD7/TCAP pin. Reset clears the ICIE bit.

- 1 = Input capture interrupts enabled
- 0 = Input capture interrupts disabled

OCIE — Output Compare Interrupt Enable

This read/write bit enables interrupts caused by an active signal on the TCMP pin. Reset clears the OCIE bit.

- 1 = Output compare interrupts enabled
- 0 = Output compare interrupts disabled

TOIE — Timer Overflow Interrupt Enable

This read/write bit enables interrupts caused by a timer overflow. Reset clears the TOIE bit.

- 1 = Timer overflow interrupts enabled
- 0 = Timer overflow interrupts disabled

Bits 4–2 — Unused

These are read/write bits that always read as logic zeros.

IEDG — Input Edge

The state of this read/write bit determines whether a positive or negative transition on the PD7/TCAP pin triggers a transfer of the contents of the timer registers to the input capture registers. Reset has no effect on the IEDG bit.

- 1 = Positive edge (low-to-high transition) triggers input capture
- 0 = Negative edge (high-to-low transition) triggers input capture

OLVL — Output Level

The state of this read/write bit determines whether a logic one or a logic zero appears on the TCMP pin when a successful output compare occurs. Reset clears the OLVL bit.

- 1 = TCMP goes high on output compare
- 0 = TCMP goes low on output compare

9.7.2 Timer Status Register

The timer status register (TSR) contains flags for the following events:

- An active signal on the PD7/TCAP pin, transferring the contents of the timer registers to the input capture registers
- A match between the 16-bit counter and the output compare registers, transferring the OLVL bit to the TCMP pin
- A timer rollover from \$FFFF to \$0000

\$0013	Bit 7	6	5	4	3	2	1	Bit 0
Read:	ICF	OCF	TOF	0	0	0	0	0
Write:								
Reset:	U	U	U	0	0	0	0	0

= Unimplemented
 U = Unaffected

Figure 9-11. Timer Status Register (TSR)

ICF — Input Capture Flag

The ICF bit is automatically set when an edge of the selected polarity occurs on the PD7/TCAP pin. Clear the ICF bit by reading the timer status register with ICF set, and then reading the low byte of the input capture registers. Reset has no effect on ICF.

1 = Input capture

0 = No input capture

OCF — Output Compare Flag

The OCF bit is automatically set when the value of the timer registers matches the contents of the output compare registers. Clear the OCF bit by reading the timer status register with OCF set, and then reading the low byte of the output compare registers. Reset has no effect on OCF.

1 = Output compare

0 = No output compare

TOF — Timer Overflow Flag

The TOF bit is automatically set when the 16-bit counter rolls over from \$FFFF to \$0000. Clear the TOF bit by reading the timer status register with TOF set, and then reading the low byte of the timer registers. Reset has no effect on TOF.

1 = Timer overflow

0 = No timer overflow

9.7.3 Timer Registers

The read-only timer registers (TRH and TRL) contain the current high and low bytes of the 16-bit counter. Reading TRH before reading TRL causes TRL to be latched until TRL is read. Reading TRL after reading the timer status register clears the timer overflow flag (TOF). Writing to the timer registers has no effect.

Figure 9-12. Timer Registers (TRH and TRL)

Reading TRH returns the current value of the high byte of the counter and causes the low byte to be latched into a buffer. The buffer value remains fixed even if the high byte is read more than once. Reading TRL reads the transparent low byte buffer and completes the read sequence of the timer registers.

Figure 9-13. Timer Register Reads

NOTE: To prevent interrupts from occurring between readings of TRH and TRL, set the interrupt mask (I bit) in the condition code register before reading TRH, and clear the mask after reading TRL.

9.7.4 Alternate Timer Registers

The read-only alternate timer registers (ATRH and ATRL) contain the current high and low bytes of the 16-bit counter. Reading ATRH before reading ATRL causes ATRL to be latched until ATRL is read. Reading does not affect the timer overflow flag (TOF). Writing to the alternate timer registers has no effect.

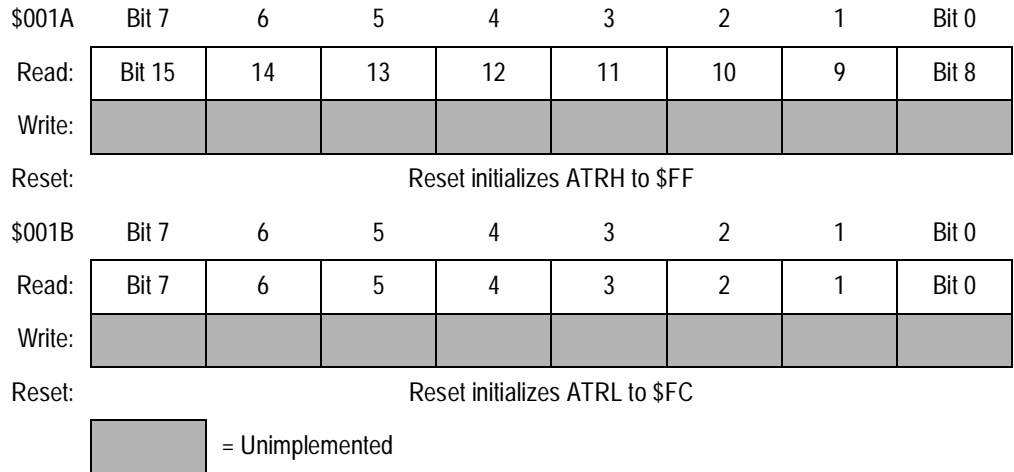

Figure 9-14. Alternate Timer Registers (ATRH and ATRL)

Reading ATRH returns the current value of the high byte of the counter and causes the low byte to be latched into a buffer.

Figure 9-15. Alternate Timer Register Reads

NOTE: To prevent interrupts between readings of ATRH and ATRL, set the interrupt mask (I bit) in the condition code register before reading ATRH, and clear the mask after reading ATRL.

9.7.5 Input Capture Registers

When a selected edge occurs on the TCAP pin, the current high and low bytes of the 16-bit counter are latched into the read-only input capture registers (ICRH and ICRL). Reading ICRH before reading ICRL inhibits further captures until ICRL is read. Reading ICRL after reading the timer status register clears the input capture flag (ICF). Writing to the input capture registers has no effect.

Figure 9-16. Input Capture Registers (ICRH and ICRL)

NOTE: To prevent interrupts between readings of ICRH and ICRL, set the interrupt mask (I bit) in the condition code register before reading ICRH, and clear the mask after reading ICRL.

9.7.6 Output Compare Registers

When the value of the 16-bit counter matches the value in the read/write output compare registers (OCRH and OCRL), the planned TCMP pin action takes place. Writing to OCRH before writing to OCRL inhibits timer compares until OCRL is written. Reading or writing to OCRL after reading the timer status register clears the output compare flag (OCF).

Figure 9-17. Output Compare Registers (OCRH and OCRL)

To prevent OCF from being set between the time it is read and the time the output compare registers are updated, use the following procedure:

1. Disable interrupts by setting the I bit in the condition code register.
2. Write to OCRH. Compares are now inhibited until OCRL is written.
3. Clear bit OCF by reading the timer status register (TSR).
4. Enable the output compare function by writing to OCRL.
5. Enable interrupts by clearing the I bit in the condition code register.

9.8 Low-Power Modes

The STOP and WAIT instructions put the MCU in low-power consumption standby modes.

9.8.1 Stop Mode

The STOP instruction suspends the timer counter. Upon exit from stop mode by external reset:

- The timer counter resumes counting from \$FFFC.
- An input capture edge during stop mode does not affect the ICF bit or the input capture registers.

Upon exit from stop mode by external interrupt:

- The counter resumes counting from the suspended value.
- An input capture edge during stop mode sets the ICF bit and transfers the suspended timer counter value to the input capture registers.

9.8.2 Wait Mode

The timer remains active after a WAIT instruction. Any enabled timer interrupt request can bring the MCU out of wait mode.

Features include:

- Master or slave operation
- Programmable MSB-first or LSB-first operation
- Interrupt-driven operation with transfer complete flag
- Data collision flag
- Master mode frequency = bus frequency \div 4
- Maximum slave mode frequency = bus frequency \div 4
- No minimum slave mode frequency

10.3 Introduction

The serial input/output port (SIOP) is a 3-wire master/slave communication port with serial clock, data input, and data output connections. The SIOP enables high-speed synchronous serial data transfer between the MCU and peripheral devices. Shift registers used with the SIOP can increase the number of parallel I/O pins controlled by the MCU. More powerful peripherals such as analog-to-digital converters and real-time clocks are also compatible with the SIOP.

Figure 10-1 shows the structure of the SIOP module.

Figure 10-2. SIOP I/O Register Summary

10.4 Operation

The master MCU initiates and controls the transfer of data to and from one or more slave peripheral devices. In master mode, a transmission is initiated by writing to the SIOP data register (SDR). Data written to the SDR is parallel-loaded and shifted out serially to the slave device(s).

Many simple slave devices are designed to only receive data from a master or to only supply data to a master. For example, when a serial-to-parallel shift register is used as an 8-bit port, the master MCU initiates transfers of 8-bit data values to the shift register. Since the serial-to-parallel shift register does not send any data to the master, the MCU ignores whatever it receives as a result of the transmission.

The SIOP is simpler than the serial peripheral interface (SPI) on some other Motorola MCUs in that:

- The polarity of the serial clock is fixed.
- There is no slave select pin.
- The direction of serial data does not automatically switch as on the SPI because the SIOP is not intended for use in multimaster systems. Most applications use one MCU as the master to initiate and control data transfer between one or more slave peripheral devices.

A programmable option allows the SIOP to transfer data MSB first or LSB first.

10.4.1 Pin Functions

The SIOP uses three pins and shares them with port B:

- PB7/SCK
- PB6/SDI
- PB5/SDO

NOTE: *Do not use the PB7/SCK, PB6/SDI, or PB5/SDO pins for general-purpose I/O while the SIOP is enabled.*

When bit 6 (SPE) of the SIOP control register (SCR) is set, the SIOP is enabled and the PB7/SCK, PB5/SDO, and PB6/SDI pins are dedicated to SIOP functions. Clearing SPE disables the SIOP and the SIOP pins become standard I/O port pins.

NOTE: *Enabling and then disabling the SIOP configures the data direction register bits associated with the SIOP pins for SIOP operation and can also change the associated port data register. After disabling the SIOP, initialize the data direction register and the port data register as the application requires.*

10.4.1.1 PB7/SCK

The PB7/SCK pin synchronizes the movement of data into and out of the MCU through the PB6/SDI and PB5/SDO pins. In master mode, the PB7/SCK pin is an output. The serial clock frequency in master mode is one-fourth the internal clock frequency.

In slave mode, the PB7/SCK pin is an input. The maximum serial clock frequency in slave mode is one-fourth the internal clock rate. Slave mode has no minimum serial clock frequency.

Figure 10-3 shows the timing relationships among the serial clock, data input, and data output. The state of the serial clock between transmissions is a logic one. The first falling edge on the PB7/SCK pin signals the beginning of a transmission, and data appears at the PB5/SDO pin. Data is captured at the PB6/SDI pin on the rising edge of the serial clock, and the transmission ends on the eighth rising edge of the serial clock.

Figure 10-3. SIOP Data/Clock Timing

Serial Input/Output Port (SIOP)

The first falling edge on PB7/SCK begins a transmission. At this time the first bit of received data is accepted at the PB6/SDI pin and the first bit of transmitted data is presented at the PB5/SDO pin.

10.4.1.2 PB5/SDO

The PB5/SDO pin is the SIOP data output. Between transfers, the state of the PB5/SDO pin reflects the value of the last bit shifted out on the previous transmission, if there was one. To preset the beginning state, write to the corresponding port data bit before enabling the SIOP. On the first falling edge on the PB7/SCK pin, the first data bit to be shifted out appears at the PB5/SDO pin.

After SPE is set, the PB5/SDO output driver can be disabled by writing a zero to the corresponding data direction register bit of the port, thereby configuring PB5/SDO as a high-impedance input.

10.4.1.3 PB6/SDI

The PB6/SDI pin is the SIOP data input. Valid SDI data must be present for an SDI setup time, t_s , before the rising edge of the serial clock and must remain valid for an SDI hold time, t_H , after the rising edge of the serial clock. (See [Table 10-1](#) and [Table 10-2](#).)

10.4.2 Data Movement

Connecting the SIOP data register of a master MCU with the SIOP of a slave MCU forms a 16-bit circular shift register. During an SIOP transfer, the master shifts out the contents of its SIOP data register on its PB5/SDO pin. At the same time, the slave MCU shifts out the contents of its SIOP data register on its PB5/SDO pin. **Figure 10-4** shows how the master and slave exchange the contents of their data registers.

Figure 10-4. Master/Slave SIOP Shift Register Operation

10.5 Timing

Figure 10-5. SIOP Timing

Table 10-1. SIOP Timing ($V_{DD} = 5.0 \text{ Vdc}$)⁽¹⁾

Characteristic	Symbol	Min	Max	Unit
Frequency of Operation Master Slave	$f_{SIOP(M)}$ $f_{SIOP(S)}$	$f_{OSC}/64$ dc	$f_{OSC}/8$ 525	MHz kHz
Cycle Time Master Slave	$t_{SCK(M)}$ $t_{SCK(S)}$	4.0 —	4.0 1920	$t_{CYC}^{(2)}$ ns
Clock (SCK) Low Time ($f_{OP} = 2.1 \text{ MHz}$) ⁽³⁾⁽⁴⁾	t_{SCKL}	932	—	ns
SDO Data Valid Time	t_V	—	200	ns
SDO Hold Time	t_{HO}	0	—	ns
SDI Setup Time	t_S	100	—	ns
SDI Hold Time	t_H	100	—	ns

- $V_{DD} = 5.0 \text{ Vdc} \pm 10\%$, $V_{SS} = 0 \text{ Vdc}$, $T_A = T_L$ to T_H unless otherwise noted.
- $t_{CYC} = 1 \div f_{OP}$
- f_{OSC} = crystal frequency; $f_{OP} = f_{OSC} \div 2 = 2.1 \text{ MHz}$ maximum
- In master mode, the frequency of SCK is $f_{OP} \div 4$.

Table 10-2. SIOP Timing ($V_{DD} = 3.3 \text{ Vdc}$)⁽¹⁾

Characteristic	Symbol	Min	Max	Unit
Frequency of Operation Master Slave	$f_{SIOP(M)}$ $f_{SIOP(S)}$	$f_{OSC}/64$ dc	$f_{OSC}/8$ 250	MHz kHz
Cycle Time Master Slave	$t_{SCK(M)}$ $t_{SCK(S)}$	4.0 —	4.0 4000	$t_{CYC}^{(2)}$ ns
Clock (SCK) Low Time ($f_{OP} = 1.0 \text{ MHz}$) ⁽³⁾⁽⁴⁾	t_{SCKL}	1980	—	ns
SDO Data Valid Time	t_V	—	400	ns
SDO Hold Time	t_{HO}	0	—	ns
SDI Setup Time	t_S	200	—	ns
SDI Hold Time	t_H	200	—	ns

- $V_{DD} = 3.3 \text{ Vdc} \pm 10\%$, $V_{SS} = 0 \text{ Vdc}$, $T_A = T_L$ to T_H unless otherwise noted
- $t_{CYC} = 1 \div f_{OP}$
- f_{OSC} = crystal frequency; $f_{OP} = f_{OSC} \div 2 = 1.0 \text{ MHz}$ maximum
- In master mode, the frequency of SCK is $f_{OP} \div 4$.

10.6 Interrupts

The SIOP does not generate interrupt requests.

10.7 I/O Registers

The following registers control and monitor SIOP operation:

- SIOP control register (SCR)
- SIOP status register (SSR)
- SIOP data register (SDR)

10.7.1 SIOP Control Register

The read/write SIOP control register (SCR) contains two bits. One bit enables the SIOP, and the other configures the SIOP for master mode or for slave mode.

\$000A	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	SPE	0	MSTR	0	0	0	0
Write:	0	SPE	0	MSTR	0	0	0	0
Reset:	0	0	0	0	0	0	0	0

Figure 10-6. SIOP Control Register (SCR)

SPE — SIOP Enable

This read/write bit enables the SIOP. Setting SPE initializes the data direction register as follows:

- The PB6/SDI pin is an input.
- The PB5/SDO pin is an output.
- The PB7/SCK pin is an input in slave mode and an output in master mode.

Clearing SPE disables the SIOP and returns the port to its normal I/O functions. The data direction register and the port data register remain in their SIOP-initialized state.

NOTE: After clearing SPE, be sure to initialize the port for its intended I/O use.

Serial Input/Output Port (SIOP)

Clearing SPE during a transmission aborts the transmission, resets the bit counter, and returns the port to its normal I/O function. Reset clears SPE.

- 1 = SIOP enabled
- 0 = SIOP disabled

MSTR — Master Mode Select

This read/write bit configures the SIOP for master mode. Setting MSTR initializes the PB7/SCK pin as the serial clock output. Clearing MSTR initializes the PB7/SCK pin as the serial clock input. MSTR can be set at any time regardless of the state of SPE. Reset clears MSTR.

- 1 = Master mode selected
- 0 = Slave mode selected

10.7.2 SIOP Status Register

The read-only SIOP status register (SSR) contains two bits. One bit indicates that a SIOP transfer is complete, and the other indicates that an invalid access of the SIOP data register occurred while a transfer was in progress.

\$000B	Bit 7	6	5	4	3	2	1	Bit 0
Read:	SPIF	DCOL	0	0	0	0	0	0
Write:								
Reset:	0	0	0	0	0	0	0	0

Figure 10-7. SIOP Status Register (SSR)

SPIF — Serial Peripheral Interface Flag

This clearable, read-only bit is set automatically on the eighth rising edge on the PB7/SCK pin and indicates that a data transmission took place. SPIF does not inhibit further transmissions. Clear SPIF by reading the SIOP status register while SPIF is set and then reading or writing the SIOP data register. Reset clears SPIF.

- 1 = Transmission complete
- 0 = Transmission not complete

DCOL — Data Collision Flag

This clearable, read-only bit is automatically set if the SIOP data register is accessed while a data transfer is in progress. Reading or writing the SIOP data register while a transmission is in progress causes invalid data to be transmitted or read. Clear DCOL by reading the SIOP status register with SPIF set and then accessing the SIOP data register. Because the clearing sequence accesses the SIOP data register, the sequence has to be completed before another transmission starts or DCOL is set again.

To clear DCOL when SPIF is not set, turn off the SIOP by writing a zero to SPE and then turn it back on by writing a one to SPE. Reset clears DCOL.

- 1 = Invalid access of SDR
- 0 = Valid access of SDR

10.7.3 SIOP Data Register

The SIOP data register (SDR) is both the transmit data register and the receive data register. To read or write the SIOP data register, the SPE bit in the SIOP control register must be set.

Figure 10-8. SIOP Data Register (SDR)

With the SIOP configured for master mode, writing to the SIOP data register initiates a serial transfer. This register is not buffered. Writing to the SIOP data register overwrites the previous contents. Reading or writing to the SIOP data register while a transmission is in progress can cause invalid data to be transmitted or received.

10.8 Low-Power Modes

The WAIT and STOP instructions put the MCU in low-power consumption standby modes.

10.8.1 Stop Mode

The STOP instruction suspends the clock to the SIOP. When the MCU exits stop mode, processing resumes after the internal oscillator stabilization delay of 4064 oscillator cycles.

A STOP instruction in a master SIOP does not suspend the clock to slave SIOPs.

10.8.2 Wait Mode

The WAIT instruction suspends the clock to the SIOP. When the MCU exits wait mode, processing resumes immediately.

A WAIT instruction in a master SIOP does not suspend the clock to slave SIOPs.

11.8	Low-Power Modes	136
11.8.1	Stop Mode	136
11.8.2	Wait Mode	136

11.2 Features

Features include:

- 8-bit conversions with ± 1.5 -LSB precision
- Four external and three internal analog input channels
- Wait mode operation

Analog-to-Digital Converter (ADC)

11.3 Introduction

The ADC consists of a single successive-approximation A/D converter, an input multiplexer to select one of four external or two internal channels, and control circuitry. **Figure 11-1** shows the structure of the ADC module.

Figure 11-1. ADC Block Diagram

Figure 11-2. ADC I/O Register Summary

11.4 Operation

The A/D conversion process is ratiometric, using two reference voltages, V_{RH} and V_{SS} . Conversion accuracy is guaranteed only if V_{RH} is equal to V_{DD} .

11.4.1 Pin Functions

The ADC uses five pins and shares them with port C:

- PC7/ V_{RH}
- PC6/AN0, PC5/AN1, PC4/AN2, and PC3/AN3

11.4.1.1 PC7/ V_{RH}

The voltage reference high pin (PC7/ V_{RH}) supplies the high reference voltage for the ratiometric conversion process. For ratiometric conversion, the supply voltage of the analog source should be the same as V_{RH} and be referenced to V_{SS} .

11.4.1.2 PC6/AN0–PC3/AN3

The multiplexer can select one of four external analog input channels (AN0, AN1, AN2, or AN3) for sampling. The conversion takes 32 cycles. The first 12 cycles sample the voltage on the selected input pin by charging an internal capacitor. In the last 20 cycles, a comparator successively compares the output of an internal D/A converter to the sampled analog input. Control logic changes the D/A converter input one bit at a time, starting with the MSB, until the D/A converter output matches the sampled analog input. The conversion is monotonic and has no missing codes. At the end of the conversion, the conversion complete flag (CCF) becomes set, and the CPU takes two cycles to move the result to the ADC data register.

NOTE: *To prevent excess power dissipation, do not simultaneously use an I/O port pin as a digital input and an analog input.*

While the ADC is on, the selected analog input reads as logic zero. The port C pins that are not selected read normally.

An analog input voltage equal to V_{RH} converts to digital \$FF; an input voltage greater than V_{RH} converts to \$FF with no overflow. An analog input voltage equal to V_{SS} converts to digital \$00. For ratiometric conversion, the source of each analog input should use V_{RH} as the supply voltage and be referenced to V_{SS} .

The clock frequency must be equal to or greater than 1 μ MHz. If the internal clock frequency is less than 1 μ MHz, the internal RC oscillator (nominally 1.5 MHz) must be used for the ADC conversion clock. Make this selection by setting the ADRC bit to logic one in the ADC status and control register.

11.5 Interrupts

The ADC cannot generate interrupt requests.

11.6 Timing and Electrical Characteristics

Table 11-1. ADC Characteristics ($V_{DD} = 5.0 \text{ Vdc}$)⁽¹⁾

Characteristic	Min	Max	Unit
Resolution	8	8	Bit
Absolute Accuracy ($4.0 > V_{RH} > V_{DD}$) ⁽²⁾	—	±1.5	LSB
Conversion Range ($PC7/V_{RH}$)	V_{SS}	V_{DD}	V
Conversion Time (Includes Sampling Time)			
External Clock	32	32	t_{AD} ⁽³⁾
Internal RC Oscillator ($ADRC = 1$)	32	32	μs
Monotonicity	Inherent (Within Total Error)		
Zero Input Reading ($V_{IN} = 0 \text{ V}$)	00	01	Hex
Full-Scale Reading ($V_{IN} = V_{RH}$)	FF	FF	Hex
Sample Acquisition Time ⁽⁴⁾			
External Clock	12	12	t_{AD} ⁽⁵⁾
Internal RC Oscillator ($ADRC = 1$)	—	12	μs
Input Capacitance PC6/AN0, PC5/AN1, PC4/AN2, PC3/AN3	—	12	pF
Analog Input Voltage	V_{SS}	V_{RH}	V
Input Leakage ⁽⁶⁾			
PC6/AN0, PC5/AN1, PC4/AN2, PC3/AN3	—	±1	μA
PC7/ V_{RH}	—	±1	
ADC On Current Stabilization Time	—	100	μs

- $V_{DD} = 5.0 \text{ Vdc} \pm 10\%$, $V_{SS} = 0 \text{ Vdc}$
- ADC accuracy may decrease proportionately as V_{RH} is reduced below 4.0 V.
- t_{AD} = cycle time of the A/D converter
- Source impedances more than 10 kΩ adversely affect internal RC charging time during input sampling.
- $t_{AD} = t_{CYC} (1 \div f_{OP})$ if MCU clock is clock source
- External system error caused by input leakage approximately equals R source times input current.

11.7 I/O Registers

The following registers control and monitor operation of the ADC:

- ADC status and control register (ADSCR)
- ADC data register (ADDR)

11.7.1 ADC Status and Control Register

The ADC status and control register (ADSCR) contains a conversion complete flag and four writable control bits. Writing to ADSCR clears the conversion complete flag and starts a new conversion sequence.

Figure 11-3. ADC Status and Control Register (ADSCR)

CCF — Conversion Complete Flag

This read-only bit is automatically set when an analog-to-digital conversion is complete, and a new result can be read from the ADC data register. Clear the CCF bit by writing to the ADC status and control register or by reading the ADC data register. Resets clear the CCF bit.

- 1 = Conversion complete
- 0 = Conversion not complete

ADRC — ADC RC (Oscillator)

This read/write bit turns on the internal RC oscillator to drive the ADC. If the internal clock frequency (f_{OP}) is less than 1 MHz, ADRC must be set. When the RC oscillator is turned on, it requires a time, t_{ADRC} , to stabilize, and results can be inaccurate during this time. Resets clear the ADRC bit.

- 1 = Internal RC oscillator drives ADC
- 0 = Internal clock drives ADC

When the internal RC oscillator is being used as the ADC clock, two limitations apply:

- Because of the frequency tolerance of the RC oscillator and its asynchronism with the internal clock, the conversion complete flag must be used to determine when a conversion sequence is complete.
- The conversion process runs at the nominal 1.5-MHz rate, but the conversion results must be transferred to the ADC data register synchronously with the internal clock; therefore, the conversion process is limited to a maximum of one channel every internal clock cycle.

ADON — ADC On

This read/write bit turns on the ADC. When the ADC is on, it requires a time, t_{ADON} , for the current sources to stabilize. During this time, results can be inaccurate. Resets clear the ADON bit.

- 1 = ADC turned on
- 0 = ADC turned off

Bits 4–2 — Not used

Bits 4–2 always read as logic zeros.

CH[2:0] — Channel Select Bits

These read/write bits select one of eight ADC input channels as shown in [Table 11-2](#). Channels 0–3 are the input pins, PC3/AN3, PC4/AN2, PC5/AN1, and PC6/AN0. Channels 4–6 can be used for reference measurements. Channel 7 is reserved for factory testing.

Table 11-2. ADC Input Channel Selection

CH[2:1:0]	Channel	Signal
000	0	AN0
001	1	AN1
010	2	AN2
011	3	AN3
100	4	V_{RH}
101	5	$(V_{RH} + V_{SS}) / 2$
110	6	V_{SS}
111	7	Reserved

Analog-to-Digital Converter (ADC)

To prevent excess power dissipation, do not use an ADC pin as an analog input and a digital input at the same time.

Using one of the port pins as the ADC input does not affect the ability to use the remaining port pins as digital inputs.

Reading a port pin that is selected as an analog input returns a logic zero.

11.7.2 ADC Data Register

The ADC data register (ADDR) is a read-only register that contains the result of the most recent analog-to-digital conversion.

\$001D	Bit 7	6	5	4	3	2	1	Bit 0
Read:	Bit 7	6	5	4	3	2	1	Bit 0
Write:								
Reset:	Unaffected by reset							

Figure 11-4. ADC Data Register (ADDR)

11.8 Low-Power Modes

11.8.1 Stop Mode

The STOP instruction turns off the ADC and aborts any current and pending conversions.

11.8.2 Wait Mode

The ADC continues to operate normally after the WAIT instruction. To reduce power consumption in wait mode:

- If the ADC is not being used, clear both the ADON and ADRC bits before entering wait mode.
- If the ADC is being used and the internal clock rate is above 1 MHz, clear the ADRC bit before entering wait mode.

Section 12. Electrical Specifications

12.1 Contents

12.2	Maximum Ratings	138
12.3	Operating Temperature Range	139
12.4	Thermal Characteristics	139
12.5	Power Considerations	140

12.11	5.0-Volt Control Timing	146
12.12	3.3 V Control Timing	147

12.2 Maximum Ratings

Maximum ratings are the extreme limits to which the MCU can be exposed without permanently damaging it.

The MCU contains circuitry to protect the inputs against damage from high static voltages; however, do not apply voltages higher than those shown in the table here. Keep V_{In} and V_{Out} within the range $V_{SS} \leq (V_{In} \text{ or } V_{Out}) \leq V_{DD}$. Connect unused inputs to the appropriate voltage level, either V_{SS} or V_{DD} .

Rating	Symbol	Value	Unit
Supply Voltage	V_{DD}	-0.3 to +7.0	V
Current Drain per Pin (Excluding V_{DD} and V_{SS})	I	25	mA
Input Voltage	V_{In}	$V_{SS} - 0.3$ to $V_{DD} + 0.3$	V
EPROM Programming Voltage	V_{PP}	16.75	V
Storage Temperature Range	T_{STG}	-65 to +150	°C

NOTE: *This device is not guaranteed to operate properly at the maximum ratings. Refer to [12.6 5.0-Volt DC Electrical Characteristics](#) and [12.7 3.3-Volt DC Electrical Characteristics](#) for guaranteed operating conditions.*

12.3 Operating Temperature Range

Package Type	Symbol	Value	Unit
MC68HC705P9P ⁽¹⁾ , DW ⁽²⁾ , S ⁽³⁾ (Standard) MC68HC705P9C ⁽⁴⁾ P, CDW, CS (Extended) MC68HC705P9V ⁽⁵⁾ P, VDW, VS (Automotive) MC68HC705P9M ⁽⁶⁾ P, MDW, MS (Automotive)	T_A	T_L to T_H 0 to 70 -40 to +85 -40 to +105 -40 to +125	°C

1. P = Plastic dual in-line package (PDIP)
2. DW = Small outline integrated circuit (SOIC)
3. S = Ceramic dual in-line package (Cerdip)
4. C = Extended temperature range (-40 to +85°C)
5. V = Automotive temperature range (-40 to +105°C)
6. M = Automotive temperature range (-40 to +125°C)

12.4 Thermal Characteristics

Characteristic	Symbol	Value	Unit
Thermal Resistance Plastic Dual In-Line Package (PDIP) Small Outline Integrated Circuit (SOIC) Ceramic Dual In-Line Package (Cerdip)	θ_{JA}	60 60 60	°C/W

12.5 Power Considerations

The average chip junction temperature, T_J , in °C can be obtained from:

$$T_J = T_A + (P_D \times \theta_{JA}) \quad (1)$$

Where:

T_A = ambient temperature in °C

θ_{JA} = package thermal resistance, junction to ambient in °C/W

$P_D = P_{INT} + P_{I/O}$

$P_{INT} = I_{CC} \times V_{CC}$ = chip internal power dissipation

$P_{I/O}$ = power dissipation on input and output pins (user-determined)

For most applications, $P_{I/O} < P_{INT}$ and can be neglected.

Ignoring $P_{I/O}$, the relationship between P_D and T_J is approximately:

$$P_D = \frac{K}{T_J + 273^\circ\text{C}} \quad (2)$$

Solving equations (1) and (2) for K gives:

$$K = P_D \times (T_A + 273^\circ\text{C}) + \theta_{JA} \times (P_D)^2 \quad (3)$$

where K is a constant pertaining to the particular part. K can be determined from equation (3) by measuring P_D (at equilibrium) for a known T_A . Using this value of K, the values of P_D and T_J can be obtained by solving equations (1) and (2) iteratively for any value of T_A .

12.8 Driver Characteristics

NOTES:

1. Shaded area indicates variation in driver characteristics due to changes in temperature and for normal processing tolerances. Within the limited range of values shown, V vs. I curves are approximately straight lines.
2. At $V_{DD} = 5.0\text{ V}$, devices are specified and tested for $V_{OL} \leq 800\text{ mV}$ @ $I_{OL} = -0.8\text{ mA}$.
3. At $V_{DD} = 3.3\text{ V}$, devices are specified and tested for $V_{OL} \leq 300\text{ mV}$ @ $I_{OL} = -0.2\text{ mA}$.

Figure 12-1. Typical High-Side Driver Characteristics

NOTES:

1. Shaded area indicates variation in driver characteristics due to changes in temperature and for normal processing tolerances. Within the limited range of values shown, V vs. I curves are approximately straight lines.
2. At $V_{DD} = 5.0\text{ V}$, devices are specified and tested for $V_{OL} \leq 400\text{ mV}$ @ $I_{OL} = 1.6\text{ mA}$.
3. At $V_{DD} = 3.3\text{ V}$, devices are specified and tested for $V_{OL} \leq 300\text{ mV}$ @ $I_{OL} = 0.4\text{ mA}$.

14.2	Introduction	151
14.3	MC Order Numbers	151

14.2 Introduction

This section contains ordering numbers for the MC68HC705P9.

14.3 MC Order Numbers

Table 14-1. Order Numbers

Package Type	Case Outline	Pin Count	Operating Temperature	Order Number
Plastic DIP ⁽¹⁾	710	28	0 to +70°C -40 to +85°C -40 to +105°C -40 to +125°C	MC68HC705P9P MC68HC705P9CP MC68HC705P9VP MC68HC705P9MP
SOIC ⁽²⁾	733	28	0 to +70°C -40 to +85°C -40 to +105°C -40 to +125°C	MC68HC705P9DW MC68HC705P9CDW MC68HC705P9VDW MC68HC705P9MDW
CERDIP ⁽³⁾	751F	28	0 to +70°C -40 to +85°C -40 to +105°C -40 to +125°C	MC68HC705P9S MC68HC705P9CS MC68HC705P9VS MC68HC705P9MS

1. DIP = dual in-line package
2. SOIC = small outline integrated circuit
3. CERDIP = ceramic DIP

A	C
accumulator (A)	C bit
ADC	case outlines
ADC (analog-to-digital converter)	CCF bit
block diagram	ceramic resonator circuit
features	CH[2:0] bits
I/O register summary	condition code register
I/O registers	(CCR)
low-power modes	COP register (COPR)
ADC data register (ADDR)	COP watchdog
ADC status and control	COP in stop mode
register (ADSCR)	COP in wait mode
addressing modes	COP register (COPR)
ADON bit	enabling and disabling
ADRC bit	features
alternate timer registers (ATRH/L)	operation
ALU	timeout period
AN[3:0] bits	COP watchdog reset
arithmetic/logic unit (ALU)	COPC bit
	COPE bit
B	CPU
bootloader ROM	block diagram
bootload procedure	control unit
bootloader circuit	features
location	instruction set summary
brownout	instruction types
bypass capacitors	instructions set
	opcode map
	registers

Index

I

I bit69, 71–72, 112–115
 I/O bits
 ADON bit135–136
 ADRC bit132, 134, 136
 AN[3:0] bits88
 C bit55
 CCF bit132, 134
 CH[2:0] bits135
 COPC bit68, 97–98
 COPE bit42
 DCOL bit126
 DDRA[7:0] bits83
 DDRB[7:5] bits86
 DDRC[7:0] bits89
 DDRD5 bit92
 EPGM bit38
 I bit69, 71–72, 112–115
 ICF bit71, 108, 111, 114, 116
 ICIE bit71, 108–109
 IEDG bit110
 IRQ bit42
 LATCH bit38
 MSTR bit126
 OCF bit71, 108, 111, 115
 OCIE bit71, 108–109
 OLVL bit104, 110
 PA[7:0] bits83
 PB[7:5] bits85

PC[7:0] bits	88	output compare registers	
PD5 bit	91	(OCRH/L)	110–111, 115
PD7 bit	91	output compare registers	
SIOP bit	42	(OCRH/OCRL)	104
SPE bit	121–122, 125, 127	port A data register (PORTA)	83
SPIF bit	126	port B data register (PORTB)	85
TOF bit	71, 108, 111–113	port C data register (PORTC)	88
TOIE bit	71, 108–109	port D data register (PORTD)	91
I/O pins		SIOP control register	
IRQ/V _{PP} pin	22, 29, 38–39, 42, 69	(SCR)	121, 125, 127
OSC1 pin	27	SIOP data register (SDR)	126–127
OSC2 pin	27	SIOP status register (SSR)	126
PB5/SDO pin	86, 120–122, 125	timer control register (TCR)	71, 109
PB6/SDI pin	86, 120–122, 125	timer registers (TRH/L)	110–112
PB7/SCK pin	85, 120–122, 125	timer status register	
PC3/AN0 pin	135	(TSR)	71, 110, 114–115
PC3/AN3 pin	88, 131	ICF bit	71, 108, 111, 114, 116
PC4/AN2 pin	88, 131, 135	ICIE bit	71, 108–109
PC5/AN1 pin	88, 131, 135	IEDG bit	110
PC6/AN0 pin	88, 131, 135	index register (X)	49–53
PC7/V _{RH} pin	88, 131	input capture interrupt	100
PD7/TCAP pin	39, 90, 103, 110–111	input capture registers	
RESET pin	28, 39, 66–68	(ICRH/L)	103, 110–111, 114, 116
TCMP pin	29, 103–104, 110, 115	instruction set	49
V _{SS} pin	26	addressing modes	50
I/O port pin termination	81	instruction set summary	58
I/O registers		instruction types	52
ADC data register (ADDR)	132, 134–136	opcode map	64
ADC status and control		internal clock	96
register (ADSCR)	132, 134	frequency	27
alternate timer registers (ATRH/L)	113	internal RC oscillator	132, 134–135
COP register (COPR)	68, 97	Interrupt	108
data direction register A (DDRA)	83	interrupts	
data direction register B (DDRB)	86	external interrupt	69
data direction register C (DDRC)	89	external interrupt logic	69
data direction register D (DDRD)	92	external interrupt timing	70
EPROM programming		interrupt flowchart	74
register (EPROG)	38	interrupt processing	72
input capture registers (ICRH/ICRL)	103	interrupt sources	68
input capture registers		interrupt stacking order	72
