

Analog LCD Display Engine for XGA and SXGA Resolutions

TARGET SPECIFICATION

Feature Overview

- Programmable Context Sensitive™ Scaling
- High-quality Up-scaling and Down-scaling
- Integrated 9-bit ADC/PLL
- IQSync™ AutoSetup
- Integrated programmable Timing Controller
- Integrated Pattern Generator
- Perfect Picture™ Technology
- sRGB 3D Color Warp
- Integrated OSD
- Advanced EMI reduction features
- Framelock operation with Safety Mode™
- Serial I²C interface
- Low power 0.18 μm process technology

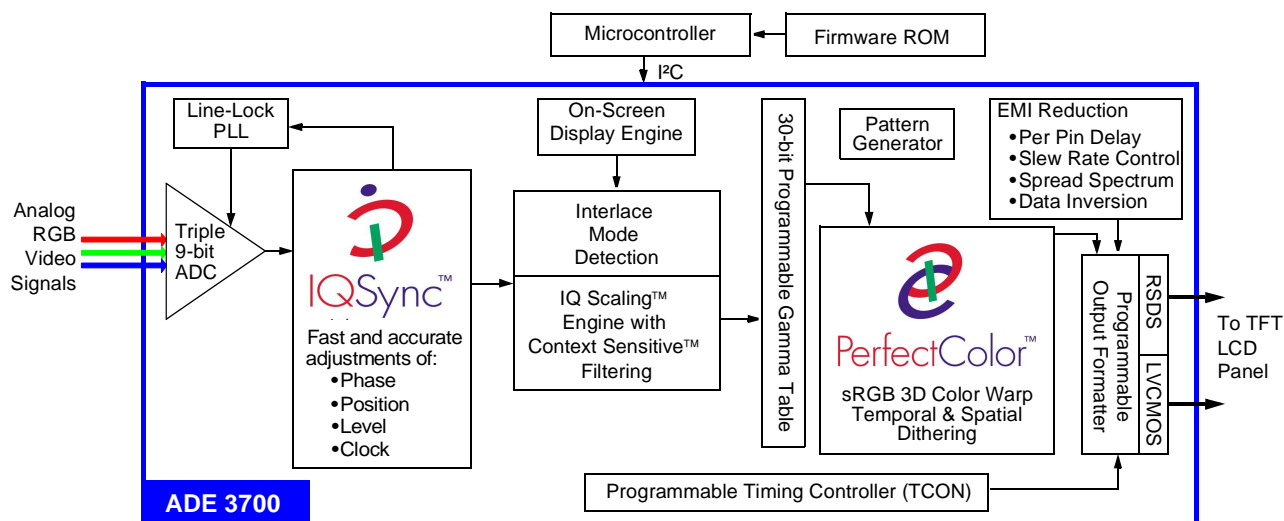

General Description

ADE3700 devices are a family of highly-integrated display engine ICs, enabling the most advanced, flexible, and cost-effective system-on-chip solutions for analog-only input LCD display applications.

The ADE3700 covers the full range of XGA and SXGA analog-only applications including Smart Panel designs.

The ADE3700 family is pin-to-pin compatible and comes in a low-cost, 128-pin LQFP package.

ADE3700 devices use the same software platform and are backward-compatible with the previous generation of ADE3xxx Scaling Engines.

LCD Scaler Product Selector

Product	Package	Output Format Support		Input Interface Support		
		Resolution	TCON	Analog	DVI	YUV
ADE3700X	128 LQFP	Up to XGA 75 Hz		Yes		
ADE3700XT	128 LQFP	Up to XGA 75 Hz	Yes	Yes		
ADE3700SX	128 LQFP	Up to SXGA 75 Hz		Yes		

Third Generation Context Sensitive™ Scaler

- Sharper text with Edge Enhancement
- RAM based coefficients for unique customization
- 5:1 Upscale and 2:1 Downscale
- Independent X - Y axis zoom and shrink

Analog RGB input

- 140 MHz 9-bit ADC
- Ultra low jitter digital Line Lock PLL
- Composite Sync and Sync on Green support

IQsync™ AutoSetup

- AutoSetup configures phase, clock, level, and position
- Supports continuous calibration for reduced user intervention
- Automatically detects activity on input
- Compatible with all standard VESA and GTF modes

Perfect Picture™ Technology

- Programmable 3D Color Warp
- Digital brightness, contrast, hue, and saturation gamma controls for all inputs
- Simple white point control
- Compatible with sRGB standard
- Video & Picture windowing
- Supports up to 7 different windows
- Independent window controls for contrast brightness, saturation, hue and gamma

Perfect Color™ Technology

- True color dithering for 12- and 18-bit panels
- Temporal and spatial dithering
- 30-bit programmable gamma table

OSD Engine

- 256 RAM based 12x18 characters
- 1- and 4-bit per pixel color characters
- Bordering, shadowing, transparency, fade-in, and fade-out effects
- Supports font rotation
- Up to 4 sub windows
- 32-entry TrueColor LUT

Programmable Timing Controller (TCON)

- Highly programmable support for XGA SmartPanels
- Dual-function LVCMOS and RSDS outputs
- Supports 18-, 24-, 36-, and 48-bit RSDS outputs
- Advanced Flicker Detection and Reduction
- 12 programmable timing signals for row/column control
- Wide range of drivers & TCON compatibility
- Simulation tools for easy programming
- Supports complex polarity generation for IPS panels

Advanced EMI Reduction Features

- Flexible data inversion / transition minimization, single, dual, and separate
- Per pin delay, 0 to 6ns in 0.4ns increments
- Adaptive Slew Rate control outputs
- Differential clock
- Spread spectrum -programmable digital FM modulation of the output clock with no external components

Output Format

- Supports resolutions up to SXGA @ 75Hz
- Supports 6- or 8-bit Panels
- Supports double or single pixel wide formats

1 General Information

The ADE3700 family of devices is capable of implementing all of the advanced features of today's LCD monitor products. For maximum flexibility, an external microcontroller (MCU) is used for controlling the ADE3700 and other monitor functions.

Figure 1: ADE3700 Block Diagram

The ADE3700 architecture unburdens the MCU from all data-intensive pixel manipulations, providing an optimal blend of features and code customizing without incurring the cost of a 16-bit processor or memory. The key interactions between the monitor MCU and the ADE3700 can be broken down into the features shown in the table below.

Table 1: ADE3700 Features (Sheet 1 of 2)

Feature	Description of ADE3700 Operation	Blocks Used	Pages
Power-up / Initialize	When power is first applied, the ADE3700 is asynchronously reset from a pin. The MCU typically programs the ADE3700 with a number of default values and sets up the ADE3700 to identify activity on any of the input pins. All pre-configured values and RAMs, such as DVI settings, line-lock PLL settings, OSD characters, LCD timing values (output sequencer), scale kernels, gamma curves, sRGB color warp, APC dithering, output pin configuration (OMUX), etc. can be pre-loaded into the ADE3700. The typical end state is that the ADE3700 is initialized into a low power mode, ready to turn active once the power button is pressed.	GLBL SMEAS LLK ADC OSD SCALER GAMMA SRGB OUTSEQ TCON APC OMUX	11 25 18 17 62 42 70 60 45 48 71 72
Activity Detect	When the monitor has been powered on, the inputs can be monitored for active video sources. Based on the activity monitors, the MCU chooses an input or power down state.	SMEAS	25

Table 1: ADE3700 Features (Sheet 2 of 2)

Feature	Description of ADE3700 Operation	Blocks Used	Pages
Sync / Timing Measurement	Once an input source is selected, all available information on frequencies and line/pixel counts is measured for the selected source and made available to the MCU.	SMEAS	25
Mode Set	Once the MCU has determined the matching video mode or calculated a video mode using a GTF algorithm, the datapath is programmed to drive the flat panel. Clock frequencies for the internal memory and datapath are also set at this time.	GLBL LLK SRT DMUX SMUX SCALER	11 18 23 37 32 42
Autotune	When the MCU calls for an autotune, the MCU sets up an iterative loop to search for the best phase, gain, offset, etc. At each step of the loop, the MCU kicks off a test in which the ADE3700 which performs extensive statistical analysis of the incoming data stream. The results of the analysis are made available to the MCU which is responsible for the optimization algorithm.	DMEAS LLK ADC SMUX SRT	47 18 17 32 23
Digital Contrast / Brightness	In response to user OSD control, the MCU can program single 8-bit registers that set brightness and contrast for each color channel independently.	SRGB	60
White Point Control	In response to user OSD control, the MCU can program three 8-bit registers that set the white point for the output.	SRGB	60
GAMMA Adjustment	The MCU can program the gamma RAMs to implement 10-bit accurate color transformations.	GAMMA	70
sRGB Control	The SRGB block allows simple, intuitive color control with just a few registers.	SRGB	60
Pattern Generation	For production testing, the ADE3700 can be programmed by the MCU to output a wide set of test patterns.	PGEN	54
Flicker Reduction	For Smart Panel applications, the MCU can set up the flicker detection block to report any correlation with the polarity inversion signal. The MCU can then change the polarity inversion to a non-correlating pattern to eliminate flicker.	FLICKER TCON	68 48
Backlight Control	The ADE3700 provides two PWM outputs for direct control of the power components in a typical backlight. The MCU sets up the registers and enables the function.	PWM	80
Low Power State	To enter a low power state, the MCU can gate of most of the clocks and put the analog blocks into a low power standby state.	GLBL	11

2 Functional Description

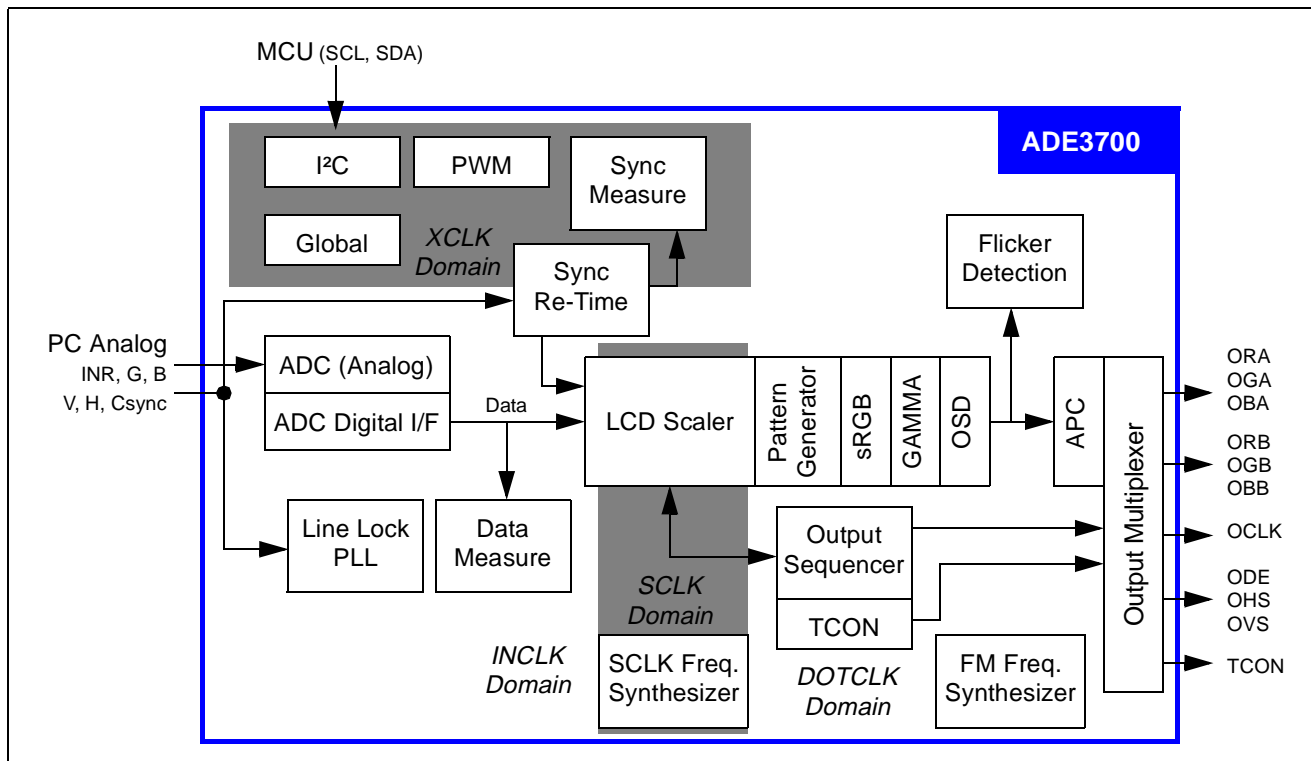

2.1 Global Control

The global control block is responsible for:

- selecting clock sources
- power control
- I²C control
- SCLK frequency synthesizer control
- block by block synchronous reset generation

The global control block runs on the XCLK clock domain which is required to be active for programming. The clock domains of all other blocks are set in the Global Control Block. For I²C access, the requested block must be driven with a valid clock frequency greater than 10 MHz. Clock domains are shown in [Figure 2](#).

Figure 2: Global Control Block Diagram

To program the SCLK frequency synthesizer to a desired frequency (f_{OUT} , in MHz), the following equations apply.

Table 3: SCLK Frequency Synthesizer Programmable Values (Sheet 1 of 2)

Frequency Range	SDIV
$f_{OUT} < 8 \times f_{XCLK}$ AND $f_{OUT} \geq 4 \times f_{XCLK}$	0
$f_{OUT} < 4 \times f_{XCLK}$ AND $f_{OUT} \geq 2 \times f_{XCLK}$	1

Table 3: SCLK Frequency Synthesizer Programmable Values (Sheet 2 of 2)

Frequency Range	SDIV
$f_{OUT} < 2 \times f_{XCLK}$ AND $f_{OUT} \geq f_{XCLK}$	2
$f_{OUT} < f_{XCLK}$ AND $f_{OUT} \geq f_{XCLK} / 2$	3
$f_{OUT} < f_{XCLK}/2$ AND $f_{OUT} \geq f_{XCLK} / 4$	4
$f_{OUT} < f_{XCLK}/4$ AND $f_{OUT} \geq f_{XCLK} / 8$	5
$f_{OUT} < f_{XCLK}/8$ AND $f_{OUT} \geq f_{XCLK} / 16$	6
$f_{OUT} < f_{XCLK}/16$ AND $f_{OUT} \geq f_{XCLK} / 32$	7

$$MD = \text{INT}(f_{XCLK} \times (2^{(6 + NDIV - SDIV)}) / f_{OUT})$$

$$PE = \text{INT}((2^{15}) \times (MD + 1 - f_{XCLK} \times (2^{(6 + NDIV - SDIV)}) / f_{OUT}))$$

where f_{XCLK} is the external crystal frequency in MHz (typically 27). The maximum SCLK frequency generated by this block is $f_{XTAL} \times 2^{(2+NDIV)}$.

For the lowest power operation, all clock sources should be set to the “zero” setting and the analog power disables should be set. In this condition, only the crystal clock domain (XCLK) is running and blocks in INCLK or DOTCLK domains may not be accessible through the I²C interface.

The following modules can have their clocks disabled to reduce power consumption when the chip is in steady-state mode: FLK, OSD, PGEN, DFT, and DMEAS. Also, the clock to the TCON can be disabled for non-Smart Panel applications. Note that the OSD module has a special power bypass bit that must be enabled when the OSD clock is disabled.

Also, the clock to all I²C registers associated with modules in the INCLK and DOTCLK domains can be disabled after the chip is configured to reduce power in steady-state mode. Note that during chip configuration, all I²C clocks must be enabled.

An asynchronous clock enable override signal must be disabled to allow control of individual module clock signals.

		R/W	[1]	0x1	Enable PGEN clock
		R/W	[0]	0x1	Enable DOTCLK to I2C registers

2.2 FM Frequency Synthesizer

The FM Frequency Synthesizer can create a clock up to eight times the crystal input clock using a digital frequency synthesizer. The modulation period and amplitude are directly controlled by I2C registers. The I2C interface runs in the LLK_CTRL clock domain, which must be active for access.

The relationship of the output frequency (f_{OUT}) to the 32-bit phase_rate value and the crystal frequency (f_{XCLK}) is:

$$f_{OUT} = f_{XCLK} * 2^{27+NDIV} / \text{phase_rate}$$

where f_{OUT} and f_{XCLK} are in MHz.

The maximum output frequency of the FM frequency synthesizer is $f_{XTAL} * 2^{(2+NDIV)}$.

Note that native duty cycle of the FM frequency synthesizer is not 50/50, so it is recommended to either enable the divide-by-two in the fm synthesizer block for frequencies up to $f_{XCLK} * 2^{(1+NDIV)}$ (typically 108 MHz) or set the output mux to a double wide output mode for pixel clocks above $f_{XCLK} * 2^{(1+NDIV)}$. This will ensure a 50% duty clock on the output.

Table 5: FM Frequency Synthesizer Registers

Register Name	Addr	Mode	Bits	Default	Description
FM_FS_CTRL	0x0830		[7:4]		Reserved
		R/W	[3]	0x0	Clear the FM synthesizer
		R/W	[2]	0x0	Clear the fs accumulator
		R/W	[1]	0x0	Activate the frequency modulation
		R/W	[0]	0x0	Divide the output by 2
FM_FS_PR_0	0x0831	R/W	[7:0]	8000000	Phase Rate

		R/W	[2:0]	0x0	Value

2.3 Analog-to-Digital Converter (ADC)

The analog port consists of three 9-bit RGB ADCs with preamp, gain/offset adjustment and digital filtering. The I2C interface for the ADC block is in the INCLK clock domain which must be active for programming.

The relationship of input voltage, gain and offset register settings to output code is approximately as follows:

$$\text{output_code_8b} = 457 \times \text{offset} / 2^8 + 181 \times \text{gain} \times \text{input_mV} / 2^{16} - 125 \times \text{gain} \times \text{offset} / 2^{16} - 219$$

Table 6: ADC Registers (Sheet 1 of 2)

Register	Addr.	Mode	Bits	Default	Description
ADC_DITHER	0x0324		[7]		Reserved
		R/W	[6]	0x0	Dither horizontally
		R/W	[5]	0x0	Dither vertically
		R/W	[4]	0x0	Dither temporally
		R/W	[3]	0x0	Force dither high
		R/W	[2]	0x0	Enable dither
			[1:0]	0x0	Reserved
ADC_OFFSET_R	0x0326	R/W	[7:0]	0x0	Offset Control, Red Channel

ADC_GAIN_B	0x032C	R/W	[7:0]	0x0	Gain Control, Blue Channel

2.4 Line Lock PLL

The Line Lock PLL recovers a sample clock from an incoming hsync source. The response characteristics of the line lock PLL can be adjusted for optimum response time and jitter filtering. The phase of the sample clock can be digitally adjusted in steps of 289 ps (with a 27-MHz crystal). The I2C interface of the line lock PLL is in the LLK_CTRL clock domain which must be active for programming.

The PLL filter has three ranges with independent filter parameters. When the phase detector error stays below a programmable threshold for a programmable number of input lines, the PLL filter coefficients are changed. Any phase detector error above the programmed threshold will return the filter to the appropriate level in one line. The operation is shown in [Figure 3](#).

Figure 3: Line Lock PLL

The digital loop filter is controlled by three parameters: MFACTOR, A and B. M_FACTOR is the desired number of clocks per input line. The A and B parameters control the response of the 2nd order digital filter. A and B are composed of a linear and exponential component designated by the L and E suffix, respectively. The relationship of these numbers to the classic 2nd order damping and natural frequency are as follows:

$$\text{Damping} = AL \times 2^{(AE-12)} \times \text{SQRT}(5 \times M_FACTOR / (BL \times 2^{BE}))$$

$$\text{Natural Frequency} = \text{SQRT}(M_FACTOR \times 5 \times BL \times 2^{(BE-34)})$$

Table 7: Line Lock PLL Registers (Sheet 1 of 4)

Register Name	Addr	Mode	Bits	Default	Description

2.5 Sync Retiming (SRT)

The Sync Retiming (SRT) block retimes incoming synchronization signals (H Sync, V Sync, etc) into the XCLK and INCLK domains.

For the XCLK domain, the SRT has the following functions:

- Retimes all sync signals going to SMEAS into the XCLK domain.
- Extracts the vertical sync signal from composite sync signals (AHSYNC and ACSYNC pins)
- Divides clocks by 1024 for activity detection purposes.
- Generates a delay-filtered version of vertical sync from a mux-selectable vertical sync source.
- Generates a coast signal in the XCLK domain for the LLPLL.

Table 8: Sync Retiming Registers (Sheet 1 of 2)

Register Name	Addr	Mode	Bits	Default	Description

2.6 Sync Measurement

The Input Sync Measurement (SMEAS) block continuously detects activity from all video sources. The module can measure the characteristics of the sync signals on any input port. The sync measurement module reports the results of the measurements to the system microcontroller.

This portion of the sync measurement is fully synchronous on the crystal clock (XCLK). Another block, the Sync Retiming Block (SRT), handles the asynchronous signal transfer of the incoming sync signals.

Input Sync Functions:

- Activity Detection
- Sync Management
- Measurement

Table 9: Sync Measurement (Sheet 1 of 8)

Register Name	Addr	Mode	Bits	Default	Description
SMEAS_ACT_CTRL	0x0100		[7:4]	0x0	Reserved
		R/W	[3]	0x0	Enable activity detection in free-running mode.
		R/W	[2]	0x0	Freeze results in free-running mode. No meaning in one shot mode. 0: Do not freeze the results. New result will be available on the next and subsequent toggle of the polling bit. 1: Freeze the current results. The polling bit will still toggle and the block continues to free-run; however, results will not be updated.
		R/W	[1]	0x0	activity detection start. In one-shot mode it triggers the start of a measurement and is reset to zero when the measurement is complete.
		R/W	[0]	0x0	activity detection mode control 0: free-running 1: one shot
SMEAS_ACT_H_SMPTM_L	0x0101	R/W	[7:0]	0x0	Sample time value for clock or hsync activity. In units of XCLK_period*256
SMEAS_ACT_H_SMPTM_H	0x0102	R/W	[7:0]	0x0	
SMEAS_ACT_V_SMPTM_L	0x0103	R/W	[7:0]	0x0	Sample time value for vsync activity in units of XCLK_period*256. jj Note: this number MUST be larger than hsync sample time.

Table 9: Sync Measurement (Sheet 7 of 8)

Register Name	Addr	Mode	Bits	Default	Description
SMEAS_STATUS_RANGE	0x0152	R	[7]	0x0	In free-running mode any of the status bits can change at the end of each measurement. In one shot mode any of the status bits can change at the completion of the measurement. The MEAS_STICKY_STATUS bit is a bitwise OR of bits[3:0] (before the bitwise OR, the mask in SMEAS_STATUS_MASK is AND in) and is sticky. The only way to reset it is for software to write a zero into this bit. This bit goes to the scaler to blank the scaler output. A write to this reg will reset it to 0.
		R	[6]	0x0	Indicates that one of the measured polarities does not match the reference value.
		R	[5]	0x0	Hsync (selected by SMEAS_H_SEL) polarity. 0: active low 1: active high
		R	[4]	0x0	Vsync (selected by SMEAS_V_SEL) polarity. 0: active low 1: active high
		R	[3]	0x0	Indicates that the vertical pulse width measurement exceeded the reference \pm tolerance range.
		R	[2]	0x0	Indicates that the horizontal per vertical measurement exceeded the reference \pm tolerance range.
		R	[1]	0x0	Indicates that the XCLKs per horizontal measurement exceeded the reference \pm tolerance range.
		R	[0]	0x0	Indicates that the XCLKs per vertical measurement exceeded the reference \pm tolerance range.
SMEAS_MEAS_POLLING	0x0153		[7:2]	0x0	Reserved
		R	[1]	0x0	Toggle on h meas free-running mode, at end of each meas. No function on one-shot mode.
		R	[0]	0x0	Toggle on v meas free-running mode, at end of each meas. No function on one-shot mode.
SMEAS_SKEW_STATUS	0x0154		[7:2]	0x0	Reserved
		R	[1]	0x0	0: hsync to vsync skew above threshold 1: hsync to vsync skew below threshold
		R	[0]	0x0	0: skew measurement running 1: skew measurement finished

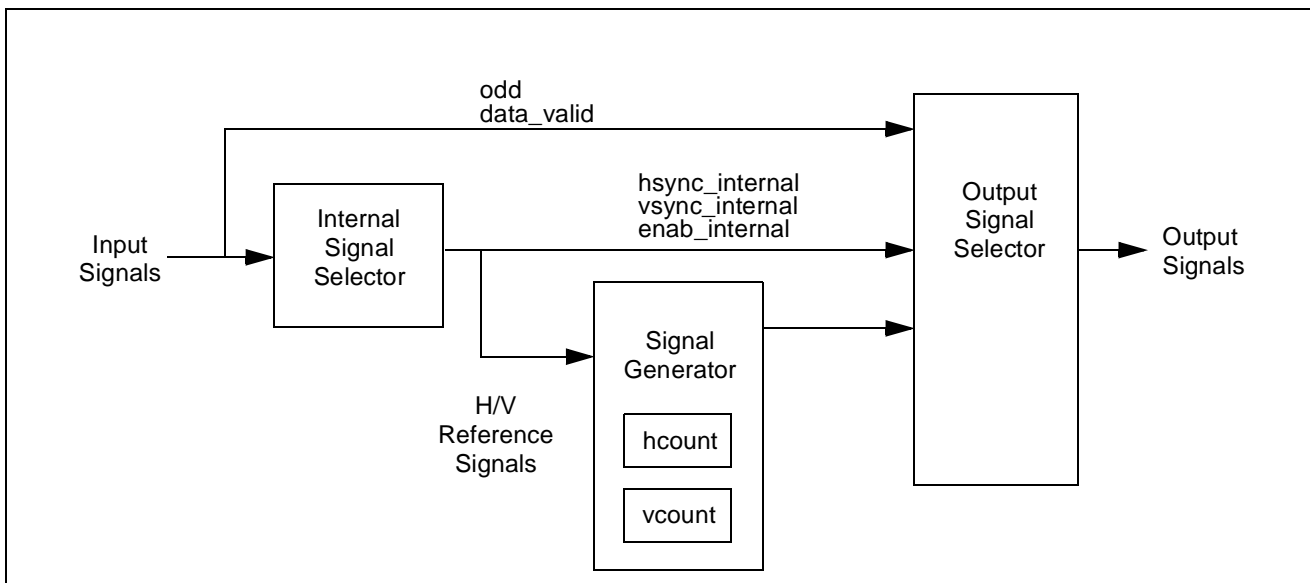

Table 9: Sync Measurement (Sheet 8 of 8)

Register Name	Addr	Mode	Bits	Default	Description
SMEAS_V_OUTOF_RNG	0x0155	R	[7:0]	0x0	The number of times the XCLKs per vertical reference/meas comparison has been out of range. Maximum is 240. Clear by setting SMEAS_CLEAR[1].
SMEAS_H_OUTOF_RNG	0x0156	R	[7:0]	0x0	The number of times the XCLKs per horizontal reference/meas comparison has been out of range. Maximum is 240. Clear by setting SMEAS_CLEAR[1].
SMEAS_HV_OUTOF_RNG	0x0157	R	[7:0]	0x0	The number of times the horizontal per vertical reference/meas comparison has been out of range. Maximum is 240. Clear by setting SMEAS_CLEAR[1].
SMEAS_VHI_OUTOF_RNG	0x0158	R	[7:0]	0x0	The number of times the vertical pulse width in XCLKs reference/meas comparison has been out of range. Maximum is 240. Clear by setting SMEAS_CLEAR[1].
SMEAS_HPOL_OUTOF_RNG	0x0159	R	[7:0]	0x0	The number of times the horizontal polarity reference/meas comparison has been out of range. Maximum is 240. Clear by setting SMEAS_CLEAR[1].
SMEAS_VPOL_OUTOF_RNG	0x015A	R	[7:0]	0x0	The number of times the vertical polarity reference/meas comparison has been out of range. Maximum is 240. Clear by setting SMEAS_CLEAR[1].

2.7 Sync Multiplexer (SMUX)

The Synchronization Multiplexer (SMUX) selects a set of sync signals from the input sources and provides them to the scaler. It generates signals that are missing, depending on the capability. The MCU can select the output sync signals between the input sources and the generated signals.

Figure 4: Sync Multiplexer Block Diagram

2.7.1 Functional Description

The internal signal selector selects which of the input sources are to be used for the internal hsync, vsync and enab signals and is controlled by I2C register SMUX_CTRL0.

The signal generator contains a horizontal and a vertical counter that are resynced using a horizontal and vertical reference signals respectively. The selection of the H/V references and the resync edge (either rising or falling) are programmed via SMUX_CTRL1[3:0]. The signal generator requires both references to be defined, or else the counters will not run properly and the generated signals (other than venab) will be invalid.

The output signal selector can be programmed to output any of the internal syncs, bypassed signals such as odd and data_valid, or the generated versions of all the signals (hsync, vsync, enab, odd, valid). Vertical enable (venab) and clamp are always generated.

The following table summarizes programming for typical modes.

Table 10: Sync Multiplexer Programming Table

Mode	Valid Inputs	Output Source for						
		Hsync	Vsync	Enab	Valid	Odd	Venab	Clamp
Analog Line Lock	LLK_HSYNC LLK_VSYNC	LLK	LLK	GEN	GEN	NA	GEN	GEN
Analog Ext. Clock	VGA_HSYNC LLK_VSYNC TESTCLK	VGA	LLK	GEN	GEN	NA	GEN	GEN

Other sources (such as composite sync) are simple variations on these basic configurations.

The programmed timing values of the generated signals (such as clamp) are relative to the reference signal and edge selected. For example, if the LLK_HSYNC falling edge is selected as the horizontal reference, then all horizontal programming values are relative to it.

Three signals are generated using programmable set/reset values: clamp and the two components that make up the input enable signal (horizontal and vertical enables). The henab and venab signals define the video window that the scaler operates on. The difference between the reset and set quantities is the number of pixels (h) or lines (v) in the input image. Clean wraparound is supported: the henab_set can be greater than the henab_rst.

The clamp pulse should be located outside the active video area, i.e. both programmed values should be in the horizontal blanking region, typically in backporch of the incoming sync.

All set/reset programming values for clamp and henab must be less than the input horizontal total. Both set/reset programming values for venab must be less than the input vertical total. The updates for the enable registers can occur in four modes:

1. No Shadowing
2. Simple Shadowing: updates occur when the upper byte of _rst is written
3. Shadowing + Blank Update: updates occur only in the next blanking region after rst_u is written
4. Shadowing + Vblank Update: updates occur in the next vblank region after rst_u is written.

This mode also advances or retards the frame trigger to the scaler to prevent glitches. It takes one frame to write H and two frames to write the V-position. With large position changes, a glitch will show up. For small changes (e.g. ± 1) no glitch is created.

The written position values are instantly available by read back, independent of shadow mode. The actual values being used by the hardware at a given time can also be read back using separate I2C addresses.

When hsync and/or vsync is generated (e.g. when enab is the only input), the relative position of the generated pulse can be set either before or after the reference edge between -128 and +127 pixels per line.

2.7.2 Example

ADC input using line lock clock:

```
omux_ctrl0 = 0x09 // select ilk hsync and vsync
omux_ctrl1 = 0x0F // choose incoming hsync and vsync as references, choose rising edges
omux_ctrl2 = 0x0C // select the original hsyncs and vsyncs, along with the generated
                // enab and valid signals
```

```
henab_set = hsync_width + hback_porch
```

```
henab_rst = hsync_width + hback_porch + in_hpixel
```

```
venab_set = vsync_width + vback_porch
```

```
venab_rst = vsync_width + vback_porch + in_vpixel
```

```
clamp_set = hsync_width + hback_porch + in_hpixel + 4 // clamp is turned on 4 after last pixel
```

```
clamp_rst = hsync_width + hback_porch -4 // clamp is turned off 4 pixels before the 1st pixel
```

VENAB_SET_HW_L	0x0216	R	[7:0]		Actual value used by hardware post shadowing.
VENAB_SET_HW_U	0x0217	R	[3:0]		Actual value used by hardware post shadowing.
VENAB_RST_HW_L	0x0218	R	[7:0]		Actual value used by hardware post shadowing.
VENAB_RST_HW_U	0x0219	R	[3:0]		Actual value used by hardware post shadowing.

2.8 Data Multiplexer

The Data Multiplexer provides the following functions:

- Debug modes (e.g. bit order swap, color swap)

Table 12: Data Mux Registers

Register Name	Addr.	Mode	Bits	Default	Description
DMUX_CHANSEL	0x0280		[7]	0x0	Reserved
		R/W	[6]	0x0	0: Normal 1: MSB/LSB byte flip
		R/W	[5:3]	0x0	If enabled by [2] 0x0: Reserved 0x1: R & G bytes are swapped 0x2: B & G bytes are swapped 0x3: R => G, G => B, B => R 0x4: R & B bytes are swapped 0x5: R => B, G => R, B => G 0x0, 0x6-0x7: Reserved
		R/W	[2]	0x0	0: normal 1: enable color swap
		R/W	[1:0]	0x0	video source select 0x0: ADC data 0x1: nc 0x2: nc 0x3: for test only

2.9 Data Measurement (DMEAS)

The Data Measurement (DMEAS) module measures several characteristics of the data and sync signals. Data measurements are taken over a programmable window as defined by an upper left (min_x, min_y) and a lower right (max_x, max_y), which may be the whole frame. Measurements are programmable either per color channel or over all color channels.

This module computes all measurements of sync and data format that are done in the INCLK domain. The Sync Measurement module does measurements in the XCLK domain. The INCLKS per DE measurement does not use the window feature. It measures the number of INCLK per DE and returns the result for every line.

All unused or reserved bits will return as zero.

Windows are relative to Sync pulses. A window defined from (0,0) - (0xFFF, 0xFFF) would go from sync to sync. The reference edge to use, rising or falling, is also programmable per X and Y coordinates. SMUX should be configured to provide a positive polarity sync to the DMEAS block. All window enables are reset to 0 and will always be reset on the rising or falling edge of the sync pulse.

Most algorithms can be run over separate or all color channels. Most algorithms also contain a threshold value to zero out noise and/or amplify edges. Algorithm, Color, Threshold, or Window Control changes are accepted at the end of a valid measurement so that they do not affect the current measurement in progress.

Software can request measurements in one of two ways:

1. All measurements, except DE_Size, are performed in One-shot mode, which is synchronous in respect to the microcontroller.
2. The DE_Size measurement can be set either to One-shot or Free-running modes. Free-running mode is asynchronous in respect to the microcontroller.

In **One-shot mode**, the block should indicate that the measurement is valid through an auto clear of the start condition.

In **Free-running mode**, the block should indicate that the measurement is valid through a polling bit. In Free-running mode, a Freeze bit is provided to freeze the results. Measurements still continue with the polling bit active, however, they are not updated if the Freeze bit is set.

2.9.1 Edge Intensity

The Edge Intensity measurement is the sum of the absolute value of the delta between adjacent pixels. A programmable threshold is applied to zero out noise and amplify edges. Equation:

$$\text{Delta_val} = \text{abs}(\text{pixelA} - \text{pixelB}) - \text{threshold};$$

$$\text{Delta_val} = \text{Delta_val} < 0 ? 0 : \text{Delta_val};$$

$$\text{Sum} += \text{Delta_val};$$

For all 3 color channels: Sum += Delta_val on Red channel + Delta_val on Green channel + Delta_val on Blue channel

2.9.2 Pixel Sum

The Pixel Sum is the sum of all selected pixels for either a specific color channel or all color channels within the window specified.

2.9.3 Minimum/Maximum Pixel

This function reports the minimum and maximum pixel found within the specified window.

2.9.4 Pixel Cumulative Distribution (PCD)

The Pixel Cumulative Distribution (PCD) function reports the total number of pixels greater than (or less than) a programmable threshold.

To switch between pixels greater than or pixels less than the threshold, a control bit is provided in the DMM_Mode register when requesting a measurement.

2.9.5 Horizontal Position

The Horizontal Position measures the start and end of video data in INCLKS clock cycles relative to the posedge of hsync.

The Data Horizontal Start is defined as the number of INCLKS clock cycles between posedge of hsync and the “first data pixel”.

First data pixel is either:

1. First pixel greater than the programmable threshold value
2. First pixel with the absolute value (current pixel - previous pixel) is greater than the programmable threshold value

The Data Horizontal End is defined as the number of INCLKS clock cycles between posedge of hsync and the “last data pixel plus one”. The search for the last pixels ends at the end of a window.

Last data pixel plus one is either:

1. Pixel after the last pixel that is greater than the programmable threshold value
2. Last pixel with the absolute value (current pixel - previous pixel) is greater than the programmable threshold value

To switch between the two threshold methods used in the first and last pixel, a control bit is provided in the DMM_Mode register when requesting a measurement.

The first and last pixels are measured for each line, and the earliest first and latest last for the selected pixel area are reported out at the end of the measurement. The intention is for “last data pixel plus one” minus “first data pixel” is to equal the horizontal width of the video format.

2.9.6 Vertical Position

The Vertical Position measures the start and end of video data in hsyncs relative to the posedge of vsync.

The Data Vertical Start is defined as the number of hsyncs signals between the positive edge of the vsync signal and the “first data pixel line”.

First data pixel line definition is the first line with at least one pixel that is greater than the programmable threshold.

The Data Vertical End is defined as the number of hsyncs between posedge of vsync and the “first blanking line after data plus one”. The first blanking line is detected then confirmed that each subsequent line contains no data pixels. The confirmation of the first blanking line measurement ends at the posedge of vsync.

The first blanking line after data definition is the row after the last row with at least one pixel greater than the programmable threshold.

The first and last data pixel lines are measured within a frame and the earliest first and latest last for the selected pixel area are reported out at the end of the measurement. The intention is for “data vertical end plus one” minus “data vertical start” is to equal the vertical height of the video format.

2.9.7 DE Size

The DE Size measures the number of INCLKS clock cycles per data enable. It is useful for DVI inputs to exactly measure the input image horizontal size.

At the end of the measurement (DE falling edge), the measured value is compared to a programmed expected value \pm a programmed threshold. If the expected value is within the threshold, the DE_size_mismatch flag is not set. If the measured size is outside of the threshold, the DE_size_mismatch flag is set.

In Free-running mode, the results are updated every line. The DE_size_mismatch flag is set at DE falling edge and reset at DE rising edge.

In One-shot mode, the results are updated once and stay that way until they are cleared by software. The DE_size_mismatch flag can only be cleared when the reset flag bit is set by software.

2.10 LCD Scaler

The LCD Scaler module resizes images from one resolution to another. It employs a 3x3 non-separable scaling filter which performs a dot product of the input pixel values with a weighting vector that is computed from the chosen filtering function. To sharpen text without introducing excessive artifacts, the output pixel's contrast level is adjusted based on the context value measured over a 3x3 grid in the relevant area of the source image.

For proper scaler operation, the SCLK frequency must be set greater than the max of DCLK and $IN_HPIXEL \times DCLK_FREQ / (DEST_HPIXEL \times PIXEL_AVG)$.

Table 15: LCD Scaler Registers (Sheet 1 of 3)

		R/W	[3]	0x0	Force output data as described in bit [1] when an abnormal condition is detected by the sync measurement module.
		R/W	[2]	0x0	When the scaler is not running, force the output data to black if this bit is 0 or to the background color if the bit is 1.
		R/W	[1]	0x0	If an abnormality is detected in the sync measurement module or if the maximum output vertical total has been reached, force the output data to black if this bit is 0 or to white if this bit is 1.
		R/W	[0]	0x0	During blanking, force output data to black if this bit is 0 or to the background color if this bit is 1.

2.11 Output Sequencer

The Output Sequencer module synchronizes timing for the output video interface. It allows sufficient flexibility to support a broad range of Smart Panel applications as well using the Output Timing Controller (TCON) module, refer to [Section 2.12](#) for more details. The timing unit is based on horizontal and vertical counters, which are locked with the input video stream.

Figure 5: Output Sequencer and Timing Controller Block Diagram

2.11.1 Frame Synchronization

Due to the limited pixel memory of the chip, the output active video needs to be perfectly synchronized with the input active video. This mode of operation is called *Frame Lock*.

Figure 6: Frame Lock Operation

2.11.2 Timing Unit

The Timing Unit consists of a 12-bit horizontal and 12-bit vertical counter. It is synchronized with the input video stream.

2.11.3 Signal Generation

The Signal Generation unit can generate all fixed control signals like hsync, vsync and data enable as well as those required to run the internal data path. The fixed control signals appear on the

alternate output sync pins (AHS, AUS, ADE) for applications that do not require the more sophisticated timing control provided by the programmable TCON module.

Table 16: Output Sequencer Registers (Sheet 1 of 2)

Register Name	Addr	Mode	Bits	Default	Description

2.12 Timing Controller (TCON)

The Output Timing Controller module provides timing for Smart Panel applications and other applications that are sensitive to output synchronization timing. The timing unit is based on horizontal and vertical counters, which are locked with the output video stream. A set of programmable comparators provides all necessary time events to generate the signals for the driver interface.

Please refer to the Programming Tool User's Manual and to the "Using TCON Outputs" application note for more details.

Table 17: TCON Registers (Sheet 1 of 7)

Register Name	Addr.	Mode	Bits	Default	Description
TCON_CONTROL	0x0B00		[7:3]		Reserved
		R/W	[2]	0x0	0: no TCON pipe delay matching 1: TCON pipe delay enabled (normal)
		R/W	[1]	0x0	Initialize SRTDs

Value	Description	Value	Description
0x00	0	0x39	2 frame + 2 line + 1 pixel toggle
0x01	1	0x3A	HCOUNT[0]
0x02	External TCON input pin	0x3B	HCOUNT[1]
0x03	I2C SRTD init bit	0x3C	VCOUNT[0]
0x04 - 0x1F	comp0 - comp27	0x3D	VCOUNT[1]
0x20 - 0x37	SRTD8 - SRTD31	0x3E	FCOUNT[0]
0x38	2 frame + 1 line + 2 pixel toggle	0x3F	FCOUNT[1]

2.13 Pattern Generator

The integrated Pattern Generator gives the ability to display a set of graphic patterns to help debugging systems and test LCD panels. It is located ahead of the color management block, so all generated colors are subject to further transforms.

The screen can be split into a programmable grid of up to 8x8 areas. In each of these areas, it is possible to display one of two independent programmable patterns.

2.13.1 Screen Split

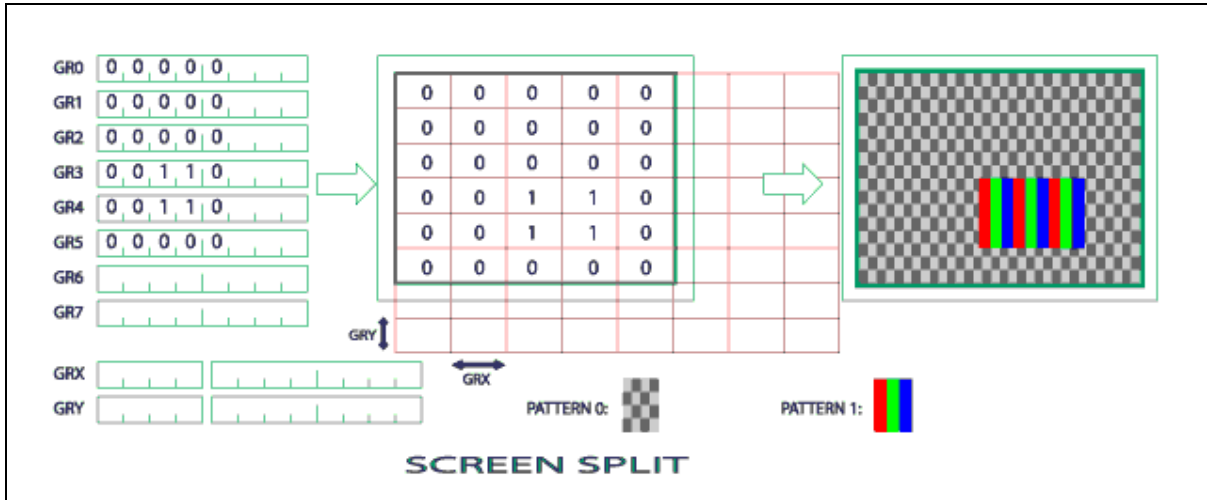

A set of eight Grid registers *grid0 - grid7* with eight bits each represents a block map of the grid of 8x8 blocks. Each bit of the Grid registers represents one rectangular (gridX)x(gridY) block of pixels which covers the LCD screen display area. Within these registers, a 0 selects Pattern 0 (defined below) and a 1 selects Pattern 1.

All cells have the same size, defined by one horizontal and one vertical grid block size registers *gridX* and *gridY*.

When the programmed block size is such that the complete 8x8 grid is larger than the total screen area, only the blocks or part of blocks that are included in the output screen space are rendered. The 8x8 block set is upper left justified, such that all blocks on the right and bottom sides that are outside of the total display area are not rendered.

When the programmed block size is such that the complete 8x8 grid is smaller than the total screen area, the part of the screen area which is outside the 8x8 grid is forced to black.

Figure 7: Pattern Generator (Screen Split)

2.13.2 Pattern Engine

In order to display two patterns simultaneously on the LCD screen, the Pattern Generator has two pattern display engines. Each engine can display horizontal or vertical bicolor stripes, bicolor checkers, color bars, gray scales or color scales. It is also possible to select the video stream from the scaler as a pattern.

The pattern engine displays a bi-directional x-y symmetric pattern. Two 24-bit colors, C0 and C1, are alternately displayed with a horizontal period of Width and vertical period of Height. Programming a large Width and a small Height generates horizontal bars whereas the opposite will generate vertical bars. Programming small numbers for Width and Height generates checker patterns.

Each of the two patterns is also given X and Y offset attributes, so that it is possible to center the pattern inside the grid blocks.

A gradient effect can be applied independently on each of the two patterns, to either or both horizontal and vertical directions. The gradient effect takes two parameters: STEP and DELTA that define a ramp.

2.13.3 Borders

The Border Generator adds a single pixel width border to the whole display area. Each of the four sides of the display can be one of 8 independent colors.

Table 19: PGEN Registers (Sheet 1 of 5)

Register Name	Addr	Mode	Bits	Default	Description

2.14 sRGB

The sRGB block performs two primary functions:

1. Parametric gamma correction on multiple windows or full screen, used for video enhancement in a window and digital contrast/brightness control. The window coordinates are set by TCON registers.
2. 3D color cube warping RGB color space.

2.14.1 Parametric Gamma, Digital Contrast / Brightness on Multiple Windows

The function can be applied to the entire window by programming the window control to full screen. Each color channel acts independently. Simple digital contrast and brightness can be programmed using this hardware function. The desired window coordinates are programmed into the TCON.

2.14.2 Color Space Warp

The 8 corners of the color cube are independently controlled in 3D space with smooth interpolation of intermediate colors. Registers are 2's complement color delta's. For example, to make WHITE more like RED, program SRGB_WHITE_R to a small positive value.

Figure 8: Color Space Warp

2.15 On-Screen Display (OSD)

The integrated On-Screen Display (OSD) controller is a character-based overlay with a high level of features and over 100 kbits of on-board dedicated RAM storage.

- 15 row by 30 column character-mapped display
- Four user-definable windows
- 12x18-pixel characters with optional horizontal and vertical doubling on a row-by-row basis
- Two 16-entry 24-bit RGB user-definable color maps
- 192 RAM-based monochrome 1 bpp characters
- 64 RAM-based graphics 4 bpp characters
- Text character attributes: foreground/background color, blinking
- Graphics character attributes: per-pixel color, vertical/horizontal mirroring
- Row attributes: double width, double height
- Window attributes: window visibility, position, size, border shadow, color table
- Global attributes: OSD visibility, OSD screen position, alpha fade in/fade out, global size doubling, rotation in ninety-degree increments
- Single-bit enable/disable

For information on OSD programming, see the OSD Programming Manual.

2.15.1 OSD Access via I2C

The OSD uses a dedicated memory space that is accessed through an I2C port. The data stream sent to the OSD register starts with two header bytes. These specify the type of transfer and the row/column position for screen map transfers, the character index for font definition transfers, or the color index for color map transfers.

A stream of OSD writes to the OSD I2C register can fill in a segment of the OSD memory space with an internal auto-incrementing index register. The protocol is as follows:

1. Issue a start sequence with the R/W bit set to W.
2. Write to the OSD register. The first byte transferred is the index of the first internal OSD register to be written. The next byte contains the data to be written to that register. Subsequent bytes are written to successive internal OSD registers.
3. Continue writing data bytes until the desired range of OSD internal registers has been written (the ADE3700 device will issue an ACK on each transfer).
4. Issue an I2C stop sequence.

Character Display

There are two 96-character monochrome fonts and two 32-character four-bit color fonts, a total of 256 characters. The four bits of color are an index into one of two 16 entry color lookup tables. Entries in the color lookup table specify a 24-bit RGB color. All fonts and the color look-up table are RAM-based and must be downloaded to the OSD’s internal RAM before use. Font addressing is as follows: character indexes 0x00-0x1F refer to color font 0, 0x20-0x7F refer to monochrome font 0, 0x80-0x9F refer to color font 1 and 0xA0-0xFF refer to monochrome font 1.

Screen Map

The OSD uses a character map of 15 rows x 30 columns. Each character occupies one byte. The value of each byte indicates the character to display.

The OSD character map is addressed by specifying the row and column as part of the data transfer.

Attribute Map

The attribute map is defined as 16 rows by 31 columns. It has an extra row and an extra column compared to the screen map.

Figure 9: Character Attribute Map

The values corresponding to printable row/column addresses provide character attributes. Each character on the screen has an attribute byte specifying (in the case of monochrome fonts) three bits of background color, four bits of foreground color, and a blink on/off bit.

Blinking, when enabled, has a period of 100 frames (50 frames on, 50 frames off).

Column 31 of each row contains row attributes. These include the fourth bit of the background color and two bits controlling double-height and double-width text.

Row 15 contains global attributes, including vertical and horizontal OSD position on the screen, alpha blending, shadow/bordering, OSD rotation, color map selection, and normal/double size.

Alpha blending allows the OSD display to be mixed with the incoming video signal for transparency

effects. An alpha value of 255 makes the OSD opaque, while a value of 0 makes the OSD invisible, with a linear ramp of transparency between these two endpoints. Separate registers control alpha for foreground and background pixels.

A fade-in/fade-out feature ramps the alpha values every six frames, starting from their current value and going up or down the sequence: 0, 16, 32, 64, 128, 192, 224, 240, 255.

Row 15 also contains definitions for the four display windows. These windows define regions on the screen to which borders and shadows can be applied. (They are not analogous to windows in a GUI display, in that they do not represent four independent data displays. There is only one character map. The windows essentially define an area around which a border can be drawn or to which attributes can be assigned.) Windows also determine which of the two color tables will be used for the characters inside. Windows have a fixed precedence: Window 0 has the highest precedence and Window 3 the lowest. When windows overlap, the precedence determines which borders will be displayed and which color tables will be used in the overlapping area.

Monochrome and color fonts are affected differently by attribute bytes. Monochrome characters are affected by shadows and borders, and have their color specified by the foreground/background attributes. Color characters interpret the attribute byte differently than monochrome characters, using it to define blinking and 90-degree rotations rather than blinking, foreground color, and background color.

Color Tables

There are two color tables, each containing sixteen entries by three bytes each, giving a 24-bit RGB value for each entry. Entry 0 is used for the shadow color for monochrome characters and borders. Color-table selection is made on a window-by-window basis.

When writing the color table, the “row” value in the first header byte is interpreted as the color table index, while the “column” value in the second header byte is encoded to select the color table (0 or 1) and the primary color (red, green, or blue). The data byte following the second header byte is written to the selected (table, index, primary) location.

Font Data

Font data is sent to the OSD through burst transfers. The first header byte selects the transfer type and provides three bits of the character index, while the second header byte selects transfer type “C” and gives the remaining five bits of offset. The data bytes for the character follow, given from top to bottom and left to right in the character cell.

A monochrome character is 27 bytes long, with two scan-lines occupying three bytes. A color character is four times as long as a monochrome character (108 bytes), with each byte containing two four-bit pixels. Both color and monochrome fonts are 12 pixels wide and 18 high.

Transfer Formats

The transfer format consists of two header bytes and a variable number of data bytes. The header bytes determine the type of transfer (character, attribute, monochrome font, color font, or color table). Addressing is by row and column in the case of character or attribute transfers, and by character index in the case of font transfers.

When writing to the color table, the “column” field determines the color table and R/G/B selection.

Table 21: OSD Access Header Definition

Header Byte	Bits	Description
First	[7:4]	Type of data transfer. Valid values are: 0x8: screen map 0x9: color LUT 0xA: attribute map 0xC: font data all others: Reserved
	[3:0]	For screen map or attribute map access, this is the row index. For color LUT access, this is the color index. For font data access, bits [2:0] are the MSB's of the character index.
Second	[7:6]	Type of data burst: 0x0: A/B modes: Only one data byte follows this header byte. 0x1: C mode: All bytes following this header byte are data bytes until the serial interface indicates an end-of-transmission. The OSD internally auto-increments after each byte. In screen and attribute map access modes the column number is incremented after each byte, wrapping to the beginning of the next row once column 29 is passed and wrapping to row 0 if row 14 is passed. Either mode may be used for display and character attribute modes, except for the off-screen attributes in column 15 and row 30, which must use mode A/B. Font definition mode must use mode C.
	[5]	must be set to zero
	[4:0]	In screen and attribute map access modes, this is the column number. In font data access mode, this gives the 5 lsb's of the character index. In color LUT access mode, it selects the table number and color to be written: 0x0: LUT 0, red 0x1: LUT 0, green 0x2: LUT 0, blue 0x3: LUT 1, red 0x4: LUT 1, green 0x5: LUT 1, blue 0x6 - 0x7: Reserved

2.16 Flicker

The Flicker block computes correlations of the image data with potential inversion patterns of the LCD which in turn allows the microcontroller to modify the polarity signal to cancel large areas of flicker. This function is only useful in SmartPanel applications.

The incoming image is scored against 8 vertical Walsh functions. All patterns are considered vertically, while horizontally the pixels are assumed to be alternating RGB components.

The scores (0 to 7) are 32-bit unsigned quantities that reflect the correlation of the programmed window area with the 8 Walsh functions.

The horizontal inversion of the LCD drivers must be programmed into FLICKER_CTRL0[2:0]. The most common setting is ++ or +- (RGB).

A calculation is completed after the number of frames programmed into the FRAME_CNT_MAX register (0xCA03). With each frame the calculation is performed on only a vertical strip. The width of that strip (in pixels) is determined by the value programmed in the HBLOCK_SIZE register (0xCA02) with the following relation: strip width = $2^{(3 + \text{HBLOCK_SIZE})}$.

The free_run/freeze_scores bit (FLICKER_CTRL0[4]) enables the final calculation to be captured easily by the MCU. The internal flicker calculation continues to run -- only the update of the I2C registers is blocked when this bit is set to prevent corruption during readout.

Refer to the Flicker Programming Guide for more details.

Table 24: Flicker Registers (Sheet 1 of 2)

Register Name	Addr	Mode	Bits	Default	Description
FLK_CTRL	0x0CA1	R/W	[7:6]	0x0	Reserved
		R/W	[5]	0x1	0: straight line uniform function 1: straight line hill function (normal)
		R/W	[4]	0x0	0: free-running 1: freeze scores Set to a 1 when the microcontroller is reading multibyte scores to prevent update corruption.
		R/W	[2:0]	0x5	horizontal subpixel polarity inversion pattern of LCD (even/odd pixels) 0x0: -R-G-B / +R+G+B 0x1: -R-G+B / +R+G-B 0x2: -R+G-B / +R-G+B (Default) 0x3: -R+G+B / +R-G-B 0x4: +R-G-B / -R+G+B 0x5: +R-G+B / -R+G-B 0x6: +R+G-B / -R-G+B 0x7: +R+G+B / -R-G-B
FLK_HBLOCK_SIZE	0x0CA2	R/W	[7:4] [3:0]	0x0	Reserved width in pixels of the per frame scored area = $2^{(3+hblock_size)}$
FLK_FRAME_CNT_MAX	0x0CA3	R/W	[7:0]	0x8	number of frames to complete one measurement total number of pixels in a line is: $frame_cnt_max * (2^{(3+hblock_size)})$ example: $hblock_size = 4$; $frame_cnt_max = 8$; In each frame only one portion of the image is being scored. The width of that portion is $2^{(3 + hblock_size)} = 128$ pixels and the height is the full height of the image. Thus the total scored area after 8 frames is $128 * 8 = 1024$ pixels wide.

2.17 Gamma

The Gamma block performs an 8-bit to 10-bit lookup table on the 3 x 8 bits (R, G, B) color data coming from the LCD Scaler. The lookup table (LUT RAM) contains the corresponding 10-bit output corrected color for each 8-bit input color.

The RAMs are individually programmable (read and write) using I2C access. The memory map is as follows:

I2C address 0x1000 to 0x11FF: Red RAM

I2C address 0x1200 to 0x13FF: Green RAM

I2C address 0x1400 to 0x15FF: Blue RAM

Even addresses are the 8-bit LSBs of the 10-bit gamma value. Odd addresses are the 2 MSBs.

Table 25: Gamma Registers

Register Name	Addr	Mode	Bits	Default	Description

2.18 APC

APC (formerly known as Arithmos Perfect Color) dithers an input 10 bit video stream down to 4-8 output bits. The dithering is done in space and time in such a way that the eye does not perceive objectionable artifacts such as:

- Fixed dither patterns
- Contours
- Flickering pixels
- Phase correlated flickering, which creates wave patterns known as “swimming”

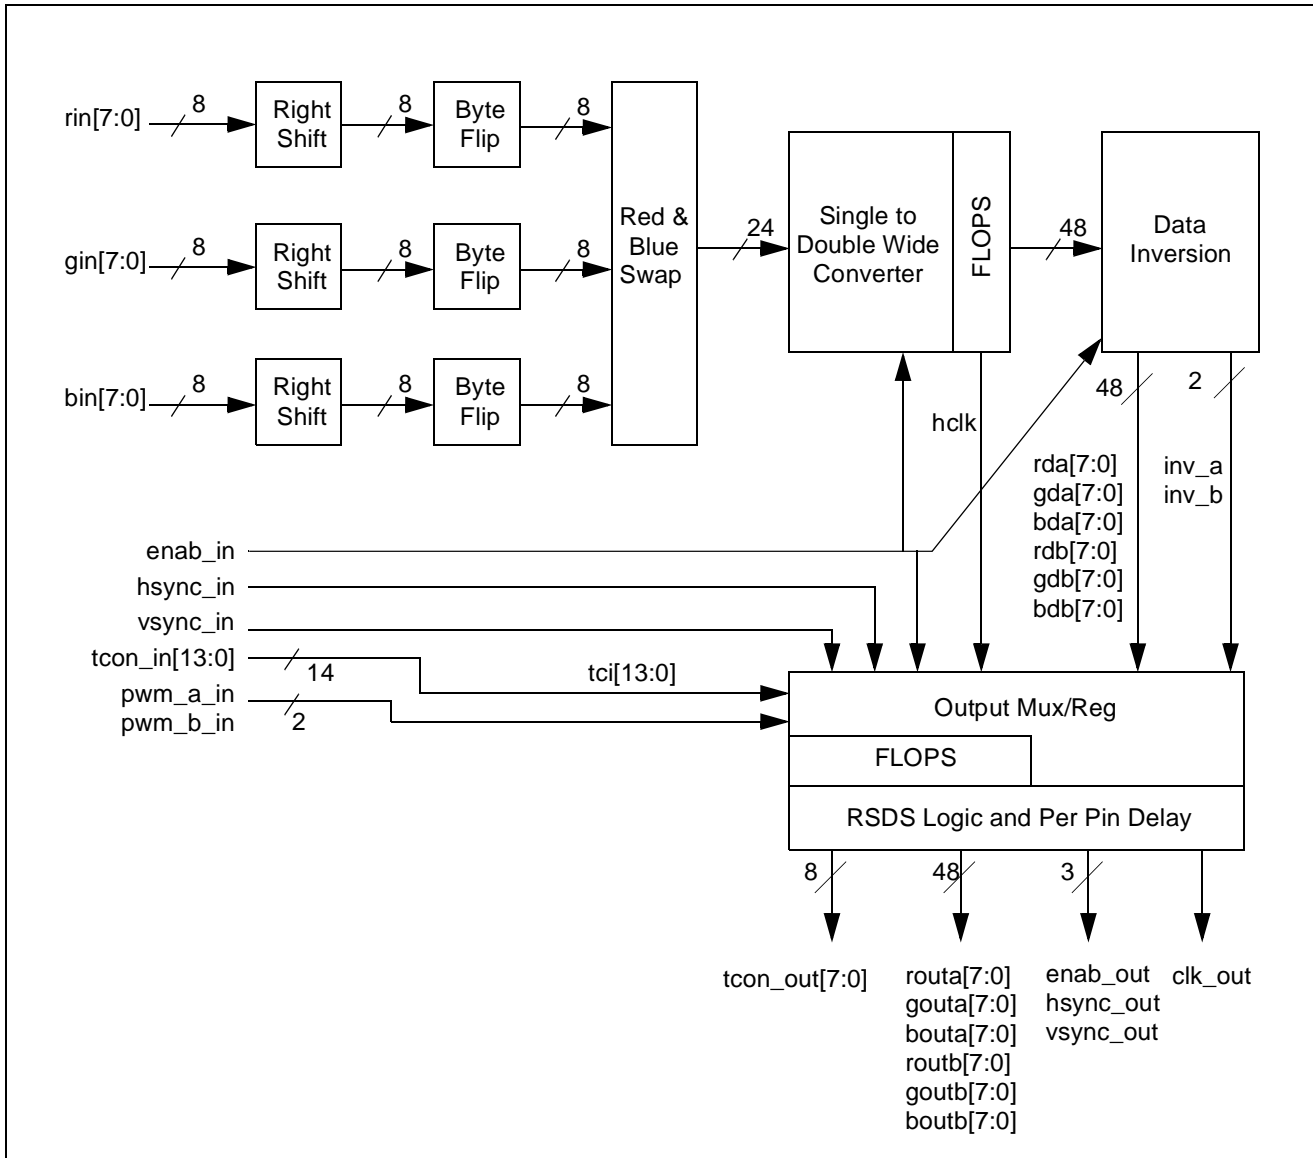

Table 26: APC Registers

Register Name	Addr	Mode	Bits	Default	Description
APC_APC0	0x0C20		[7]		Reserved
		R/W	[6:5]	0x0	Frame Modulation Period - 1
		R/W	[4:1]	0x0	0x0 - 0x3: 8-bit out 0x4: 4b out 0x5: 5b out 0x6: 6b out 0x7: 7b out 0x8: 8-bit out
		R/W	[0]	0x0	0: normal 1: disable APC -- truncate LSBs
APC_APC1	0x0C21		[7:2]		Reserved
		R/W	[1]	0x0	Offset the phase LUT
		R/W	[0]	0x0	Offset the dither LUT

2.19 Output Multiplexer

The Output Multiplexer formats the single wide data stream from the output of the APC block into a single or double wide data path for the flat panel. The architecture is shown in Figure 10.

Figure 10: Output Mux Block Diagram

Latency is not important, as long as the timing relationship between hsync, vsync, enab and data is preserved at the output. In Double Wide mode, the first pixel must be properly aligned even if the number of pixels in blanking or active are odd. The divide-by-2 circuit can be set to resync per line (based on data_enab and hsync_in edge) and per frame (based on vsync_in edge). The most reliable timing is when hsync and vsync are in the “low” counts of the timing core counters (i.e. hsync_set and hsync_rst are both below the active data region start/end counts). In the event that hsync and vsync are in the “high” (after active region) counts, the device should be set to sync to data_enab_re.

The Per Pin Delay and RSDS logic occur after the last latch and are implemented on all channels to maintain delay balance between signals that go into RSDS mode (data and clk/hsync) and those that do not (de/vsync and tcon).

2.19.1 Sub Block Function

2.19.1.1 Right Shift

- shifts right from 0 to 4 positions, fills from the top with zeroes
- out_mux_ctrl1[2:0]

2.19.1.2 Byte Flip

- flips data bits in a byte from LSB to MSB, i.e. out[7:0] = in[0:7]
- out_mux_ctrl0[4]

2.19.1.3 Red & Blue Swap

- swaps red and blue channels, i.e. out[23:0] = {in[7:0],in[15:8],in[23:16]}
- out_mux_ctrl0[3]

2.19.1.4 Single to Double Wide Converter

- in Single Wide mode (out_mux_ctrl0[1] = 0)
 - flops all data into either A or B channels depending on out_mux_ctrl0[2]
 - either inv_a or inv_b is active depending on active channel
- in Double Wide mode (out_mux_ctrl0[1] = 1)
 - flops data into A/B or B/A positions depending on out_mux_ctrl0[2].
 - divides clock by 2 (hclk = half speed DCLK), resyncing each line with data enable
 - output data transitions as posedge/negedge as set in out_mux_ctrl0[5]
 - can handle odd output htotal (i.e. all divide by 2's and state machines must be resynced per line)

2.19.1.5 Data Inversion

- resyncs at the end of each line to inactive state with data enable falling edge –
- invert is possible on the first pixel – compares 1st pixel to blanking value
- compares subsequent 24-bit/48-bit data to the last output; if more bits flip (i.e. hamming distance > active_bit_width/2), invert data word and toggle invert pin
- counts only active bits in hamming distance as determined by right shift and bit flip settings; zeroes out non active data signals at output
- controls:
 - out_mux_ctrl1[4]
 - A and B channels have separate independent
 - A and B channels treated as one 48-bit channel, inv_a = inv_b
 - out_mux_ctrl1[5]
 - data invert output polarity
 - out_mux_ctrl1[6]
 - data invert enable
- data invert pins can also be driven by tcon srtid[26] and srtid[27] for panel balancing (out_mux_ctrl2[6] and out_mux_ctrl2[7])
- data can be inverted at the front end of the data inversion detection using tcon signals, either separate or combined channels (out_mux_ctrl3[0])

2.19.1.6 Output Mux / Reg

- combines all signals to form the desired outputs

- last point the data is flopped with DCLK before the pins
- gated clock available from tcon_srtcd[12] in tcon mode
- see tables 2.2 - 2.5 for configurations.

2.19.2 RSDS

In RSDS mode, clk and hsync outputs are the differential clock pair. All 48 data ports are combined into neighboring pairs (e.g. orb0 and orb1 are differential pairs in RSDS mode). the lower index is the positive sense differential output. TCON, data_enab and vsync outputs are unchanged. data_enab and vsync can be used to output LVCMOS data inversion signals independent of RSDS mode.

The following table indicates the pin, timing and data relationships in RSDS mode.

Table 31: RSDS Mode Specifications

RSDS Time	clk_o	hsync_o	o[r,g,b][a,b](2n)	o[r,g,b][a,b](2n+1)
t	0	1	bit from 2n	!bit from 2n
t+1	1	0	bit from 2n+1	!bit from 2n+1

Table 31: RSDS Mode Specifications (Continued)

RSDS Time	clk_o	hsync_o	o[r,g,b][a,b](2n)	o[r,g,b][a,b](2n+1)
t+2	0	1	bit from 2n	!bit from 2n
t+3	1	0	bit from 2n+1	!bit from 2n+1

Note: *hsync_o* is the positive clock signal according to the RSDS definition.

2.19.3 Per Pin Delay

Each of the 60 outputs has a per pin programmable delay. The delay is calibrated on the fly to the XCLK period, which is assumed to be 37ns. Each pin can be delayed by up to 6ns in 0.4ns increments. Code 0x0 is the least delay, code 0xF is the maximum delay. The setting is accurate to ± 0.8 ns across PVT. The calibration and resetting is done once per frame after the falling edge of vertical enable to prevent glitches from delay mux changes in the active data period. The delays are active in RSDS and normal output modes if enabled in the OUT_MUX_CTRL2 register.

Table 32: Output Mux Registers (Sheet 1 of 4)

Register Name	Addr	Mode	Bits	Default	Description
OMUX_CTRL_0	0x0C30	R/W	[7]	0x0	in 2 ppc, 0: data invert for A+B comb. 1: data invert A/B separate
		R/W	[6:4]	0x0	0x0 - 0x4: right shift per 8-bit R/G/B 0x5 - 0x7: Reserved
		R/W	[3]	0x0	0: normal 1: flip msbs to lsbs
		R/W	[2]	0x0	0: normal 1: swap R and B data
		R/W	[1]	0x0	0: in 1 ppc, A channel active 0: in 2 ppc, Left on A, Right on B 1: in 1 ppc, B channel active 1: 2ppc, Left on B, Right on A
		R/W	[0]	0x0	0: single wide, one pix/clock (ppc) 1: double wide, two pix/clock
OMUX_CTRL_1	0x0C31	R/W	[7]	0x0	Vsync Output Polarity
		R/W	[6]	0x0	Hsync Output Polarity
		R/W	[5]	0x0	Data Enable Output Polarity
		R/W	[4]	0x0	Clock Output Invert
		R/W	[3]	0x0	Data Invert Output Polarity
		R/W	[2]	0x0	Data Invert Enable
		R/W	[1]	0x0	0: TCON outputs set to zero 1: TCON outputs active
		R/W	[0]	0x0	0: all data outputs set to zero 1: output enabled

Table 32: Output Mux Registers (Sheet 2 of 4)

Register Name	Addr	Mode	Bits	Default	Description
OMUX_CTRL_2	0x0C32	R/W	[7]	0x0	Separate TCON driven invert enable
		R/W	[6]	0x0	TCON driven invert pin enable
		R/W	[5]	0x0	RSDS enable
		R/W	[4]	0x0	Per Pin Delay Enable
		R/W	[3]	0x0	Resync on Vsync Falling Edge
		R/W	[2]	0x0	Resync on Vsync Rising Edge
		R/W	[1]	0x0	Resync on Hsync Falling Edge
		R/W	[0]	0x0	Resync on Hsync Rising Edge
OMUX_DLY_BA0	0x0C50	R/W	[7:4]	0x0	Delay for OBA1
		R/W	[3:0]	0x0	Delay for OBA0
OMUX_DLY_BA2	0x0C4F	R/W	[7:4]	0x0	Delay for OBA3
		R/W	[3:0]	0x0	Delay for OBA2
OMUX_DLY_BA4	0x0C4E	R/W	[7:4]	0x0	Delay for OBA5
		R/W	[3:0]	0x0	Delay for OBA4
OMUX_DLY_BA6	0x0C4D	R/W	[7:4]	0x0	Delay for OBA7
		R/W	[3:0]	0x0	Delay for OBA6
OMUX_DLY_GA0	0x0C4C	R/W	[7:4]	0x0	Delay for OGA1
		R/W	[3:0]	0x0	Delay for OGA0
OMUX_DLY_GA2	0x0C4B	R/W	[7:4]	0x0	Delay for OGA3
		R/W	[3:0]	0x0	Delay for OGA2
OMUX_DLY_GA4	0x0C4A	R/W	[7:4]	0x0	Delay for OGA5
		R/W	[3:0]	0x0	Delay for OGA4
OMUX_DLY_GA6	0x0C49	R/W	[7:4]	0x0	Delay for OGA7
		R/W	[3:0]	0x0	Delay for OGA6
OMUX_DLY_RA0	0x0C48	R/W	[7:4]	0x0	Delay for ORA1
		R/W	[3:0]	0x0	Delay for ORA0
OMUX_DLY_RA2	0x0C47	R/W	[7:4]	0x0	Delay for ORA3
		R/W	[3:0]	0x0	Delay for ORA2
OMUX_DLY_RA4	0x0C46	R/W	[7:4]	0x0	Delay for ORA5
		R/W	[3:0]	0x0	Delay for ORA4
OMUX_DLY_RA6	0x0C45	R/W	[7:4]	0x0	Delay for ORA7
		R/W	[3:0]	0x0	Delay for ORA6
OMUX_DLY_BB0	0x0C44	R/W	[7:4]	0x0	Delay for OBB1
		R/W	[3:0]	0x0	Delay for OBB0

Table 32: Output Mux Registers (Sheet 3 of 4)

Register Name	Addr	Mode	Bits	Default	Description
OMUX_DLY_BB2	0x0C43	R/W	[7:4]	0x0	Delay for OBB3
		R/W	[3:0]	0x0	Delay for OBB2
OMUX_DLY_BB4	0x0C42	R/W	[7:4]	0x0	Delay for OBB5
		R/W	[3:0]	0x0	Delay for OBB4
OMUX_DLY_BB6	0x0C41	R/W	[7:4]	0x0	Delay for OBB7
		R/W	[3:0]	0x0	Delay for OBB6
OMUX_DLY_GB0	0x0C40	R/W	[7:4]	0x0	Delay for ORB1
		R/W	[3:0]	0x0	Delay for ORB0
OMUX_DLY_GB2	0x0C3F	R/W	[7:4]	0x0	Delay for ORB3
		R/W	[3:0]	0x0	Delay for ORB2
OMUX_DLY_GB4	0x0C3E	R/W	[7:4]	0x0	Delay for ORB5
		R/W	[3:0]	0x0	Delay for ORB4
OMUX_DLY_GB6	0x0C3D	R/W	[7:4]	0x0	Delay for ORB7
		R/W	[3:0]	0x0	Delay for ORB6
OMUX_DLY_RB0	0x0C3C	R/W	[7:4]	0x0	Delay for ORB1
		R/W	[3:0]	0x0	Delay for ORB0
OMUX_DLY_RB2	0x0C3B	R/W	[7:4]	0x0	Delay for ORB3
		R/W	[3:0]	0x0	Delay for ORB2
OMUX_DLY_R_B4	0x0C3A	R/W	[7:4]	0x0	Delay for ORB5
		R/W	[3:0]	0x0	Delay for ORB4
OMUX_DLY_R_B6	0x0C39	R/W	[7:4]	0x0	Delay for ORB7
		R/W	[3:0]	0x0	Delay for ORB6
OMUX_DLY_TCON_0	0x0C38	R/W	[7:4]	0x0	Delay for TCON1
		R/W	[3:0]	0x0	Delay for TCON0
OMUX_DLY_TCON_2	0x0C37	R/W	[7:4]	0x0	Delay for TCON3
		R/W	[3:0]	0x0	Delay for TCON2
OMUX_DLY_TCON_4	0x0C36	R/W	[7:4]	0x0	Delay for TCON5
		R/W	[3:0]	0x0	Delay for TCON4
OMUX_DLY_TCON_6	0x0C35	R/W	[7:4]	0x0	Delay for TCON7
		R/W	[3:0]	0x0	Delay for TCON6
OMUX_DLY_VS_ENAB	0x0C34	R/W	[7:4]	0x0	Delay for VSYNC
		R/W	[3:0]	0x0	Delay for ENAB
OMUX_DLY_CLK_HS	0x0C33	R/W	[7:4]	0x0	Delay for CLK
		R/W	[3:0]	0x0	Delay for HSYNC

Table 32: Output Mux Registers (Sheet 4 of 4)

Register Name	Addr	Mode	Bits	Default	Description
OMUX_CTRL3	0x0C51	R/W	[7:3]		Reserved
		R/W	[2]	0x0	PWM mux mode
		R/W	[1]	0x0	PWM enable
		R/W	[0]	0x0	TCON data invert enable, with computed data invert pin.
OMUX_REFCOUNT	0x0C52		[7:6]		Reserved
		R	[5:0]	0x0	Returns a value that indicates the ADE gate speed -- a function of temp and voltage higher = faster logic

2.20 Pulse Width Modulation (PWM)

The PWM block generates two signals that can be used to control backlight inverter switching power components directly. It is derived from XCLK and can be powered up independently of the DOTCLK and INCLK domains. The frequency, duty cycle, polarity and overlap/non-overlap are programmable. The output frequency can be free-running or locked to the output vsync signal.

Table 33: PWM Registers (Sheet 1 of 2)

Register Name	Addr	Mode	Bits	Default	Description
PWM_CTRL0	0x01A0	R	[7]	0x0	PWM status 0: unlocked 1: locked
		R/W	[6]	0x0	0: lock to CYCLES_PER_FRAME from the free-running state machine 1: lock to CYCLES_PER_FRAME register setting
		R/W	[5]	0x0	PWM_A polarity 0: active low 1: active high
		R/W	[4]	0x0	PWM_B polarity 0: active low 1: active high
		R/W	[3]	0x0	0: normal operation 1: force PWM outputs to polarity settings
		R/W	[2]	0x0	0: change period or duty cycle at the end of the current cycle 1: smooth change, period or duty cycle increment/decrement every PWM_STEP_DELAY cycle
		R/W	[1]	0x0	0: free-running 1: lock to out_vsync
		R/W	[0]	0x0	0: disable PWM output 1: enable PWM output

Table 33: PWM Registers (Sheet 2 of 2)

Register Name	Addr	Mode	Bits	Default	Description
PWM_CTRL1	0x01A1	R/W	[7:4]	0x0	Lock 2 nd order gain (power of 2) 0x0 = max 0x3 = typical 0xF = min.
		R/W	[3:0]	0x0	Lock gain (power of 2) 0x0 = max 0x6 = typical 0xF = min.
PWM_PERIOD_L	0x01A2	R/W	[7:0]	0x0	Period-2 in free-running mode, in XCLKs
PWM_PERIOD_H	0x01A3	R/W	[7:0]		
PWM_DUTY_L	0x01A4	R/W	[7:0]	0x0	Duty cycle of PWM in XCLKs
PWM_DUTY_H	0x01A5	R/W	[7:0]		
PWM_OVERLAP_L	0x01A6	R/W	[7:0]	0x0	Non-overlap of PWMs in XCLKs
PWM_OVERLAP_H	0x01A7	R/W	[7:0]		
PWM_STEP_DELAY	0x01A8	R/W	[7:0]	0x0	In smooth change mode, the number of cycles skipped before the period/duty registers are incremented/decremented
PWM_CYCLES_PER_FRAME_L	0x01A9	R/W	[7:0]	0x0	The number of cycles per frame in frame lock mode when not using the internally generated cycles per frame from a previous free-running mode
PWM_CYCLES_PER_FRAME_H	0x01AA	R/W	[7:0]		

2.21 DFT Block

Table 34: DFT Registers (Sheet 1 of 3)

Register Name	Addr	Mode	Bits	Default	Description
DFT_TEST_MODE	0x0F00		[7:4]		Reserved
		R/W	[3]	0x0	trigger video bus MFSR
		R/W	[2]	0x0	enable output pin MFSR
		R/W	[1]	0x0	clear output pin MFSR
		R/W	[0]	0x0	output pin test override
DFT_MUX_OUT_MODE	0x0F01		[7:6]		Reserved
		R/W	[5:0]	0x0	mux selector for output porta/b and syncs
DFT_FLOP_OUT_MODE	0x0F02		[7:6]		Reserved
		R/W	[5:0]	0x0	mux selector for synchronous digital debug bus
DFT_CLK_OUT_MODE	0x0F03	R/W	[7:6]	0x0	divide-by selector for clocks to OCLK pin f _{out} = selected clock / (2 ^ value)
		R/W	[5:0]	0x0	mux selector for clocks to OCLK pin
DFT_CLK_1_MODE	0x0F04	R/W	[7:6]	0x0	divide-by selector for clocks to CLKOUT pin f _{out} = selected clock / (2 ^ value)

Table 34: DFT Registers (Sheet 2 of 3)

Register Name	Addr	Mode	Bits	Default	Description
DFT_CLK_2_MODE	0x0F05	R/W	[5:0]	0x0	mux selector for clocks to CLKOUT pin
DFT_OUT_DISAB_0	0x0F06	R/W	[7:0]	0x0	Disable Port A Red Output in Test Mode
DFT_OUT_DISAB_1	0x0F07	R/W	[7:0]	0x0	Disable Port A Green Output in Test Mode
DFT_OUT_DISAB_2	0x0F08	R/W	[7:0]	0x0	Disable Port A Blue Output in Test Mode
DFT_OUT_DISAB_3	0x0F09	R/W	[7:0]	0x0	Disable Port B Red Output in Test Mode
DFT_OUT_DISAB_4	0x0F0A	R/W	[7:0]	0x0	Disable Port B Green Output in Test Mode
DFT_OUT_DISAB_5	0x0F0B	R/W	[7:0]	0x0	Disable Port B Blue Output in Test Mode
DFT_OUT_DISAB_6	0x0F0C	R/W	[7:3]	0x0	Disable TCON Bits [4:0] in Test Mode
		R/W	[2]	0x0	Disable Vert Sync Output in Test Mode
		R/W	[1]	0x0	Disable Data Enab Output in Test Mode
		R/W	[0]	0x0	Disable Horz Sync Output in Test Mode
DFT_OUT_DISAB_7	0x0F0D		[7:5]		Reserved
		R/W	[4]	0x0	Disable CLKOUT Output In Test Mode
		R/W	[3]	0x0	Disable OCLK Output in Test Mode
		R/W	[2:0]	0x0	Disable TCON Bits [7:5] in Test Mode
DFT_STIM_CTRL	0x0F0E		[7:6]		Reserved
		R/W	[0]	0x0	Internal Stimulus Bus Enable
DFT_STIM_EN_0	0x0F0F	R/W	[7]	0x0	SCL Test Stimulus Enable
		R/W	[6:2]		Reserved
		R/W	[1]	0x0	ADC Test Stimulus Enable
		R/W	[0]	0x0	NC
DFT_STIM_EN_1	0x0F10		[7:6]		Reserved
		R/W	[5]	0x0	TCON test bypass
		R/W	[4]	0x0	OMUX test stimulus enable
		R/W	[3]	0x0	APC test stimulus enable
		R/W	[2]	0x0	OSD test stimulus enable
		R/W	[1]	0x0	SCL bypass
DFT_BIST_STATUS	0x0F11		[7:6]		Reserved
		R	[5]		Gamma RAM BIST end
		R	[4]		OSD CS RAM BIST end
		R	[3]		OSD DRB RAM BIST
		R	[2]		OSD MB RAM BIST end
		R	[1]		SCL coeff. RAM BIST end
		R	[0]		SCL line buffer RAM BIST end

Table 34: DFT Registers (Sheet 3 of 3)

Register Name	Addr	Mode	Bits	Default	Description
DFT_BIST_RESULT_0	0x0F12		[7:6]		Reserved
		R	[5]		SCL coeff RAM 2 BIST fail
		R	[4]		SCL coeff RAM 1 BIST fail
		R	[3]		SCL line buffer 4 BIST fail
		R	[2]		SCL line buffer 3 BIST fail
		R	[1]		SCL line buffer 2 BIST fail

DFT_MFSR_DONE	0x0F14		[7:1]		Reserved
		R	[0]		done signal
DFT_MFSR_SIG_0	0x0F15	R	[7:0]	0x0	video bus MFSR
DFT_MFSR_SIG_1	0x0F16	R	[7:0]		
DFT_MFSR_SIG_2	0x0F17	R	[7:0]		
DFT_MFSR_SIG_3	0x0F18	R	[7:0]		

2.22 I²C RAM Addresses

Table 35: I²C RAM Addresses

Name	Start Addr	End Addr	Description
GAM_RED	0x1000	11FF	Gamma LUT, Red, LSB0,MSB0,LSB1,... (256x10)
GAM_GREEN	0x1200	13FF	Gamma LUT, Green, (256x10)
GAM_BLUE	0x1400	15FF	Gamma LUT, Blue, (256x10)
OSD_MB	0x1700	175F	OSD Color LUTs (32x24)
OSD_CS	0x3000	5F3F	OSD Character Map (1344x36x2 copies)
OSD_DRB	0x6000	647F	OSD Screen Map (1152x8)
SCL_COEFF	0x9000	98FF	Scaler coefficient RAM (256x36x2 copies)
SCL_LINE1	0x9900	A7FF	Scaler line buffer 1 (1280x24)
SCL_LINE2	0xA800	B6FF	Scaler line buffer 2 (1280x24)
SCL_LINE3	0xB700	C5FF	Scaler line buffer 3 (1280x24)
SCL_LINE4	0xC600	D4FF	Scaler line buffer 4 (1280x24)

3 Electrical Specifications

3.1 Absolute Maximum Ratings

Symbol	Parameter	Min.	Typ.	Max.	Unit
AVDD18 DVDD18 XVDD18 LVDD18	Supply voltage			1.95	V
AVDD33 DVDD33	Supply voltage			3.6	V
VIN	Max voltage on 5 volt tolerant input pins			6.1	V
T _{STG}	Storage temperature	-40		+150	°C

3.2 Power Consumption Matrices

Table 36: ADE3700x

Symbol	Parameter	Min	Typ*	Max**	Unit
	Supply Current (Analog Input, XGA @75Hz, 78.75MHz)				
I _{AVDD18}	1.8V analog supply (I _{AVDD18})		195	203	mA
I _{DVDD18}	1.8V digital supply (I _{DVDD18})		228	257	mA
I _{AVDD33}	3.3V analog supply (I _{AVDD33})		102	105	mA
I _{DVDD33}	3.3V digital supply (I _{DVDD33})		44	51	mA
P _{TOTANA}	Total Power Consumption (Analog Input, XGA @75Hz, 78.75MHz)		1.25	1.48	W

* Measured at nominal voltage supplies

** Measured at +10% voltage supplies

Table 37: ADE3700xs

Symbol	Parameter	Min	Typ*	Max**	Unit
	Supply Current (Analog Input, XGA @75Hz, 135MHz)				
I _{AVDD18}	1.8V analog supply (I _{AVDD18})		200	207	mA
I _{DVDD18}	1.8V digital supply (I _{DVDD18})		351	401	mA
I _{AVDD33}	3.3V analog supply (I _{AVDD33})		104	108	mA
I _{DVDD33}	3.3V digital supply (I _{DVDD33})		68	80	mA
P _{TOTANA}	Total Power Consumption (Analog Input, XGA @75Hz, 135MHz)		1.56	1.89	W

* Measured at nominal voltage supplies

** Measured at +10% voltage supplies

3.3 Nominal Operating Conditions

Symbol	Parameter	Min.	Typ.	Max.	Unit
AVDD18 DVDD18 XVDD18 LVDD18	Supply Voltage	1.71	1.8	1.89	V
AVDD33 DVDD33	Supply Voltage	3.135	3.3	3.465	V
f_{XTAL}	Crystal Frequency		27		MHz
T_{OPER}	Ambient Operating Temperature	0		+70	°C

3.4 Preliminary Thermal Data

Symbol	Parameter	Min.	Typ.	Max.	Unit
R_{thJA}	Junction-to-Ambient Thermal Resistance, 144-pin package			25	°C/W
R_{thJA}	Junction-to-Ambient Thermal Resistance, 128-pin package			35	°C/W

3.5 Preliminary DC Specifications

Test Conditions: DVDD33 = AVDD33 = 3.3V, DVDD18 = AVDD18 = XVDD18 = LVDD18 = 1.8V and $T_{AMB} = 25^{\circ}\text{C}$

3.5.1 LVTTTL 5 Volt Tolerant Inputs With Hysteresis

YUV[0:7], YUVCLK, HSYNC, VSYNC, CSYNC, TCON_IN, SCL, RESETN

Symbol	Parameter	Condition	Min.	Typ.	Max.	Unit
V_{IH}	High Level Input Voltage		2.0			V
V_{IL}	Low Level Input Voltage				0.8	V
V_{HYST}	Schmitt Trigger Hysteresis		0.4			V

3.5.2 LVTTTL 5 Volt Tolerant Inputs

XCLK_EN

Symbol	Parameter	Condition	Min.	Typ.	Max.	Unit
V_{IH}	High Level Input Voltage		2.0			V
V_{IL}	Low Level Input Voltage				0.8	V

3.5.3 LVTTTL 5 Volt Tolerant I/O With Hysteresis

SDA

Symbol	Parameter	Condition	Min.	Typ.	Max.	Unit
V _{IH}	High Level Input Voltage		2.0			V
V _{IL}	Low Level Input Voltage				0.8	V
V _{HYST}	Schmitt Trigger Hysteresis		0.4			V

3.5.4 LVTTTL Outputs

OBA[0:7], OGA[0:7], ORA[0:7], OBB[0:7], OGB[0:7], ORB[0:7], OHS, OVS, ODE, OCLK

Symbol	Parameter	Condition	Min.	Typ.	Max.	Unit
V _{IH}	High Level Input Voltage		2.0			V
V _{IL}	Low Level Input Voltage				0.8	V
I _{IH}	High Level Input Current	V _{IN} = V _{DD}			-10	μA
I _{IL}	Low Level Input Current	V _{IN} = 0V			10	μA

3.6 Preliminary AC Specifications

Symbol	Parameter	Condition	Min.	Typ.	Max.	Unit
V _{rds_diff}	RSDS Differential Output Voltage	RSDS mode	100	200	400	mV
V _{rsrc_cm}	RSDS Common Mode Output Voltage	680 ohm + 50 ohm external termination to 1.3V	1.1	1.3	1.5	V
Trise, Tfall	RSDS Transition Time To 90%	CL = 30pF			3	ns
INL	ADC Integral Nonlinearity (9-bit)			1.5		LSB
DNL	ADC Differential Nonlinearity (9-bit)	no missing codes		1.5		LSB
V _{adc_in}	ADC Input Voltage Range		0.5		1	Vp-p
ENOB	ADC Effective Number Of Bits	135 MSPS Input = 65 MHz sine at 95% FS		7.5		bits
R _{adc_in}	ADC Input Resistance			200		Kohms
C _{adc_in}	ADC Input Capacitance				8	pF
F _{adc}	ADC Sample Frequency		20		140	MHz
ADC gain step	ADC Gain Step Size			0.05		dB
ADC offset step	ADC Offset Step Size			4		mV
C _{adc_ext}	ADC External AC Coupling Cap			0.1		uF

4 Package Mechanical Data

	Dimensions (mm)			Dimensions (inches)		
	Min.	Typ.	Max.	Min.	Typ.	Max.

5 Revision History

Table 38: Summary of Modifications

Date	Version	Description
12 August 2002	0.1	First Draft
23 August 2002	0.2	Addition of diagram on Cover. Modification of Description and Product Selector info on 1st page. Modification of Section 2.7.1: Functional Description (SMUX) and Table 11: Sync Multiplexer Registers . Modification of Table 7: Line Lock PLL Registers , Table 14: Data Measurement Registers , Table 15: LCD Scaler Registers and Table 24: Flicker Registers .
17 October 2002	0.3	Device named changed from ADE3700X to ADE3700. Modification of block diagram and table on cover.
26 Nov 2002	0.4	Modification of registers SMEAS_V_CTRL and GLBL_INCLK_GATE_CTRL
4 Dec 2002	0.5	Modification of package data (128-pin LQFP).
9 Jan 2003	0.6	Changes to Pin Description information. Update of Timing Controller information.
10 July 2003	0.7	Inclusion of Section 3.2: Power Consumption Matrices on page 84 .
