	247,251	LCDC : modify the explanation	
	252----255	LCDC : modify the value(insert 1 page)	

	248	LCDC ：TA3OUT equation modify	
	294,296	SPEC : t_{DW},t_{WW} modify	

Note : Each page number corresponds to each revision when modified.

CMOS 16-Bit Microcontrollers

TMP91C820AF

1. OUTLINE AND FEATURES

TMP91C820AF is a high-speed 16-bit microcontroller designed for the control of various mid- to large-scale equipment.
TMP91C820AF comes in a 144-pin flat package.
Listed below are the features.

(1) High-speed 16-bit CPU (900/L1 CPU)
- Instruction mnemonics are upward-compatible with TLCS-90/900
- 16 Mbytes of linear address space
- General-purpose registers and register banks
- 16-bit multiplication and division instructions; bit transfer and arithmetic instructions
- Micro DMA: Four-channels (1.0 μs/2 bytes at 16 MHz)

(2) Minimum instruction execution time: 111ns (at 36 MHz)

(3) Built-in RAM: 8 Kbytes
Built-in ROM: 8 Kbytes

(4) External memory expansion
- Expandable up to 136M bytes (shared program/data area)
- Can simultaneously support 8-/16-bit width external data bus
  ⋯ Dynamic data bus syzing
- Separate bus system

(5) 8-bit timers: 4 channels

(6) 16-bit timer/event counter : 1 channel

(7) General-purpose serial interface: 3 channels
- UART/Synchronous mode
- IrDA

(8) Serial bus interface: 1 channel
- I^2C bus mode/clock synchronous select mode

(9) LCD controller

- Shift register/built-in RAM LCD driver
- Supported 16,8 and 4 Gray-levels and Black and White
- Hardware Blinking Cursor

(10) SDRAM Controller

- Supported 16M,64M and 128Mbit-SDRAM with 16bit Data-bus

(11) Timer for real-time clock (RTC)

- Based on TC8521A

(12) Key-on wake up (Interrupt key input)

(13) 10-bit A/D converter: 8 channels

(14) Watch dog timer

(15) Melody/alarm generator

- Melody: Output of clock 4 to 5461Hz
- Alarm: Output of the 8 kinds of alarm pattern
- Output of the 5 kinds of interval interrupt

(16) Chip select/Wait controller: 4 channels

(17) MMU

- Expandable up to 136M bytes (4 local area/8bank method)

(18) Interrupts: 43 interrupts

- 9 CPU interrupts: Software interrupt instruction and illegal instruction
- 28 internal interrupts: Seven selectable priority levels
- 6 external interrupts: Seven selectable priority levels(4-edge selectable)

(19) Input/output ports: 77 pins (at External 16-bit data bus memory)

(20) Stand-by function

Three Halt modes: Idle2 (programmable), Idle1, Stop

(21) Triple-clock controller

- Clock doubler (DFM)
- Clock gear function: Select a High-frequency clock fc to fc/16
- RTC (fs=32.768kHz)

(22) Operating voltage

- VCC = 2.7 V to 3.6 V (fc max = 27 MHz)
- VCC = 3.0 V to 3.6 V (fc max = 36 MHz)

(23) Package

- 144-pin QFP: LQFP144 - P -1616 - 0.40
- 144-pad Dice form

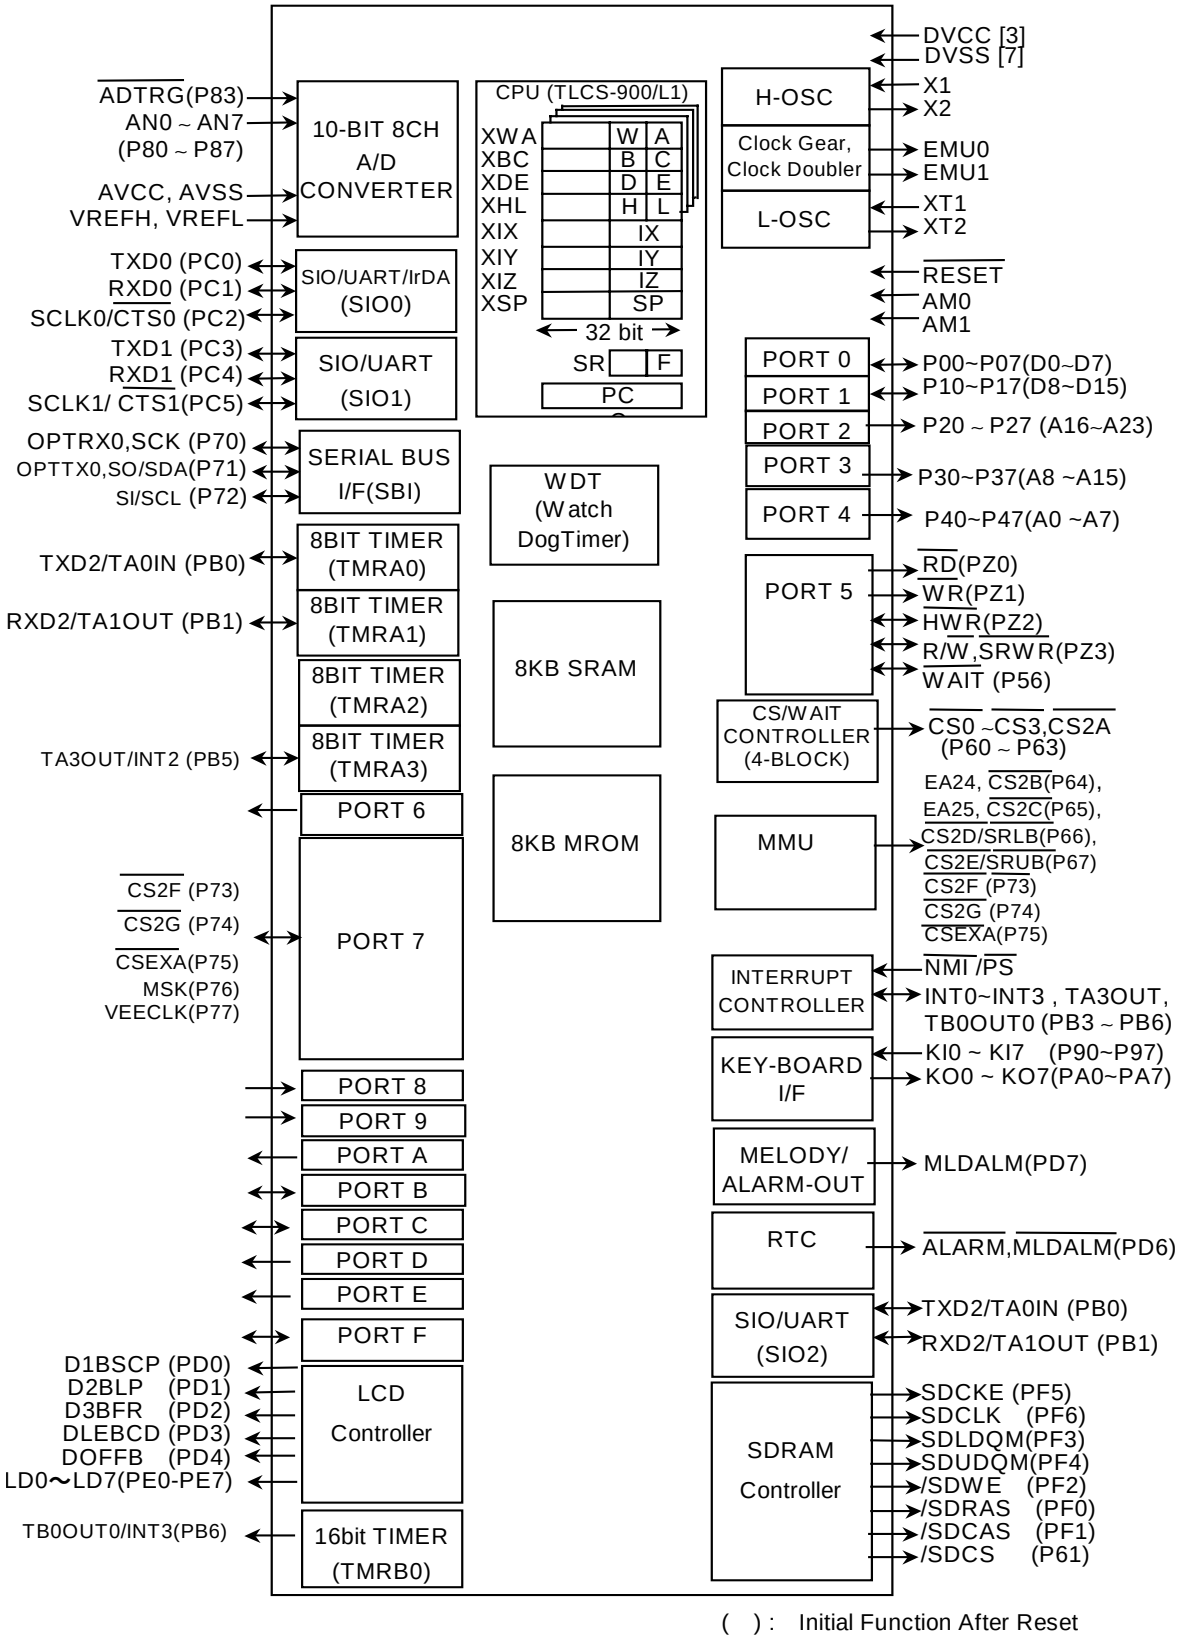

Figure 1.1 TMP91C820A Block Diagram

2. PIN ASSIGNMENT AND PIN FUNCTIONS

The assignment of input/output pins for the TMP91C820AF, their names and functions are as follows:

2.1 Pin Assignment Diagram

Figure 2.1 shows the pin assignment of the TMP91C820AF.

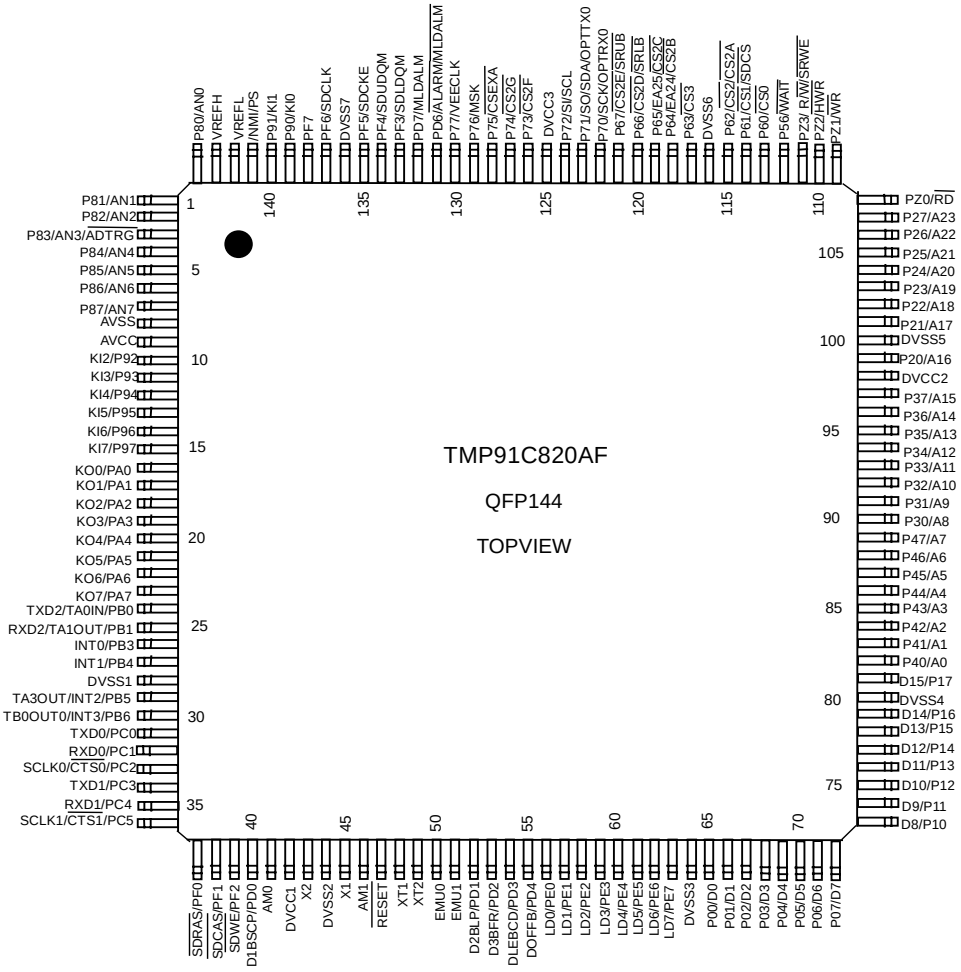

Figure 2.1 Pin assignment diagram (144-pin QFP)

PAD layout

(Chip size 5.75mm ×5.63mm) Unit: μm

2.2 Pin Names and Functions

The names of the input/output pins and their functions are described below.

Table 2.2 Pin names and functions.

Pin Name	Number of Pins	I/O	Functions
P00 to P07 D0 to D7	8	I/O I/O	Port 0: I/O port that allows I/O to be selected at the bit level Data (lower): bits 0 to 7 of data bus
P10 to P17 D8 to D15	8	I/O I/O	Port 1: I/O port that allows I/O to be selected at the bit level (When used to the external 8bit bus) Data (upper): bits 8 to15 of data bus
P20 to P27 A16 to A23	8	Output Output	Port 2: I/O port Address: bits 16 to 23 of address bus
P30 to P37 A8 to A15	8	Output Output	Port 3: I/O port Address: bits 8 to 15 of address bus
P40 o P47 A0 to A7	8	Output Output	Port 4: I/O port Address: bits 0 to 7 of address bus
PZ0 /RD	1	Output Output	Port Z0:Output port Read: strobe signal for reading external memory
PZ1 /WR	1	Output Output	Port Z1:Output port Write: strobe signal for writing data to pins D0 to D7
PZ2 /HWR	1	I/O Output	Port Z2: I/O port (with pull-up resistor) High Write: strobe signal for writing data to pins D8 to D15
PZ3 $R/\overline{W}$ /SRWR	1	I/O Output Output	Port Z3: I/O port (with pull-up resistor) Read/Write: 1 represents Read or Dummy cycle; 0 represents write cycle. Write for SRAM: strobe signal for writing data .
P56 /WAIT	1	I/O Input	Port 56: I/O port (with pull-up resistor) Wait: pin used to request CPU bus wait
P60 /CS0	1	Output Output	Port 60:Output port Chip select 0: Outputs “0” when address is within specified address area.
P61 /CS1 /SDCS	1	Output Output Output	Port 61:Output port Chip Select 1: outputs “0” when address is within specified address area Chip Select for SDRAM: outputs “0” when address is within SDRAM address area
P62 /CS2 /CS2A	1	Output Output Output	Port 62: Output port Chip Select 2: outputs “0” when address is within specified address area Expand Chip Select: 2A: outputs 0 when address is within specified address area
P63 /CS3	1	Output Output	Port 63:Output port Chip Select 3: outputs “0” when address is within specified address area
P64 EA24 /CS2B	1	Output Output Output	Port 64: Output port Chip Select 24: outputs “0” when address is within specified address area Expand Chip Select: 2B: outputs “0” when address is within specified address area
P65 EA25 /CS2C	1	Output Output Output	Port 65: Output port Chip Select 25: outputs “0” when address is within specified address area Expand Chip Select: 2C: outputs “0” when address is within specified address area
P66 /CS2D /SRLB	1	Output Output Output	Port 66: Output port Expand Chip Select: 2D: outputs “0” when address is within specified address area Lower Byte enable for SRAM: outputs “0” when lower-data is enable.
P67 /CS2E /SRUB	1	Output Output Output	Port 67: Output port Expand Chip Select: 2E: outputs “0” when address is within specified address area Upper Byte enable for SRAM: outputs “0” when upper-data is enable.

Pin Name	Number of Pins	I/O	Functions
P70 SCK OPTRX0	1	I/O I/O Input	Port 70: I/O port Serial bus interface clock I/O data at SIO mode Serial-0 recive data
P71 S0 SDA OPTRX0	1	I/O Output I/O Output	Port 71: I/O port Serial bus interface send data at SIO mode Serial bus interface send/recive data at I2C mode Open drain output mode by programmable Serial-0 send data
P72 SI SCL	1	I/O Output Output	Port 72: I/O port Serial bus interface recive data at SIO mode Serial bus interface clock I/O data at I2C mode Open drain output mode by programmable
P73 /CS2F	1	I/O Output	Port 73: I/O port Expond Chip Select 2F: outputs outputs “0” when address is within specified address area
P74 /CS2G	1	I/O Output	Port 74: I/O port Expond Chip Select 2G: outputs outputs “0” when address is within specified address area
P75 /CSEXA	1	I/O Output	Port 75: I/O port Expand Chip Select EXA: outputs outputs “0” when address is within specified address area
P76 MSK	1	I/O Input	Port 76: I/O port Mask : Use for disable to output VEECLK for LCD-driver
P77 VEECLK	1	I/O Output	Port 77: I/O port Output 32.768KHz clock to LCD-driver. (can be disabled by MSK-pin)
P80 to P87 AN0 to AN7 ADTRG	8	Input Input Input	Port 80 to 87 port: Pin used to input ports Analog input 0 to 7: Pin used to Input to A/D conveter A/D trigger: Signal used to request A/D start (with used to P83)
P90 to P97 KI0 to KI7	8	Input Input	Port: 90 to 97 port: Pin used to input ports Key input 0 to 7: Pin used of Key on wake-up 0 to 7 (schmitt input, with pull-up register)
PA0 to PA7 KO0 to KO7	8	Output Output	Port: A0 to A7 port: Pin used to output ports Key output 0 to 7: Pin used of Key-scan strobe 0 to 7
PB0 TA0IN TXD2	1	I/O Input Output	Port B0: I/O port 8bit timer 0 input: Timer 0 input Serial 2 send data: Open drain output pin by programmable
PB1 TA1OUT RXD2	1	I/O Output Input	Port B1: I/O port 8bit timer 1 output: Timer 1 output Serial 2 receive data
PB3 INT0	1	I/O input	Port B3: I/O port Interrupt request pin0: Interrupt request pin with programmable level / rising / Falling edge
PB4 INT1	1	I/O input	Port B4: I/O port Interrupt request pin1: Interrupt request pin with programmable rising / Falling edge

Pin Name	Number of Pins	I/O	Functions
PB5 INT2 TA3OUT	1	I/O Input Output	Port B5: I/O port Interrupt request pin2 : Interrupt request pin with programmable rising /falling edge 8bit timer 3 output: Timer 3 output 8bit timer 3 output: Timer 2 output or Timer 3 output
PB6 INT3 TB0OUT0	1	I/O Input Outout	Port B6 : I/O port Interrupt request pin3: Interrupt request pin with programmable rising /falling edge Timer B0 output 8bit timer 0 output: Timer 0 output or Timer 1 output
PC0 TXD0	1	I/O Output	Port C0: I/O port Serial 0 send data: Open drain output pin by programmable
PC1 RXD0	1	I/O Input	Port C1: I/O port Serial 0 receive data
PC2 SCLK0 $\overline{\text{CTS0}}$	1	I/O I/O Input	Port C2: I/O port Serial 0 clock I/O Serial 0 data send enable (Clear to Send)
PC3 TXD1	1	I/O Output	Port C3: I/O port Serial 1 send data: Open drain output pin by programmable
PC4 RXD1	1	I/O Input	Port C4: I/O port Serial 1 receive data
PC5 SCLK1 $\overline{\text{CTS1}}$	1	I/O I/O Input	Port C5: I/O port Serial 1 clock I/O Serial 1 data send enable (Clear to Send)
PD0 D1BSCP	1	Output Output	Port D0: Output port LCD driver output pin
PD1 D2BLP	1	Output Output	Port D1: Output port LCD driver output pin
PD2 D3BFR	1	Output Output	Port D2: Output port LCD driver output pin
PD3 DLEBCD	1	Output Output	Port D3: Output port LCD driver output pin
PD4 DOFFB	1	Output Output	Port D4: Output port LCD driver output pin
PD6 /ALARM /MLDALM	1	Output Output Output	Port D6: Output port RTC alarm output pin Melody / Alarm output pin (inverted)
PD7 MLDALM	1	Output Output	Port D7: Output port Melody / Alarm output pin
PE0 to PE7 LD0 to LD7	8	I/O Output	Port E0 to E7: I/O port Data Bus for LCD-driver
PF0 /SDRAS	1	I/O Output	Port F0: Output port Row Address Storobe for SDRAM: outputs “0” when address is within SDRAM address area
PF1 /SDCAS	1	I/O Output	Port F1: Output port Column Address Storobe for SDRAM: outputs “0” when address is within SDRAM address area

Pin Name	Number of Pins	I/O	Functions
PF2 /SDWE	1	Output Output	Port F2: Output port Write Enable for SDRAM
PF3 SDLDQM	1	Output Output	Port F3: Output port Lower Data enable for SDRAM
PF4 SDUDQM	1	Output Output	Port F4: Output port Upper Data enable for SDRAM
PF5 SDCKE	1	Output Output	Port F5: Output port Clock Enable for SDRAM
PF6 SDCLK	1	Output Output	Port F6: Output port Clock for SDRAM
PF7	1	Output	Port F7: Output port
/PS /NMI	1	Input Input	Power Save mode setting terminal Non-Maskable Interrupt Request : interrupt request pin with programmable falling edge level or with both edge levels programmable
AM0 to 1	2	Input	Operation mode: Fixed to AM1="1",AM0="1" when using internal-ROM. Fixed to AM1="0",AM0="1" when using external-ROM by 16-bit external bus. Fixed to AM1="0",AM0="0" when using external-ROM by 8-bit external bus.
EMU0	1	Output	Open pin
EMU1	1	Output	Open pin
$\overline{\text{RESET}}$	1	Input	Reset: initializes TMP91C820AF. (With pull-up resistor)
VREFH	1	Input	Pin for reference voltage input to AD converter (H)
VREFL	1	Input	Pin for reference voltage input to AD converter (L)
X1/X2	2	I/O	High-frequency oscillator connection pins
XT1/XT2	2	I/O	Low-frequency oscillator connection pins
AVCC	1		Power supply pin for AD converter
AVSS	1		GND pin for AD converter (0 V)
DVCC	3		Power supply pins (All Vcc pins should be connecyed with the power Supply pin).
DVSS	7		GND pins (All pins shuold be connected with GND(0V).

3. OPERATION

This following describes block by block the functions and operation of the TMP91C820A.
Notes and restrictions for eatch book are outlined in " 6, Precautions and Restrictions " at the end of this manual.

3.1 CPU

The TMP91C820A incorporates a high-performance 16-bit CPU (the 900/L1 CPU). For CPU operation, see the "TLCS-900/L1 CPU".
The following describe the unique function of the CPU used in the TMP91C820A; these functions are not covered in the TLCS-900/L1 CPU section.

3.1.1 Reset

When resetting the TMP91C820A microcontroller, ensure that the power supply voltage is within the operating voltage range, and that the internal high-frequency oscillator has stabilized. Then hold the /RESET input to Low level for at least 10 system clocks (ten states: 80 μs at 4 MHz).
When the reset is accept, the CPU:

- Sets as follows the program counter (PC) in accordance with the reset vector stored at address FFFF00H to FFFF02H:

  PC<7 to 0> ← value at FFFF00H address
  PC<15 to 8> ← value at FFFF01H address
  PC<23 to 16> ←value at FFFF02H address
- Sets the stack pointer (XSP) to 100H.
- Sets bits <IFF2:0> of the status register (SR) to 111 (sets the interrupt level mark register to level 7).
- Sets the <MAX> bit of the status register to 1 (MAX mode).
  (Note: As this product does not support MIN mode, do not write a 0 to the <MAX>)
- Clears bits <RFP2:0> of the status register to 000 (sets the register bank to 0).

When reset is released, the CPU starts executing instructions in accordance with the program counter settings. CPU internal registers not mentioned above do not change when the reset is released.
When the reset is accepted, the CPU sets internal I/O, ports, and other pins as follows.

- Initializes the internal I/O registers.
- Sets the port pins, including the pins that also act as internal I/O, to general-purpose input or output port mode.

(Note1) The CPU internal register(except to PC,SR,XSP) and internal RAM data do not change by resetting.

Figure 3.1.1 is a reset timing of the TMP91C820A.

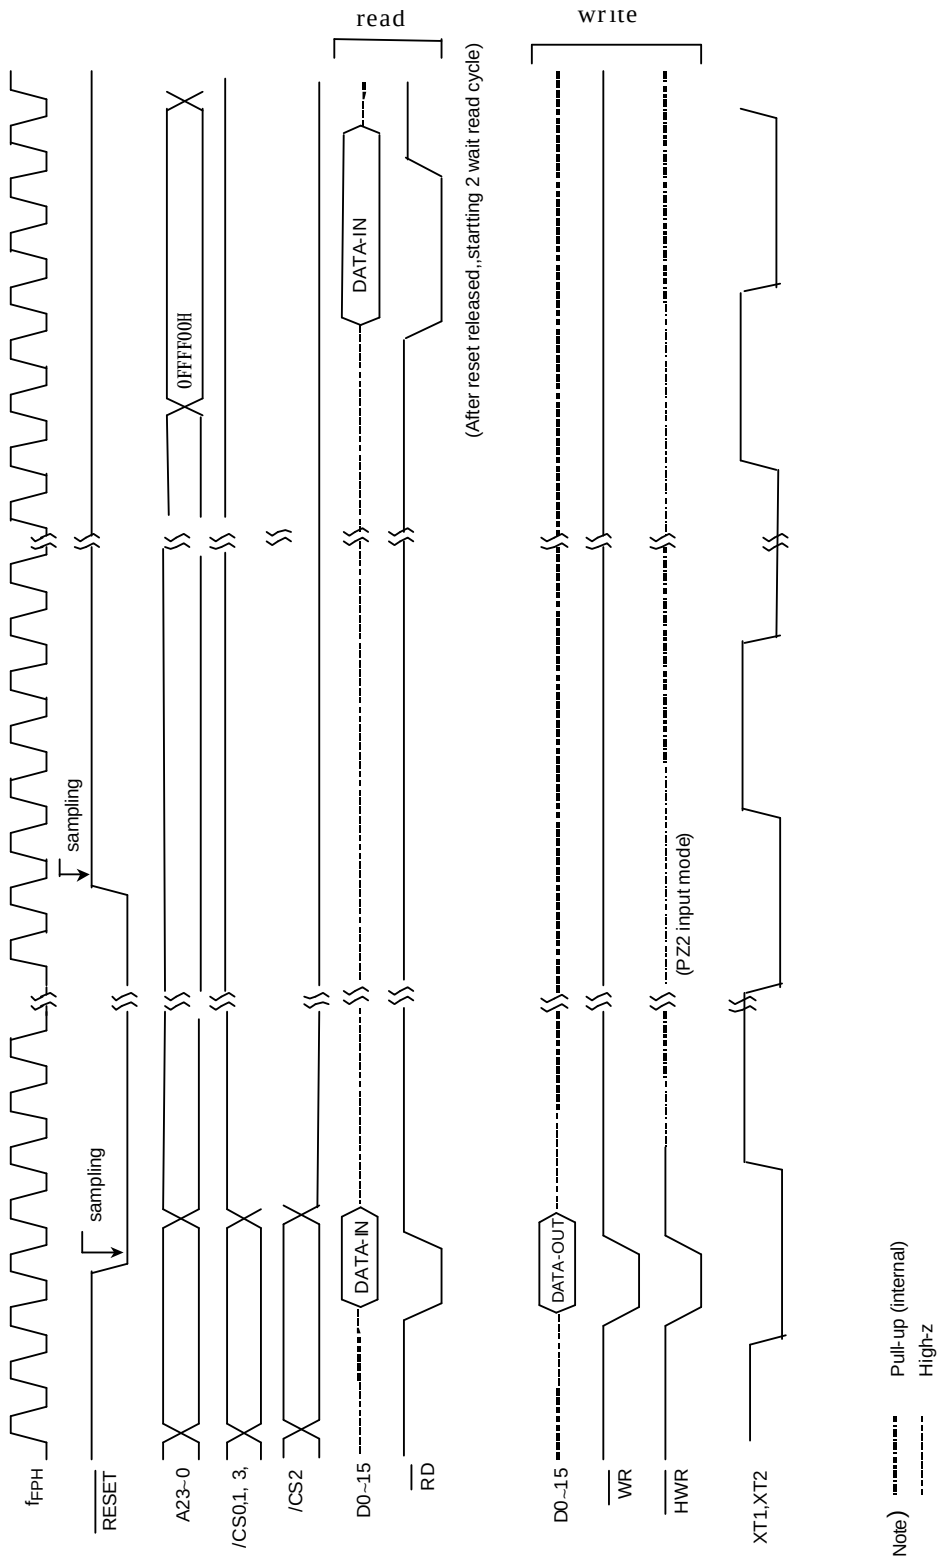

Figure 3.1.1 TMP91C820A Reset Timing Example (the case of using external ROM)

3.2 Memory Map

Figure 3.2.1 is a memory map of the TMP91C820A.

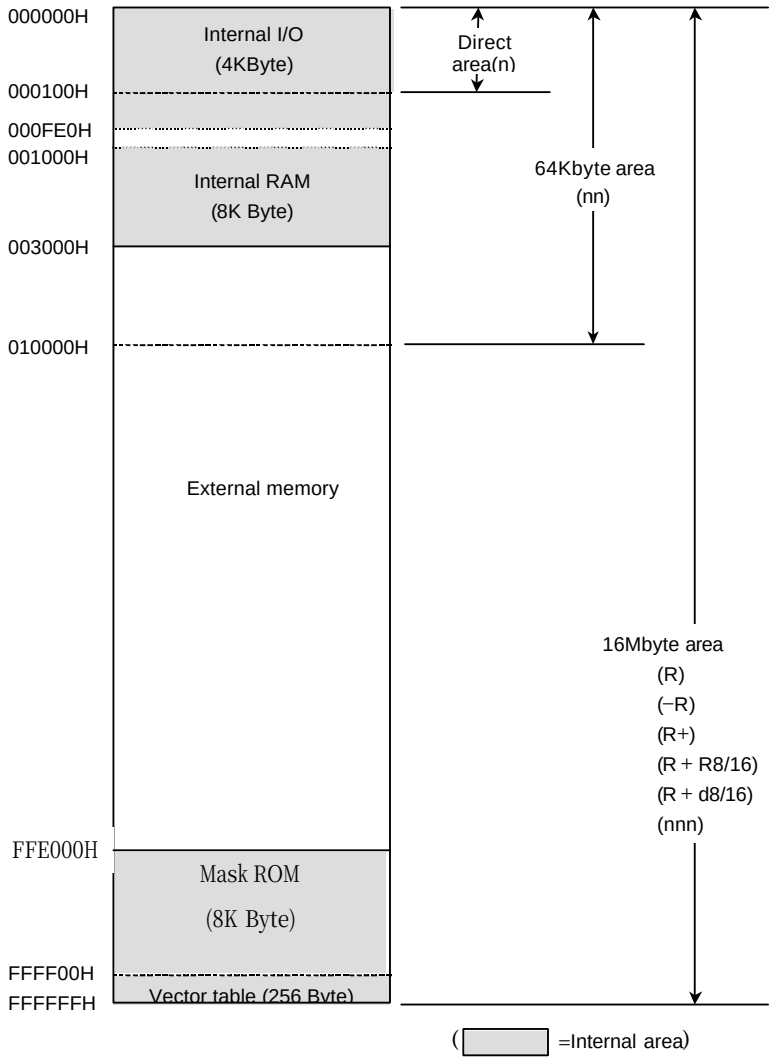

Figure 3.2.1 Memory Map

(note) : Address 000FE0H – 000FEFH is assigned for the external memory area of Built-in RAM type LCD driver.

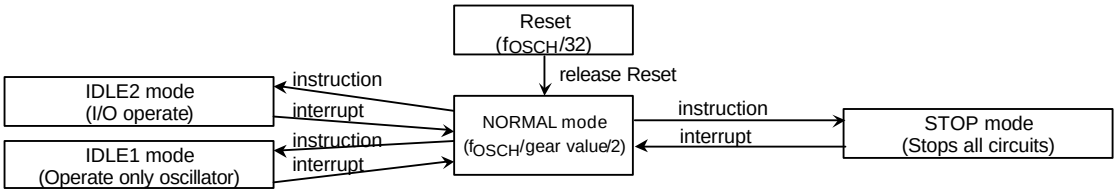
3.3 Triple Clock Function and Standby Function

TMP91C820A contains (1) a clock gear, (2) clock doubler (DFM), (3) standby controller and (4) noise-reducing circuit. It is used for low-power, low-noise systems.

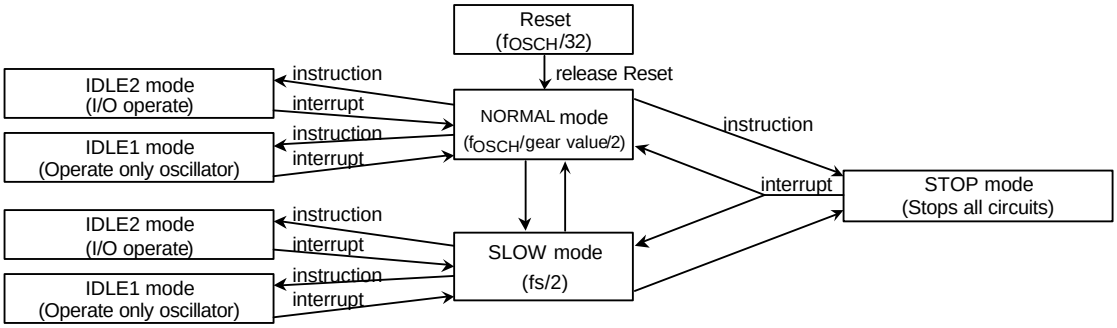
This chapter is organized as follows:

The clock operating modes are as follows: (a) Single Clock Mode (X1, X2 pins only), (b) Dual Clock Mode (X1, X2, XT1 and XT2 pins) and (c) Triple Clock Mode (the X1, X2, XT1 and XT2 pins and DFM).

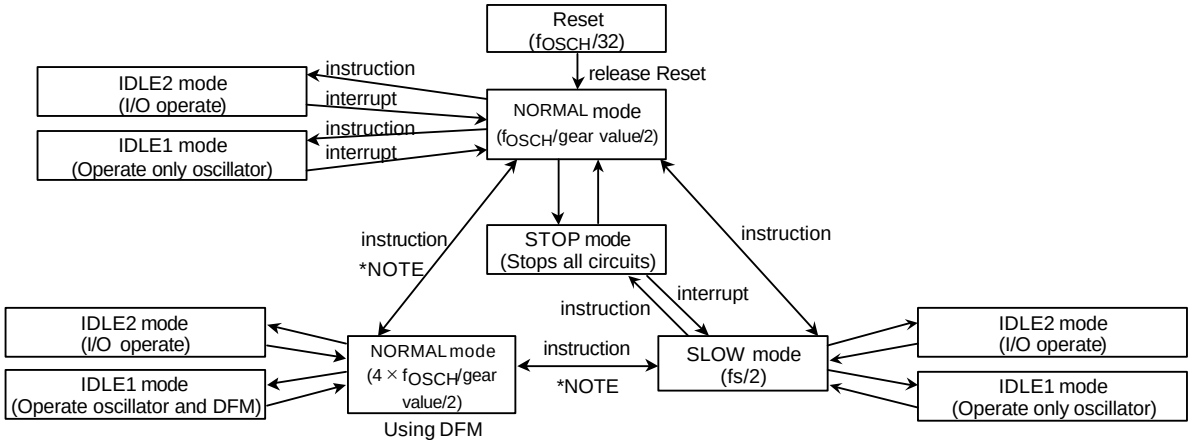
Figure 3.3.1 shows a transition figure.



(a) Single clock mode transition figure



(b) Dual clock mode transition fiigure



(c) Triple clock mode trasision Figure

***NOTE)**

- It's prohibited to control DFM in SLOW mode when shifting from SLOW mode to NORMAL mode with use of DFM. (DFM Start up/Stop/Change Write to DFMCR0<ACT1:0> resister)
- If you shift from NORMAL mode with use of DFM to NORMAL mode, the instruction should be separated into two procedures as below. Change CPU clock ->Stop DFM circuit
- It's prohibited to shift from NORMAL mode with use of DFM to STOP mode directly. You should set NORMAL mode once, and then shift to STOP mode.(You should stop high frequency oscillator after you stop DFM.)

Figure 3.3.1 System clock block diagram

The clock frequency input from the X1 and X2 pins is called fc and the clock frequency input from the XT1 and XT2 pins is called fs. The clock frequency selected by SYSCR1<SYSCK> is called the system clock f_{FPH}. The system clock f_{SYS} is defined as the divided clock of f_{FPH}, and one cycle of f_{SYS} is defined to as one state.

Limitation point on the use of DFM

1. It's prohibited to execute DFM enable/disable control in the SLOW mode(fs) (write to DFMCR0<ACT1:0>="10"). You should control DFM in the NORMAL mode.

2. If you stop DFM operation during using DFM(DFMCR0<ACT1:0>="10") , you shouldn't execute that change the clock f_{DFM} to f_{OSCH} and stop the DFM at the same time. Therefore the above executions should be separated into two procedures as showing below.

```
LD      (DFMCR0),C0H    ;  change the clock fDFM to fOSCH
LD      (DFMCR0),00H    ;  DFM stop
```

3. If you stop high frequency oscillator during using DFM (DFMCR0<ACT1:0>="10") , you should stop DFM before you stop high frequency oscillator.

Please refer to 3.3.5 Clock Doubler (DFM) for the details.

Note : When getting access to the logic address 000000H to 003000H and FFE000H to FFFFFFH , A0 to A23 holds the previous address.

3.3.3 System clock controller

The system clock controller generates the system clock signal (f_{SYS}) for the CPU core and internal I/O. It contains two oscillation circuits and a clock gear circuit for high-frequency (fc) operation. The register SYSCR1<SYSCK> changes the system clock to either fc or fs, SYSCR0<XEN> and SYSCR0<XTEN> control enabling and disabling of each oscillator, and SYSCR1<GEAR0 to GEAR2> sets the high-frequency clock gear to either 1, 2, 4, 8 or 16 (fc, fc/2, fc/4, fc/8 or fc/16). These functions can reduce the power consumption of the equipment in which the device is installed.

The combination of settings <XEN> = 1, <XTEN> = 0, <SYSCK> = 0 and <GEAR0~GEAR2> = 100 will cause the system clock (f_{SYS}) to be set to fc/32 (fc/16× 1/2) after a Reset.

For example, f_{SYS} is set to 0.5 MHz when the 16-MHz oscillator is connected to the X1 and X2 pins.

(1) Switching from Normal Mode to Slow Mode

When the resonator is connected to the X1 and X2 pins, or to the XT1 and XT2 pins, the warm-up timer can be used to change the operation frequency after stable oscillation has been attained.

The warm-up time can be selected using SYSCR2<WUPTM0,WUPTM1>.

This warm-up timer can be programmed to start and stop as shown in the following examples 1 and 2.

Table 3.3.1 shows the warm-up time.

Note 1: When using an oscillator (other than a resonator) with stable oscillation, a warm-up timer is not needed.

Note 2: The warm-up timer is operated by an oscillation clock. Hence, there may be some variation in warm-up time.

Table 3.3.1 Warming-up times

Warming-up Time SYSCR2 <WUPTM1,WUPTM0>	Change to Normal Mode	Change to Slow Mode
01 (2^8 / frequency)	16 (μs)	7.8 (ms)
10 (2^{14} / frequency)	1.024 (ms)	500 (ms)
11 (2^{16} / frequency)	4.096 (ms)	2000 (ms)

at f_{OSCH} = 16 MHz,
fs = 32.768 kHz

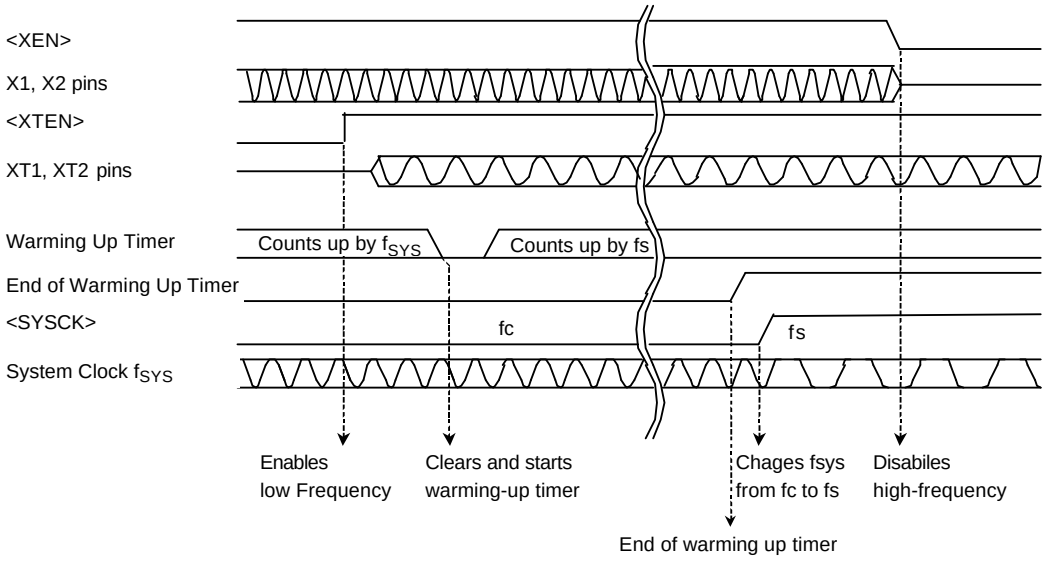
Example 1-Setting the clock

Changing from high frequency (fc) to low frequency (fs).

```
SYSCR0    EQU   00E0H
SYSCR1    EQU   00E1H
SYSCR2    EQU   00E2H
          LD    (SYSCR2), X–11– –X–B  ;  Sets warm-up time to 2^16/fs.
          SET   6, (SYSCR0)           ;  Enables low-frequency oscillation.
          SET   2, (SYSCR0)           ;  Clears and starts warm-up timer.
WUP:      BIT   2, (SYSCR0)           ;  } Detects stopping of warm-up timer.
          JR    NZ, WUP               ;  }
          SET   3, (SYSCR1)           ;  Changes f_SYS from fc to fs.
          RES   7, (SYSCR0)           ;  Disables high-frequency oscillation.
```

(Note) "x" means don't care

"-" means no change



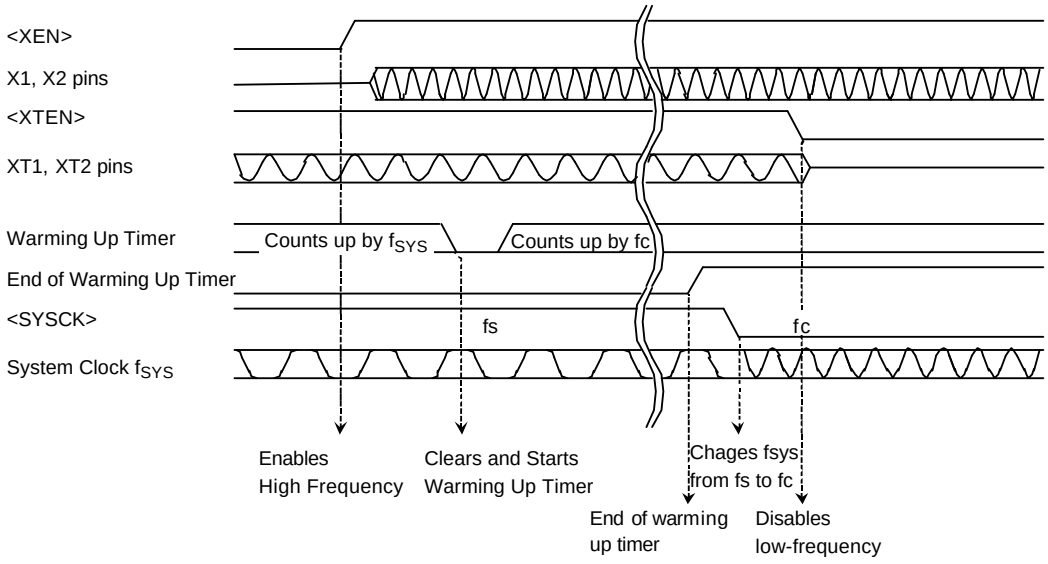
Example 2-Setting the clock

Changing from low frequency (fs) to high frequency (fc).

```
SYSCR0   EQU   00E0H
SYSCR1   EQU   00E1H
SYSCR2   EQU   00E2H
         LD    (SYSCR2), X–10– –X–B   ;   Sets warm-up time to 2^14/fc.
         SET   7, (SYSCR0)            ;   Enables high-frequency oscillation.
         SET   2, (SYSCR0)            ;   Clears and starts warm-up timer.
WUP:     BIT   2, (SYSCR0)            ;  }
         JR    NZ, WUP                ;  } Detects stopping of warm-up timer.
         RES   3, (SYSCR1)            ;   Changes f_SYS from fs to fc.
         RES   6, (SYSCR0)            ;   Disables low-frequency oscillation.
```

(Note) "x" means don't care

"-" means no change



(2) Clock gear controller

When the high-frequency clock fc is selected by setting SYSCR1<SYSCK> = 0, f_{FPH} is set according to the contents of the Clock Gear Select Register SYSCR1<GEAR0 to GEAR2> to either fc, fc/2, fc/4, fc/8 or fc/16. Using the clock gear to select a lower value of f_{FPH} reduces power consumption.

Example 3

Changing to a high-frequency gear

```
SYSCR1    EQU    00E1H
          LD     (SYSCR1), XXXX0000B   ;   Changes fSYS to fc/2.
          LD     (SYSCR1), XXXX0100B   ;   Changes fSYS to fc/32.
```

X: Don't care

(High-speed clock gear changing)

To change the clock gear, write the register value to the SYSCR1<GEAR2-0> register.It is necessary the warmming up time until changing after writing the register value.

There is the possibility that the instruction next to the clock gear changing instruction is executed by the clock gear before changing.To execute the instruction next to the clock gear switching instruction by the clock gear after changing,input the dummy instruction as follows (instruction to execute the write cycle).

(Example)

```
SYSCR1    EQU    00E1H
          LD     (SYSCR1), XXXX0001B   ;   Changes fSYS to fc/4.
          LD     (DUMMY), 00H          ;   Dummy instruction
Instruction to be executed after clock gear has changed
```

3.3.4 Prescaler clock controller

For the internal I/O (TMRA01 to 23, SIO0 to 1,SBI) there is a prescaler which can divide the clock.

The ϕT clock input to the prescaler is either the clock f_{FPH} divided by 2 or the clock fc/16 divided by 2. The setting of the SYSCR0 <PRCK0 to PRCK1> register determines which clock signal is input.

The ϕT0 clock input to the prescaler is either the clock f_{FPH} divided by 4 or the clock fc/16 divided by 4. The setting of the SYSCR0 <PRCK0 to PRCK1> register determines which clock signal is input.

3.3.5 Clock doubler (DFM)

DFM outputs the f_{DFM} clock signal, which is four times as fast as f_{OSCH}. It can use the low-frequency oscillator, even though the internal clock is high-frequency.

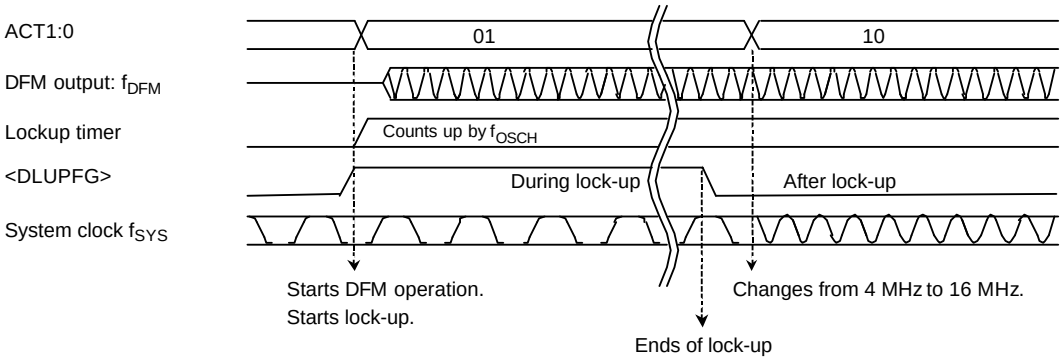
A Reset initializes DFM to Stop status, setting to DFMCR0-register is needed before use.

Like an oscillator, this circuit requires time to stabilize. This is called the lock-up time.

The following example shows how DFM is used.

```
DFMCR0   EQU   00E8H
DFMCR1   EQU   00E9H
         LD    (DFMCR1),0BH          ;  Parameter setting
         LD    (DFMCR0), 01X0XXXXB   ;  Set lock-up time to 2^12/4 MHz
                                     Enables DFM operation and starts lock-up.
LUP:     BIT   5, (DFMCR0)           ;  } Detects end of lock-up
         JR    NZ, LUP               ;  }
         LD    (DFMCR0), 10X0XXXXB   ;  Changes fc from 4 MHz to 16 MHz.
```

X: Don't care



(note) Input frequency limitation and correction for DFM

Recommend to use Input frequency(High speed oscillation) for DFM in the following condition.

f_{OSCH} = 4 ~ 6.75MHz (Vcc = 2.7~ 3.6V) : write 0BH to DFMCR1

Limitation point on the use of DFM

1. It's prohibited to execute DFM enable/disable control in the SLOW mode(fs) (write to DFMCR0<ACT1:0>="10"). You should control DFM in the NORMAL mode.

2. If you stop DFM operation during using DFM (DFMCR0<ACT1:0>="10") , you shouldn't execute the commands that change the clock f_{DFM} to f_{OSCH} and stop the DFM at the same time. Therefore the above execution should be separated into two procedures as showing below.

```
LD      (DFMCR0),C0H    ;   Change the clock fDFM to fOSCH
LD      (DFMCR0),00H    ;   DFM stop
```

3. If you stop high frequency oscillator during using DFM(DFMCR0<ACT1:0>="10") , you should stop DFM before you stop high frequency oscillator.

Examples of settings are below.

(1) Start Up / Change Control

(OK) Low frequency oscillator operation mode(f_s) (high frequency oscillator STOP)
→ High frequency oscillator start up → High frequency oscillator operation mode(f_{OSCH})→DFM start up → DFM use mode (f_{DFM})

```
        LD      (SYSCR0),  11---1--B    ; High frequency oscillator start up/ Warming up start
WUP:    BIT     2,(SYSCR0)              ;
        JR      NZ,WUP                  ;   Check for the flag of warming up end
        LD      (SYSCR1),  ----0---B    ; Change the system clock fs to fOSCH
        LD      (DFMCR0),01-0----B      ; DFM start up / lock up start
LUP:    BIT     5, (DFMCR0)             ;
        JR      NZ,LUP                  ;   Check for the flag of lock up end
        LD      (DFMCR0),10-0----B      ; Change the system clock fOSCH to fDFM
```

(OK) Low frequency oscillator operation mode(f_s) (high frequency oscillator Operate)
→ High frequency oscillator operation mode(f_{OSCH})→DFM start up → DFM use mode (f_{DFM})

```
        LD      (SYSCR1),  ----0---B    ; Change the system clock fs to fOSCH
        LD      (DFMCR0), 01-0---B      ; DFM start up / lock up start
LUP:    BIT     5, (DFMCR0)             ;
        JR      NZ,LUP                  ;   Check for the flag of lock up end
        LD      (DFMCR0),10-0----B      ; Change the system clock fOSCH to fDFM
```

(NG) Low frequency oscillator operation mode(f_s) (high frequency oscillator STOP)
→ High frequency oscillator start up → DFM start up → DFM use mode (f_{DFM})

```
        LD      (SYSCR0),11---1--B ; High frequency oscillator start up/ Warming up start
WUP:    BIT     2,(SYSCR0)              ;
        JR      NZ,WUP                  ;   Check for the flag of warming up end
        LD      (DFMCR0),01-0----B      ; DFM start up / lock up start
LUP:    BIT     5, (DFMCR0)             ;
        JR      NZ,LUP                  ;   Check for the flag of lock up end
        LD      (DFMCR0),10-0----B      ; Change the internal clock fOSCH to fDFM
        LD      (SYSCR1),  -----0---B   ; Change the system clock fs to fDFM
```

（2） Change / Stop Control

(OK) DFM use mode (f_{DFM})→ High frequency oscillator operation mode(f_{OSCH})→ DFM Stop → Low frequency oscillator operation mode(f_s)→High frequency oscillator stop

```
LD      (DFMCR0),11------B      ; Change the system clock fDFM to fOSCH
LD      (DFMCR0),00------B      ; DFM stop
LD      (SYSCR1), ----1---B     ; Change the system clock fOSCH to fs
LD      (SYSCR0), 0-------B     ; High frequency oscillator stop
```

(NG) DFM use mode (f_{DFM})→ Low frequency oscillator operation mode(f_s)→ DFM stop →High frequency oscillator stop

```
LD      (SYSCR1), ----1---B     ; Change the system clock fDFM to fS
LD      (DFMCR0),11------B      ; Change the internal clock (fC) fDFM to fOSCH
LD      (DFMCR0),00------B      ; DFM stop
LD      (SYSCR0), 0-------B     ; High frequency oscillator stop
```

(OK) DFM use mode (f_{DFM})→Set the STOP mode →High frequency oscillator operation mode (f_{OSCH})→ DFM stop→ HALT(High frequency oscillator stop)

```
LD      (SYSCR2), ----01--B     ; Set the STOP mode
                                (This command can execute before use of DFM)
LD      (DFMCR0),11------B      ; Change the system clock fDFM to fOSCH
LD      (DFMCR0),00------B      ; DFM stop
HALT                            ; Shift to STOP mode
```

(NG) DFM use mode (f_{DFM})→Set the STOP mode→ HALT(High frequency oscillator stop)

```
LD      (SYSCR2), ----01--B     ; Set the STOP mode
                                (This command can execute before use of DFM)
HALT                            ; Shift to STOP mode
```

3.3.6 Noise reduction circuits

Noise reduction circuits are built in, allowing implementation of the following features.

(1) Reduced drivability for high-frequency oscillator
(2) Reduced drivability for low-frequency oscillator
(3) Single drive for high-frequency oscillator
(4) SFR protection of register contents
(5) ROM protection of register contents

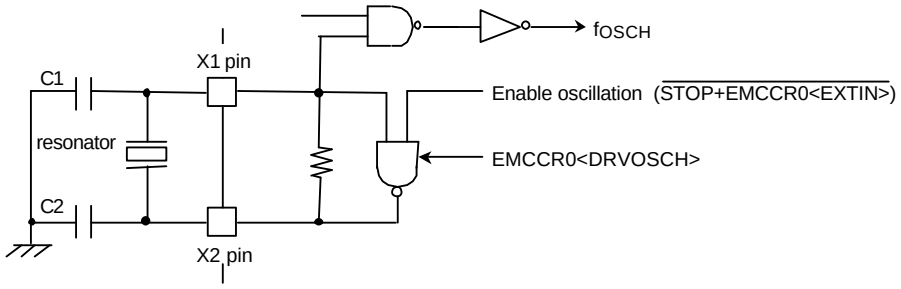
The above functions are performed by making the appropriate settings in the EMCCR0 to EMCCR3 registers.

(1) Reduced drivability for high-frequency oscillator

(Purpose)

Reduces noise and power for oscillator when a resonator is used.

(Block diagram)



(Setting method)

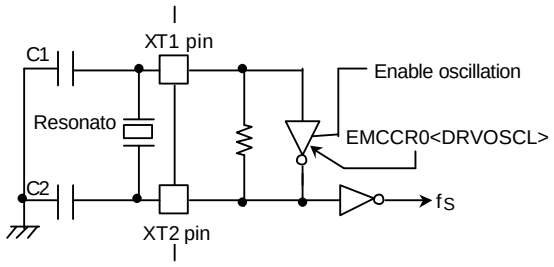
The drivability of the oscillator is reduced by writing"0" to EMCCR0<DRVOSCH> register. By reset, <DRVOSCH> is initialized to "1" and the oscillator starts oscillation by normal drivability when the power-supply is on.

(2) Reduced drivability for low-frequency oscillator

(Purpose)

Reduces noise and power for oscillator when a resonator is used.

(Block diagram)



(Setting method)

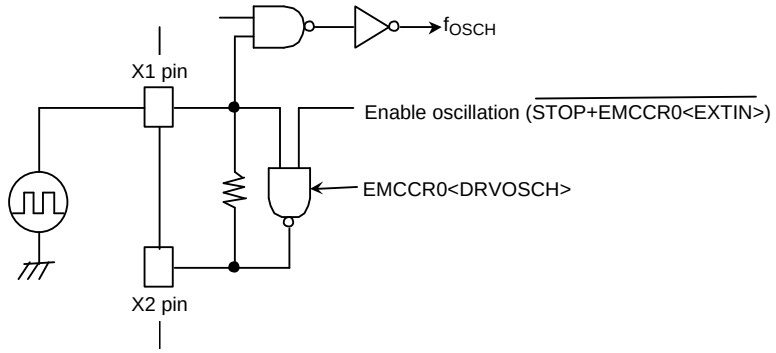
The drivability of the oscillator is reduced by writing 0 to the EMCCR0<DRVOSCL> register. By Reset, <DRVOSCL> is initialized to "1".

(3) Single drive for high-frequency oscillator

(Purpose)

Not need twin-drive and protect mistake-operation by inputted noise to X2 pin when the external-oscillator is used.

(Block diagram)



(Setting method)

The oscillator is disabled and starts operation as buffer by writing "1" to EMCCR0<EXTIN> register.X2-pin is always outputted"1".

By reset,<EXTIN> is initialized to "0".

(4) Runaway provision with SFR protection register

(Purpose)

Provision in runaway of program by noise mixing.

Write operation to specified SFR is prohibited so that provision program in runaway prevents that it is it in the state which is fetch impossibility by stopping of clock, memory control register (CS/WAIT controller, MMU) is changed.

And error handling in runaway becomes easy by INTP0 interruption.

Specified SFR list

1. CS/WAIT controller

   B0CS, B1CS, B2CS, B3CS, BEXCS,
   MSAR0, MSAR1, MSAR2, MSAR3,
   MAMR0, MAMR1, MAMR2, MAMR3

2. MMU

   LOCAL0/1/2/3

3. Clock gear

   SYSCR0, SYSCR1, SYSCR2, EMCCR0,EMCCR3

4. DFM

   DFMCR0/1

(Operation explanation)

Execute and release of protection (write operation to specified SFR) become possible by setting up a double key to EMCCR1 and EMCCR2 register.

(Double key)

1st-KEY : Succession writes in 5AH at EMCCR1 and A5H at EMCCR2

2nd-KEY : Succession writes in A5H at EMCCR1 and 5AH at EMCCR2

A state of protection can be confirmed by reading EMCCR0<PROTECT>.

By reset, protection becomes OFF.

And INTP0 interruption occurs when write operation to specified SFR was executed with protection on state.

(5) Runaway provision with ROM protection register

(Purpose)

Provision in runaway of program by noise mixing.

(Operation explanation)

When writes operation was executed for external three kinds of ROM by runaway of program, INTP1 is occurred and detects runaway function.

Three kinds of ROM is fixed as for Flash-ROM(Option-Program ROM), Data-ROM, Program-ROM are as follows on the logical address memory map.

1. Flash-ROM: Address 400000H to 7FFFFH
2. Data-ROM: Address 800000H to BFFFFH
3. Program-ROM: Address C00000H-FFFFFFH

For these address, admission / prohibition of detection of write operation sets it up with EMCCR3<ENFROM, ENDROM, ENPROM>. And INTP1 interruption occurred with which ROM area in the case that occurred can confirm each with EMCCR3<FFLAG, DFLAG, and PFLAG>. This flag is cleared when write in "0".

3.3.7 Standby controller

(1) Halt Modes

When the HALT instruction is executed, the operating mode switches to Idle2, Idle1 or Stop Mode, depending on the contents of the SYSCR2<HALTM1,HALTM0> register.

The subsequent actions performed in each mode are as follows:

① IDLE2: Only the CPU halts.

The internal I/O is available to select operation during IDLE2 mode.by setting the following register.

Table 3.3 2 Shows the registers of setting operation during IDLE2 mode.

Table 3.3.2 SFR seting operation during IDLE2 mode

Internal I/O	SFR
TMRA01	TA01RUN<I2TA01>
TMRA23	TA23RUN<I2TA23>
TMRB0	TB0RUN<I2TB0>
SIO0	SC0MOD1<I2S0>
SIO1	SC1MOD1<I2S1>
A/D converter	ADMOD1<I2AD>
WDT	WDMOD<I2WDT>
SBI	SBI0BR1<I2SBI0>

② Idle1: Only the oscillator and the RTC (real-time clock) continue to operate.

③ Stop: All internal circuits stop operating.

The operation of each of the different Halt Modes is described in Table 3.3.3.

Table 3.3.3 I/O operation during Halt Modes

<table>
<tr><td colspan="2">Halt Mode</td><td>IDLE2</td><td>IDLE1</td><td>STOP</td></tr>

Interrupt controller</td><td rowspan="2">Operate</td></tr>
<tr><td>RTC,MLD</td><td>Operational available</td></tr>
</table>

(2) How to release the Halt mode

These HALT states can be released by resetting or requesting an interrupt. The halt release sources are determined by the combination between the states of interrupt mask register <IFF2-0> and the halt modes. The details for releasing the HALT status are shown in Table 3.3 4.

- Released by requesting an interrupt

The operating released from the halt mode depends on the interrupt enabled status.When the interrupt request level set before executing the HALT instruction exceeds the value of interrupt mask register,the interrupt due to the source is processed after releasing the halt mode,and CPU status executing an instruction that follows the HALT instruction. When the interrupt request level set before executing the HALT instruction is less than the value of the interrupt mask register,releasing the halt mode is not executed.(in non-maskable interrupts,interrupt processing is processed after releasing the halt mode regardless of the value of the mask register.) However only for INT0~INT4 and RTC interrupts,even if the interrupt request level set before executing the HALT instruction is less than the value of the interrupt mask register, releasing the the halt mode is executed. In this case,interrupt processing, and CPU starts executing the instruction next to the HALT instruction,but the interrupt request flag is held at "1".

- Releasing by resetting

Releasing all halt status is executed by resetting.

When the Stop mode is released by RESET,it is necessry enough resetting time (see table 3.3.5) to set the operation of the oscillator to be stable.

When releasing the halt mode by resetting, the internal RAM data keeps the state before the "HALT" instruction is executed. However the other settings contents are initialized. (Releasing due to interrupts keeps the state before the "HALT" instruction is executed.)

Table 3.3.4 Source of Halt state clearance and Halt clearance operation

Status of Received Interrupt			Interrupt Enabled (interrupt level) ≥ (interrupt mask)			Interrupt Disabled (interrupt level) < (interrupt mask)		
Halt mode			Idle2	Idle1	Stop	Idle2	Idle1	Stop
Source of Halt state clearance	Interrupt	NMI	◎	◎	◎*1	–	–	–
		INTWDT	◎	×	×*1	–	–	–
		INT0 to3 (Note1)	◎	◎	◎*1	○	○	○*1
		INTALM0 to 4	◎	◎	×	○	○	×
		INTTA0 to 3,INTTB00 to 01	◎	×	×	×	×	×
		INTRX0 to 2,TX0 to 2	◎	×	×	×	×	×
		INTSS0 to 2	◎	×	×	×	×	×
		INTAD	◎	×	×*1	×	×	×*1
		INTKEY	◎	◎	◎*1	○	○	○*1
		INTRTC	◎	◎	×	○	○	×
		INTSBI	◎	×	×	×	×	×
		INTLCD	◎	×	×	×	×	×
		RESET	◎	◎	◎	◎	◎	◎

◎: After clearing the Halt mode, CPU starts interrupt processing. (RESET initializes the microcont.)

○: After clearing the Halt mode, CPU resumes executing starting from instruction following the HALT instruction.

×: It can not be used to release the halt mode.

–: The priority level (interrupt request level) of non-maskable interrupts is fixed to 7, the highest priority level. There is not this combination type.

*1: Releasing the halt mode is executed after passing the warmming-up time.

Note 1: When the Halt mode is cleared by an INT0 interrupt of the level mode in the interrupt enabled status, hold level H until starting interrupt processing. If level L is set before holding level L, interrupt processing is correctly started.

(Example - clearing Idle1 Mode)

An INT0 interrupt clears the Halt state when the device is in Idle1 Mode.

820FH   LD     XX, XX  <──────────────────────────────┘
```

(3) Operation

① IDLE2 Mode

In Idle2 Mode only specific internal I/O operations, as designated by the Idle2 Setting Register, can take place. Instruction execution by the CPU stops.

Figure 3.3 6 illustrates an example of the timing for clearance of the Idle2 Mode Halt state by an interrupt.

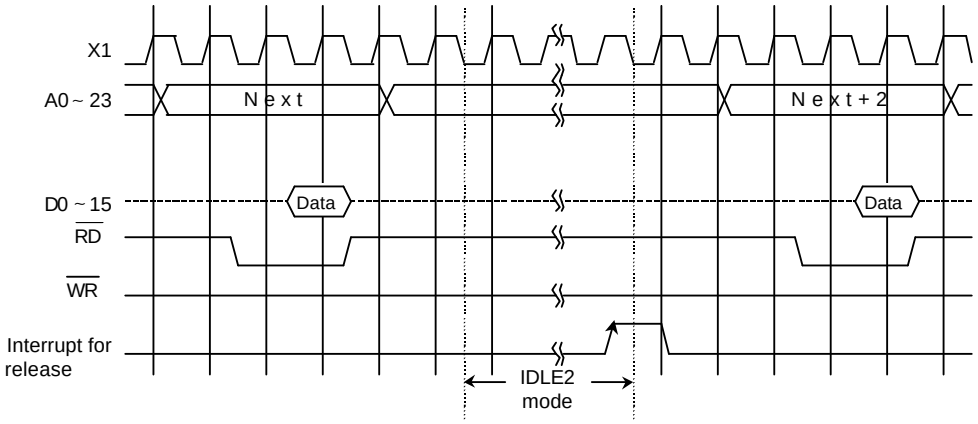

Figure 3.3.6 Timing chart for Idle2 Mode Halt state cleared by interrupt

② Idle1 Mode

In Idle1 Mode, only the internal oscillator and the RTC,MLD continue to operate. The system clock in the MCU stops. The pin status in the IDLE1 mode is depended on setting the register SYSCR2<SELDRV,DRVE>. Table 3.3 6 summarizes the state of these pins in the IDLE mode1.

In the Halt state, the interrupt request is sampled asynchronously with the system clock; however, clearance of the Halt state (i.e. restart of operation) is synchronous with it.

Figure 3.3 7 illustrates the timing for clearance of the Idle1 Mode Halt state by an interrupt.

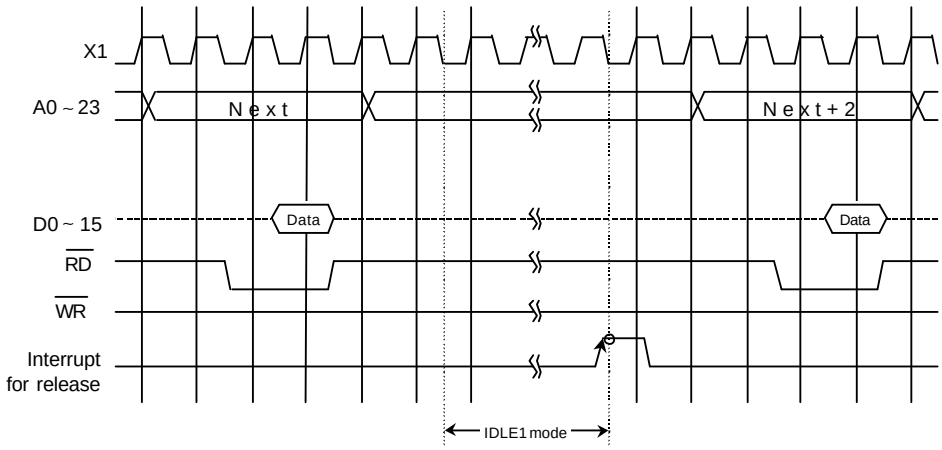

Figure 3.3.7 Timing chart for Idle1 Mode Halt state cleared by interrup

③ Stop Mode

When Stop Mode is selected, all internal circuits stop, including the internal oscillator Pin status in Stop Mode depends on the settings in the SYSCR2<DRVE> register. Table 3.3.6 summarizes the state of these pins in Stop Mode.

After Stop Mode has been cleared system clock output starts when the warm-up time has elapsed, in order to allow oscillation to stabilize. After Stop Mode has been cleared, either Normal Mode or Slow Mode can be selected using the SYSCR0<RSYSCK> register. Therefore, <RSYSCK>, <RXEN> and <RXTEN> must be set See the sample warm-up times in Table 3.3.5.

Figure 3.3.8 illustrates the timing for clearance of the Stop Mode Halt state by an interrupt.

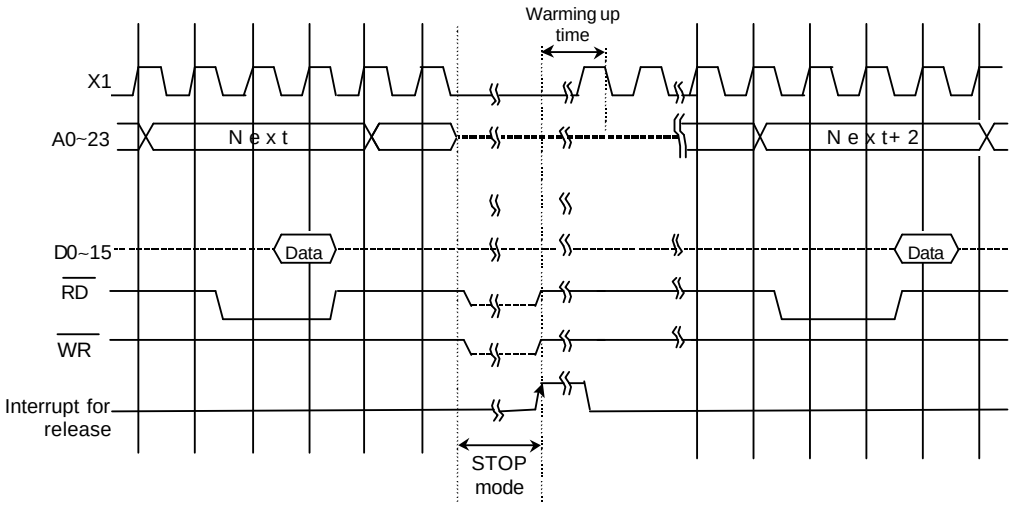

Figure 3.3.8 Timing chart for Stop Mode Halt state cleared by interrupt

Table 3.3.5 Sample warm-up times after clearance of Stop Mode

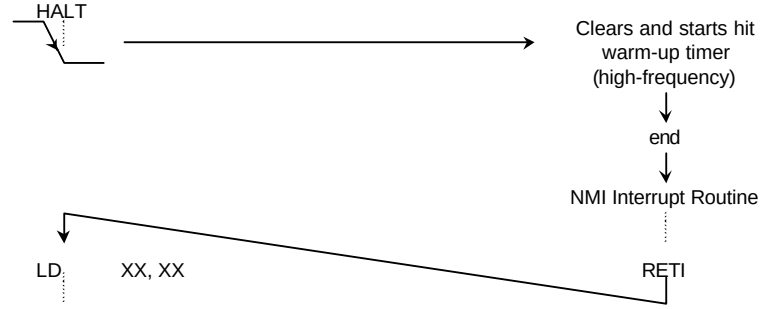
@f_{OSCH} = 16 MHz, fs = 32.768 kHz

SYSCR0 <RSYSCK>	SYSCR2<WUPTM1,WUPTM0>		
	01 (2^8)	10 (2^{14})	11 (2^{16})
0 (fc)	16 μs	1.024 ms	4.096 ms
1 (fs)	7.8 ms	500 ms	2000 ms

(Setting Example)

The Stop mode is entered when the low frequency operates, and high frequency operates after releasing due to NMI.

```
Address
         SYSCR0   EQU   00E0H
         SYSCR1   EQU   00E1H
         SYSCR2   EQU   00E2H
8FFDH            LD    (SYSCR1), 08H              ; fSYS = fs/2
9000H            LD    (SYSCR2), X–1001X1B        ; Sets Warming Up Time to 2^14/fOSCH
9002H            LD    (SYSCR0), 011000 – –B      ; Operates High Frequency after released.
                                                      – : no change
9005H
         NMI     HALT
```



Note: When different modes are used before and after STOP mode as the above mentioned , there is possible to release the HALT mode without changing the operation mode by acceptance of the halt release interrupt request during execution of “HALT” instruction (during 8 state).In the system which accepts the interrupts during execution ”HALT” instruction, set the same operation mode before and after the STOP mode.

Table 3.3.6 Pin states in IDLE1/Stop Mode

Pin name	input/output		<DRVE> = 0	<DRVE> = 1
P00 to P07(D0 to 7)	Input mode		–	–

		STOP	–	–
X2,XT2	Output	IDLE1	Output	Output
		STOP	"H" Level output	"H" Level output

- : Input for input mode/input pin is invalid; output mode/output pin is at high impedance.

Input: Input gate in operation. Fix input voltage to "L" or "H" so that input pin stays constant.

Output: Output state

PU*: Programmable pull-up pin. Input gate disabled state. No through-current even if the pin is set to high impedance.

Note: In case of, PF5 to SDCKE setting and it shift to IDLE1/STOP mode during Self Refresh mode, SDCKE output maintain even anything <DRVE> bit data.

3.4 Interrupts

Interrupts are controlled by the CPU Interrupt Mask Register SR<IFF2:0> and by the built-in interrupt controller.

The TMP91C820A has a total of 43 interrupts divided into the following five types:

- Interrupts generated by CPU: 9 sources
  (Software interrupts,Illegal Instruction interrupt)
- Internal interrupts: 28 sources
- Interrupts on external pins ($\overline{\text{NMI}}$ and INT0 to INT3,INTKEY): 6 sources

A (fixed) individual interrupt vector number is assigned to each interrupt.

One of seven (variable) priority levels can be assigned to each maskable interrupt.

The priority level of ono-maskable interrupts is fixed at 7,the highest level.

When an interrupt is generated, the interrupt controller sends the piority of that interrupt to the CPU.If multiple interrupts are generated simultaneously,the interrupt controller sends the interrupt with the highest priority to the CPU.(The highest priority possible is level 7,used for non-maskable interrupts.)

The CPU compares the priority level of the interrupt with the value of the CPU interrupt mask register <IFF2:0>. If the priority level of the interrupt is higher than the value of the interrupt mask register, the CPU accepts the interrupt.

However, software interrupts and illegal instruction interrupts generated by the CPU are processed without comparison with the <IFF2:0> value.

The interrupt mask register <IFF2:0> value can be updated using the value of the EI instruction(executing EI num sets the content of <IFF2:0> to num). For example, specifying EI3 enables the acceptance of maskable interrupts whose priority level set in the interrupt controller is 3 or higher, and enables the acceptance of non-maskable interrupts.However, if EI or EI0 is specified, maskable interrupts with a priority level of 1 or higher and non-maskable interrupts are accepted (operationally identical to “EI”1).

Operationally,the DI instruction (<IFF2:IFF0>is 7) is identical to the EI 7 instruction,but as the priority level of maskable interrupts is 0 to 6,the DI instruction is used to dasable maskable interrupt. The EI instruction is vaild immediately after execution begins.(With TLCS-90,the EI instruction is vaild after execution of the instruction following the EI insutruction.)

In addition to the general-purpose interrupt processing mode described above, TLCS-900/L1 interrupts have a micro DMA processing mode as well.

Because the CPU transfers (byte transfer,or 4-byte transfer) automatically in micro DMA mode, this mode can be used for speeding up interrupt processing, such as transferring data to I/O.TMP91C８20Also has a micro DMA soft start function for requesting micro DMA processing by software not by interrupt.

Figure 3.4.1 shows the overall interrupt processing flow.

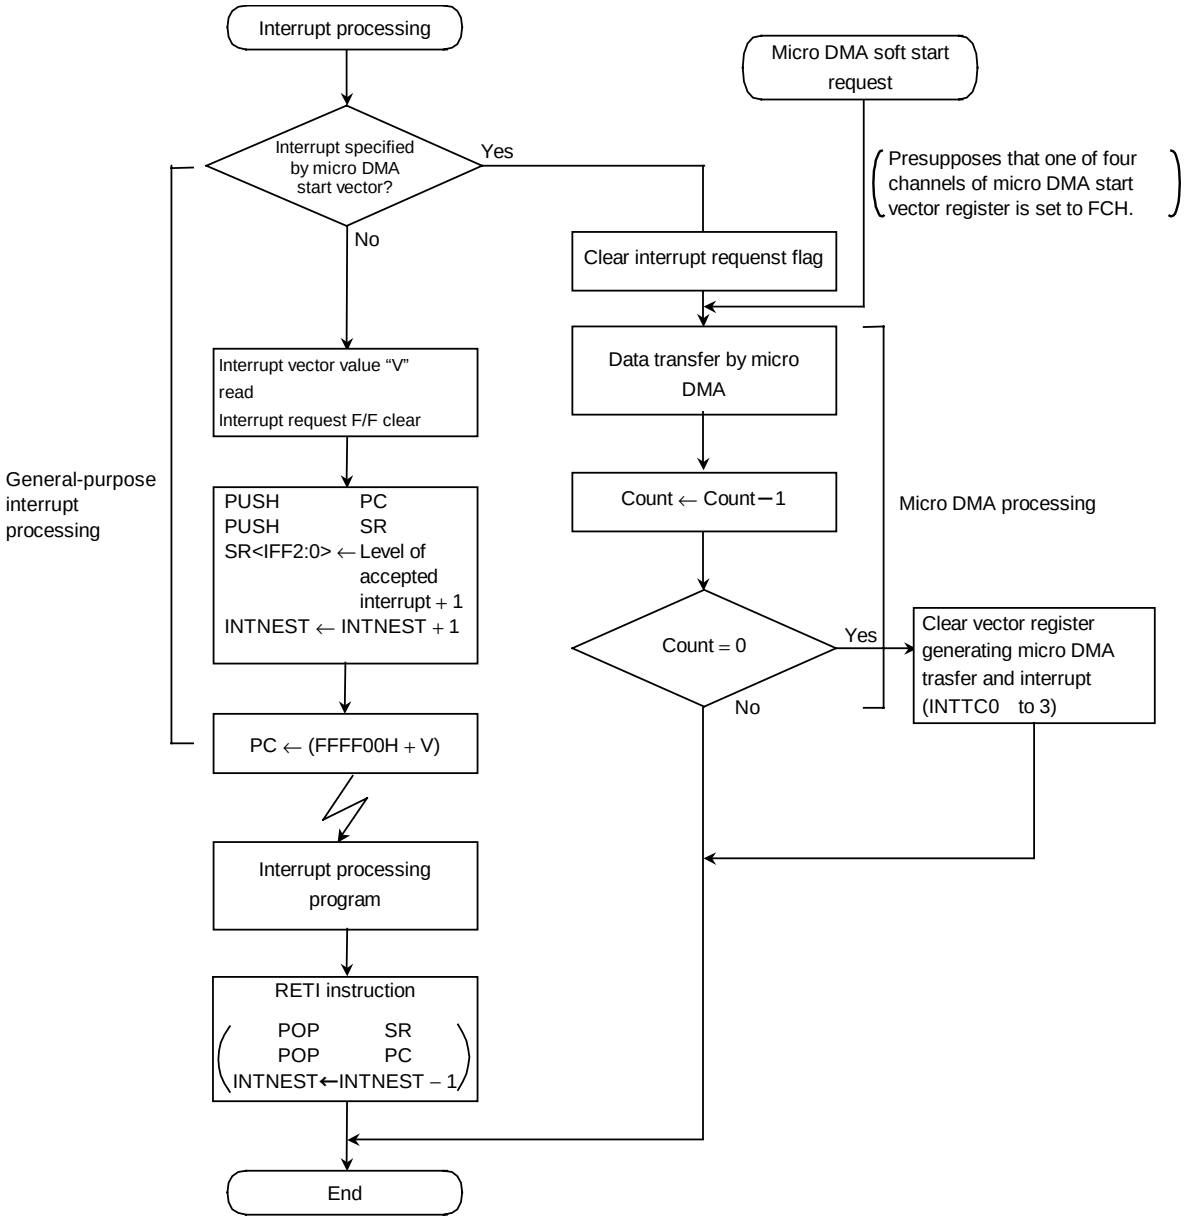

Figure 3.4.1 Interrupt and micro DMA processing sequence

3.4.1 General-purpose interrupt processing

When the CPU accepts an interrupt, it usually performs the following sequence of operations. However, in the case of software interrupts and Illegal Instruction interrupts generated by the CPU, the CPU skips steps ① and ③ and executes only steps ②, ④ and ⑤.

① The CPU reads the interrupt vector from the interrupt controller.
If there are simultaneous interrupts set to same level, the interrupt controller generates an interrupt vector in accordance with the default priority and clears the interrupt request.
(The default priority is already fixed for each interrupt: the smaller the vector value, the higher the priority level.)

② The CPU pushes the Program Counter (PC) and Status Register (SR) onto the top of the stack (pointed to by XSP).

③ The CPU sets the value of the CPU's Interrupt Mask Register <IFF2:IFF0> to the priority level for the accepted interrupt plus 1. However, if the priority level for the accepted interrupt is 7, the register's value is set to 7.

④ The CPU increments the interrupt nesting counter INTNEST by 1.

⑤ The CPU jumps to the address indicated by the data at address FFFF00H + interrupt vecto**r**, and starts the interrupt processing routine.

When the CPU completed the interrupt processing, use the RETI instruction to return to the main routine. RETI restores the contents of the Program Counter and the Status Register from the stack and decrements the Interrupt Nesting counter INTNEST by 1.
Non-maskable interrupts cannot be disabled by a user program. Maskable interrupts, however, can be enabled or disabled by a user program. A program can set the priority level for each interrupt source. (A priority level setting of 0 or 7 will disable an interrupt request.)

If an interrupt request is received for an interrupt with a priority level equal to or greater than the value set in the CPU Interrupt Mask Register <IFF2:IFF0>, the CPU will accept the interrupt. The CPU Interrupt Mask Register <IFF2:IFF0> is then set to the value of the priority level for the accepted interrupt plus 1.
If, during interrupt processing, an interrupt is generated with a higher level than the interrupt begin currently processed, or if, during non-maskable interrupt processing, a non-maskable interrupt request is generated from another source, the CPU suspends the currently processing routine and accepts the later interrupt. Then, after the CPU finished processing the later interrupt, the CPU returns to the interrupt it previously suspended and resumes processing.

If the CPU receives a request for another interrupt while performing processing steps ① to ⑤, the second interrupt is sampled immediately after execution of the first instruction for its interrupt processing routine. Specifying DI as the start instruction disables maskable interrupt nesting. (Note: In the 900 and 900/L, sampling is performed before execution of the start instruction.)

A Reset initializes the Interrupt Mask Register <IFF2:IFF0> to 111, disabling all maskable interrupts.

Table 3.4.1 shows the TMP91C820A interrupt vectors and micro DMA start vectors. FFFF00H to FFFFFFH (256 bytes) is designated as the interrupt vector area.

Table 3.4.1 TMP91C820A interrupt vectors and micro DMA start vectors

Default Priority	Type	Interrupt source and source of micro DMA request	Vector value(V)	Vector reference Address	Micro DMA start vector
1	Non-Maskable	"Reset" or 「SWI 0」 instruction	0000H	FFFF00H	–

3.4.2 Micro DMA processing

In addition to general-purpose interrupt processing, the TMP91C820A supprots a micro DMA function. Interrupt requests set by micro DMA perform micro DMA processing at the highest priority level for maskable interrupts (level 6), regardless of the priority level of the particular interrupt source. Because the micro DMA function has been implemented with the cooperative operation of CPU, when CPU is a state of stand-by by HALT instruction, the requirement of micro DMA will be ignored (pending).

(1) Micro DMA operation

When an interrupt request is generated by an interrupt source specified by the micro DMA start vector register, the micro DMA triggers a micro DMA request to the CPU at interrupt priority level 6 and starts processing the request. The four micro DMA channels allow micro DMA processing to be set for up to four types of interrupts at any one time.

When micro DMA is accepted, the interrupt request flip-flop assigned to that channel is cleared. The data are automatically transferred from the transfer source address to the transfer destination address set in the control register, and the transfer counter is decremented by 1. If the decremented counter reads other than 0, DMA processing ends with no change in the value of the micro DMA start vector register. If the decremented reading is 0, the micro DMA transfer end interrupt (INTTC0 to INTTC3) passes from the CPU to the interrupt controller. In addition, the micro DMA start vector register is cleared to 0, the next micro DMA is disabled and micro DMA processing completes.

If a micro DMA request is set for more than one channel at a time, the priority is not based on the interrupt priority level but on the channel number: the smaller the channel number the higher the priority (Channel 0 (high)→ channel 3 (low)).

If an interrupt request is triggered for the interrupt source in use during the interval between the clearing of the micro DMA start vector and the next setting, general-purpose interrupt processing executes at the interrupt level set. Therefore, if only using the interrupt for starting the micro DMA (not using the interrupts as a general-purpose interrupt), first set the interrupts level to 0 (interrupt requests disabled).

If using micro DMA and general-purpose interrupts together as described above, first set the level of the interrupt used to start micro DMA processing lower than all the other interrupt levels. In this case, the cause of general interrupt is limited to the edge interrupt.

Example: When using external interrupt INT0-3 to start micro DMA0-3 set:

Interrupt level for external interrupts INT0 to INT3 ····· 1
Interrupt levels for other interrupts ····· 2 to 6

As with other maskable interrupts, the priority of the micro DMA transfer end interrupts is determined by the interrupt level and by the default priority.

While the register for setting the transfer source/transfer destination addresses is a 32-bit control register, this register can only effectively output 24-bit addresses. Accordingly, micro DMA can access 16M bytes (the upper eight bits of the 32 bits are not valid).
Three micro DMA transfer modes are supported: 1-byte transfer, 2-byte (one-word) transfer, and 4-byte transfer. After a transfer in any mode, the transfer source / destination addresses are incremented, decremented, or remain unchanged.

This simplifies the transfer of data from I/O to memory, from memory to I/O , and from I/O to I/O. For details of the transfer modes, see 3.4.2 (4) ,Transfer Mode Register. As the transfer counter is a 16-bit counter, micro DMA processing can be set for up to 65536 times per interrupt source.(The micro DMA processing count is maximized when the transfer counter initial value is set to 0000H.)

Micro DMA processing can be started by the 31 interrupts shown in the micro DMA start vectors of Table 3.4(1) and by the micro DMA soft start, making a total of 32 interrupts.
Figure 3.4(2) shows the word transfer micro DMA cycle in transfer destination address INC mode (except for Counter mode, the same as for other modes).

(The conditions for this cycle are based on an external 16-bit bus, 0 waits, trandfer source/transfer destination addresses both even-numberd values).

① Word transfer

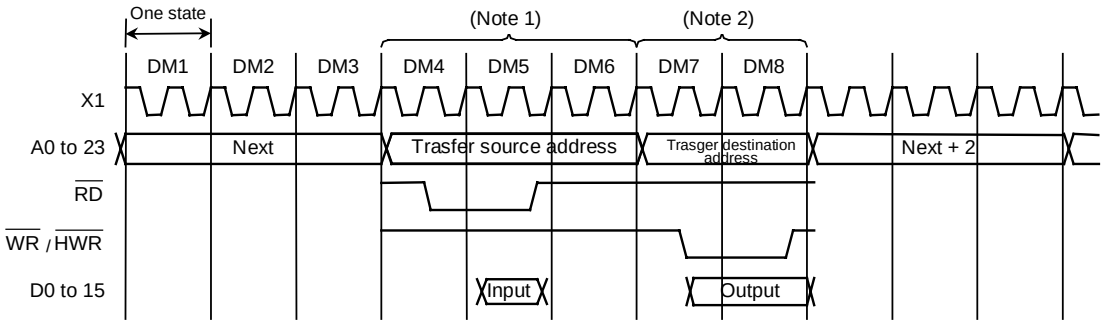

Figure 3.4.2 Timing for micro DMA cycle

States 1 to 3: Instruction fetch cycle (gets next address code).
If three or more instruction codes are inserted in the instruction queue buffer,this cycle becomes a dummy cycle.

States 4 to 5: Micro DMA Read cycle

State 6:Dummy cycle (the address bus remains unchanged from state 5)

States 7 to 8: Micro DMA Write cycle

Note 1: If the source address area is an 8-bit bus, it is incremented by two states.
If the source address area is a 16-bit bus and the address starts from an odd number, it is incremented by two states.

Note 2: If the destination address area is an 8-bit bus, it is incremented by two states.
If the destination address area is a 16-bit bus and the address starts from an odd number, it is incremented by two states.

(2) Soft start function

In addition to starting the micro DMA function by interrupts, TMP91C820A includes a micro DMA software start function that starts micro DMA on the generation of the write cycle to the DMAR register.

Writing "1" to each bit of DMAR register causes micro DMA once. At the end of transfer, the bit of the DMAR register which support the end channel are automatically cleared to "0".

Only one-channel can be set for DMA request at once. (Do not write "1" to more than one bit.)

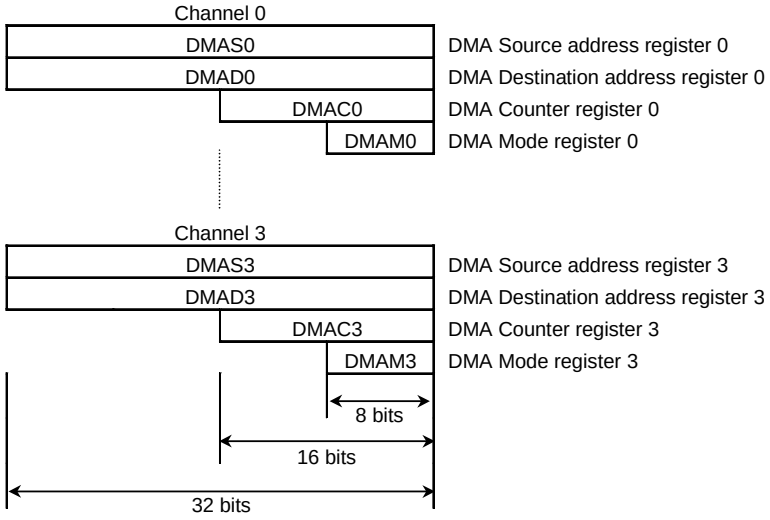
When writing again "1" to the DMAR register, check whether the bit is "0" before writing "1".

When a burst is specified by DMAB register, data is continuously transferred until the value in the micro DMA transfer counter is "0" after start up of the micro DMA.

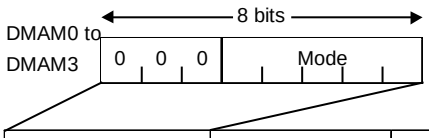
Symbol	NAME	Address	7	6	5	4	3	2	1	0
DMAR	DMA Request Register	89h (no RMW)					DMA Request			
							DMAR3	DMAR2	DMAR1	DMAR0
							R/W			
							0	0	0	0

(3) Transfer control registers

The transfer source address and the transfer destination address are set in the following registers. An instruction of the form "LDC cr,r" can be used to set these registers.



(4) Detailed description of the Transfer Mode Register



Note: When setting a value in this register, write 0 to the upper three bits.

			Number of Transfer Bytes	Mode Description	Number of Execution States (※)	Minimum Execution Time @ fc = 16 MHz
000 (fixed)	000	00	Byte transfer	Transfer Destination Address INC Mode ••••••••••••••••••••••••••• I/O to memory (DMADn+) ← (DMASn) DMACn ← DMACn – 1 If DMACn = 0, then INTTCn is generated.	8 states	1000 ns
		01	Word transfer		12 sates	1500 ns
		10	4-byte transfer

	101	00	Counter Mode •••••••••••• For counting number of times interrupt is generated DMASn ← DMASn + 1 DMACn ← DMACn – 1 If DMACn = 0, then INTTCn is generated.		5 sates	625 ns

(*) For external 16-bit bus, 0 waits, word /4-byte transfer mode, transfer source/transfer destination addresses both have even-numbered values.

Note: n Corresponding micro DMA channels 0 to 3

DMADn +/DMASn+: Post-increment (increments register value after transfer)

DMADn –/DMASn–: Post-decrement (decrements register value after transfer)

The I/Os in the table mean fixed address; memory means increment and decrement addresses.

Do not use undefined code, that is, codes other than those listed above for the transfer mode register.

3.4.3 Interrupt controller operation

The block diagram in Figure 3.4.3 shows the interrupt circuits. The left-hand side of the diagram shows the interrupt controller circuit. The right-hand side shows the CPU interrupt request signal circuit and the halt release circuit.

For each of the 36 interrupt channels there is an interrupt request flag (consisting of a flip-flop), an interrupt priority setting register and a micro DMA start vector register. The interrupt request flag latches interrupt requests from the peripherals. The flag is cleared to zero in the following cases: when reset occurs, when the CPU reads the channel vector of an interrupt it has received, when the CPU receives a micro DMA request (when micro DMA is set), when the micro DMA burst transfer is terminated, and when an instruction that clears the interrupt for that channel is executed (by writing "0" to the clear bit in the interrupt priority setting register).

An interrupt priority can be set independently for each interrupt source by writing the priority to the interrupt priority setting register (e.g. INTE0AD or INTE12). Six interrupt priorities levels (1 to 6) are provided. Setting an interrupt source's priority level to 0 (or 7) disables interrupt requests from that source. The priority of non-maskable interrupts (NMI pin interrupts and Watchdog Timer interrupts) is fixed at 7. If interrupt request with the same level are generated at the same time, the default priority (the interrupt with the lowest priority or, in other words, the interrupt with the lowest vector value) is used to determine which interrupt request is accepted first.

The 3rd and 7th bits of the interrupt priority setting register indicate the state of the interrupt request flag and thus whether an interrupt request for a given channel has occurred.

The interrupt controller sends the interrupt request with the highest priority among the simulateous interrupts and its vector address to the CPU. The CPU compares the priority value <IFF2 to 0> et in the Status Register by the interrupt request signal with the priority value set;if the latter is higher, the interrupt is accepted. Then the CPU sets a value higher than the priority value by 1 in the CPU SR <IFF2 to 0>.Interrupt request where the priority value equals or is higher than the set value are accepted simultaneously during the previous interrupt routine.

When interrupt processing is completed (after execution of the RETI instruction), the CPU restores the priority value saved in the stack before the interrupt was generated to the CPU SR<IFF2 to 0> . The interrupt controller also has four registers used to store the micro DMA start vector. Writing the start vector of the interrupt source for the micro DMA processing (see Table 3.4.1), enables the corresponding interrupt to be processed by micro DMA processing. The values must be set in the micro DMA parameter register (e.g. DMAS and DMAD) prior to the micro DMA processing.

INT0 level Enable

0	Rising edge detect INT
1	"H" level INT

$\overline{NMI}$ rising edge Enable

0	INT request generation at falling edge
1	INT request generation at rising/falling edge

(3) Interrupt request flag clear register

The interrupt request flag is cleared by writing the appropriate micro DMA start vector, as given in Table 3.4 1, to the register INTCLR.

For example, to clear the interrupt flag INT0, perform the following register operation after execution of the DI instruction.

INTCLR ← 0AH Clears interrupt request flag INT0.

Symbol	NAME	Address	7	6	5	4	3	2	1	0
INTCLR	Interrupt Clear Control	88H (no RMW)			CLRV5	CLRV4	CLRV3	CLRV2	CLRV1	CLRV0
			W							
			0	0	0	0	0	0	0	0
			Interrupt Vector							

(4) Micro DMA start vector registers

This register assigns micro DMA processing to an interrupt source. The interrupt source with a micro DMA start vector that matches the vector set in this register is assigned as the micro DMA start source. When the micro DMA transfer counter value reaches zero, the micro DMA transfer end interrupt corresponding to the channel is sent to the interrupt controller, the micro DMA start vector register is cleared, and the micro DMA start source for the channel is cleared. Therefore, to continue micro DMA processing, set the micro DMA start vector register again during the processing of the micro DMA transfer end interrupt.

If the same vector is set in the micro DMA start vector registers of more than one channel; the channel with the lowest number has a higher priority.

Accordingly, if the same vector is set in the micro DMA start vector registers of two channels, the interrupt generated in the channel with the lower number is executed until micro DMA transfer is complete. If the micro DMA start vector for this channel is not set again, the next micro DMA is started for the channel with the higher number. (Micro DMA chaining)

Symbol	NAME	Address	7	6	5	4	3	2	1	0
DMA0V	DMA0 Start Vector	80H (no RMW)			DMA0 Start Vector					
					DMA0V5	DMA0V4	DMA0V3	DMA0V2	DMA0V1	DMA0V0

					DMA3V5	DMA3V4	DMA3V3	DMA3V2	DMA3V1	DMA3V0
					R/W					
					0	0	0	0	0	0

(5) Micro DMA burst specification

Specifying the micro DMA burst continues the micro DMA transfer until the transfer counter register reaches zero after micro DMA start. Setting a bit which corresponds to the micro DMA channel of the DMAB registers mentioned below to “1” specifies a burst.

Symbol	NAME	Address	7	6	5	4	3	2	1	0
DMAR	DMA Software Request Register	89H (no RMW)					DMAR3	DMAR2	DMAR1	DMAR0
							R/W	R/W	R/W	R/W
							0	0	0	0
							1: DMA Software request			
DMAB	DMA Burst Register	8AH (no RMW)					DMAB3	DMAB2	DMAB1	DMAB0
							R/W			
							0	0	0	0

(6) Notes

The instruction execution unit and the bus interface unit of this CPU operate independently. Therefore, immediately before an interrupt is generated, if the CPU fetches an instruction that clears the corresponding interrupt request flag, the CPU may execute the instruction that clears the interrupt request flag between accepting and reading the interrupt vector. In this case, the CPU reads the default vector 0008H and reads the interrupt vector address FFFF08H.

To avoid the avobe plogram, place instructions that clear interrupt request flags after a DI instruction.

In the case of changing the value of the interrupt mask register <IFF2:0> by execution of POP SR instruction, disable an interrupt by DI instruction before execution of POP SR instruction.

In addition, take care as the following 2 circuits are exceptional and demand special attention.

INT0 Level Mode	In Level Mode INT0 is not an edge-triggered interrupt. Hence, in Level Mode the interrupt request flip-flop for INT0 does not function. The peripheral interrupt request passes through the S input of the flip-flop and becomes the Q output. If the interrupt input mode is changed from Edge Mode to Level Mode, the interrupt request flag is cleared automatically.

	If the CPU enters the interrupt response sequence as a result of INT0 going from 0 to 1, INT0 must then be held at 1 until the interrupt response sequence has been completed. If INT0 is set to Level Mode so as to release a Halt state, INT0 must be held at 1 from the time INT0 changes from 0 to 1 until the Halt state is released. (Hence, it is necessary to ensure that input noise is not interpreted as a 0, causing INT0 to revert to 0 before the Halt state has been released.)
	When the mode changes from Level Mode to Edge Mode, interrupt request flags which were set in Level Mode will not be cleared. Interrupt request flags must be cleared using the following sequence.
	DI
	LD (IIMC), 00H; Switches interrupt input mode from Level Mode to Edge Mode.
	LD (INTCLR), 0AH; Clears interrupt request flag.
	EI

INTRX	The interrupt request flip-flop can only be cleared by a Reset or by reading the Serial Channel Receive Buffer. It cannot be cleared by an instruction.

Note: The following instructions or pin input state changes are equivalent to instructions that clear the interrupt request flag.

INT0: Instructions which switch to Level Mode after an interrupt request has been generated in Edge Mode. The pin input changes from High to Low after an interrupt request has been generated in Level Mode. (H → L)

INTRX: Instructions which read the Receive Buffer

3.5 Port Functions

The TMP91C820A features 126 bit settings which relate to the various I/O ports.
As well as general-purpose I/O port functionality, the port pins also have I/O functions which relate to the built-in CPU and internal I/Os. Table 3.5.1 lists the functions of each port pin. Table 3.5.2 lists I/O registers and their specifications.

Table 3.5.1 Port functions (1/2) (R:PU= with programmable pull-up resistor)
(U= with pull-up resistor)

Port name	Pin name	Number of pins	Direction	R	Direction Setting unit	Pin name for built-in function

Note1: As for input ports of SIO1 to SIO3: (OPTTX0,OPTRX0,TXD0,TRX0,SCCLK0,/CTS0, TXD1,TRX1,SCCLK1,/CTS1, TXD2,RXD2), logical selection for output data or input data is determined by the output latch register Pn of each port.

Note2: When P71/72 are used as SDA/SCL open drain outputs, P7ODE<ODEP72: 71> is used to set the open drain output mode.

Note3: In case using P76 for MSK port, set to P7FC<P76F>.

Note4: When P80 to P87 are used as AD converter input channels, ADMOD1<ADCH2: 0> is used to select the channel.

Note5: When P83 is used as /ADTRG input, ADMOD1<ADTRGE> is used to enable External-trigger-input.

Note6: In case using PC1 for RXD0 port, set "1" to P7FC2<P70FC>.

After a Reset the port pins listed below function as general-purpose I/O port pins.

A Reset sets I/O pins, which can be programmed for either input, or output to be input ports pins. Setting the port pins for internal function use must be done in software.

3.5.1 Port 0 (P00 to P07)

Port 0 is an 8-bit general-purpose I/O port. Each bit can be set individually for input or output using the control register P0CR. Resetting resets all bits of the output latch P0, the control register P0CR to 0 and sets Port 0 to Input Mode.In addition to functioning as a general-purpose I/O port, Port 0 can also function as an data bus (D0 to 7).

When external memory is accesed ,the port automatically functions as the data bus (D0 to D7) and all bits of P0CR are cleared to 0.

Note2: When functioning as a data bus(D0 to D7), P0CR is cleared to 0.

Figure3.5.2 Registers for Port 0

3.5.2 Port 1 (P10 to P17)

Port 1 is an 8-bit general-purpose I/O port. Each bit can be set individually for input or output using the control register P1CR and the function register P1FC. Resetting resets all bits of the output latch P1, the control register P1CR and the function register P1FC to 0 and sets Port 1 to Input Mode.

In addition to functioning as a general-purpose I/O port, Port 1 can also function as an data bus (D8 to 15).

Figure3.5.10 Port Registers for Port 4

3.5.6 Port Z (PZ0 to PZ3)

Port Z is an 4-bit general-purpose I/O port(P50 and P51 are used for output only). I/O is set using control register PZCR and PZFC. Resetting resets all bits of the output latch PZ to “1”.

In addition to functioning as a general-purpose I/O port, Port Z also functions as I/O for the CPU’s control / status signal.

When PZ0 pin is defined as /RD strobe signal output mode (<PZ0F>="1"), clearing the output latch register <PZ0> to "0" outputs the /RD strobe (used for the peused static RAM) from the PZ0 pin even when the internal addressed. If the output latch register <PZ0> remains “1”, the /RD strobe signal is output only when the external address are is accessed.

Resetting initializes PZ2 and PZ3 pins to input mode with pull-up register.

Setting the AM1 and AM0 pins as shown below and resetting the device initialize PZ0 and PZ1 pins to the following function pins.

AM1	AM0	PZ0F PZ1F	Function Setting after reset is released	
			PZ0 function	PZ1 function
0	0	1	/RD pin	/WR pin
0	1	1	/RD pin	/WR pin
1	0	—	Don't use this setting	Don't use this setting

0	"0" output	"1" output
1	/WR is only output during external accesses.	

/HWR setting

PZFC<PZ2F>	1
PZCR<PZ2C>	1

Note 1: Read-Modify-write is prohibited for registers PZCR and PZFC.

Note 2: When Port Z is used in Input Mode, the PZ register controls the built-in pull-up resistor. Read-Modify-Write is prohibited in Input Mode or I/O Mode. Setting the built-in pull-up resistor may be depended on the states of the input pin.

Figure3.5.14 Port Register for Port Z

3.5.7 Port 5 (P56)

Port 5 is an 1-bit general-purpose I/O port. I/O is set using control register P5CR and P5FC. Resetting resets all bits of the output latch P5 to "1".

In addition to functioning as a general-purpose I/O port, Port 5 also functions as I/O for the CPU's control / status signal.

Resetting initializes P56 pins to input mode with pull-up register.

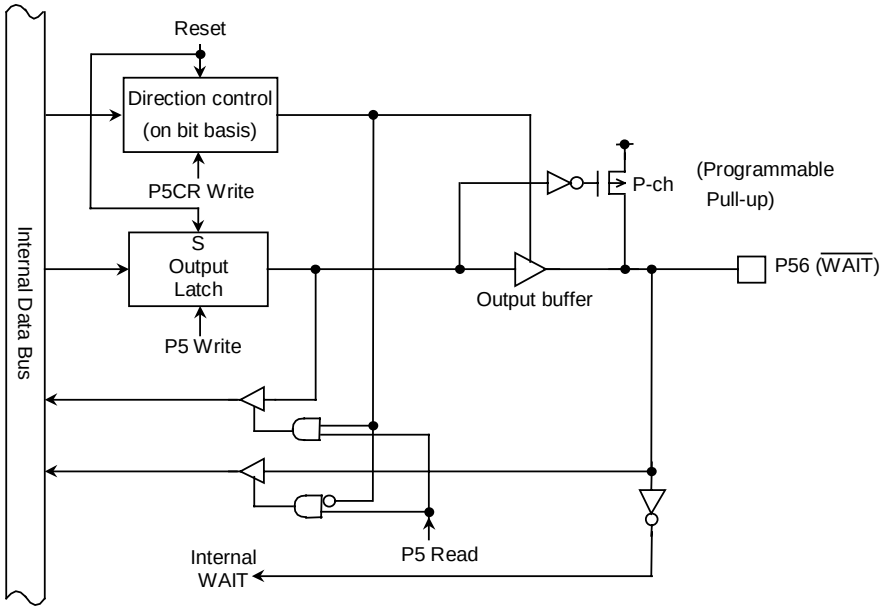

Figure3.5.15 Port 5 (P56)

Note 1: When the P53/WAIT pin is to be use as the WAIT pin, P5CR<P53C> must be set to 0 and <Bn W2 to BnW0> in the chip select/wait control register must be set 010.

Figure3.5.16 Port Register for Port 5

3.5.8 Port6 (P60 to P67)

Port60 to 67 are 8bit output ports. Resetting sets output latch of P62 to “0” and output latches of P60 to P61, P63 to P67 to “1”.

Port6 also function as chip-select output (/CS0 to /CS3), extend address output (EA24, EA25), extend chip-select output (/CS2A, /CS2B, /CS2C, /CS2D, /CS2E), SRAM byte control output (/SRUB, /SRLB), and SDRAM chip-select output (/SDCS).

Writing “1” in the corresponding bit of P6FC, P6FC2 enables the respective functions.

Resetting resets the P6FC, P6FC2 to “0”, and sets all bits to output ports.

(Note) Read-modify-write is prohibited for P6FC and P6FC2 .

Figure 3.5.18 Register for Port 6

3.5.9 Port7 (P70 to P77)

Port 7 is an 8-bit general-purpose I/O port. I/O can be set on bit basis using the control register. Resetting sets Port 7 to input port and all bits of output latch to"1".

In addition to functioning as a general-purpose I/O port, Port 7 also functions as follows.

1. Input/output function for serial bus interface(SCK,SO/SDA.SI/SCL)
2. Input/output function for IrDA (OPTRX0,OPTTX0)
3. Extend chip-select output (/CS2F,/CS2G,/CSEXA)
4. Clock control function for voltage booster of external LCD driver (MSK,VEECLK)

Writing "1" in the corresponding bit of P7FC, P7FC2 enables the respective functions.

Resetting resets the P7FC, P7FC2 to "0", and sets all bits to input ports.

(1) Port70 (SCK, OPTRX0))

Port70 is a general-purpose I/O port. It is also used as SCK (clock signal for SIO mode) and OPTRX0 (receive input for IrDA mode of SIO0).

Used as OPTRX0, it is possible to logical-invert by P7<P70>.

For PortC1, RXD0 or OPTRX0 is used P7FC2<P70F2>.

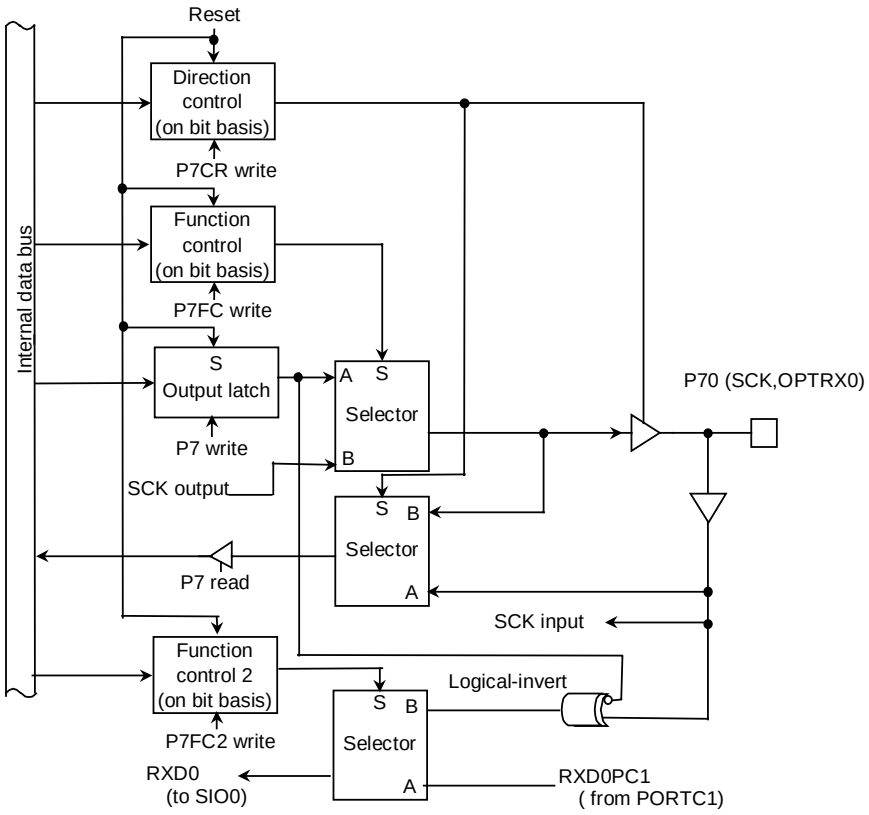

Figure 3.5.19 P70

(2) Port71 (SO/SDA/OPTTX0)

Port71 is a general-purpose I/O port. It is also used as SDA (data input for I^2C mode), SO (data output for SIO mode) for serial bus interface and OPTTX0 (transmit output for IrDA mode of SIO0).

Used as OPTTX0, it is possible to logical-invert by P7<P71>.

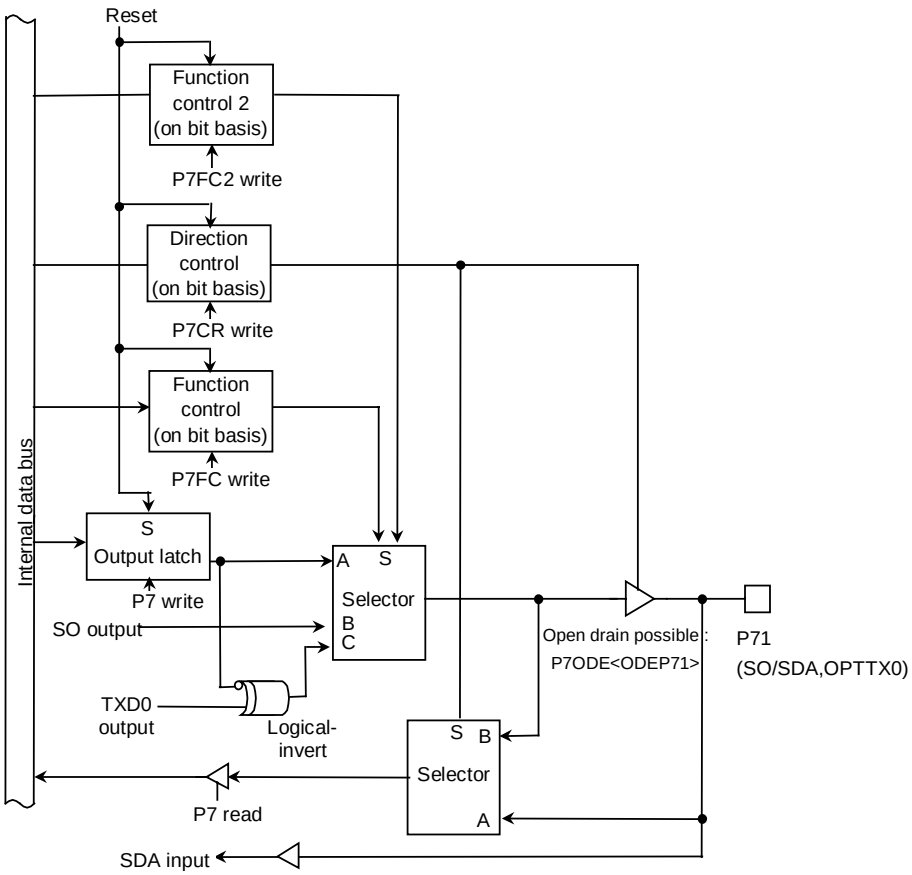

Figure 3.5.20 Port 71

(3) Port 72 (SI/SCL)

Port72 is a general-purpose I/O port. It is also used as SI (data input for SIO mode), SCL (clock input/output for I^2C mode) for serial bus interface.

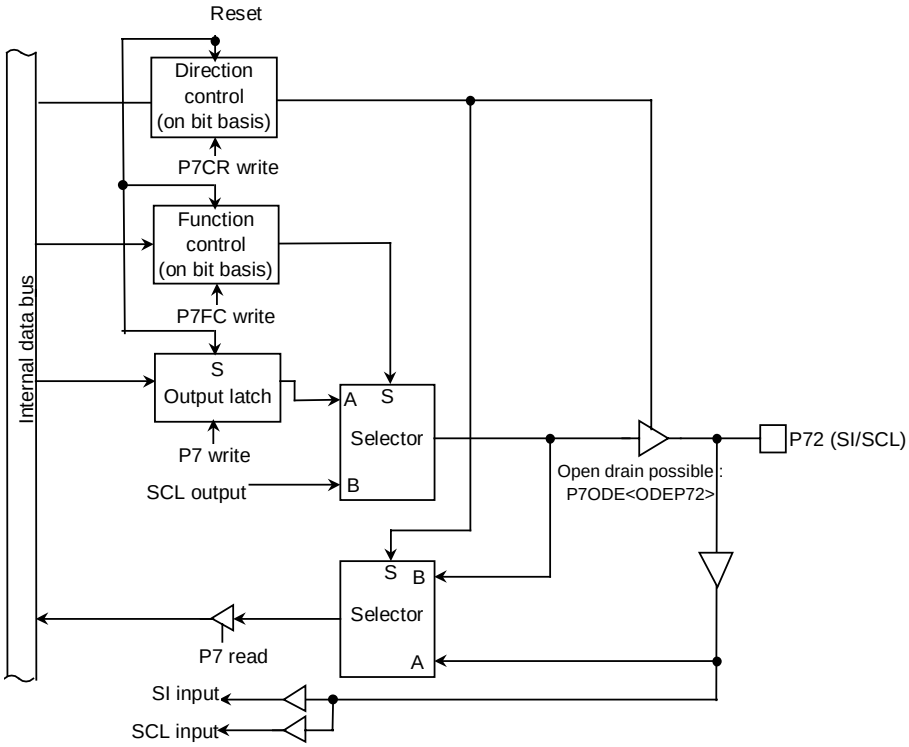

Figure 3.5.21 Port 72

(4) Port 73 (/CS2F),74(/CS2G),75(/CSEXA)

Port73 to 75 are general-purpose I/O ports. These are also used as control signal for extend chip-select output.

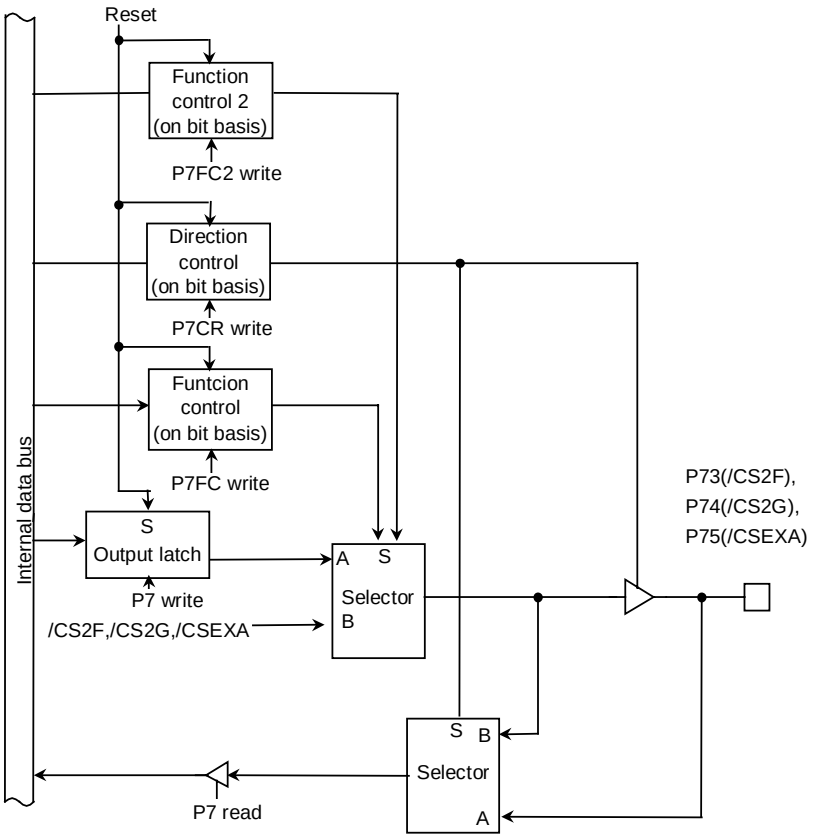

Figure 3.5.22(4) Port 73,74,75

(5) Port 76(MSK),77(VEECLK)

Port76 and 77 are general-purpose I/O ports. These are also used as clock control function for voltage booster of external LCD driver.

MSK pin (P76) is an input pin from external LCD driver, clock output from VEECLK pin is controlled by state of this pin. Logic of this pin is controlled with P7FC<P76F>.

VEECLK pin outputs clock of 32KHz for voltage booster or "0" level according to request from MSK pin. VEECLK output is controlled with P7FC<P77F>.

Figure 3.5.23 Register for Port 7

3.5.10 Port 8 (P80 to P87)

Port 8 is an 8-bit input port and can also be used as the analog input pins for the internal AD converter. P83 can also be used as ADTRG pin for the AD converter.

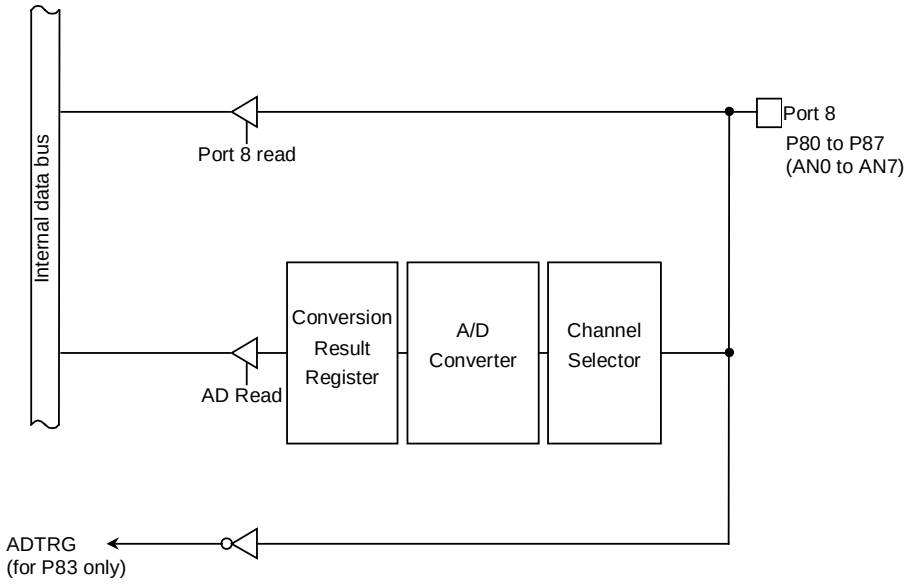

Figure 3.5.25 Port 8

Figure 3.5.26 Register for Port 8

3.5.11 Port 9 (P90 to P97)

Port 90 to 97 are 8-bit input ports with pull-up resistor. In addition to functioning as general-purpose I/O port, port 90 to 97 can also Key-on wake-up function as Key board interface. The various functions can each be enabled by writing a “1” to the corresponding bit of the Port 9 Function Register (P9FC). Resetting resets all bits of the register P9FC to “0” and sets all pins to be input port.

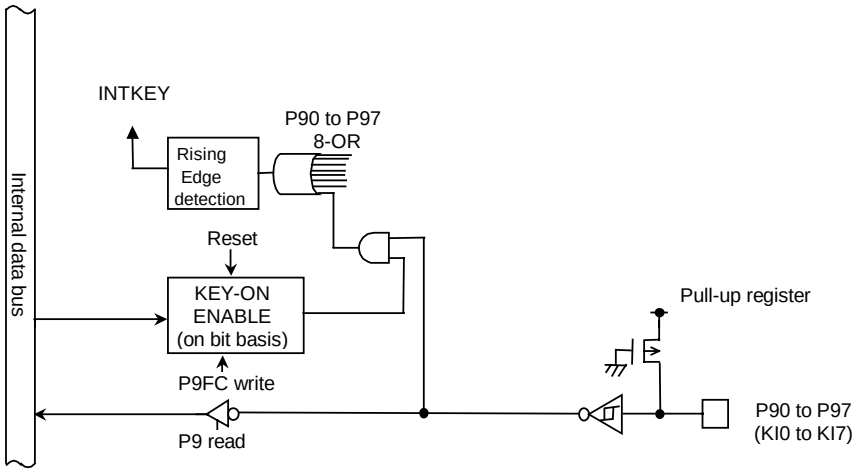

Figure 3.5.27 Port 9

When P9FC=”1”, if either of input of KI0-KI7 pins falls down, INTKEY interrupt is generated. INTKEY interrupt can be used to release all HALT mode.

3.5.12 Port A (PA0 to PA7)

Port A0 to PA7 are 8-bit output ports, and also used key-board interface pin KO0 to KO7 which can set open drain output buffer.

Writing "1" in the corresponding bit of the port A function register (PAFC) enable the open drain output.

Resetting reset bits of the registers PA to "1" and PAFC to "0", and all pin outputs "1".

Figure3.5.30 Register for Port A

3.5.13 Port B (PB0 to PB6)

Port B is a 6-bit general-purpose I/O port. Each bit can be set individually for input or output. Resetting sets Port B to be an input port.

In addition to functioning as a general-purpose I/O port, Port B can also function as I/O pin for timers (TA0IN, TA1OUT, TA3OUT, TB0OUT0), input pin for external interruption (INT0 to INT3), and I/O for serial channels 2 (TXD2,RXD2). Above setting is used the function register PBFC and PBFC2. Edge select of external interruption establishes it with IIMC register, which there is in interruption controller.

(1) PB0 (TA0IN, TXD2)

As well as functioning as I/O port pins, port B0 can also function as serial channel TXD output pins. In case of use TXD2, it is possible to logical invert by setting the register PB<PB0>.

And port B0 has a programmable open drain function which can be control the register PBODE<ODEPB0>.

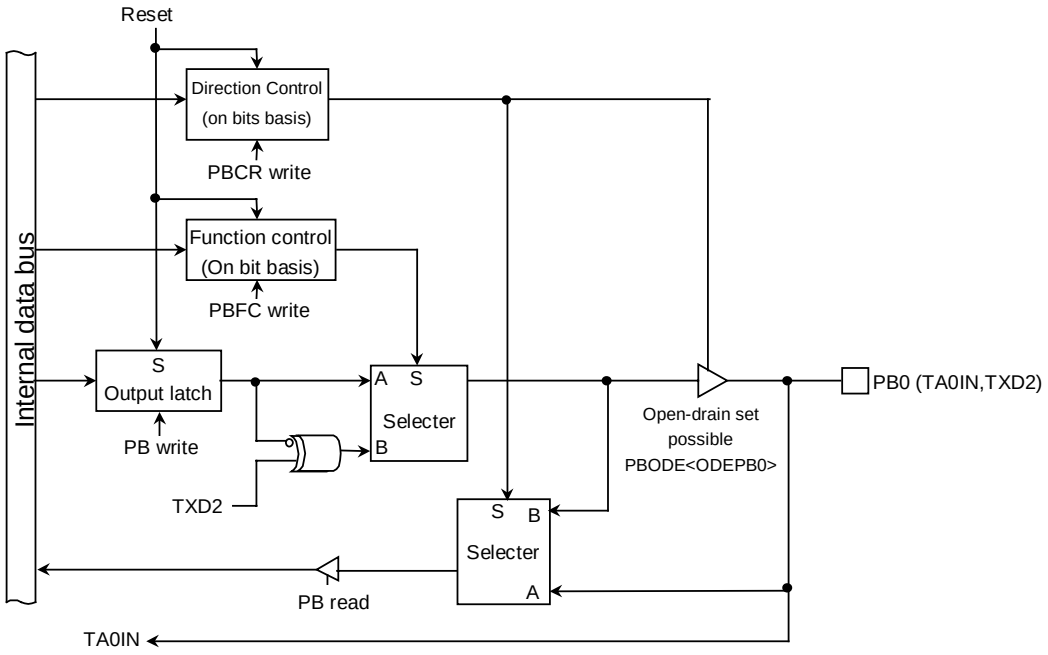

Figure 3.5.31 Port B0

(2) PB1 (TA1OUT, RXD2)

Port B1 is I/O port pins and can also is used as RXD input for the serial channels. In case of use RXD2, it is possible to logical invert by setting the register PB<PB1>.

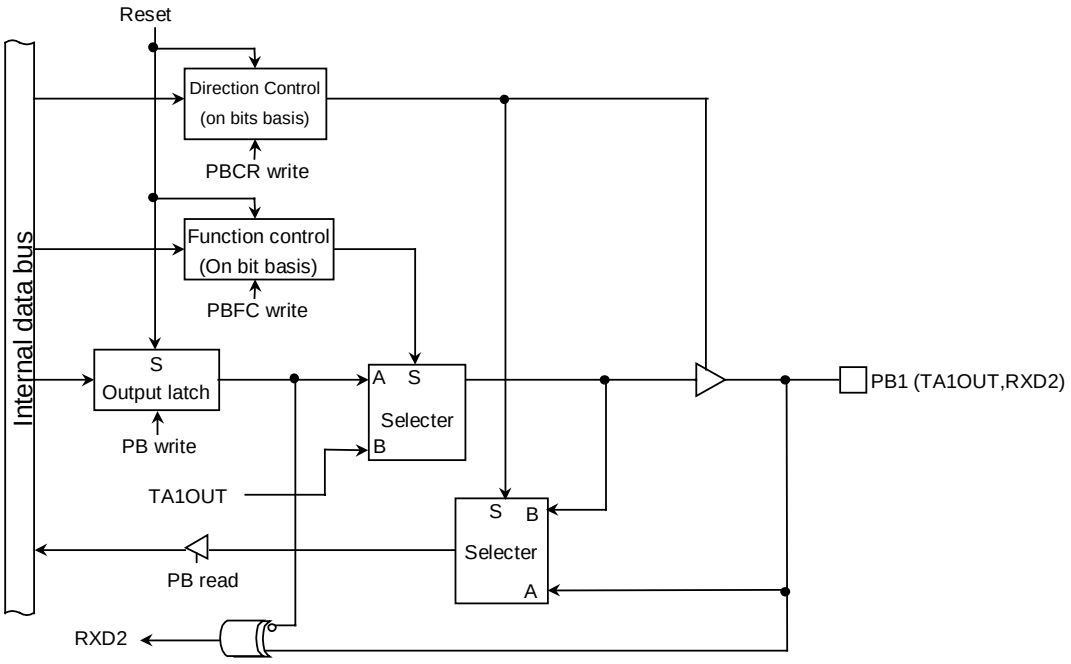

Figure 3.5.32 Port B1

Note 1: Read-Modify-Write is prohibited for the registers PBCR, PBFC and PBODE.

Note 2: PB0/TA0IN pin does not have a register changing PORT/FUNCTION.
For example, when it is used as an input port, the input signal is inputted to 8 bit timer.

Note 3: PB1/RXD1 pin does not have a register changing PORT/FUNCTION.
For example, when it is used as an input port, the input signal is inputted to SIO as the serial receive data.

Figure 3.5.35 Register for Port B

3.5.14 Port C (PC0 to PC5)

Port C0 to C5 are 6-bit general-purpose I/O ports. Each bit can be set individually for input or output. Resetting sets PC0 to PC5 to be an input ports. It also sets all bits of the output latch register to “1”.

In addition to functioning as general-purpose I/O port pins, PC0 to PC5 can also function as the I/O for serial channels 0 and 1. A pin can be enabled for I/O by writing a “1” to the corresponding bit of the Port C Function Register (PCFC).

Resetting resets all bits of the registers PCCR and PCFC to 0 and sets all pins to be input ports .

(1) Port C0, C3 (TXD0/TXD1)

As well as functioning as I/O port pins, port C0 and C3 can also function as serial channel TXD output pins. In case of use TXD0/TXD1, it is possible to logical invert by setting the register PC<PC0,PC3>.

And ports C0 to C3 have a programmable open drain function, which can be control the register PCODE<ODEPC0, ODEPC3>.

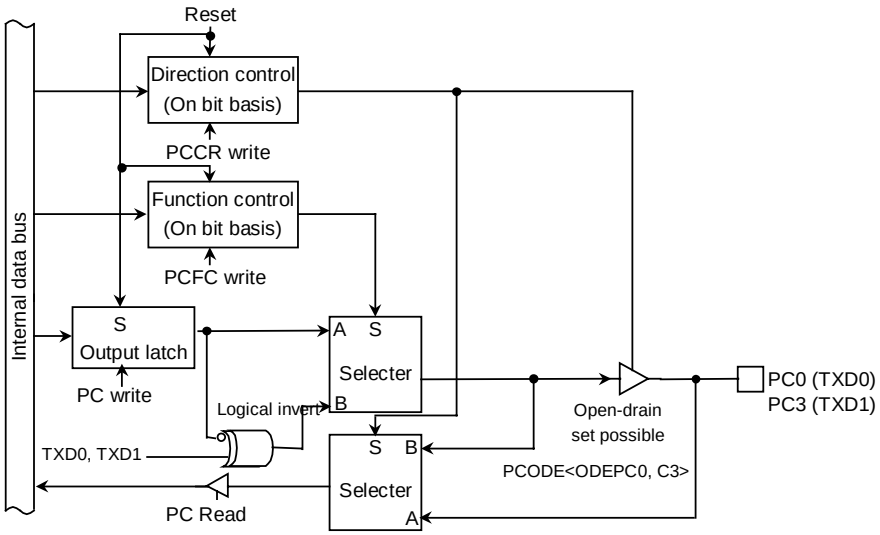

Figure 3.5.36 Port C0 and C3

(2) Port C1, C4 (RXD0, 1)

Port C1 and C4 are I/O port pins and can also is used as RXD input for the serial channels. In case of use RXD0/RXD1, it is possible to logical invert by setting the register PC<PC1,PC4>.

And input data of SIO0 can be select from RXD/PC1 pin or OPTRX0/P70 by setting the register PCFC2<P70F2>.

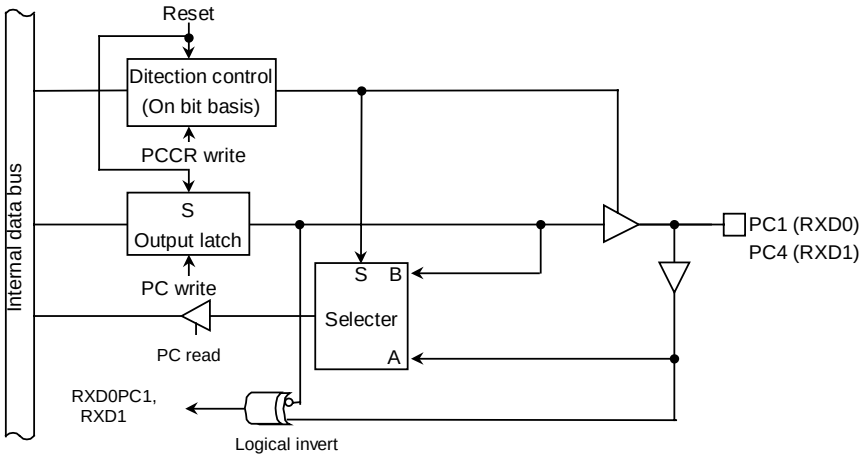

Figure 3.5.37 Port C1 and C4

(3) Port C2 (/CTS0, SCLK0), C5 (/CST1, SCLK1)

Port C2 and C4 are I/O port pins and can also is used as /CTS input or SCLK input/output for the serial channels. In case of use /CTS,SCLK, it is possible to logical invert by setting the register PC<PC2,PC5>.

Figure 3.5.39 Register for Port C

3.5.15 Port D (PD0 to PD7)

Port D is an 8-bit output port. Resetting sets the output latch PD to “1”, and PD0 to PD7 pin output “1”.

In addition to functioning as output port, Port D also function as output pin for LCD controller (D1BSCP, D2BLP, D3BFR, DLEBCD and DOFFB), output pin for RTC alarm (/ALARM) and output pin for melody/alarm generator (MLDALM, /MLDALM). Above setting is used the function register PDFC.

Only PD6 has two output function which /ALARM and /MLDALM. This selection is used PD<PD6>. Resetting resets the function register PDFC to “0”, and sets all ports to output ports.

Figure3.5.42 Register for Port D

3.5.16 Port E (PE0 to PE7)

Port E is an 8-bit general-purpose I/O ports. Each bit can be set individually for input or output using the control register PECR. Resetting , the control register PECR to “0” and sets Port E to input ports. It also sets all bits of the output latch register to “1”.

In addition to functioning as a general-purpose I/O port, Port E can also function as an data bus for LCD controller (LD0 to LD7). Above setting is used the function register PEFC.

Figure3.5.44 Register for Port E

3.5.17 Port F (PF0 to PF7)

Port F is an 8-bit output port. Resetting sets the output latch PF to “1”, and PF0 to PF7 pin output “1”.

In addition to functioning as output port, Port F also function as output pin for SDRAM controller (SDCKE,SDCLK,SDLDQM,SDUDQM,/SDWE), and output pin for SSIO (SSCLK). Above setting is used the function register PFFC.

Figure3.5.46 Register for Port F

3.6 Chip Select/Wait Controller

On the TMP91C820A, four user-specifiable address areas (/CS0 to /CS3) can be set. The data bus width and the number of waits can be set independently for each address area (/CS0 to /CS3 and others).

The pins /CS0 to /CS3 (which can also function as port pins P60 to P63) are the respective output pins for the areas CS0 to CS3. When the CPU specifies an address in one of these areas, the corresponding /CS0 to /CS3 pin outputs the Chip Select signal for the specified address area (in ROM or SRAM). However, in order for the Chip Select signal to be output, the Port 6 Function Register P6FC must be set.

/CS2A to /CS2G and /CSEXA (CS pin except /CS0 to /CS3) are made by MMU.

These pins is /CS pin that area and BANK value is fixed without concern in setting of CS/WAIT controller.

The areas CS0 to CS3 are defined by the values in the Memory Start Address Registers MSAR0 to MSAR3 and the Memory Address Mask Registers MAMR0 to MAMR3.
The Chip Select/Wait Control Registers B0CS to B3CS and BEXCS should be used to specify the Master Enable/Disable status the data bus width and the number of waits for each address area.

The input pin controlling these states is the bus wait request pin (/WAIT).

3.6.1 Specifying an Address Area

The CS0 to CS3 address areas are specified using the start address registers (MSAR0 to MSAR3) and memory address mask registers (MAMR0 to MAMR3).
At each bus cycle, a compare operation is performed to determine if the address on the specified a location in the CS0 to CS3 area. If the result of the comparison is a match, this indicates an access to the corresponding CS area. In this case, the /CS0 to /CS3 pin outputs the chip select signal and the bus cycle operates in accordance with the settings in chip select/wait control register B0CS to B3CS. (See 3.6.2, Chip Select/Wait Control Registers.)

(1) Memory Start Address Registers

Figure 3.6.1 shows the Memory Start Address Registers. The Memory Start Address Registers MSAR0 to MSAR3 set the start addresses for the CS0 to CS3 areas. Set the upper eight bits (A23 to A16) of the start address in <S23: S16>. The lower 16 bits of the start address (A15 to A0) are permanently set to 0. Accordingly, the start address can only be set in 64-Kbyte increments, starting from 000000H. Figure 3.6.2 shows the relationship between the start address and the start address register value.

Memory Start Address Registers (for areas CS0 to CS3)

		7	6	5	4	3	2	1	0
MSAR0 (00C8H) / MSAR1 (00CAH)	bit Symbol	S23	S22	S21	S20	S19	S18	S17	S16
	Read/Write	R/W							
MSAR2 (00CCH) / MSAR3 (00CEH)	After reset	1	1	1	1	1	1	1	1
	Function	Determines A23 to A16 of start address.							

→ Sets start addresses for areas CS0 to CS3.

Figure 3.6.1 Memory Start Address Register

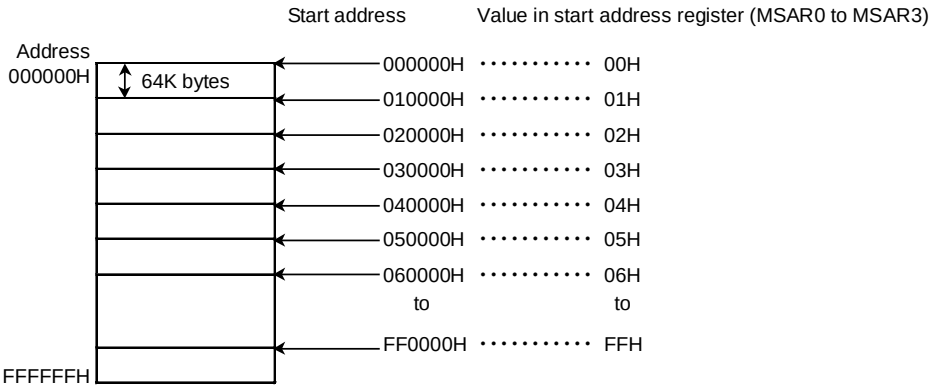

Figure 3.6.2 Relationship between Start Address and start Address Register Value

(2) Memory Address Mask Registers

Figure 3.6.3 shows the Memory Address Mask Registers. Memory address mask registers MAMR0 to MAMR3 are used to set the size of the CS0 to CS3 areas by specifying a mask for each bit of the start address set in memory start address registers MAMR0 to MAMR3. The compare operation used to determine if an address is in the CS0 to CS3 areas is only performed for bus address bits corresponding to bits set to "0" in these registers. Also, the address bits that can be masked by MAMR0 to MAMR3 differ between CS0 to CS3 areas. Accordingly, the size that can be each area is different.

Memory address mask register (for CS0 area)

MAMR0 (00C9H)

	7	6	5	4	3	2	1	0
bit Symbol	V20	V19	V18	V17	V16	V15	V14 to 9	V8
Read/Write	R/W							
After Reset	1	1	1	1	1	1	1	1
Function	Sets size of CS0 area 0: used for address compare							

Range of possible settings for CS0 area size: 256 bytes to 2 Mbytes

Memory address mask register (CS1)

MAMR1 (00CBH)

	7	6	5	4	3	2	1	0
bit Symbol	V21	V20	V19	V18	V17	V16	V15 to 9	V8
Read/Write	R/W							
After Reset	1	1	1	1	1	1	1	1
Function	Sets size of CS1 area 0: Used for address compare							

Range of possible settings for CS1 area size: 256 bytes to 4M bytes.

Memory address mask register (CS2, CS3)

MAMR2 (00CDH) / MAMR3 (00CFH)

	7	6	5	4	3	2	1	0
bit Symbol	V22	V21	V20	V19	V18	V17	V16	V15
Read/Write	R/W							
After reset	1	1	1	1	1	1	1	1
Function	Sets size of CS2 or CS3 area 0: used for address compare							

Range of possible settings for CS2 and CS3 area sizes: 32 Kbytes to 8 Mbytes.

Figure 3.6.3 Memory Address mask Registers

(3) Setting Memory Start Addresses and Address Areas

Figure 3.6.4 show an example of specifying a 64-Kbyte-address area starting from 010000H using the CS0 areas.

Set “01H” in memory start address register MSAR0<S23: 16>(corresponding to the upper 8 bits of the start address). Next, calculate the difference between the start address and the anticipated end address (01FFFFH) based on the size of the CS0 area. Bits 20 to 8 of the result correspond to the mask value to be set for the CS0 area. Setting this value in memory address mask register MAMR0<V20: 8>sets the area size This example sets 07H in MAMR0 to specify a 64K-byte area.

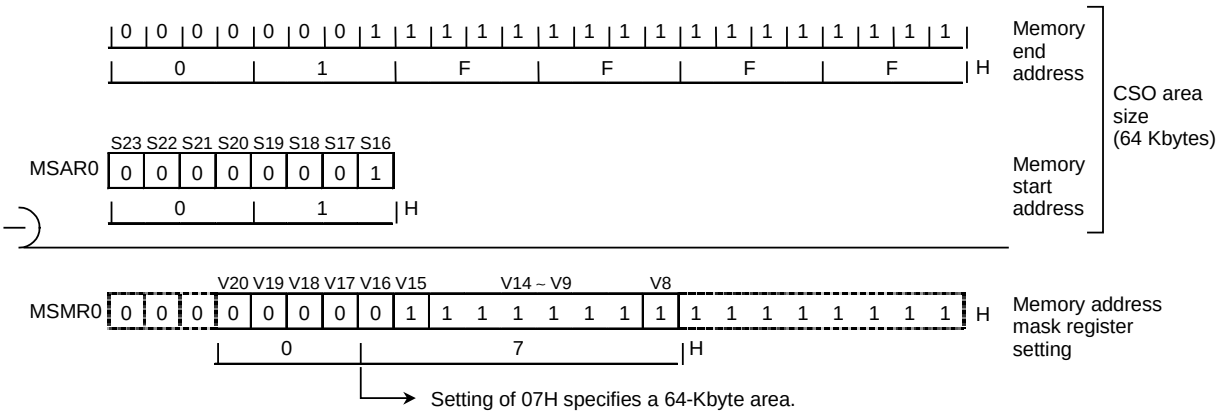

Figure 3.6.4 Example showing how to set the CS0 area

After a reset, MSAR0 to MSAR3 and MAMR0 to MAMR3 are set to “FFH”. B0CS<B0E>, B1CS<B1E> and B3CS<B3E> are reset to “0”. This disabling the CS0, CS1 and CS3 areas. However, as B2CS<B2M> to “0” and B2CS<B2E> to “1”, CS2 is enabled from 000FE0H-000FFFH to 003000H-FFFFFFH in TMP91C820A. Also, the bus width and number of waits specified in BEXCS are used for accessing addresses outside the specified CS0 to CS3 area. (See 3.6.2, Chip Select/Wait Control Registers.)

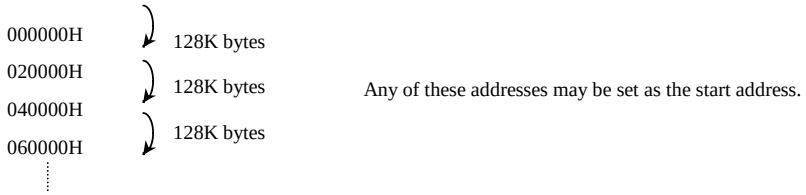
(4) Address Area Size Specification

Table 3.6.1 shows the relationship between CS area and area size.△ Indicates areas that cannot be set by memory start address register and address mask register combinations. When setting an area size using a combination indicated by △ , set the start address mask register in the desired steps starting from 000000H.

If the CS2 area is set to 16M-bytes or if two or more areas overlap, the smaller CS area number has the higher priority.

Example: To set the area size for CS0 to 128 Kbytes:

① Valid start addresses



② Invalid start addresses

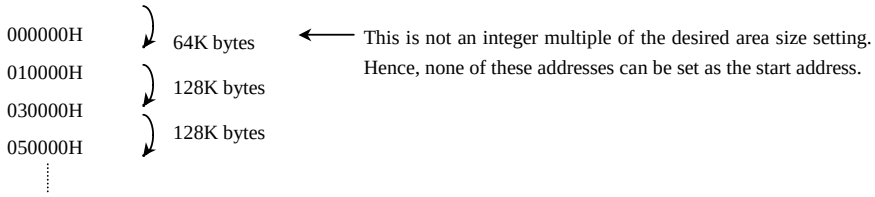


Table 3.6.1 Valid area sizes for each CS area

Size (bytes) / CS area	256	512	32 K	64 K	128 K	256 K	512 K	1 M	2 M	4 M	8 M
CS0	○	○	○	○	△	△	△	△	△		
CS1	○	○		○	△	△	△	△	△	△	
CS2			○	○	△	△	△	△	△	△	△
CS3			○	○	△	△	△	△	△	△	△

Note: △ Indicates areas that cannot be set by memory start address register and address mask register combinations.

3.6.2 Chip Select/Wait Control Registers

Figure 3.6.5 lists the Chip Select/Wait Control Registers.

The Master Enable/Disable, Chip Select output waveform, data bus width and number of wait states for each address area (CS0 to CS3 and others) are set in their respective chip select/wait control registers, B0CS to B3CS and BEXCS.

Figure 3.6.5 Chip Select/Wait Control Registers

(1) Master Enable bits

Bit 7 (<B0E>, <B1E>, <B2E> or <B3E>) of a chip select/wait control register is the master bit, which is used to enable or disable settings for the corresponding address area. Writing "1" to this bit enables the settings. Reset disables (sets to "0")<B0E>, <B1E> and <B3E>, and enabled (sets to "1") <B2E>. This enables area CS2 only.

(2) Data bus width selection

Bit 3 (<B0BUS>, <B1BUS>, <B2BUS>, <B3BUS> or <BEXBUS>) of a chip select/wait control register specifies the width of the data bus. This bit should be set to "0" when memory is to be accessed using a 16-bit data bus and to "1" when an 8-bit data bus is to be used.
This process of changing the data bus width according to the address being accessed is known as "dynamic bus sizing". For details of this bus operation see Table 3.6.2.

Table 3.6.2 Dynamic bus sizing

Operand Data Bus Width	Operand Start Address	Memory Data Bus Width	CPU Address	CPU Data		Contorol for READ cycle							Controll for WRITE cycle						
				D15 to D8	D7 to D0	R/W	/RD	/WR	/HWR	/SRLB	/SRUB	/SRWR	R/W	/RD	/WR	/HWR	/SRLB	/SRUB	/SRWR
8 bits	2n+0 (Even number)	8 bits	2n+0	XXXX	b7-b0	H	L	H	H	L	H	H	L	H	L	H	L	H	L
		16 bits	2n+0	XXXX	b7-b0														
	2n+1 (Odd number)	8 bits	2n+1	XXXX	b7-b0					L	H				L	H	L	H	
		16 bits	2n+1	b7-b0	XXXX					H	L				H	L	H	L	
16 bits	2n+0 (Even number)	8 bits	2n+0 2n+1	XXXX XXXX	b7-b0 b15-b8					L	H				L	H	L	H	
		16 bits	2n+0	b15-b8	b7-b0					L	L				L	L	L	L	
	2n+1 (Odd number)	8 bits	2n+1 2n+2	XXXX XXXX	b7-b0 b15-b8					L	H				L	H	L	H	
		16 bits	2n+1 2n+2	b7-b0 XXXX	XXXX b15-b8					H L	L H				H L	L H	H L	L H	
32 bits	2n+0 (Even number)	8 bits	2n+0 2n+1 2n+2 2n+3	XXXX XXXX XXXX XXXX	b7-b0 b15-b8 b23-b16 b31-b24					L	H				L	H	L	H	
		16 bits	2n+0 2n+2	b15-b8 b31-b24	b7-b0 b23-b16					L	L				L	L	L	L	
	2n+1 (Odd number)	8 bits	2n+1 2n+2 2n+3 2n+4	XXXX XXXX XXXX XXXX	b7-b0 b15-b8 b23-b16 b31-b24					L	H				L	H	L	H	
		16 bits	2n+1 2n+2 2n+4	b7-b0 b23-b16 XXXX	XXXX b15-b8 b31-b24					H L L	L L H				H L L	L L H	H L L	L L H	

XXXX: Indicates that the input data from these bits are ignored during a read. During a write, indicates that the bus for these bits goes too high-impedance; also, that the write strobe signal for the bus remains inactive.

(3) Wait control

Bits 0 to 2 (<B0W0 to B0W2>, <B1W0 to B1W2>, <B2W0 to B2W2>, <B3W0 to B3W2>, <BEXW0 to BEXW2>) of a chip select/wait control register specify the number of waits that are to be inserted when the corresponding memory area is accessed.
The following types of wait operation can be specified using these bits. Bit settings other than those listed in the table should not be made.

Table 3.6.3 Wait operation settings

<BxW2 ~ BxW0>	No. of Waits	Wait Operation
000	2WAIT	Inserts a wait of 2 states, irrespective of the $\overline{\text{WAIT}}$ pin state.
001	1WAIT	Inserts a wait of 1 state, irrespective of the $\overline{\text{WAIT}}$ pin state.
010	1WAIT + N	Samples the state of the $\overline{\text{WAIT}}$ pin after inserting a wait of one state. If the $\overline{\text{WAIT}}$ pin is Low, the waits continue and the bus cycle is extended until the pin goes high.
011	0WAIT	Ends the bus cycle without a wait, regardless of the $\overline{\text{WAIT}}$ pin state.
100	Reserved	Invalid setting
101	3WAIT	Inserts a wait of 3 state, irrespective of the $\overline{\text{WAIT}}$ pin state.
110	4WAIT	Inserts a wait of 4 state, irrespective of the $\overline{\text{WAIT}}$ pin state.
111	8WAIT	Inserts a wait of 8 state, irrespective of the $\overline{\text{WAIT}}$ pin state.

A Reset sets these bits to “000” (2 waits).

(4) Bus width and wait control for an area other than CS0 to CS3

The chip select/wait control register BEXCS controls the bus width and number of waits when memory locations, which are not in one of the four user-specified address areas (CS0 to CS3), are accessed. The BEXCS register settings are always enabled for areas other than CS0 to CS3.

(5) Selecting 16-Mbyte area/specified address area

Setting B2CS<B2M> (bit 6 of the chip select/wait control register for CS2) to “0” designates the 16-Mbyte area (000FE0H-000FFFH, 003000H-FF7FFFH) as the CS2 area. Setting B2CS<B2M> to “1” designates the address area specified by the start address register MSAR2 and the address mask register MAMR2 as CS2 (i.e. if B2CS<B2M> = 1, CS2 is specified in the same manner as CS0, CS1 and CS3 are).
A Reset clears this bit to “0”, specifying CS2 as 16-M bytes address area.

(6) Procedure for setting chip select/wait control

When using the chip select/wait control function, set the registers in the following order:

① Set the Memory Start Address Registers MSAR0 to MSAR3.

Set the start addresses for CS0 to CS3.

② Set the Memory Address Mask Registers MAMR0 to MAMR3.

Set the sizes of CS0 to CS3.

③ Set the chip select/wait control registers B0CS to B3CS.

Set the Chip Select output waveform, data bus width, number of waits and Master Enable/Disable status for /CS0 to /CS3.

The CS0 to S3 pins can also function as pins P60 to P63. To output a Chip Select signal using one of these pins, set the corresponding bit in the Port 6 Function Register P6FC to “1”. If a CS0 “to S3 address is specified which is actually an internal I/O and RAM area address, the CPU accesses the internal address area and no Chip Select signal is output on any of the /CS0 to /CS3 pins.

Setting example:

In this example CS0 is set to be the 64-Kbyte area 010000H to 01FFFFH. The bus width is set to 16 bits and the number of waits is set to 0.

MSAR0 = 01H..... Start address: 010000H

MAMR0 = 07H..... Address area: 64 Kbytes

B0CS = 83H..... ROM/SRAM, 16-bit data bus, zero waits, CS0 area settings enabled

3.6.3 Connecting external memory

Figure 3.6.6 shows an example of how to connect external memory to the TMP91C820A.
In this example the ROM is connected using a 16-bit bus. The RAM and I/O are connected using an 8-bit bus.

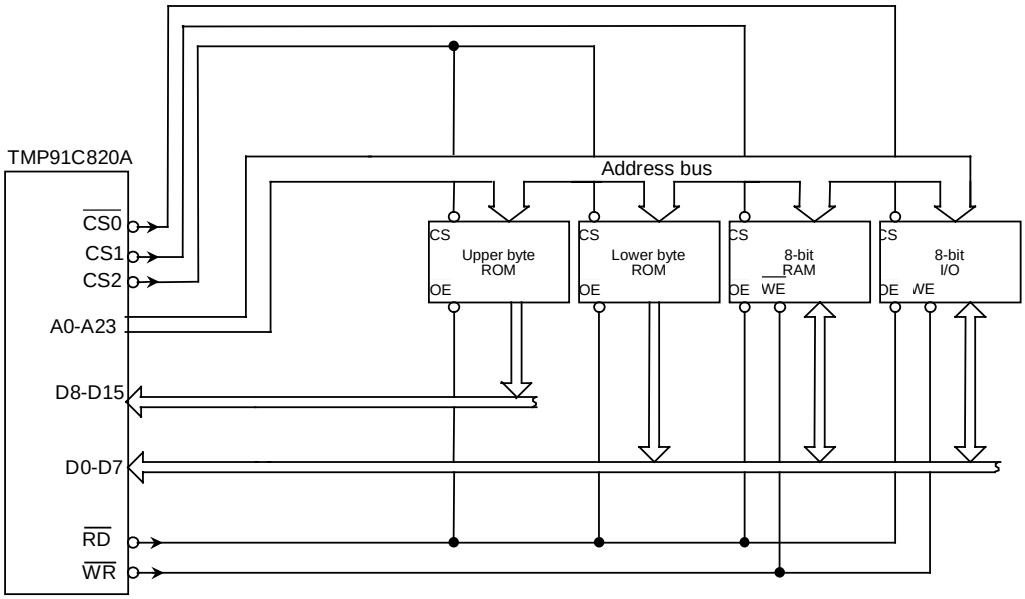

Figure 3.6.6 Example of external memory connection
(ROM uses 16-bit bus; RAM and I/O use 8-bit bus.)

A Reset clears all bits of the Port 6 Control Register P6CR and the Port 6 Function Register P6FC to "0" and disables output of the CS signal. To output the CS signal, the appropriate bit must be set to "1".

3.7 8-bit Timers (TMRA)

The TMP91C820A features 4 built-in 8-bit timers.
These timers are paired into four modules: TMRA01 and TMRA23. Each module consists of two channels and can operate in any of the following four operating modes.

- 8-Bit Interval Timer Mode
- 16-Bit Interval Timer Mode
- 8-Bit Programmable Square Wave Pulse Generation Output Mode (PPG: variable duty cycle with variable period)
- 8-Bit Pulse Width Modulation Output Mode (PWM – variable duty cycle with constant period)

Figure 3.7.1 to Figure 3.7.2 Show block diagrams for TMRA01 and TMRA23.
Each channel consists of an 8-bit up-counter, an 8-bit comparator and an 8-bit timer register. In addition, a timer flip-flop and a prescaler are provided for each pair of channels.
The operation mode and timer flip-flops are controlled by five controls SFR (special-function registers).
Each of the two modules (TMRA01 and TMRA23) can be operated independently. All modules operate in the same manner; hence only the operation of TMRA01 is explained here.
The contents of this chapter are as follows.

3.7.1 Block diagrams
3.7.2 Operation of each circuit
3.7.3 SFR
3.7.4 Operation in each mode
(1) 8-Bit Timer Mode
(2) 16-Bit Timer Mode
(3) 8-Bit PPG (programmable pulse generation) Output Mode
(4) 8-Bit PWM (pulse width modulation) Output Mode
(5) Mode settings

Table 3.7.1 Registers and pins for each module

Module		TMRA01	TMRA23
External pin	Input pin for external clock	TA0IN (shared with PB0)	No
	Output pin for timer flip-flop	TA1OUT (shared with PB1)	TA3OUT (shared with PB5)
SFR (address)	Timer run register	TA01RUN (0100H)	TA23RUN (0108H)

3.7.2 Operation of each circuit

(1) Prescaler

A 9-bit prescaler generates the input clock to TMRA01.

The clock φT0 is divided by 4 and input to this prescaler. φT0 can be either f_{FPH} or fc/16 and is selected using the Prescaler Clock Selection Register SYSCR0<PRCK1,PRCK0>.

The prescaler operation can be controlled using TA01RUN<TA0PRUN> in the timer control register. Setting <TA0PRUN> to "1" starts the count; setting <TA0PRUN> to "0" clears the prescaler to zero and stops operation. Table 3.7 (2) shows the various prescaler output clock resolutions.

Table 3.7.2 Prescaler output clock resolution

@fc = 16 MHz, fs = 32.768 kHz

System Clock Selection <SYSCK>	Prescaler Clock Selection <PRCK1,PRCK0>	Gear Value <GEAR2~GEAR0>	Prescaler Output Clock Resolution			
			φT1	φT4	φT16	φT256
1 (fs)	00 (f_{FPH})	XXX	$fs/2^3$ (244 μs)	$fs/2^5$ (977 μs)	$fs/2^7$ (3.9 μs)	$fs/2^{11}$ (62.5 μs)
0 (fc)		000 (fc)	$fc/2^3$ (0.5 μs)	$fc/2^5$ (2.0 μs)	$fc/2^7$ (8.0 μs)	$fc/2^{11}$ (128 μs)
		001 ($fc_{/2}$)	$fc/2^4$ (1.0 μs)	$fc/2^6$ (4.0 μs)	$fc/2^8$ (16 μs)	$fc/2^{12}$ (256 μs)
		010 ($fc_{/4}$)	$fc/2^5$ (2.0 μs)	$fc/2^7$ (8.0 μs)	$fc/2^9$ (32 μs)	$fc/2^{13}$ (512 μs)
		011 ($fc_{/8}$)	$fc/2^6$ (4.0 μs)	$fc/2^8$ (16 μs)	$fc/2^{10}$ (64 μs)	$fc/2^{14}$ (1024 μs)
		100 ($fc_{/16}$)	$fc/2^7$ (8.0 μs)	$fc/2^9$ (32 μs)	$fc/2^{11}$ (128 μs)	$fc/2^{15}$ (2048 μs)
	10 ($fc_{/16}$ CLOCK)	XXX	$fc/2^7$ (8.0 μs)	$fc/2^9$ (32 μs)	$fc/2^{11}$ (128 μs)	$fc/2^{15}$ (2048 μs)

xxx: Don't care

(2) Up-counters (UC0 and UC1)

These are 8-bit binary counters which count up the input clock pulses for the clock specified by TA01MOD.

The input clock for UC0 is selectable and can be either the external clock input via the TA0IN pin or one of the three internal clocks φT1, φT4 or φT16. The clock setting is specified by the value set in TA01MOD<TA01CLK1,TA01CLK0>.

The input clock for UC1 depends on the operation mode. In 16-Bit Timer Mode, the overflow output from UC0 is used as the input clock. In any mode other than 16-Bit Timer Mode, the input clock is selectable and can either be one of the internal clocks φT1, φT16 or φT256, or the comparator output (the match detection signal) from TMRA0.

For each interval timer the timer operation control register bits TA01RUN<TA0RUN> and TA01RUN<TA1RUN> can be used to stop and clear the up-counters and to control their count. A Reset clears both up-counters, stopping the timers.

(3) Timer registers (TA0REG and TA1REG)

These are 8-bit registers, which can be used to set a time interval. When the value set in the timer register TA0REG or TA1REG matches the value in the corresponding up-counter, the Comparator Match Detect signal goes Active. If the value set in the timer register is 00H, the signal goes Active when the up counter overflows.

The TA0REG are double buffer structure, each of which makes a pair with register buffer.

The setting of the bit TA01RUN<TA0RDE> determines whether TA0REG's double buffer structure is enabled or disabled. It is disabled if <TA0RDE> = "0" and enabled if <TA0RDE> = "1". When the double buffer is enabled, data is transferred from the register buffer to the timer register when a 2^n-1 overflow occurs in PWM Mode, or at the start of the PPG cycle in PPG Mode. Hence the double buffer cannot be used in Timer Mode.

A Reset initializes <TA0RDE> to "0", disabling the double buffer. To use the double buffer, write data to the timer register, set <TA0RDE> to "1", and write the following data to the register buffer. Figure 3.7.3 show the configuration of TA0REG.

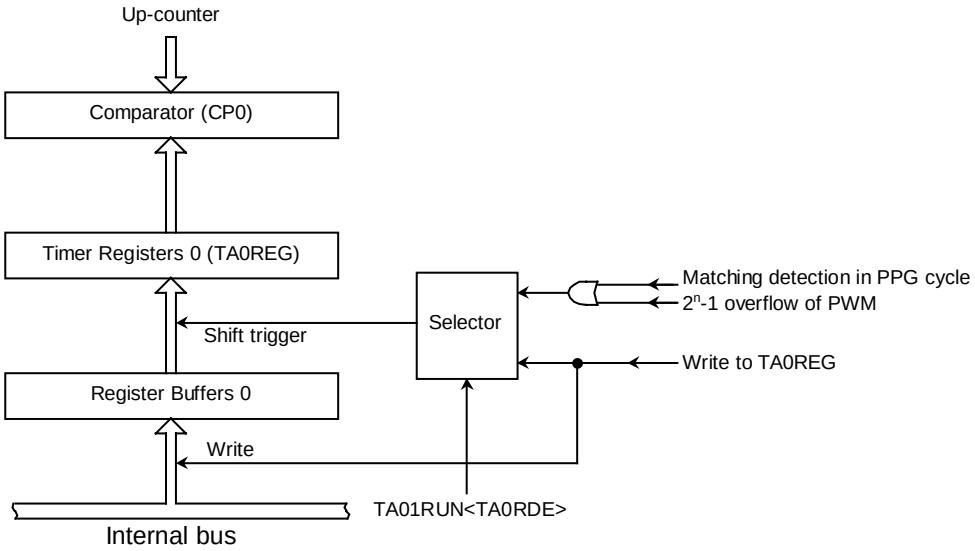

Figure 3.7.3 Configuration of TA0REG

Note: The same memory address is allocated to the timer register and the register buffer. When <TA0RDE> = 0, the same value is written to the register buffer and the timer register; when <TA0RDE> = 1, only the register buffer is written to.

The address of each timer register is as follows.

TA0REG: 000102H	TA1REG: 000103H
TA2REG: 00010AH	TA3REG: 00010BH

All these registers are write-only and cannot be read.

(4) Comparator (CP0)

The comparator compares the value in an up counter with the value set in a timer register. If they match, the up counter is cleared to zero and an interrupt signal (INTTA0 or INTTA1) is generated. If timer flip-flop inversion is enabled, the timer flip-flop is inverted at the same time.

(5) Timer flip-flop (TA1FF)

The timer flip-flop (TA1FF) is a flip-flop inverted by the match detects signal (8-bit comparator output) of each interval timer.

Whether inversion is enabled or disabled is determined by the setting of the bit TA1FFCR<TAFF1IE> in the Timer flip-flops Control Register A Reset clears the value of TA1FF to “0”. Writing“01”or”10”to TA1FFCR<TAFF1C1, TAFF1C0>sets TA1FF to 0 or 1. Writing “00” to these bits inverts the value of TA1FF (this is known as software inversion).

The TA1FF signal is output via the TA1OUT pin (which can also be used as PB1). When this pin is used as the timer output, the timer flip-flop should be set beforehand using the Port B Function Register PBCR, PBFC.

3.7.4 Operation in each mode

(1) 8-Bit Timer Mode

Both TMRA0 and TMRA1 can be used independently as 8-bit interval timers.

① Generating interrupts at a fixed interval (using TMRA1)

To generate interrupts at constant intervals using TMRA1 (INTTA1), first stop TMRA1 then set the operation mode, input clock and a cycle to TA01MOD and TA1REG register, respectively. Then, enable the interrupt INTTA1 and start TMRA1 counting.

Example: To generate an INTTA1 interrupt every 20 μseconds at fc = 16 MHz, set each register as follows:

∗ Clock state
System clock: High frequency (fc)
Prescaler clock: f_{FPH}

	MSB							LSB	
	7	6	5	4	3	2	1	0	
TA01RUN	← –	–	X	X	–	–	0	–	Stop TMRA1 and clear it to 0.
TA01MOD	← 0	0	X	X	1	0	-	-	Select 8-Bit Timer Mode and select ϕT1 (0.5 μs at fc = 16 MHz) as the input clock.
TA1REG	← 0	0	1	0	1	0	0	0	Set TA1REG to 20 μs ÷ ϕT1 = 40 = 28H
INTETA01	← X	1	0	1	–	–	–	–	Enable INTTA1 and set it to Level 5.
TA01RUN	← –	X	X	X	–	1	1	–	Start TMRA1 counting.

Note: X = Don't care; "–" = No change

Select the input clock using Table 3.7 2.

Note: The input clocks for TMRA0 and TMRA1 are different from as follows.
TMRA0: TA0IN input, ϕT1, ϕT4 or ϕT16
TMRA1: Match output of TMRA0,ϕT1, ϕT16, ϕT256

② Generating a 50% duty ratio square wave pulse

The state of the timer flip-flop (TA1FF) is inverted at constant intervals and its status output via the timer output pin (TA1OUT).

Example: To output a 3.0-μs square wave pulse from the TA1OUT pin at fc = 16 MHz, use the following procedure to make the appropriate register settings. This example uses TMRA1; however, either TMRA0 or TMRA1 may be used.

∗ Clock state
System clock: High frequency (fc)
Clock gear: 1 (fc)
Prescaler clock: f_{FPH}

		7	6	5	4	3	2	1	0	
TA01RUN	←	–	X	X	X	–	–	0	–	Stop TMRA1 and clear it to 0.
TA01MOD	←	0	0	X	X	0	1	–	–	Select 8-Bit Timer Mode and select ϕT1 (0.5 μs at fc = 16 MHz) as the input clock.
TA1REG	←	0	0	0	0	0	0	1	1	Set the timer register to 3.0 μs ÷ ϕT1 ÷ 2 = 3
TA1FFCR	←	X	X	X	X	1	0	1	1	Clear TA1FF to "0" and set it to invert on the match detects signal from TMRA1.
PBCR	←	X	–	–	–	–	X	1	–	Set PB1 to function as the TA1OUT pin.
PBFC	←	X	–	–	–	–	X	1	–	
TA01RUN	←	–	X	X	X	–	1	1	–	Start TMRA1 counting.

Note: X = Don't care; "–" = No change

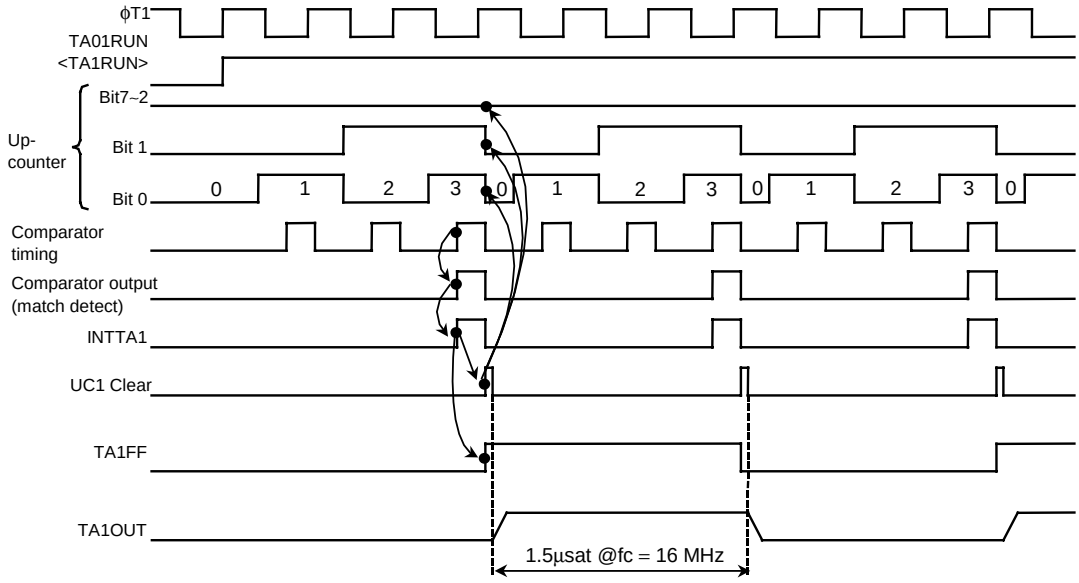

Figure 3.7.8 Square wave output timing chart (50% Duty)

③ Making TMRA1 count up on the match signal from the TMRA0 comparator

Select 8-Bit Timer Mode and set the comparator output from TMRA0 to be the input clock to TMRA1.

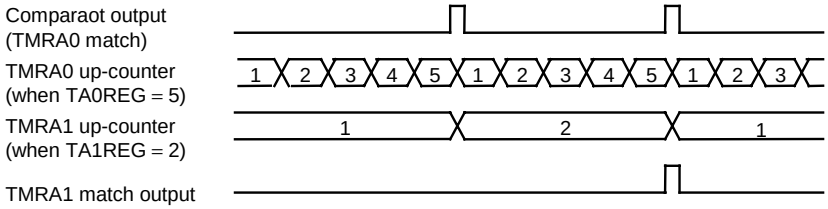

Figure 3.7.9 TMRA1 count up on signal from TMRA0

(2) 16-Bit Timer Mode

Pairing the two 8-bit timers TMRA0 and TMRA1 configures a 16-bit interval timer.

To make a 16-bit interval timer in which TMRA0 and TMRA1 are cascaded together, set TA01MOD <TA01M1, TA01M0> to 01.

In 16-Bit Timer Mode, the overflow output from TMRA0 is used as the input clock for TMRA1, regardless of the value set in TA01MOD<TA01CLK1, TA01CLK0>. Table 3.7 (2) shows the relationship between the timer (interrupt) cycle and the input clock selection.

Setting example: To generate an INTTA1 interrupt every 0.5 seconds at fc = 16 MHz, set the timer registers TA0REG and TA1REG as follows:

∗ Clock state

System clock: High frequency (fc)
Clock gear: 1 (fc)
Prescaler clock: f_{FPH}

If ϕT16 (8.0 μs at 16 MHz) is used as the input clock for counting, set the following value in the registers:
0.5 s ÷ 8.0 μs = 62500 = F424H; i.e. set TA1REG to F4H and TA0REG to 24H.

The comparator match signal is output from TMRA0 each time the up-counter UC0 matches TA0REG, though the up-counter UC0 is not be cleared.
In the case of the TMRA1 comparator, the match detect signal is output on each comparator pulse on which the values in the up counter UC1 and TA1REG match. When the match detect signal is output simultaneously from both the comparator TMRA0 and TMRA1, the up-counters UC0 and UC1 are cleared to 0 and the interrupt INTTA1 is generated. Also, if inversion is enabled, the value of the timer flip-flop TA1FF is inverted.

Example: When TA1REG = 04H and TA0REG = 80H

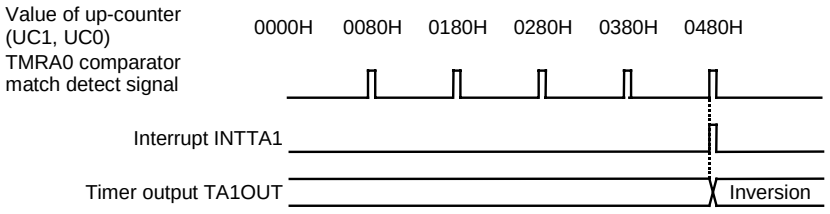

Figure 3.7.10 Timer output by 16-Bit Timer Mode

(3) 8-Bit PPG (Programmable Pulse Generation) Output Mode

Square wave pulses can be generated at any frequency and duty ratio by TMRA0. The output pulses may be active-Low or active-High. In this mode TMRA1 cannot be used.
TMRA0 outputs pulses on the TA1OUT pin (which can also be used as P71).

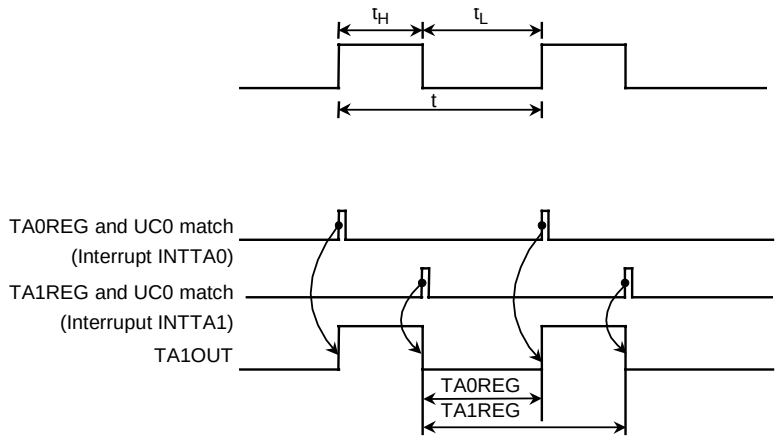

Figure 3.7.11 8 bit PPG output waveforms

In this mode a programmable square wave is generated by inverting the timer output each time the 8-bit up-counter (UC0) matches the value in one of the timer registers TA0REG or TA1REG. The value set in TA0REG must be smaller than the value set in TA1REG.
Although the up counter for TMRA1 (UC1) is not used in this mode, TA01RUN<TA1RUN> should be set to "1" so that UC1 is set for counting.
Figure 3.7.12 shows a block diagram representing this mode.

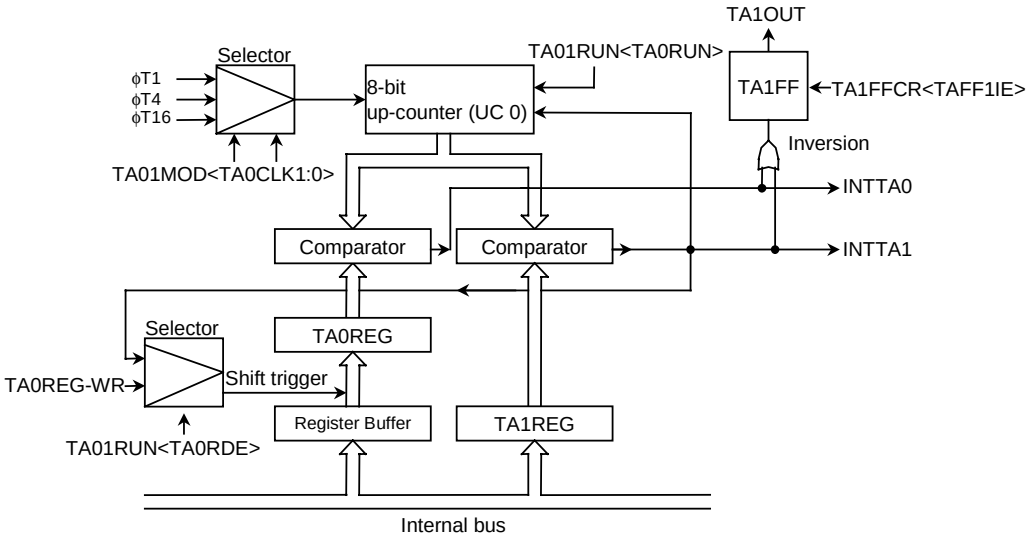

Figure 3.7.12 Block diagram of 8-Bit PPG Output Mode

If the TA0REG double buffer is enabled in this mode, the value of the register buffer will be shifted into TA0REG each time TA1REG matches UC0.
Use of the double buffer facilitates the handling of low-duty waves (when duty is varied).

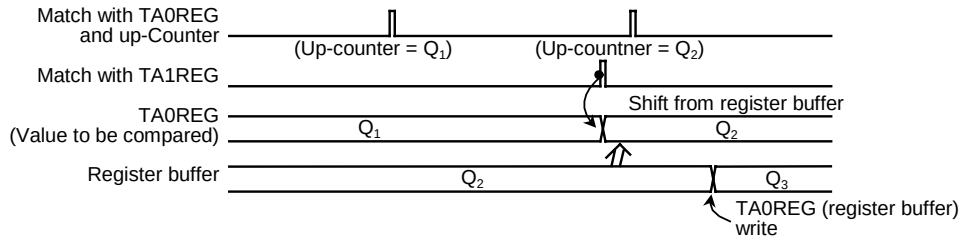

Figure 3.7.13 Operation of register buffer

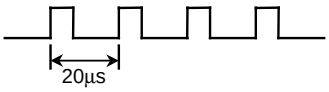
Example: To generate 1/4-duty 50-kHz pulses (at fc = 16 MHz):



* Clock state
System clock: High frequency (fc)
Clock gear: 1 (fc)
Prescaler clock: f_{FPH}

Calculate the value, which should be set in the timer register.

To obtain a frequency of 50 kHz, the pulse cycle t should be: t = 1/50 kHz = 20 μs

ϕT1 = 0.5 μs (at 16 MHz);

20 μs ÷ 0.5 μs = 40

Therefore set TA1REG to 40 (28H)

The duty is to be set to 1/4: t × 1/4 = 20 μs × 1/4 = 5 μs

5 μs ÷ 0.5 μs = 10

Therefore, set TA0REG = 10 = 0AH.

		7	6	5	4	3	2	1	0	
TA01RUN	←	0	X	X	X	–	0	0	0	Stop TMRA0 and TMRA01 and clear it to “0”.
TA01MOD	←	1	0	X	X	X	X	0	1	Set the 8-bit PPG mode, and select ϕT1 as input clock.
TA0REG	←	0	0	0	0	1	0	1	0	Write 0AH
TA1REG	←	0	0	1	0	1	0	0	0	Write 28H
TA1FFCR	←	X	X	X	X	0	1	1	X	Set TA1FF, enabling both inversion and the double buffer.
										Writing “10” provides negative logic pulse.
PBCR	←	X	–	–	–	–	X	1	–	Set PB1 as the TA1OUT pin.
PBFC	←	X	–	–	–	–	X	1	–	
TA01RUN	←	1	X	X	X	–	1	1	1	Start TMRA0 and TMRA01 counting.

Note: X = Don’t care; “–” = No change

(4) 8-Bit PWM Output Mode

This mode is only valid for TMRA0. In this mode, a PWM pulse with the maximum resolution of 8 bits can be output.

When TMRA0 is used the PWM pulse is output on the TA1OUT pin (which is also used as P71). TMRA1 can also be used as an 8-bit timer.

The timer output is inverted when the up-counter (UC0) matches the value set in the timer register TA0REG or when $2^n - 1$ counter overflow occurs (n = 6, 7 or 8 as specified by TA01MOD<PWM01 to PWM00>). The up-counter UC0 is cleared when $2^n - 1$ counter overflow occurs.

The following conditions must be satisfied before this PWM mode can be used.

Value set in TA0REG < value set for $2^n - 1$ counter overflow

Value set in TA0REG ≠ 0

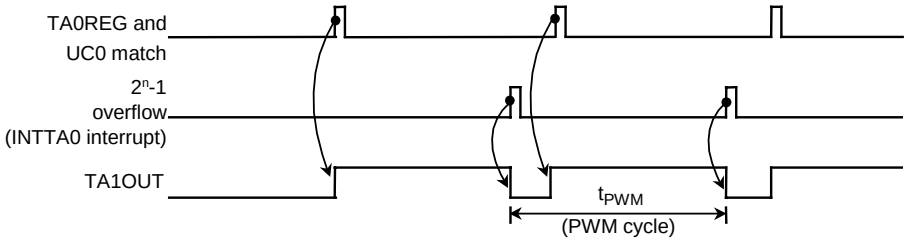


Figure 3.7.14 8-bit PWM waveforms

Figure 3.7.15 shows a block diagram representing this mode.

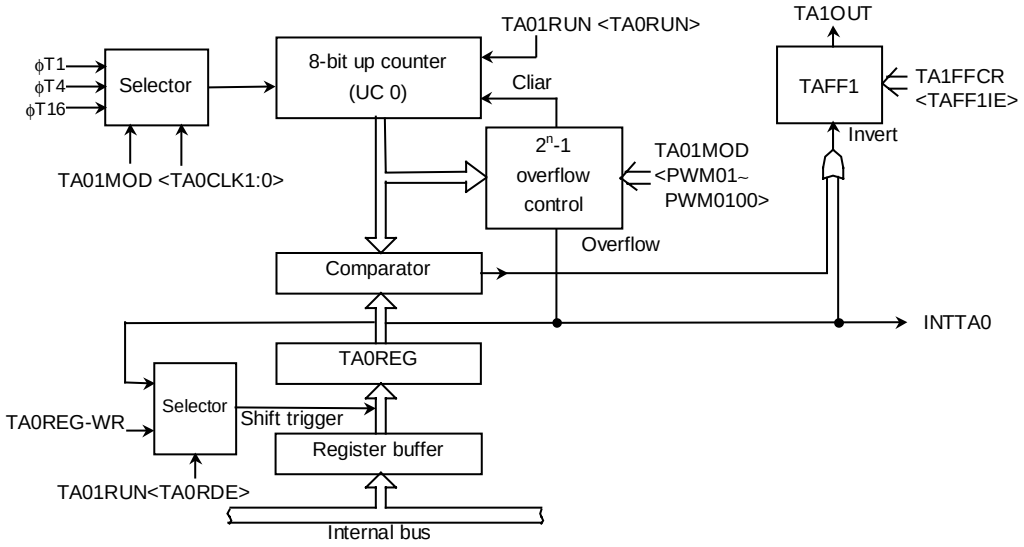

Figure 3.7.15 Block diagram of 8-Bit PWM Mode

In this mode the value of the register buffer will be shifted into TA0REG if $2^n - 1$ overflow is detected when the TA0REG double buffer is enabled.
Use of the double buffer facilitates the handling of low duty ratio waves.

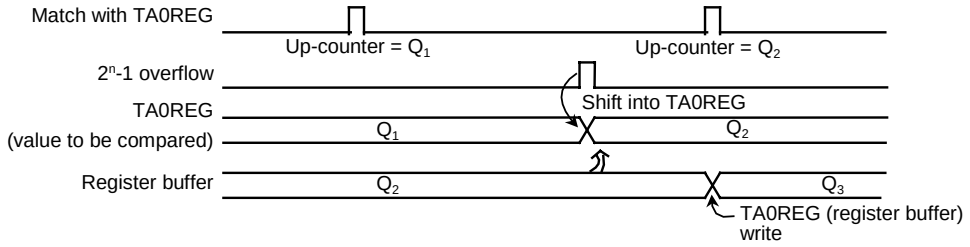

Figure 3.7.16 Register buffer operation

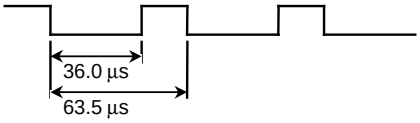
Example: To output the following PWM waves on the TA1OUT pin at fc = 16 MHz:



∗ Clock state
System clock: High frequency (fc)
Clock gear: 1 (fc)
Prescaler clock: f_{FPH}

To achieve a 63.5-µs PWM cycle by setting ϕT1 to 0.5 µs (at fc = 16 MHz):
63.5 µs ÷ 0.5 µs = 127=$2^n - 1$
Therefore n should be set to 7.
Since the low-level period is 36.0 µs when ϕT1 = 0.5 µs,
set the following value for TA0REG:
36.0 µs ÷ 0.5 µs = 72 = 48H

	MSB							LSB	
	7	6	5	4	3	2	1	0	
TA01RUN ←	–	X	X	X	–	–	–	0	Stop TMRA0 and clear it to 0.
TA01MOD ←	1	1	1	0	–	–	0	1	Select 8-Bit PWM Mode (cycle: 2^7-1) and select ϕT1 as the input clock.
TA0REG ←	0	1	0	0	1	0	0	0	Write 48H.
TA1FFCR ←	X	X	X	X	1	0	1	X	Clear TA1FF to 0; enable the inversion and double buffer.
PBCR ←	X	–	–	–	–	X	1	–	Set PB1 and the TA1OUT pin.
PBFC ←	X	–	–	–	–	X	1	–	
TA01RUN ←	1	X	X	X	–	1	-	1	Start TMRA0 counting.

Note: X = Don't care; "–" = No change

8-bit timer × 1 channel	11	–	ϕT1, ϕT16 , ϕT256 (01, 10, 11)	–	Output disabled

Note:"–" = Don't care

(6) LCDC and MELODY/ALARM circuit supply mode

This function can operate only TMRA3. It can use LCDC or MELODY/ALARM souce clock TA3 clock generated by TMRA3. But this function is special mode, without low clock (XTIN,XTOUT), so keep the rule under below.

OPERATE

1. clock genelate by timer 3 (32KHz,50% duty)
2. clock supply start (<TA3LCDE>=1 or <TA3MLD>=1)
3. need set-up time (more 100 μS :32KHz 3clk)
4. LCDC or MELODY/ALARM start to operate

STOP

1. LCDC or MELODY/ALARM stop to operate
2. clock supply cut off (<TA3LCDE>=0 or <TA3MLD>=0)

EMCCR0 (00E3H)

	7	6	5	4	3	2	1	0

3.8 External memory extension function (MMU)

This is MMU function which can expand program / data area to 136M byte by having 4 local area.

Address pins to external memory are 2 extended address bus pins (EA24,EA25) and 8 extended chip select pins (/CS2A to /CS2G and /CSEXA) in addition to 24 address bus pins (A0 ～ A23) which are common specification of TLCS-900 and 4 chip select pins (/CS0 ～ /CS3) output from CS/WAIT controller.

The feature and the recommendation setting method of two types are shown below.

In addition, AH in the table is the value which numb er address 23-16 displayed as hex.

Purpose	Item	For many kinds class extended memory
Program-ROM	Maximum memory size	2MB:common2+14MB:bank (16MB×1pcs)
	Used local area, BANK number	LOCAL2(AH=C0 -DF: 2MB ×7BANK)
	Setting CS/WAIT	Set up AH=80 -FF to CS2
	Used /CS pin	/CS2A
Data-ROM	Maximum memory size	96MB(16MB×6pcs)
	Used local area, BANK number	LOCAL3(AH=80-BF:4MB×24BANK)
	Setting CS/WAIT	Set up AH=80 -FF to CS2
	Used /CS pins	/CS2B,/CS2C,/CS2D,/CS2E,/CS2F,/CS2G
Data-SDRAM*	Maximum memory size	2MB:common1+14MB:bank (16MB×1pcs)
	Used local area, BANK number	LOCAL1(AH=40-5F: 2MB ×7BANK))
	Setting CS/WAIT	Set up AH=40 -7F to CS1
	Used /CS pin	/CS1
Data-RAM	Maximum memory size	1MB:common0+7MB:bank (8MB×1pcs)
	Used local area, BANK number	LOCAL0(AH=10-1F: 1MB ×7BANK))
	Setting CS/WAIT	Set up AH=00 -1F to CS3
	Used /CS pin	/CS3
Extended memory -1	Maximum memory size	1MB(1MB×1pcs)
	Used local area, BANK number	None
	Setting CS/WAIT	Set up AH=20 -2F to CS0
	Used /CS pin	/CS0
Extended memory-2	Maximum memory size	256KB(256KB×1pcs)
	Used local area, BANK number	None
	Setting CS/WAIT	Set up AH=30 -3F to /CSEX
	Used /CS pin	/CSEXA
Extended memory-3 (Direct address assigned built-in type LCD driver	Maximum memory size	256KB(64KB×4pcs)
	Used local area, BANK number	None
	Setting CS/WAIT	Set up AH=30 -3F to /CSEX
	Used /CS pin	D1BSCP,D2BLP,D3BFR,DLEBCD
Extended memory-4	Maximum memory size	512KB
	Used local area, BANK number	None
	Setting CS/WAIT	Set up AH=30 -3F to /CSEX
	Used /CS pin	None

***Note: SDRAM must be mapped in LOCAL1 area. It can't use othe area!**

3.8.1 Recommendable memory map

The recommendation logic address memory map at the time of variety extension memory correspondence is shown in Fig. 3.8.1 (1). And, a physical-address map is shown in Fig. 3.8.1 (2).

However, when memory area is less than 16M bytes and is not expanded, please refer to section of CS/WAIT controller. Setting of register in MMU is not necessary.

Since it is being fixed, the address of a local-area cannot be changed.

When SDRAM is used, must locate to LOCAL1 area

3.8.4 Operational description

Set up bank value and bank use in bank setting-register of each local area of LOCAL register in common area. Moreover, in that case, a combination pin is set up and the CS/WAIT controller simultaneously sets up mapping. When CPU outputs logical address of the local area, MMU outputs physical address to the outside pin according to value of bank setting-register. Access of external memory becomes possible therefore.

Please do not use as bank that overlaps with another bank since this common area overlaps with either of eight banks of local area on the physical map.

Example program is as next page follows

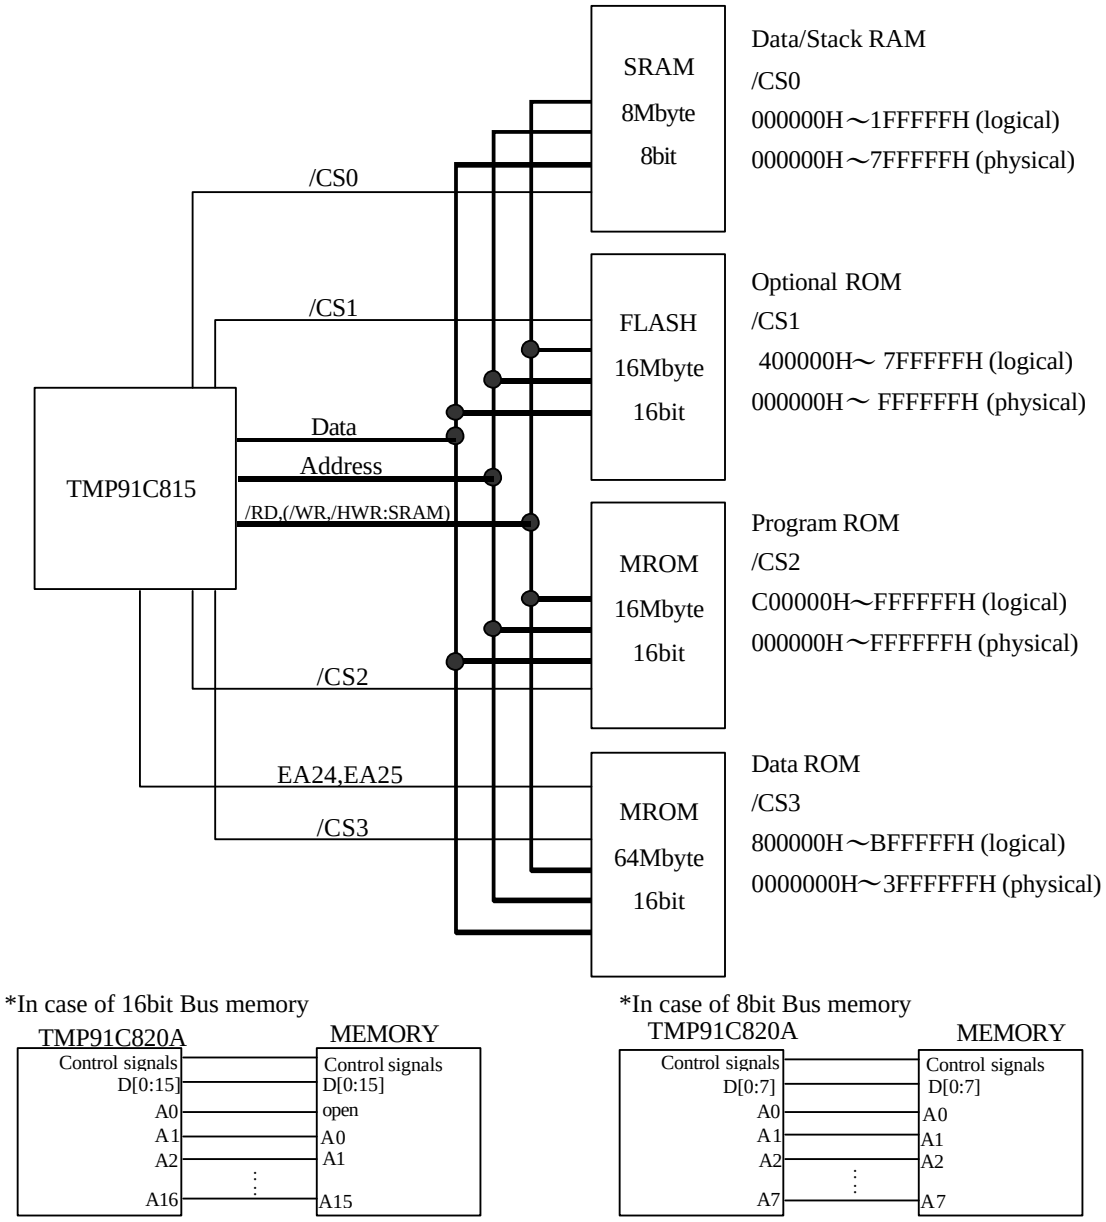

Figure 3.8.4.1 H/W Setting Example

At Figure 3.8.4.1, it shows example of connection TMP91C820A and some memories: Program ROM:MROM,16Mbyte, Data ROM:MROM,64Mbyte, Data RAM:SRAM,8Mbyte, 8bit bus, Display RAM:SDRAM,16Mbyte.

In case of 16bit bus memory connection, it need to shift 1bit address bus from TMP91C820A and 8bit bus case, direct connection address bus from TMP91C820A.

In that figure, Logical address and physical address are shown. And each memory allot each chip select signal, RAM:/CS0, SDRAM:/CS1, Program MROM:/CS2, Data MROM:/CS3. In case of this example, as Data MROM is 64Mbyte, this MROM connect to EA24 and EA25.

Initial condition after reset, because TMP91C820A access from CS2 area, CS2 area allots to Program ROM. It can set free setting except Program ROM.

Figure 3.8.4.2 Bank Operation S/W Example1

Secondly, it shows example of initial setting at Figure 3.8.4.2

Because /CS0 connect to RAM: 8bit bus, 8Mbyte, it need to set 8bit bus. At this example, it set 1-wait setting. In the same way /CS1 set to 16bit bus and 0-wait, /CS2 set 16bit bus and 0-wait, /CS3 set 16bit bus and 3-wait.

By CS/WAIT controller, each chip selection signal's memory size, don't set actual connect memory size, need to set that logical address size: fitting to each local area. Actual physical address is set by each area's BANK register setting.

CSEX setting of CS/WAIT controller is except above CS0～CS3's setting. This program example isn't used CSEX setting.

Finally pin condition is set. PORT60～65 set to /CS0,1,2,3,EA24,EA25 and SDRAM condition.

```

Figure 3.8.4.3 Bank Operation S/W Example2

Here shows example of data access between one BANK and other BANK. Figure 3.8.4.3is one software example. A dot line square area shows one memory and each dot line square shows /CS2's Program ROM and /CS3's Data ROM. Program start from E00000H address, firstly, write to BANK register of LOCAL3 area upper 5-bit address of access point.

In case of this example, because most upper address bit of physical address is EA25, most upper address bit of BANK register is meaningless. 4-bits of upper 5-bits address means 16-BANKs. After setting BANK5, accessing 800000～BFFFFFH address: logical local3 address, actually access to physical 1400000～1700000H address.

Figure 3.8.4.4 Bank Operation S/W Exapmle3

At Figure 3.8.4.4, it shows example of program jump.

In the same way with before example, two dot line squares show each /CS2's program ROM and /CS1's(SDCS) SDRAM. Program start from E00000H common address, firstly, write to BANK register of LOCAL2 area upper 3-bit address of jumping point.

After setting BANK1, jumping C00000～DFFFFFH address: logical local2 address, actually jump to physical 2000000～3FFFFFH address. When return to common area, it can only jump to E00000～FFFFFFH without writing to BANK register of LOCAL2 area.

By a way of setting of BANK register, the setting that BANK address and common address conflict with is possible. When two kinds or more logical addresses to show common area exist, management of BANK is confused. We recommends not to use The BANK setting, BANK address and common address conflict with.

When using LCD display data for SDRAM, we recommend setting display area to common area in SDRAM. Because of, LCD displays DMA occeur at sycronousless. If SDRAM bank is changed, you don't need to care only common area.

It is a mark paid attention to here, it needs to go by way of common area by all means when moves from a bank to a bank. In other words, it must write to BANK register only in common area and it prohibits writing the BANK registers in BANK area. If it modify the BANK register's data in BANK area, **program run-away**.

3.9 Serial Channels

TMP91C820A includes three serial I/O channels. For each channels either UART Mode (asynchronous transmission) or I/O Interface Mode (synchronous transmission) can be selected.

(Channel 2 can be selected only UART mode.)

- I/O Interface Mode
  - Mode 0: For transmitting and receiving I/O data using the synchronizing signal SCLK for extending I/O.
- UART Mode
  - Mode 1: 7-bit data
  - Mode 2: 8-bit data
  - Mode 3: 9-bit data

In Mode 1 and Mode 2 a parity bit can be added. Mode 3 has a wake-up function for making the master controller start slave controllers via a serial link (a multi-controller system).

Figure 3.9.2, 3, 4 are block diagrams for each channel.

Each Channel can be used independently.

Each channel operates in the same fashion except for the following points; hence only the operation of Channel 0 is explained below.

Table 3.9.1 Differences between Channels 0 to 2

	Channel 0	Channel 1	Channel 2
Pin Name	TXD0 (PC0) RXD0 (PC1) $\overline{\text{CTS0}}$ /SCLK0 (PC2)	TXD1 (PC3) RXD1 (PC4) $\overline{\text{CTS1}}$ /SCLK1 (PC5)	TXD2 (PB0) RXD2 (PB1)
IrDA Mode	Yes	No	No

This chapter contains the following sections:

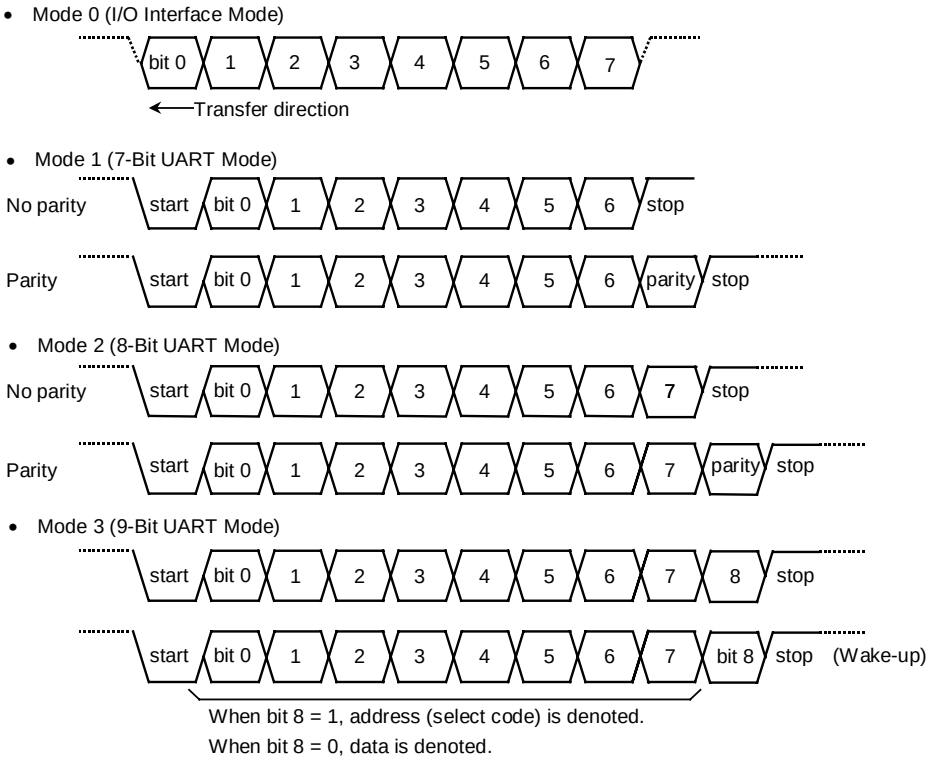

Figure 3.9.1 Data formats

3.9.1 Block diagrams

Figure 3.9.2 is a block diagram representing Serial Channel 0.

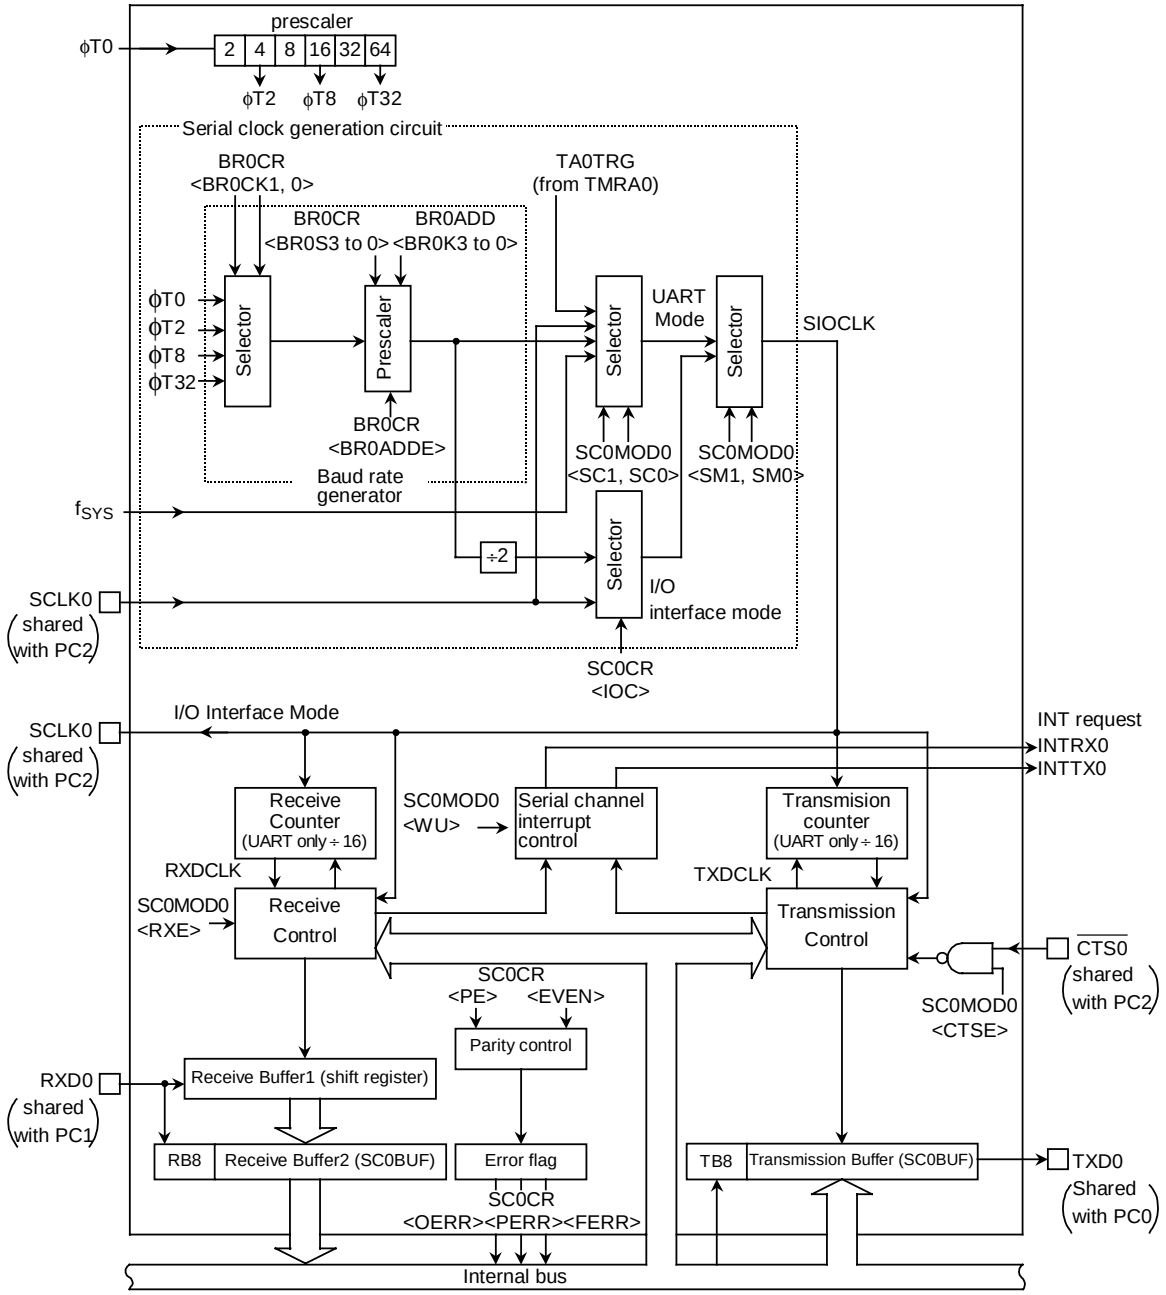

Figure 3.9.2 Block diagram of the Serial Channel 0

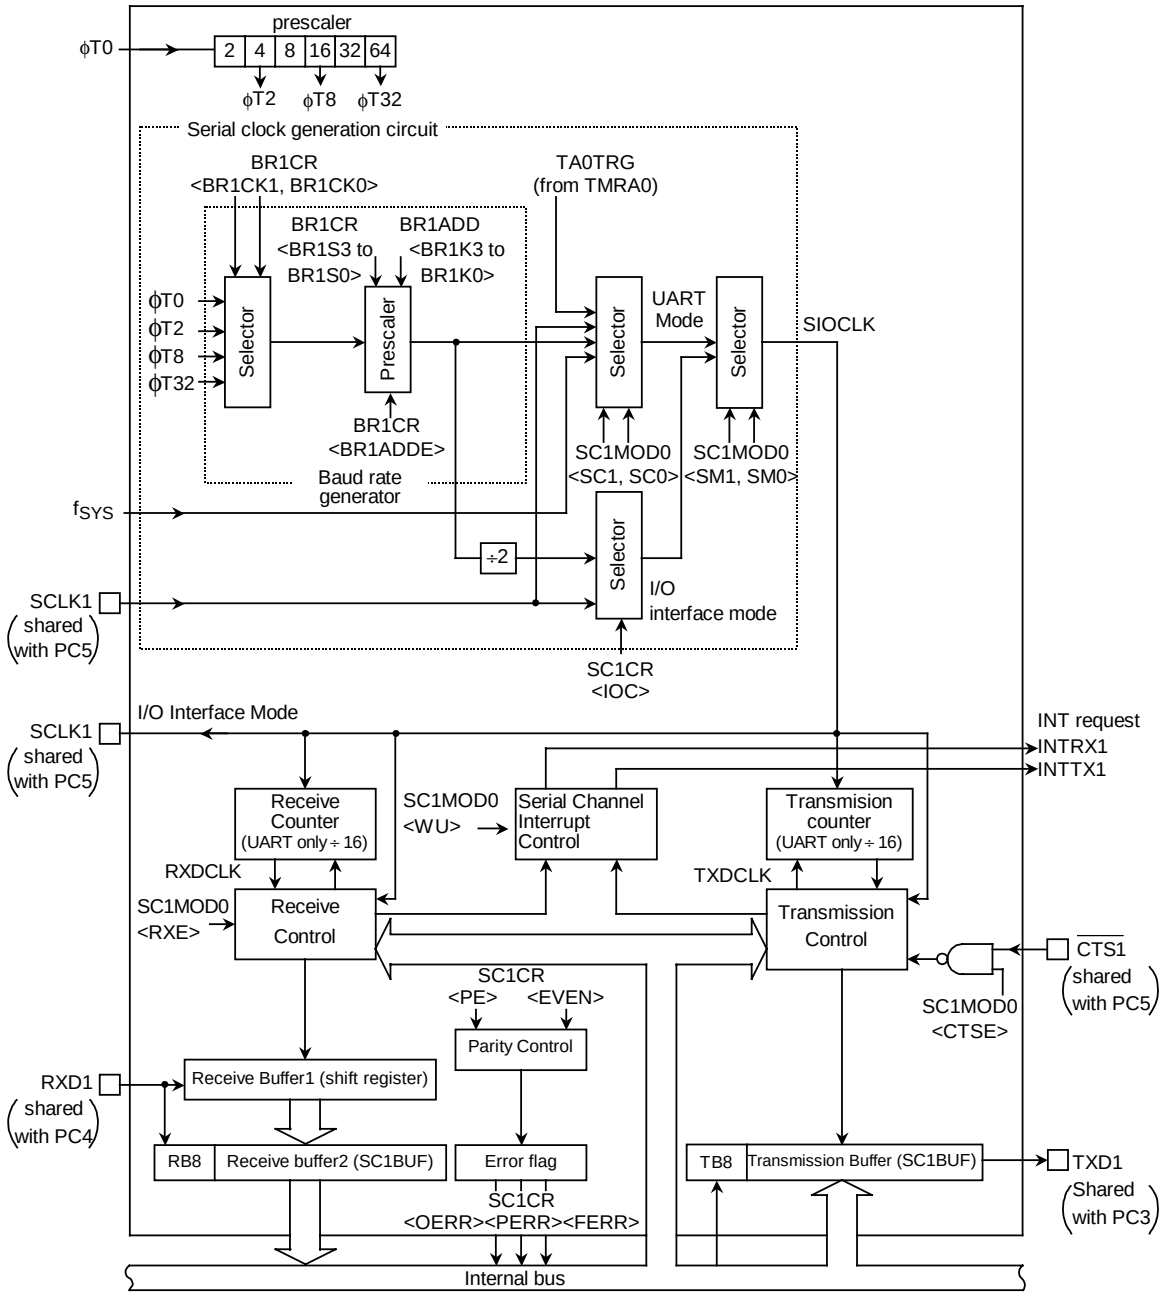

Figure 3.9.3 Block diagram of the Serial Channel 1

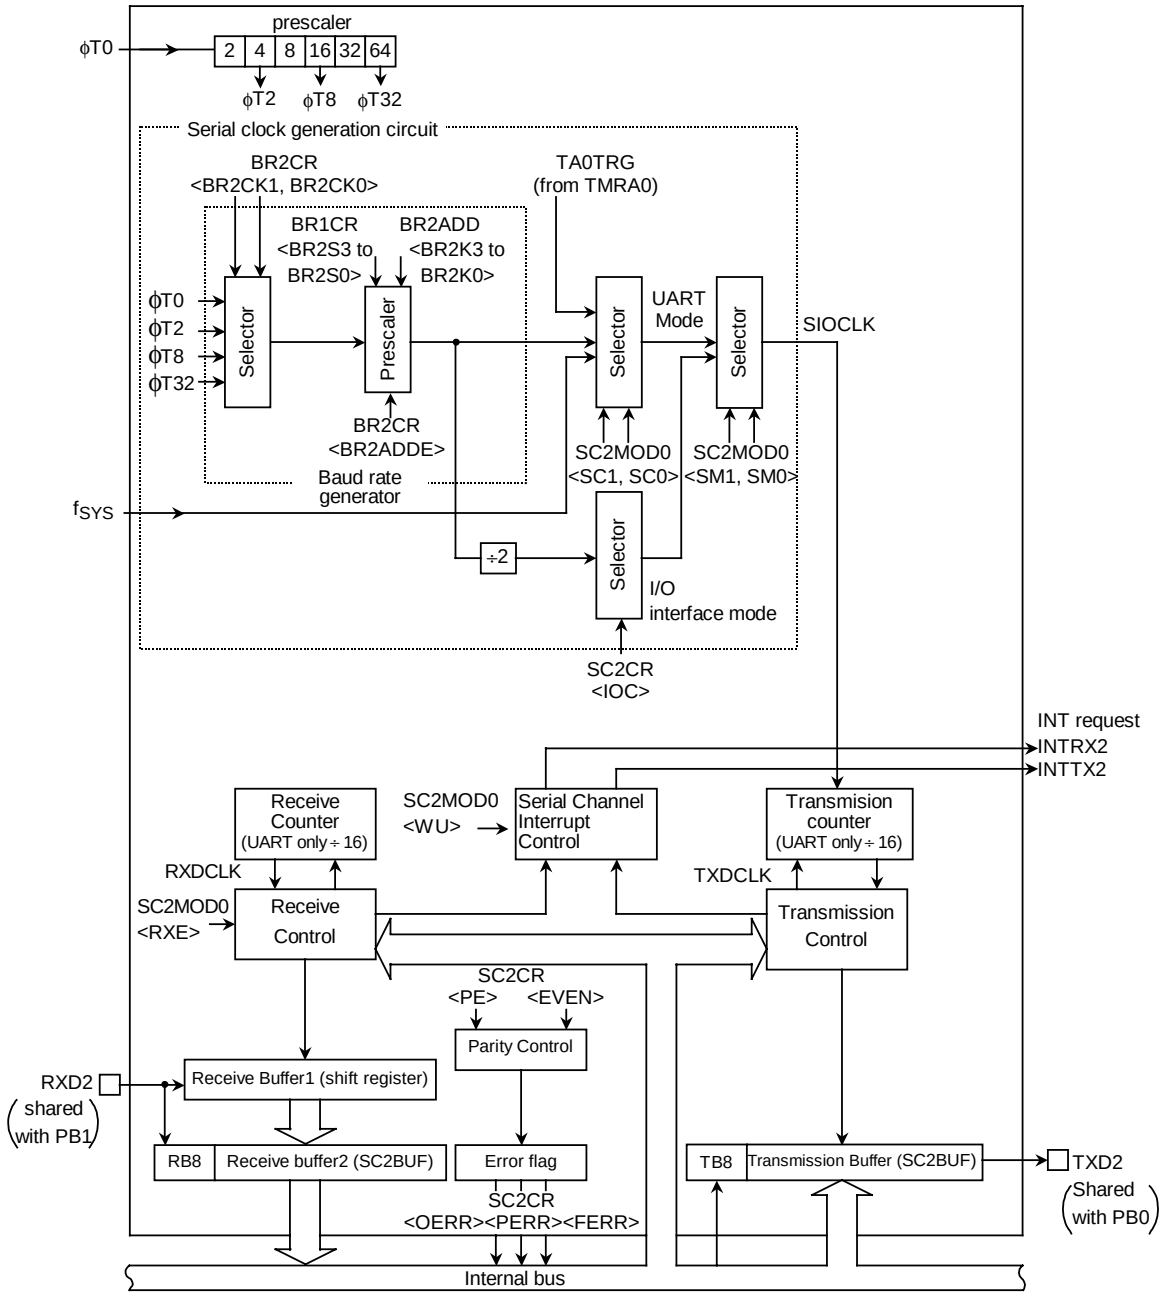

Figure 3.9.4 Block diagram of the Serial Channel 2

3.9.2 Operation of each circuit

(1) Prescaler, Prescaler clock selects

There is a 6-bit prescaler for waking serial clock. The clock selected using SYSCR<PRCK1:PRCK0> is divided by 4 and input to the prescaler as **ϕ**T0. The prescaler can be run by selecting the baud rate generator as the waking serial clock.
Table 3.9.2 shows prescaler clock resolution into the baud rate generator.

Table 3.9.2 Prescaler Clock Resolution to Baud Rate Generator

Select System Clock <SYSCK>	Select Prescaler Clock <PRCK1 to PRCK0>	Gear Value <GEAR2 to GEAR0>	Prescaler Output Clock Resolution			
			ϕT0	ϕT2	ϕT8	ϕT32
1 (fs)	00 (f_{FPH})	XXX	$fs/2^2$	$fs/2^4$	$fs/2^6$	$fs/2^8$
0 (fc)		000 (fc)	$fc/2^2$	$fc/2^4$	$fc/2^6$	$fc/2^8$
		001 ($fc/2$)	$fc/2^3$	$fc/2^5$	$fc/2^7$	$fc/2^9$
		010 ($fc/4$)	$fc/2^4$	$fc/2^6$	$fc/2^8$	$fc/2^{10}$
		011 ($fc/8$)	$fc/2^5$	$fc/2^7$	$fc/2^9$	$fc/2^{11}$
		100 ($fc/16$)	$fc/2^6$	$fc/2^8$	$fc/2^{10}$	$fc/2^{12}$
	10 ($fc/16$ clock)	XXX	–	$fc/2^8$	$fc/2^{10}$	$fc/2^{12}$

Note: X = Don't care; "–" = Cannot be used

The Baud Rate Generator selects between 4 clock inputs: ϕT0, ϕT2, ϕT8, and ϕT32 among the prescaler outputs.

(2) Baud rate generator

The baud rate generator is a circuit, which generates transmission and receiving clocks that determine the transfer rate of the serial channels.

The input clock to the baud rate generator, ϕT0, ϕT2, ϕT8 or ϕT32, is generated by the 6-bit prescaler which is shared by the timers. One of these input clocks is selected using the BR0CR<BR0CK1 to BR0CK0> field in the Baud Rate Generator Control Register.

The baud rate generator includes a frequency divider, which divides the frequency by 1 or N + (16 – K) / 16 or 16 values, determining the transfer rate.

The transfer rate is determined by the settings of BR0CR<BR0ADDE, BR0S3 to BR0S0> and BR0ADD<BR0K3 to BR0K0>.

- In UART Mode

(1) When BR0CR<BR0ADDE> = 0

The settings BR0ADD<BR0K3 to BR0K0> are ignored. The baud rate generator divides the selected prescaler clock by N, which is set in BR0CK<BR0S3 to BR0S0>. (N = 1, 2, 3 ⋯ 16)

(2) When BR0CR<BR0ADDE> = 1

The N + (16 – K) / 16 division function is enabled. The baud rate generator divides the selected prescaler clock by N + (16 – K) / 16 using the value of N set in BR0CR<BR0S3 to BR0S0> (N = 2, 3 ⋯ 15) and the value of K set in BR0ADD<BR0K3 to R0K0> (K = 1, 2, 3 ⋯ 15)

Note: If N = 1 or N = 16, the N + (16 – K) / 16 division function is disabled. Set BR0CR<BR0ADDE> to 0.

- In I/O Interface Mode

The N + (16 – K) / 16 division function is not available in I/O Interface Mode. Set BR0CR<BR0ADDE> to 0 before dividing by N.

The method for calculating the transfer rate when the baud rate generator is used is explained below.

- In UART Mode

$$\text{Baud Rate} = \frac{\text{Input clock of baud rate generator}}{\text{Frequency divider for baud rate generator}} \div 16$$

- In I/O Interface Mode

$$\text{Baud Rate} = \frac{\text{Input clock of baud rate generator}}{\text{Frequency divider for baud rate generator}} \div 2$$

- Integer divider (N divider)

For example, when the source clock frequency (fc) = 12.288 MHz, the input clock frequency = ϕT2 (fc/16), the frequency divider N (BR0CR<BR0S3 to BR0S0>) = 5, and BR0CR<BR0ADDE> = 0, the baud rate in UART Mode is as follows:

∗ Clock state
- System clock: High frequency (fc)
- Clock gear: 1 (fc)
- Prescaler clock: System clock

$$\text{Baud Rate} = \frac{fc/16}{5} \div 16$$

$$= 12.288 \times 10^6 \div 16 \div 5 \div 16 = 9600 \text{ (bps)}$$

Note: The N + (16 – K) / 16 division function is disabled and setting BR0ADD<BR0K3 to BR0K0> is invalid.

- N+(16-K)/16 divider (UART Mode only)

Accordingly, when the source clock frequency (fc) = 4.8 MHz, the input clock frequency = ϕT0 , the frequency divider N (BR0CR<BR0S3 to BR0S0>) = 7, K (BR0ADD<BR0K3 to BR0K0>) = 3, and BR0CR <BR0ADDE> = 1, the baud rate in UART Mode is as follows:

∗ Clock state
- System clock: High frequency (fc)
- Clock gear: 1 (fc)
- Prescaler clock: System clock

$$\text{Baud Rate} = \frac{fc/4}{7 + (16 - 3)/16} \div 16$$

$$= 4.8 \times 10^6 \div 4 \div (7+13/16) \div 16 = 9600 \text{ (bps)}$$

Table 3.9.3, Table 3.9.4 show examples of UART Mode transfer rates.

Additionally, the external clock input is available in the serial clock. (Serial Channels 0, 1). The method for calculating the baud rate is explained below:

- In UART Mode

  Baud rate = external clock input frequency ÷ 16

  It is necessary to satisfy (external clock input cycle)> = fc / 4

- In I/O Interface Mode

  Baud rate = external clock input frequency

  It is necessary to satisfy (external clock input cycle) >=16 / fc

Table 3.9.3 Transfer rate selection

(when baud rate generator Is used and BR0CR <BR0ADDE> = 0)

Unit (kbps)

fc [MHz]	Input Clock / Frequency Divider	φT0	φT2	φT8	φT32
9.830400	2	76.800	19.200	4.800	1.200
	4	38.400	9.600	2.400	0.600
	8	19.200	4.800	1.200	0.300
	0	9.600	2.400	0.600	0.150
12.288000	5	38.400	9.600	2.400	0.600
	A	19.200	4.800	1.200	0.300
14.745600	3	76.800	19.200	4.800	1.200
	6	38.400	9.600	2.400	0.600
	C	19.200	4.800	1.200	0.300

Note 1: Transfer rates in I/O Interface Mode are eight times faster than the values given above.

Note 2: The values in this table are calculated for when fc is selected as the system clock, the clock gear is set for fc and the system clock is the prescaler clock input.

Table 3.9.4 Selection of Transfer Rate

(When TMRA0 with input Clock φT1 is used)

Unit (kbps)

fc / TA0REG0	12.288 MHz	12 MHz	9.8304 MHz	8 MHz	6.144 MHz
1H	96		76.8	62.5	48
2H	48		38.4	31.25	24
3H	32	31.25			16
4H	24		19.2		12
5H	19.2				9.6
8H	12		9.6		6
AH	9.6				4.8
10H	6		4.8		3
14H	4.8				2.4

Method for calculating the transfer rate (when TMRA0 is used):

$$\text{Transfer rate} = \frac{\text{Clock frequency determined by SYSCR0<PRCK1, PRCK0>}}{\text{TA0REG} \times \underline{8} \times 16}$$

(when TMRA0 (input clock φT1) is used)

Note 1: The TMRA0 match detect signal cannot be used as the transfer clock in I/O Interface Mode.

Note 2: The values in this table are calculated for when fc is selected as the system clock, the clock gear is set for fc and the system clock is the prescaler clock input.

(3) Serial clock generation circuit

This circuit generates the basic clock for transmitting and receiving data.

- In I/O Interface Mode

In SCLK Output Mode with the setting SC0CR<IOC> = 0, the basic clock is generated by dividing the output of the baud rate generator by 2, as described previously.
In SCLK Input Mode with the setting SC0CR<IOC> = 1, the rising edge or falling edge will be detected according to the setting of the SC0CR<SCLKS> register to generate the basic clock.

- In UART Mode

The SC0MOD0 <SC1, SC0> setting determines whether the baud rate generator clock, the internal system clock fSYS, the match detect signal from timer TMRA0 or the external clock (SCLK0) is used to generate the basic clock SIOCLK.

(4) Receiving counter

The receiving counter is a 4-bit binary counter used in UART Mode, which counts up the pulses of the SIOCLK clock. It takes 16 SIOCLK pulses to receive 1 bit of data; each data bit is sampled three times – on the 7th, 8th and 9th clock cycles.
The value of the data bit is determined from these three samples using the majority rule.
For example, if the data bit is sampled respectively as 1, 0 and 1 on 7th, 8th and 9th clock cycles, the received data bit is taken to be 1. A data bit sampled as 0, 0 and 1 is taken to be 0.

(5) Receiving control

- In I/O Interface Mode

In SCLK Output Mode with the setting SC0CR<IOC> = 0, the RXD0 signal is sampled on the rising edge of the shift clock which is output on the SCLK0 pin.
In SCLK Input Mode with the setting SC0CR<IOC> = 1, the RXD0 signal is sampled on the rising or falling edge of the SCLK0 input, according to the SC0CR<SCLKS> setting.

- In UART Mode

The receiving control block has a circuit, which detects a start bit using the majority rule. Received bits are sampled three times; when two or more out of three samples are 0, the bit is recognized as the start bit and the receiving operation commences.
The values of the data bits that are received are also determined using the majority rule.

(6) The Receiving Buffers

To prevent Overrun errors, the Receiving Buffers are arranged in a double-buffer structure. Received data is stored one bit at a time in Receiving Buffer 1 (which is a shift register). When 7 or 8 bits of data have been stored in Receiving Buffer 1, the stored data is transferred to Receiving Buffer 2 (SC0BUF); this causes an INTRX0 interrupt to be generated. The CPU only reads Receiving Buffer 2 (SC0BUF). Even before the CPU reads receiving Buffer 2 (SC0BUF), the received data can be stored in Receiving Buffer 1. However, unless Receiving Buffer 2 (SC0BUF) is read before all bits of the next data are received by Receiving Buffer 1, an overrun error occurs. If an Overrun error occurs, the contents of Receiving Buffer 1 will be lost, although the contents of Receiving Buffer 2 and SC0CR<RB8> will be preserved.

SC0CR<RB8> is used to store either the parity bit – added in 8-Bit UART Mode – or the most significant bit (MSB) – in 9-Bit UART Mode.

In 9-Bit UART Mode the wake-up function for the slave controller is enabled by setting SC0MOD0<WU> to 1; in this mode INTRX0 interrupts occur only when the value of SC0CR<RB8> is 1.

(7) Transmission counter

The transmission counter is a 4-bit binary counter which is used in UART Mode and which, like the receiving counter, counts the SIOCLK clock pulses; a TXDCLK pulse is generated every 16 SIOCLK clock pulses.

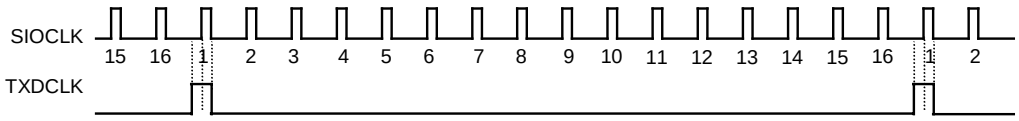

Figure 3.9.5 Generation of the transmission clock

(8) Transmission controller

- In I/O Interface Mode

In SCLK Output Mode with the setting SC0CR<IOC> = 0, the data in the Transmission Buffer is output one bit at a time to the TXD0 pin on the rising edge of the shift clock which is output on the SCLK0 pin.

In SCLK Input Mode with the setting SC0CR<IOC> = 1, the data in the Transmission Buffer is output one bit at a time on the TXD0 pin on the rising or falling edge of the SCLK0 input, according to the SC0CR<SCLKS> setting.

- In UART Mode

When transmission data sent from the CPU is written to the Transmission Buffer, transmission starts on the rising edge of the next TXDCLK, generating a transmission shift clock TXDSFT.

Handshake function

Serial Channels 0, 1 each has a CTS pin. Use of this pin allows data can be sent in units of one frame; thus, Overrun errors can be avoided. The handshake functions is enabled or disabled by the SC0MOD <CTSE> setting.

When the CTS0 pin foes High on completion of the current data send, data transmission is halted until the CTS0 pin foes Low again. However, the INTTX0 Interrupt is generated, it requests the next data send to the CPU. The next data is written in the Transmission Buffer and data sending is halted. Though there is no RTS pin, a handshake function can be easily configured by setting any port assigned to be the RTS function. The RTS should be output "High" to request send data halt after data receive is completed by software in the RXD interrupt routine.

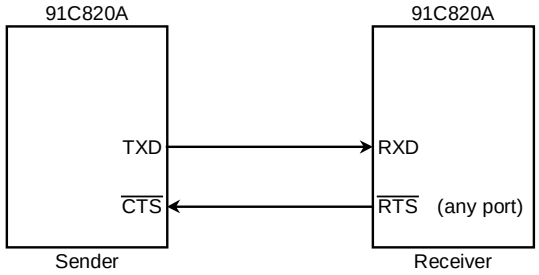

Figure 3.9.6 Handshake function

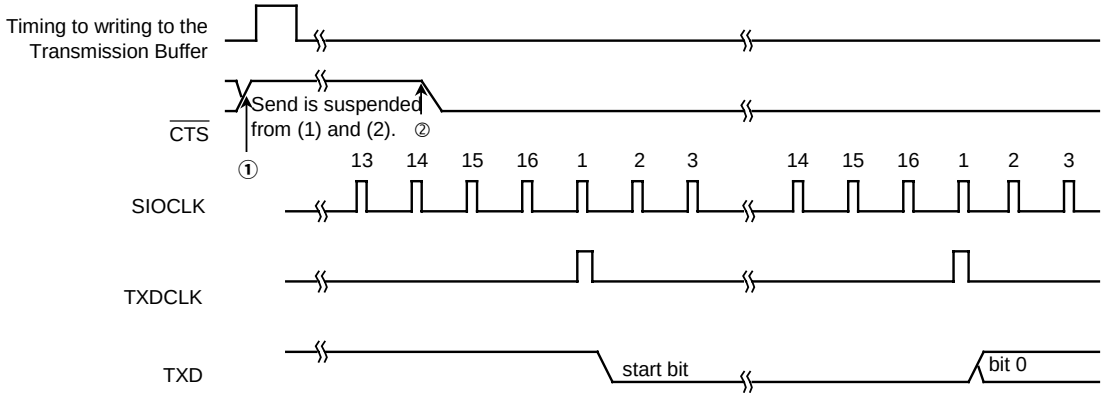

Note 1: If the CTS signal goes High during transmission, no more data will be sent after completion of the current transmission.

Note 2: Transmission starts on the first falling edge of the TXDCLK clock after the CTS signal has fallen.

Figure 3.9.7 CTS (Clear to send) Timing

(9) Transmission Buffer

The Transmission Buffer (SC0BUF) shifts out and sends the transmission data written from the CPU form the least significant bit (LSB) in order. When all the bits are shifted out, the Transmission Buffer becomes empty and generates an INTTX0 interrupt.

(10) Parity control circuit

When SC0CR<PE> in the Serial Channel Control Register is set to 1, it is possible to transmit and receive data with parity. However, parity can be added only in 7-Bit UART Mode or 8-Bit UART Mode. The SC0CR<EVEN> field in the Serial Channel Control Register allows either even or odd parity to be selected.

In the case of transmission, parity is automatically generated when data is written to the Transmission Buffer SC0BUF. The data is transmitted after the parity bit has been stored in SC0BUF<TB7> in 7-Bit UART Mode or in SC0MOD0<TB8> in 8-Bit UART Mode. SC0CR<PE> and SC0CR<EVEN> must be set before the transmission data is written to the Transmission Buffer.

In the case of receiving, data is shifted into Receiving Buffer 1, and the parity is added after the data has been transferred to Receiving Buffer 2 (SC0BUF), and then compared with SC0BUF<RB7> in 7-Bit UART Mode or with SC0CR<RB8> in 8-Bit UART Mode. If they are not equal, a Parity error is generated and the SC0CR<PERR> flag is set.

(11) Error flags

Three error flags are provided to increase the reliability of data reception.

1. Overrun error <OERR>

   If all the bits of the next data item have been received in Receiving Buffer 1 while valid data still remains stored in Receiving Buffer 2 (SC0BUF), an Overrun error is generated.

2. Parity error <PERR>

   The parity generated for the data shifted into Receiving Buffer 2 (SC0BUF) is compared with the parity bit received via the RXD pin. If they are not equal, a Parity error is generated.

3. Framing error <FERR>

   The stop bit for the received data is sampled three times around the center. If the majority of the samples are 0, a Framing error is generated.

(12) Timing generation

① In UART Mode

Receiving

Mode	9-Bit (Note)	8-Bit + Parity (Note)	8-Bit, 7-Bit + Parity, 7-Bit
Interrupt timing	Center of last bit (bit 8)	Center of last bit (parity bit)	Center of stop bit
Framing error timing	Center of stop bit	Center of stop bit	Center of stop bit
Parity error timing	—	Center of last bit (parity bit)	Center of last bit (parity bit)
Overrun error timing	Center of last bit (bit 8)	Center of last bit (parity bit)	Center of stop bit

Note: In 9-Bit and 8-Bit + Parity Modes, interrupts coincide with the ninth bit pulse.
Thus, when servicing the interrupt, it is necessary to wait for a 1-bit period (to allow the stop bit to be transferred) to allow checking for a framing error.

Transmitting

Mode	9-Bit	8-Bit + Parity	8-Bit, 7-Bit + Parity, 7-Bit
Interrupt timing	Just before stop bit is transmitted	Just before stop bit is transmitted	Just before stop bit is transmitted

② I/O interface

Transmission Interrupt timing	SCLK Output Mode	Immediately after rise of last SCLK signal. (See figure 3.9 19.)
	SCLK Input Mode	Immediately after rise of last SCLK signal Rising Mode, or immediately after fall in Falling Mode. (See figure 3.9 20.)
Receiving Interrupt timing	SCLK Output Mode	Timing used to transfer received to data Receive Buffer 2 (SC0BUF) (i.e. immediately after last SCLK). (See figure 3.9 21.)
	SCLK Input Mode	Timing used to transfer received data to Receive Buffer 2 (SC0BUF) (i.e. immediately after last SCLK). (See figure 3.9 22.)

Figure 3.9.22 Serial Mode Control Register 1 (channel 2, SC2MOD1)

3.9.4 Operation in each mode

(1) Mode 0 (I/O Interface Mode)

This mode allows an increase in the number of I/O pins available for transmitting data to or receiving data from an external shift register.

This mode includes the SCLK output mode to output synchronous clock SCLK and SCLK input mode to input external synchronous clock SCLK.

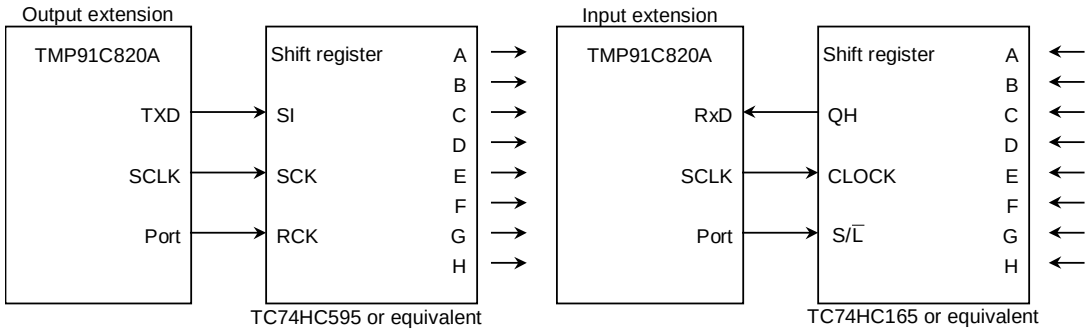

Figure 3.9.23 SCLK Output Mode connection example

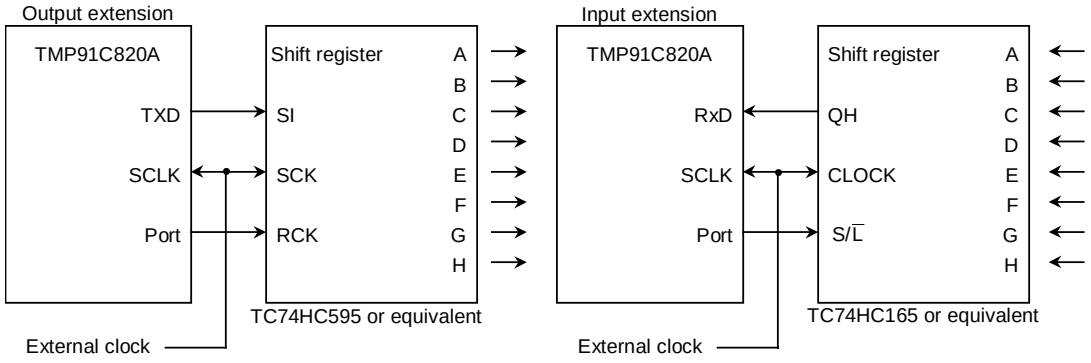

Figure 3.9.24 Example of SCLK Input Mode Connection

① Transmission

In SCLK output mode 8-bit data and a synchronous clock are output on the TXD0 and SCLK0 pins respectively each time the CPU writes the data to the Transmission Buffer. When all data is output, INTES0 <ITX0C> will be set to generate the INTTX0 interrupt.

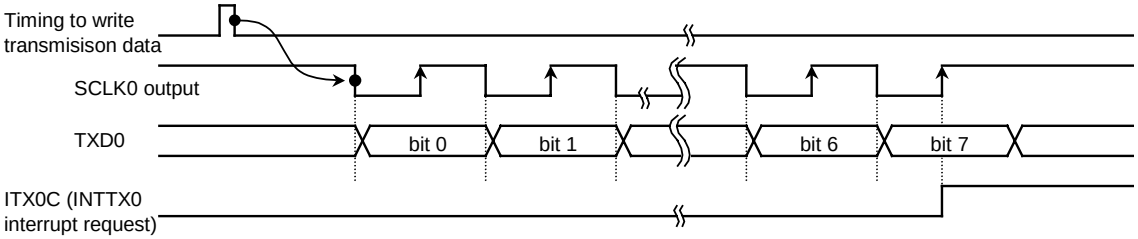

Figure 3.9.25 Transmitting Operation in I/O Interface Mode (SCLK0 Output Mode)
(Channel 0)

In SCLK Input Mode, 8-bit data is output on the TXD0 pin when the SCLK0 input becomes active after the data has been written to the Transmission Buffer by the CPU.

When all data is output, INTES0 <ITX0C> will be set to generate INTTX0 interrupt.

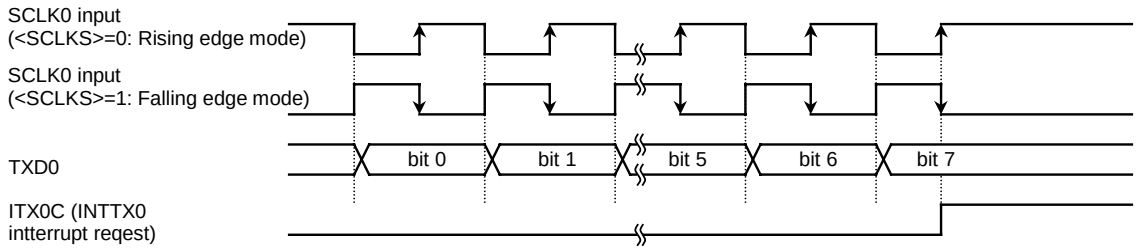

Figure 3.9.26 Transmitting Operation in I/O Interface Mode (SCLK0 Input Mode)
(channel 0)

② Receiving

In SCLK output mode, the synchronous clock is outputted from SCLK0 pin and the data is shifted to Receiving Buffer 1. This starts when the Receive Interrupt flag INTES0<IRX0C> is cleared by reading the received data. When 8-bit data are received, the data will be transferred to Receiving Buffer 2 (SC0BUF according to the timing shown below) and INTES0<IRX0C> will be set to generate INTRX0 interrupt.
The outputting for the first SCLK0 starts by setting SC0MOD0<RXE>to 1.

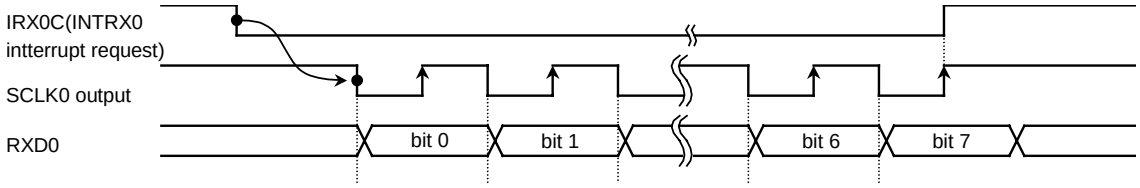

Figure 3.9.27 Receiving operation in I/O Interface Mode (SCLK0 Output Mode)
(Channel 0)

In SCLK input mode, the data is shifted to Receiving Buffer 1 when the SCLK input becomes active after the receive Interrupt flag INTES0 <IRX0C> is cleared by reading the received data. When 8-bit data is received, the data will be shifted to Receiving Buffer 2 (SC0BUF according to the timing shown below) and INTES0 <IRX0C> will be set again to be generate INTRX0 interrupt.

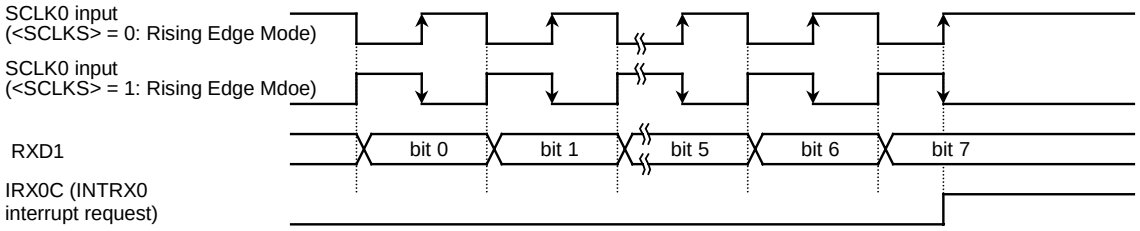

Figure 3.9.28 Receiving Operation in I/O interface Mode (SCLK0 Input Mode)
(Channel 0)

Note: The system must be put in the Receive Enable state (SCMOD0<RXE> = 1) before data can be received.

③ Transmission and Receiving (Full Duplex Mode)

When the full duplex mode is used, set the level of Receive Interrupt to "0" and set enable the level of Transmit interrupt. In the transmit interrupt program, read the receiving buffer before setting the next transmit data.
The example is following.

Example: Channel 0, SCLK output
Baud rate = 9600 bps
fc = 14.7456 MHz

System clock : High frequency (fc)
Clock gear : 1 (fc)
Prescaler clock : f_{FPH}

Main routine

	7	6	5	4	3	2	1	0	
									Set the INTTX0 level to 1.
INTES0	0	0	0	1	0	0	0	0	Set the INTRX0 level to 0.
PCCR	–	–	–	–	–	1	0	1	Set PC0, PC1 and PC2 to function as the TXD0, RXD0 and SCLK0 pins respectively.
PCFC	–	–	–	–	–	1	–	1	
SC0MOD0	0	0	0	0	0	0	0	0	Select I/O Interface Mode.
SC0MOD1	1	1	0	0	0	0	0	0	Select Full Duplex Mode.
SC0CR	0	0	0	0	0	0	0	0	Sclk_out, transmit on negative edge, receive on positive edge
BR0CR	0	0	1	1	0	0	1	1	Baud rate = 9600 bps
SC0MOD0	0	0	1	0	0	0	0	0	Enable receiving
SC0BUF	*	*	*	*	*	*	*	*	Set the transmit data and start.

INTTX0 interrupt routine

Acc SC0BUF									Read the receiving buffer.
SC0BUF	*	*	*	*	*	*	*	*	Set the next transmit data.

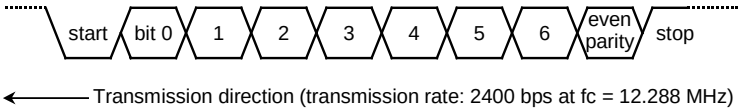
Note: X = Don't care; "–" = No change

(2) Mode 1 (7-bit UART Mode)

7-Bit UART Mode is selected by setting the Serial Channel Mode Register SC0MOD0<SM1, SM0> field to 01.

In this mode a parity bit can be added. Use of a parity bit is enabled or disabled by the setting of the Serial Channel Control Register SC0CR<PE> bit; whether even parity or odd parity will be used is determined by the SC0CR<EVEN> setting when SC0CR<PE> is set to 1 (enabled).

Setting example: When transmitting data of the following format, the control registers should be set as described below. This explanation applies to Channel 0.



* Clock state
System clock: High frequency (fc)
Clock gear: 1 (fc)
Prescaler clock: System clock

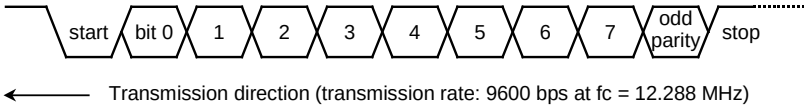
		7	6	5	4	3	2	1	0	
P9CR	←	–	–	–	–	–	–	–	1	} Set PC0 to function as the TXD0 pin.
P9FC	←	–	–	–	–	–	–	–	1	
SC0MOD	←	X	0	–	X	0	1	0	1	Select 7-Bit UART Mode.
SC0CR	←	X	1	1	X	X	X	0	0	Add even parity.
BR0CR	←	0	0	1	0	0	1	0	1	Set the transfer rate to 2400 bps.
INTES0	←	1	1	0	0	–	–	–	–	Enable the INTTX0 interrupt and set it to Interrupt Level 4.
SC0BUF	←	*	*	*	*	*	*	*	*	Set data for transmission.

Note: X = Don't care; "–" = No change

(3) Mode 2 (8-Bit UART Mode)

8-Bit UART Mode is selected by setting SC0MOD0<SM1, SM0> to 10. In this mode a parity bit can be added (use of a parity bit is enabled or disabled by the setting of SC0CR<PE>); whether even parity or odd parity will be used is determined by the SC0CR<EVEN> setting when SC0CR<PE> is set to 1 (enabled).

Setting example: When receiving data of the following format, the control registers should be set as described below.



* Clock state
System clock: High frequency (fc)
Clock gear: 1 (fc)
Prescaler clock: System clock

Main settings

		7	6	5	4	3	2	1	0	
P9CR	←	–	–	–	–	–	–	0	–	Set PC1 to function as the TXD0 pin.
SC0MOD	←	–	0	1	X	1	0	0	1	Enable receiving in 8-Bit UART Mode.
SC0CR	←	X	0	1	X	X	X	0	0	Add even parity.
BR0CR	←	0	0	0	1	0	1	0	1	Set the transfer rate to 9600 bps.
INTES0	←	–	–	–	–	1	1	0	0	Enable the INTTX0 interrupt and *set it to Interrupt Level 4*.

Interrupt processing

Acc	← SC0CR AND 00011100	Check for errors.
if Acc	≠ 0 then ERROR	
Acc	← SC0BUF	Read the received data.

Note: X = Don't care; "–" = No change

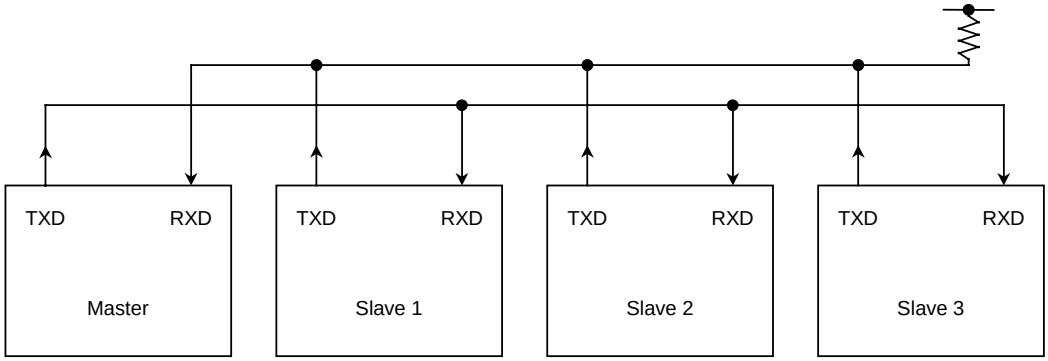
(4) Mode 3 (9-Bit UART Mode)

9-Bit UART Mode is selected by setting SC0MOD0<SM1, SM0> to 11. In this mode parity bit cannot be added.

In the case of transmission the MSB (9th bit) is written to SC0MOD0<TB8>. In the case of receiving it is stored in SC0CR<RB8>. When the buffer is written and read, the MSB is read or written first, before the rest of the SC0BUF data.

Wake-up function

In 9-Bit UART Mode, the wake-up function for slave controllers is enabled by setting SC0MOD0<WU> to 1. The interrupt INTRX0 occurs only when<RB8> = 1.



Note: The TXD pin of each slave controller must be in Open-Drain Output Mode.

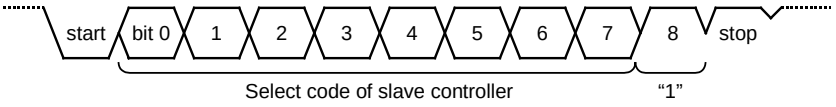
Figure 3.9.29 Serial Link using Wake-up function

Protocol

① Select 9-Bit UART Mode on the master and slave controllers.

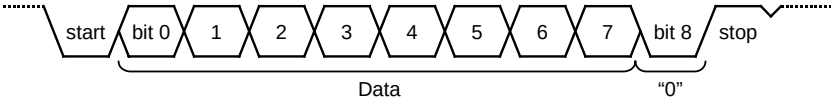
② Set the SC0MOD0<WU> bit on each slave controller to 1 to enable data receiving.

③ The master controller transmits one-frame data including the 8-bit select code for the slave controllers. The MSB (bit 8)<TB8> is set to 1.



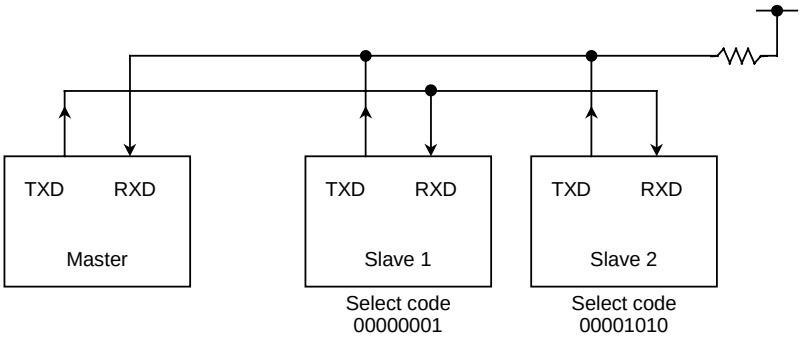
④ Each slave controller receives the above frame. Each controller checks the above select code against its own select code. The controller whose code matches clears its WU bit to 0.

⑤ The master controller transmits data to the specified slave controller whose SC0MOD<WU> bit is cleared to 0. The MSB (bit 8) <TB8> is cleared to 0.



⑥ The other slave controllers (whose <WU> bits remain at 1) ignore the received data because their MSB (bit 8 or <RB8>) are set to 0, disabling INTRX0 interrupts.
The slave controller (WU bit = 0) can transmit data to the master controller, and it is possible to indicate the end of data receiving to the master controller by this transmission.

Setting example: To link two slave controllers serially with the master controller using the internal clock f_{SYS} as the transfer clock.



Since Serial Channels 0 and 1 operate in exactly the same way, Channel 0 only is used for the purposes of this explanation.

- Setting the master controller

Main

INTRX0 interrupt

Acc ← SC0BUF
if Acc = select code
Then SC0MOD0 ← - - - 0 - - - - Clear <WU> to 0.

3.9.5 Support for IrDA

SIO0 includes support for the IrDA 1.0 infrared data communication specification. Figure 3.9.30 shows the block diagram.

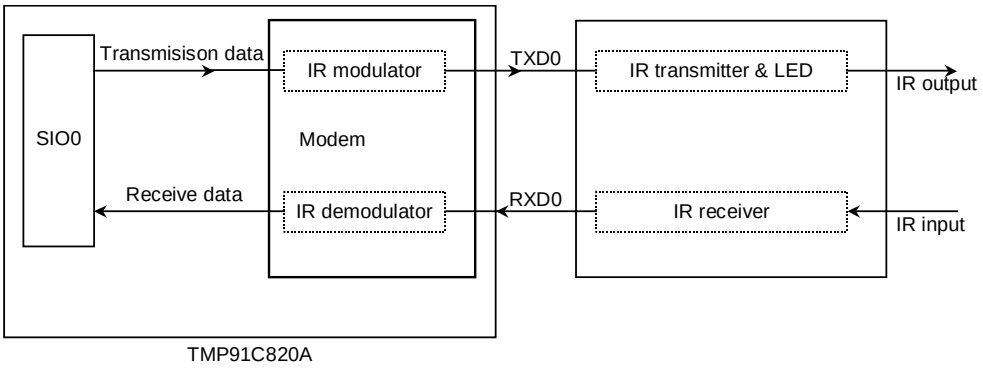

Figure 3.9.30 Block Diagram

(1) Modulation of the transmission data

When the transmit data is 0, the modem outputs 1 to TXD0 pin with either 3/16 or 1/16 times for width of baud-rate. The pulse width is selected by the SIRCR<PLSEL>. When the transmit data is 1, the modem outputs 0.

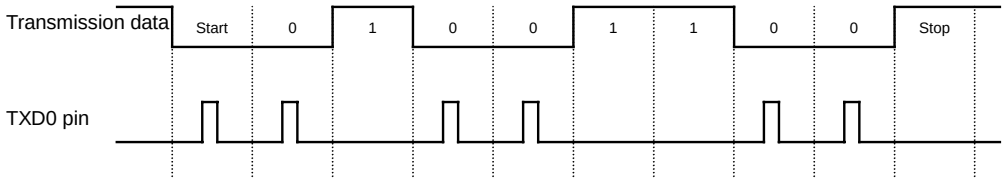

Figure 3.9.31 Transmission example

(2) Modulation of the receive data

When the receive data is the effective width of pulse “1”, the modem outputs “0” to SIO0. Otherwise the modem outputs “1” to SIO0. The effective pulse width is selected by SIRCR<SIRWD3 to SIRWD0>.

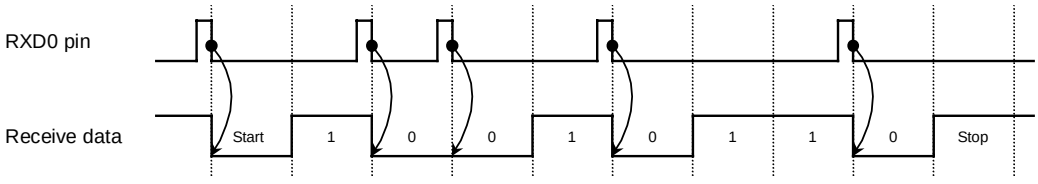

Figure 3.9.32 Receiving example

(3) Data format

The data format is fixed as follows:

- Data length: 8-bit
- Parity bits: none
- Stop bits: 1

(4) SFR

Figure 3.9.33 shows the control register SIRCR. Set the data SIRCR during SIO0 is stopping. The following example describes how to set this register:

1) SIO setting ; Set the SIO to UART Mode.
↓
2) LD (SIRCR), 07H ; Set the receive data pulse width to 16×.
3) LD (SIRCR), 37H ; TXEN, RXEN Enable the Transmission and receiving.
↓
4) Start transmission and receiving for SIO0 ; The modem operates as follows:
• SIO0 starts transmitting.
• IR receiver starts receiving.

(5) Notes

The IrDA 1.0 specification is defined in Table 3.9.5.

Table 3.9.5 Baud rate and pulse width specifications

Baud Rate	Modulation	Rate Tolerance (% of rate)	Pulse Width (minimum)	Pulse Width (typical)	Pulse width (maximum)
2.4 kbps	RZI	±0.87	1.41 µs	78.13 µs	88.55 µs
9.6 kbps	RZI	±0.87	1.41 µs	19.53 µs	22.13 µs
19.2 kbps	RZI	±0.87	1.41 µs	9.77 µs	11.07 µs
38.4 kbps	RZI	±0.87	1.41 µs	4.88 µs	5.96 µs
57.6 kbps	RZI	±0.87	1.41 µs	3.26 µs	4.34 µs
115.2 kbps	RZI	±0.87	1.41 µs	1.63 µs	2.23 µs

The pulse width is defined either baud rate TX 3/16 or 1.6 µs (1.6 µs is equal to 3/16 pulse width when baud rate is 115.2 kbps).
The TMP91C820A has the function selects the pulse width of Transmission either 3/16 or 1/16. But 1/16 pulse width can be selected when the baud rate is equal or less than 38.4 kbps.
As the same reason, + (16-k)/16 division function in the baud rate generator of SIO0 can not be used to generate 115.2 kbps baud rate.
Also when the 38.4 kbps and 1/16 pulse width, + (16-k)/16 division function can not be used.

Table 3.9.6 Baud rate and pulse width for (16 – k) / 16 division function

Pulse Width	Baud Rate					
	115.2 kbps	57.6 kbps	38.4 kbps	19.2 kbps	9.6 kbps	2.4 kbps

Figure 3.9.33 IrDA Control Register

3.10 Serial Bus Interface (SBI)

The TMP91C820A has a 1-channel serial bus interface which employs a clocked-synchronous 8-bit SIO mode and an I^2C bus mode.

The serial bus interface is connected to an external device through P71 (SDA) and P72 (SCL) in the I^2C bus mode; and through P70 (SCK), P71 (SO), P72 (SI) in the clocked-synchronous 8-bit SIO mode.
Each pin is specified as follows.

	P7ODE <ODE72, ODE71>	P7CR <P72C, P71C, P70C>	P7FC <P72F, P71F, P70F>
I^2C Bus Mode	11	11X	11X
Clocked Synchronous 8-Bit SIO Mode	XX	011 010	111

X: Don't care

3.10.1 Configuration

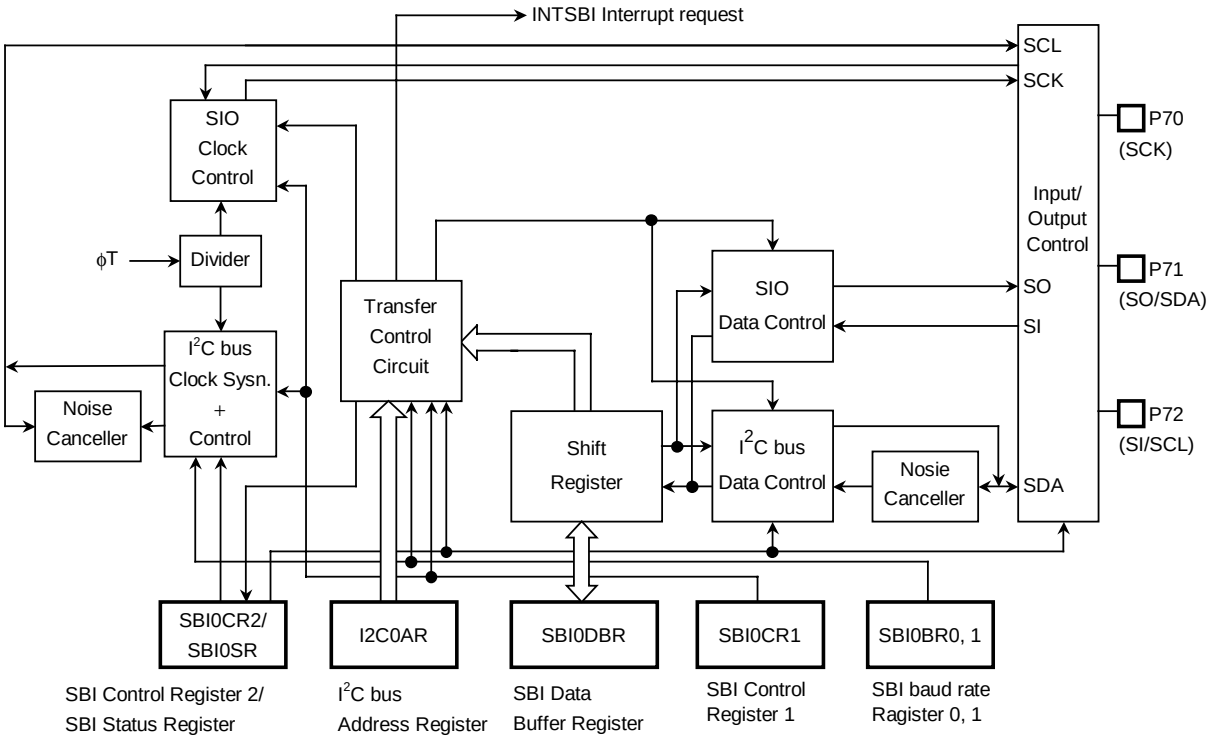

Figure 3.10.1 Serial Bus Interface (SBI)

3.10.2 Serial Bus Interface (SBI) Control

The following registers are used to control the serial bus interface and monitor the operation status.

- Serial bus interface control register 1 (SBI0CR1)
- Serial bus interface control register 2 (SBI0CR2)
- Serial bus interface data buffer register (SBI0DBR)
- I^2C bus address register (I2C0AR)
- Serial bus interface status register (SBI0SR)
- Serial bus interface baud rate register 0 (SBI0BR0)
- Serial bus interface baud rate register 1 (SBI0BR1)

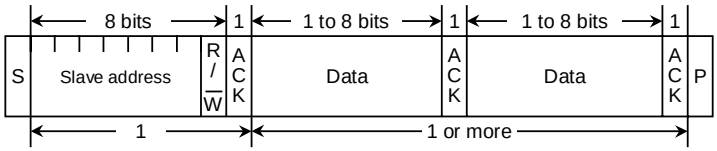
The above registers differ depending on a mode to be used.

Refer to Section "3.10.4 I2C bus Mode Control" and "3.10.7 Clocked-synchronous 8-bit SIO Mode Control".

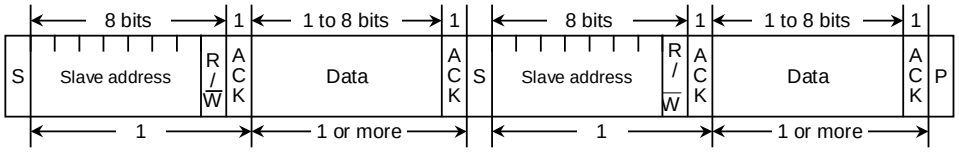
3.10.3 The Data Formats in the I^2C Bus Mode

The data formats in the I^2C bus mode is shown below.

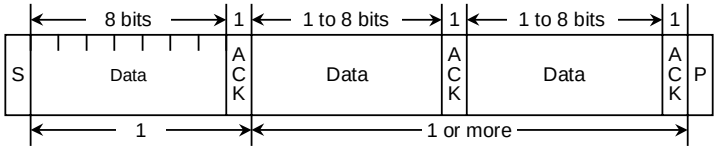
(a) Addressing format



(b) Addressing format (with restart)



(c) Free data format (data transferred from master device to slave device)



Note: S: Start condition

R / $\overline{W}$: Direction bit

ACK: Acknowledge bit

P: Stop condition

Figure 3.10.2 Data format in the I^2C Bus Mode

3.10.4 I^2C Bus Mode Control

Figure 3.10.6 Registers for the I^2C Bus Mode

3.10.5 Control in I^2C Bus Mode

(1) Acknowledge Mode Specification

Set the SBI0CR1<ACK> to 1 for operation in the acknowledge mode. The TMP91C820A generates an additional clock pulse for an Acknowledge signal when operating in Master Mode, it counts a clock pulse for an acknowledge signal when operating in the slave mode. In the transmitter mode during the clock pulse cycle, the SDA pin is released in order to receive the acknowledge signal from the receiver. In the receiver mode during the clock pulse cycle, the SDA pin is set to the Low in order to generate the acknowledge signal.

Clear the <ACK> to 0 for operation in the Non-Acknowledge Mode, The TMP91C820A does not generate a clock pulse for the Acknowledge signal when operating in the Master Mode, and it does not count a clock pulse as an Acknowledge signal when operating in Slave Mode.

(2) Number of transfer bits

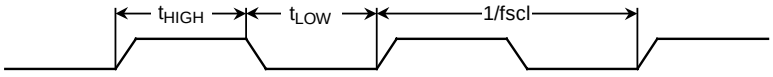
The SBI0CR1<BC2 to BC0> is used to select a number of bits for next transmitting and receiving data.

Since the <BC2 to BC0> is cleared to 000 as a start condition, a slave address and direction bit transmission are executed in 8 bits. Other than these, the <BC2 to 0> retains a specified value.

(3) Serial clock

① Clock source

The SBI0CR1 <SCK2 to SCK0> is used to select a maximum transfer frequency outputted on the SCL pin in Master Mode.



$t_{LOW} = 2^n/f_{SBI}$

$t_{HIGH} = 2^n/f_{SBI} + 8/f_{SBI}$

$fscl = 1/(t_{Low} + t_{HIGH})$

$= \frac{f_{SBI}}{2^n + 8}$

SBI0CR1 <SCK2~SCK0>	n
000	5
001	6
010	7
011	8
100	9
101	10
110	11

Note: It's prohibit to use to fc/16 prescaler clock when SBI block use.
(I2C bus & clock synchronous)

Figure 3.10.7 Clock Source

② Clock synchronization

In the I^2C bus mode, in order to wired-AND a bus, a master device which pulls down a clock line to low-level, in the first place, invalidate a clock pulse of another master device which generates a high-level clock pulse. The master device with a high-level clock pulse needs to detect the situation and implement the following procedure.

The TMP91C820A has a clock synchronization function for normal data transfer even when more than one master exists on the bus.

The example explains the clock synchronization procedures when two masters simultaneously exist on a bus.

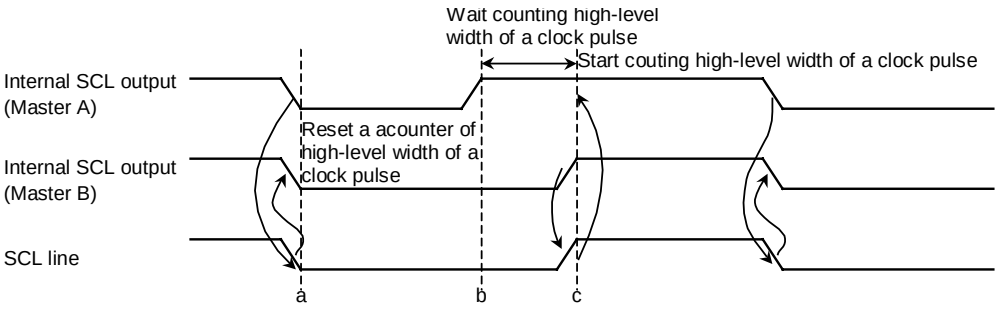


Figure 3.10.8 Clock Synchronization

As Master A pulls down the internal SCL output to the Low level at point “a”, the SCL line of the bus becomes the Low-level. After detecting this situation, Master B resets a counter of High-level width of an own clock pulse and sets the internal SCL output to the Low-level.

Master A finishes counting Low-level width of an own clock pulse at point “b” and sets the internal SCL output to the High-level. Since Master B holds the SCL line of the bus at the Low-level, Master A wait for counting high-level width of an own clock pulse. After Master B finishes counting low-level width of an own clock pulse at point “c” and Master A detects the SCL line of the bus at the High-level, and starts counting High-level of an own clock pulse. The clock pulse on the bus is determined by the master device with the shortest High-level width and the master device with the longest Low-level width from among those master devices connected to the bus.

(4) Slave address and address recognition mode specification

When the TMP91C820A is used as a slave device, set the slave address <SA6 to SA0> and <ALS> to the I2C0AR. Clear the <ALS> to “0” for the address recognition mode.

(5) Master/Slave selection

Set the SBI0CR2<MST> to “1” for operating the TMP91C820A as a master device. Clear the SBI0CR2<MST> to “0” for operation as a slave device. The <MST> is cleared to “0” by the hardware after a stop condition on the bus is detected or arbitration is lost.

(6) Transmitter/Receiver selection

Set the SBI0CR2<TRX> to "1" for operating the TMP91C820A as a transmitter. Clear the <TRX> to "0" for operation as a receiver. When data with an addressing format is transferred in Slave Mode, when a slave address with the same value that an I2C0AR or a GENERAL CALL is received (all 8-bit data are "0" after a start condition), the <TRX> is set to "1" by the hardware if the direction bit ($R / \overline{W}$) sent from the master device is "1", and is cleared to "0" by the hardware if the bit is "0". In the Master Mode, after an Acknowledge signal is returned from the slave device, the <TRX> is cleared to "0" by the hardware if a transmitted direction bit is "1", and is set to "1" by the hardware if it is "0". When an Acknowledge signal is not returned, the current condition is maintained.
The <TRX> is cleared to "0" by the hardware after a stop condition on the I^2C bus is detected or arbitration is lost.

(7) Start/Stop condition generation

When the SBI0SR<BB> is "0", 8-bit data which are set to SBI0DBR are output on a bus after generating a start condition by writing "1" to the SBI0CR2 <MST, TRX, BB, PIN>. It is necessary to set transmitted data to the data buffer register (SBI0DBR) and set "1" to <ACK> beforehand.

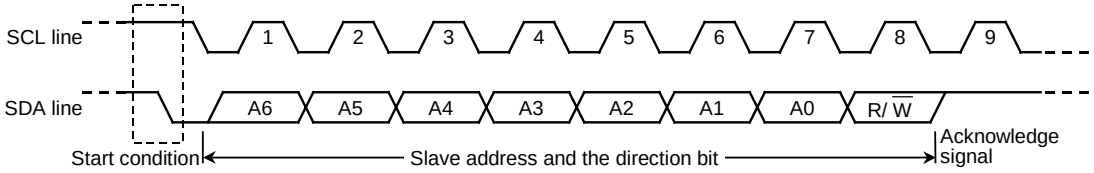

Figure 3.10.9 Start condition generation and slave address generation

When the <BB> is "1", a sequence of generating a stop condition is started by writing "1" to the <MST, TRX, PIN>, and "0" to the <BB>. Do not modify the contents of <MST, TRX, BB, and PIN> until a stop condition is generated on a bus.

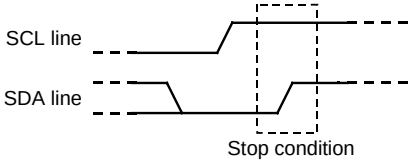

Figure 3.10.10 Stop condition generation

The state of the bus can be ascertained by reading the contents of SBI0SR<BB>. SBI0SR<BB> will be set to 1 if a start condition has been detected on the bus, and will be cleared to 0 if a stop condition has been detected.

And about generation of stop condition in master mode, there are some limitation point. Please refer to " **エラー! 参照元が見つかりません。**(4) Stop condition generation ".

(8) Interrupt service requests and interrupt cancellation

When a serial bus interface interrupt request (INTS2) occurs, the SBI0CR2 <PIN> is cleared to "0". During the time that the SBI0CR2<PIN> is "0", the SCL line is pulled down to the Low level. The <PIN> is cleared to "0" when a 1-word of data is transmitted or received. Either writing / reading data to / from SBI0DBR sets the <PIN> to "1".

The time from the <PIN> being set to "1" until the SCL line is released takes t_{LOW}.

In the address recognition mode (<ALS> = 0), <PIN> is cleared to "0" when the received slave address is the same as the value set at the I2C0AR or when a GENERAL CALL is received (all 8-bit data are "0" after a start condition). Although SBI0CR2<PIN> can be set to "1" by the program, the <PIN> is not clear it to "0" when it is written "0".

(9) Serial bus interface operation mode selection

SBI0CR2<SBIM1 to SBIM0> is used to specify the serial bus interface operation mode. Set SBI0CR2<SBIM1 to SBIM0> to "10" when the device is to be used in I^2C Bus Mode.

Switch a mode to port after confirming a bus is free.

(10) Arbitration lost detection monitor

Since more than one master device can exist simultaneously on the bus in I^2C Bus Mode, a bus arbitration procedure has been implemented in order to guarantee the integrity of transferred data. Data on the SDA line is used for I^2C bus arbitration.

The following shows an example of a bus arbitration procedure when two master devices exist simultaneously on the bus. Master A and Master B output the same data until point "a". After Master A outputs "L" and Master B, "H", the SDA line of the bus is wire-AND and the SDA line is pulled down to the Low-level by Master A. When the SCL line of the bus is pulled up at point b, the slave device reads the data on the SDA line, that is, data in Master A. A data transmitted from Master B becomes invalid. The state in Master B is called "ARBITRATION LOST". Master B device, which loses arbitration releases the internal SDA output in order not to affect data, transmitted from other masters with arbitration. When more than one master sends the same data at the first word, arbitration occurs continuously after the second word.

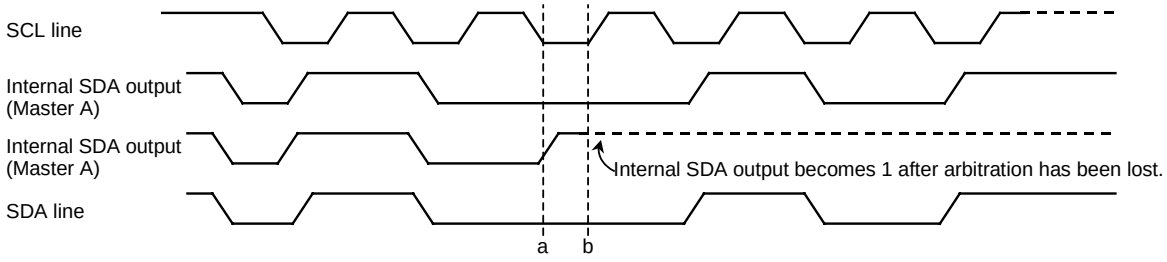

Figure 3.10.11 Arbitration Lost

The TMP91C820A compares the levels on the bus's SDA line with those of the internal SDA output on the rising edge of the SCL line. If the levels do not match, arbitration is lost and SBI0SR<AL> is set to "1".

When SBI0SR<AL> is set to "1", SBI0SR<MST, TRX> are cleared to "00" and the mode is switched to Slave Receiver Mode.

SBI0SR<AL> is cleared to "0" when data is written to or read from SBI0DBR or when data is written to SBI0CR2.

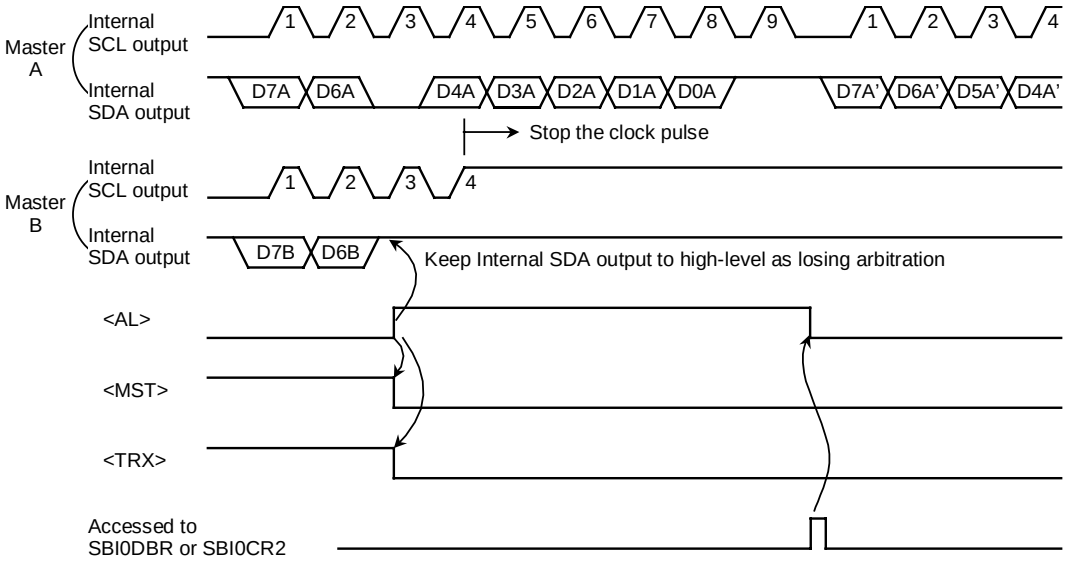

Figure 3.10.12 Example of when TMP91C820A is a Master Device B
(D7A = D7B, D6A = D6B)

(11) Slave address match detection monitor

SBI0SR<AAS> is set to "1" in Slave Mode, in Address Recognition Mode (i.e. when I2C0AR<ALS> = "0"), when a GENERAL CALL is received, or when a slave address matches the value set in I2C0AR. When I2C0AR<ALS> = "1", SBI0SR<AAS> is set to "1" after the first word of data has been received. SBI0SR<AAS> is cleared to "0" when data is written to or read from the data buffer register SBI0DBR.

(12) GENERAL CALL detection monitor

SBI0SR<AD0> is set to "1" in Slave Mode, when a GENERAL CALL is received (all 8-bit received data is "0", after a start condition). SBI0SR<AD0> is cleared to "0" when a start condition or stop condition is detected on the bus.

(13) Last received bit monitor

The SDA line value stored at the rising edge of the SCL line is set to the SBI0SR<LRB>. In the acknowledge mode, immediately after an INTS2 interrupt request is generated, an acknowledge signal is read by reading the contents of the SBI0SR<LRB>.

(14) Software Reset function

The software Reset function is used to initialize the SBI circuit, when SBI is rocked by external noises, etc.

An internal Reset signal pulse can be generated by setting SBI0CR2<SWRST1, SWRST0> to "10" and "01". This initializes the SBI circuit internally. All command registers and status registers are initialized as well.

SBI0CR2<SWRST1, SWRST0> is automatically cleared to "00" after the SBI circuit has been initialized.

(15) Serial Bus Interface Data Buffer Register (SBI0DBR)

The received data can be read and transferred data can be written by reading or writing the SBI0DBR.

In the master mode, after the start condition is generated the slave address and the direction bit are set in this register.

(16) I^2CBUS Address Register (I2C0AR)

I2C0AR<SA6 to SA0> is used to set the slave address when the TMP91C820A functions as a slave device.

The slave address output from the master device is recognized by setting the I2C0AR<ALS> to "0". The data format is the addressing format. When the slave address is not recognized at the <ALS> = "1", the data format is the free data format.

(17) Baud Rate Register (SBI0BR1)

Write "1" to SBI0BR1<P4EN> before operation commences.

(18) Setting register for IDLE2 mode operation (SBI0BR0)

SBI0BR0<I2SBI0> is the register setting operation/stop during IDLE2-mode. Therefor, setting <I2SBI0> is necessary before the HALT instruction is executed.

3.10.6 Data Transfer in I^2C Bus Mode

(1) Device initialization

Set the SBI0BR1<P4EN>, SBI0CR1<ACK, SCK2 to SCK0>, Set SBI0BR1 to "1" and clear bits 7 to 5 and 3 in the SBI0CR1 to "0".
Set a slave address <SA6 to SA0> and the <ALS> (<ALS> = "0" when an addressing format) to the I2C0AR.
For specifying the default setting to a slave receiver mode, clear "0" to the <MST, TRX, BB> and set "1" to the <PIN>, "10" to the <SBIM1 to SBIM 0>.

(2) Start condition and slave address generation

① Master Mode

In the Master Mode, the start condition and the slave address are generated as follows.
Check a bus free status (when <BB>= "0").
Set the SBI0CR1<ACK> to "1" (Acknowledge Mode) and specify a slave address and a direction bit to be transmitted to the SBI0DBR.
When SBI0CR2<BB> = "0", the start condition are generated by writing "1111" to SBI0CR2<MST, TRX, BB, PIN>. Subsequently to the start condition, nine clocks are output from the SCL pin. While eight clocks are output, the slave address and the direction bit which are set to the SBI0DBR. At the 9th clock, the SDA line is released and the acknowledge signal is received from the slave device.
An INTS2 interrupt request occurs at the falling edge of the 9th clock. The <PIN> is cleared to "0". In the Master Mode, the SCL pin is pulled down to the Low-level while <PIN> is "0". When an interrupt request occurs, the <TRX> is changed according to the direction bit only when an acknowledge signal is returned from the slave device.

② Slave Mode

In the Slave Mode, the start condition and the slave address are received.
After the start condition is received from the master device, while eight clocks are output from the SCL pin, the slave address and the direction bit which are output from the master device are received.
When a GENERAL CALL or the same address as the slave address set in I2C0AR is received, the SDA line is pulled down to the Low-level at the 9th clock, and the acknowledge signal is output.
An INTS2 interrupt request occurs on the falling edge of the 9th clock. The <PIN> is cleared to "0".
In Slave Mode the SCL line is pulled down to the Low-level while the <PIN> = "0".

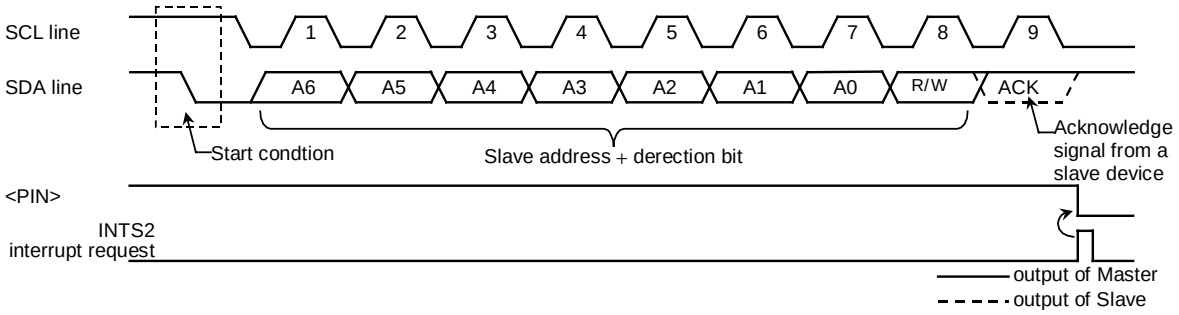

Figure 3.10.13 Start Condition Generation and Slave Address Transfer

(3) 1-word Data Transfer

Check the <MST> by the INTS2 interrupt process after the 1-word data transfer is completed, and determine whether the mode is a master or slave.

① If <MST> = “1” (Master Mode)

Check the <TRX> and determine whether the mode is a transmitter or receiver.

When the <TRX> = “1” (Transmitter mode)

Check the <LRB>. When <LRB> is “1”, a receiver does not request data. Implement the process to generate a stop condition (Refer to 3.10.6 (4)) and terminate data transfer.
When the <LRB> is “0”, the receiver is requests new data. When the next transmitted data is 8 bits, write the transmitted data to SBI0DBR. When the next transmitted data is other than 8 bits, set the <BC2 to BC0>, set the <ACK> to “1” and write the transmitted data to SBI0DBR. After written the data, <PIN> becomes “1”, a serial clock pulse is generated for transferring a new 1-word of data from the SCL pin, and then the 1-word data is transmitted. After the data is transmitted, an INTS2 interrupt request occurs. The <PIN> becomes “0” and the SCL line is pulled down to the Low-level. If the data to be transferred is more than one word in length, repeat the procedure from the <LRB> checking above.

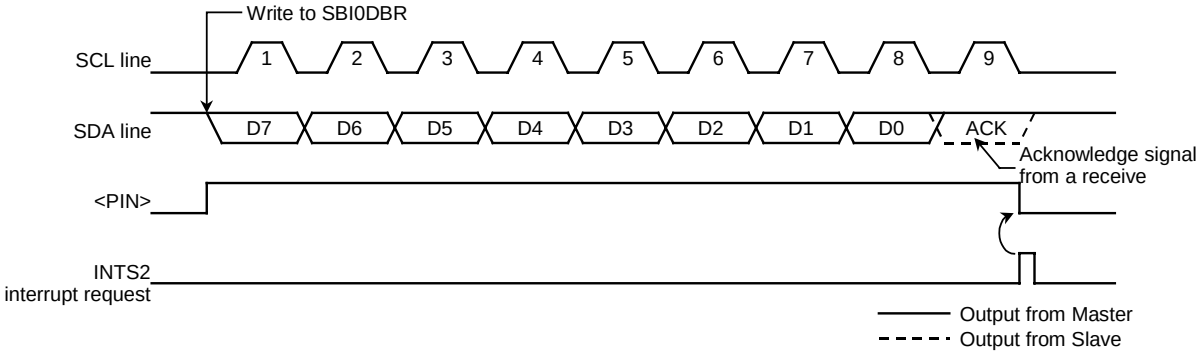

Figure 3.10.14 Example in which <BC2 to BC0> = “000” and <ACK> = “1” in Transmitter Mode

When the <**TRX**> is "0" (Receiver mode)

When the next transmitted data is 8 bits, write the transmitted data to SBI0DBR. When the next transmitted data is other than 8 bits, set <BC2 to BC0> again. Set <ACK> to "1" and read the received data from SBI0DBR to release the SCL line (data which is read immediately after a slave address is sent is undefined). After the data is read, <PIN> becomes "1". The TMP91C820A outputs a serial clock pulse to the SCL to transfer new 1-word of data and sets the SDA pin to "0", When the acknowledge signal is set to Low-level at the final bit.

An INTS2 interrupt request then occurs and the <PIN> becomes "0", Then the TMP91C820A pulls down the SCL pin to the Low-level. The TMP91C820A outputs a clock pulse for 1-word of data transfer and the acknowledge signal each time that received data is read from the SBI0DBR.

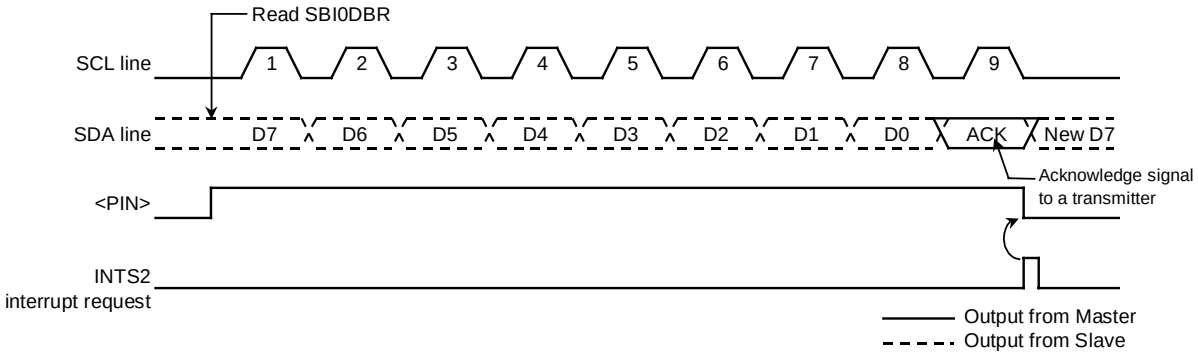

Figure 3.10.15 Example of when <BC2 to 0> = "000", <ACK> = "1" in Receiver Mode

In order to terminate the transmission of data to a transmitter, clear <ACK> to "0" before reading data which is 1-word before the last data to be received. The last data word does not generate a clock pulse as the Acknowledge signal. After the data has been transmitted and an interrupt request has been generated, set <BC2 to BC0> to "001" and read the data. The TMP91C820A generates a clock pulse for a 1-bit data transfer. Since the master device is a receiver, the SDA line on the bus remains High. The transmitter interprets the High signal as an ACK signal. The receiver indicates to the transmitter that data transfer is complete.

After the one data bit has been received and an interrupt request been generated, the TMP91C820A generates a stop condition (see Section 3.10.6 (4)) and terminates data transfer.

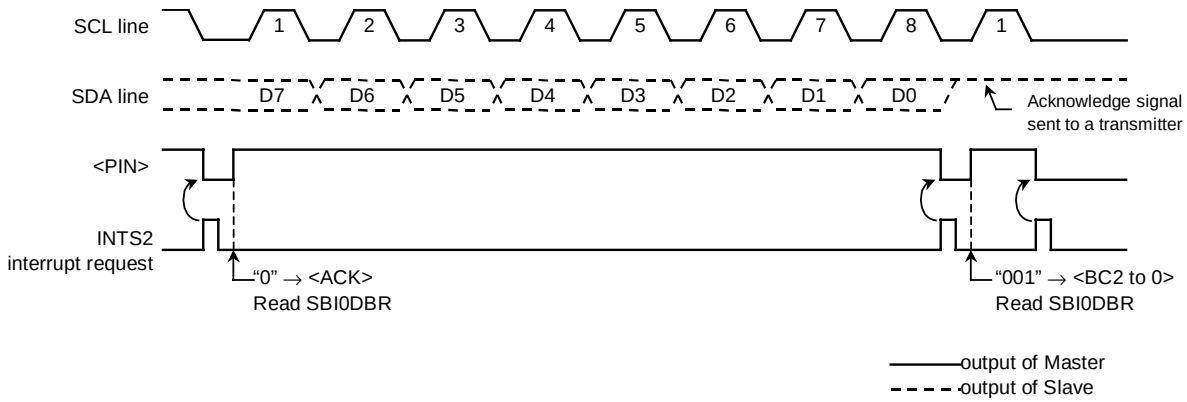

Figure 3.10.16 Termination of data Transfer in Master Receiver Mode

② If <MST> = 0 (Slave Mode)

In the slave mode, an INTS2 interrupt request occurs when the TMP91C820A receives a slave address or a GENERAL CALL from the master device, or when a GENERAL CALL is received and data transfer is complete, or after matching received address. In the master mode, the TMP91C820A operates in a slave mode if it losing arbitration. An INTS2 interrupt request occurs when a word data transfer terminates after losing arbitration. When an INTS2 interrupt request occurs the <PIN> is cleared to "0" and the SCL pin is pulled down to the Low-level. Either reading / writing from / to the SBI0DBR or setting the <PIN> to "1" will release the SCL pin after taking t_{LOW} time.

In the slave mode the TMP91C820A operates either in normal slave mode or in slave mode after losing arbitration.

Check the SBI0SR<AL>, <TRX>, <AAS>, and <AD0> and implements processes according to conditions listed in the next table.

Table 3.10.1 Operation in the Slave Mode

<TRX>	<AL>	<AAS>	<AD0>	Conditions	Process
1	1	1	0	The TMP91C820A loses arbitration when transmitting a slave address and receives a slave address for which the value of the direction bit sent from another master is "1".	Set the number of bits a word in <BC2 to BC0> and write the transmitted data to SBI0DBR
	0	1	0	In Salve Receiver Mode the TMP91C820A receives a slave address for which the value of the direction bit sent from the master is "1".	
		0	0	In Salve Transmitter Mode a single word of is transmitted. Set <BC2 to BC0> to the number of bits in a word.	Check the <LRB> setting. If <LRB> is set to "1", set <PIN> to "1" since the receiver win no request the data which follows. Then, cleat <TRX> to "0" to release the bus. If <LRB> is cleared to "0" of and write the transmitted data to SBI0DBR since the receiver requests next data.
0	1	1	1/0	The TMP91C820A loses arbitration when transmitting a slave address and receives a slave address or GENERAL CALL for which the value of the direction bit sent from another master is "0".	Read the SBI0DBR for setting the <PIN> to "1" (reading dummy data) or set the <PIN> to "1".
		0	0	The TMP91C820A loses arbitration when transmitting a slave address or data and terminates word data transfer.	
	0	1	1/0	In Slave Receiver Mode the TMP91C820A receives a slave address or GENERAL CALL for which the value of the direction bit sent from the master is "0".	
		0	1/0	In Slave Receiver Mode the TMP91C820A terminates receiving word data.	Set <BC2 to BC0> to the number of bits in a word and read the received data from SBI0DBR.

(4) Stop condition generation

When SBI0SR<BB> = 1, the sequence for generating a stop condition can be initiated by writing “1” to SBI0CR2<MST,TRX,PIN> and “0” to SBI0CR2<BB>. Do not modify the contents of SBI0CR2<MST,TRX,PIN,BB> until a stop condition has been generated on the bus. When the bus’s SCL line has been pulled Low by another device, the TMP91C820A generates a stop condition after the other device has released the SCL line and SDA rises.

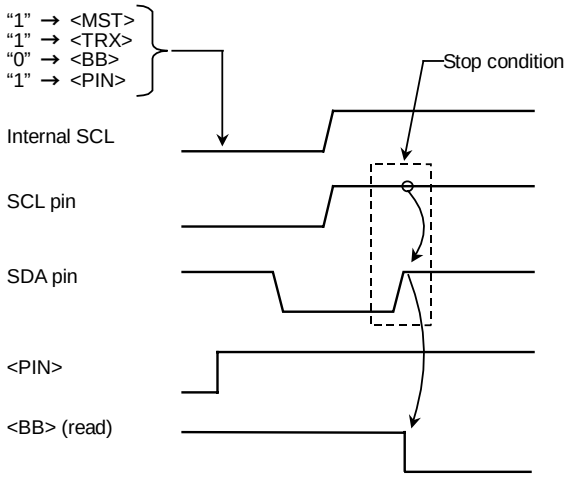

Figure 3.10.17 Stop condition generation (Single-master)

(5) Restart

Restart is used during data transfer between a master device and a slave device to change the data transfer direction. The following description explains how to restart when the TMP91CW12 is in Master Mode.

Clear SBI0CR2<MST,TRX,BB> to 0 and set SBI0CR2<PIN> to 1 to release the bus. The SDA line remains High and the SCL pin is released. Since a stop condition has not been generated on the bus, other devices assume the bus to be in Busy state. Monitor the value of SBI0SR<BB> until it becomes 0 so as to ascertain when the TMP91CW12's SCL pin is released. Check the <LRB> until it becomes 1 to check that the SCL line on a bus is not pulled down to the low-level by other devices. After confirming that the bus remains in a free state, generate a start condition using the procedure described in 3.10.6 (2).

In order to satisfy the set-up time requirements when restarting, take at least 4.7 μs of waiting time by software from the time of restarting to confirm that the bus is free until the time to generate the start condition.

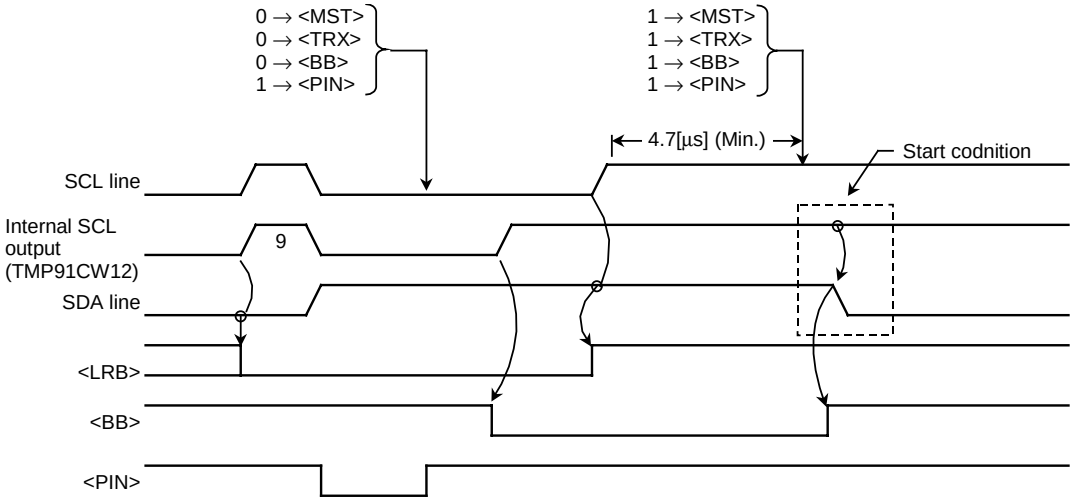

Figure 3.10.18 Timing diagram for TMP91C820A Restart

3.10.7 Clocked Synchronous 8-Bit SIO Mode control

The following registers are used to control and monitor the operation status when the Serial Bus Interface (SBI) is being operated in Clocked Synchronous 8-Bit SIO Mode.

Figure 3.10.21 Registers for the SIO Mode

(1) Serial Clock

① Clock source

SBI0CR1<SCK2 to SCK0> is used to select the following functions:

Internal Clock

In Internal Clock Mode one of seven frequencies can be selected. The serial clock signal is output to the outside on the SCK pin. The SCK pin goes high when data transfer starts. When the device is writing (in Transmit Mode) or reading (in Receive Mode), data cannot follow the serial clock rate, so an automatic wait function is executed which automatically stops the serial clock and holds the next shift operation until reading or writing has been completed.

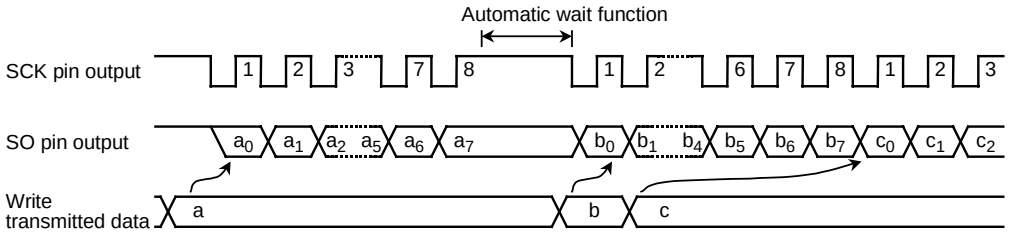

Figure 3.10.22 Automatic-wait Function

External clock (<SCK2 to SCK0> = “111”)

An external clock input via the SCK pin is used as the serial clock. In order to ensure the integrity of shift operations, both the high and Low-level serial clock pulse widths shown below must be maintained. The maximum data transfer frequency is 1 MHz (when fc = 16 MHz).

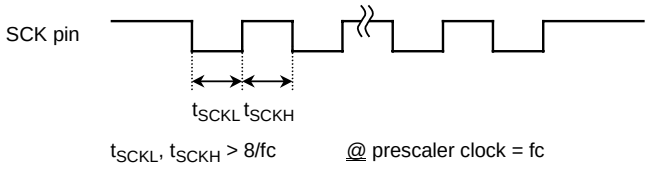

Figure 3.10.23 Maximum data transfer frequency when external clock input used

② Shift edge

Data is transmitted on the leading edge of the clock and received on the trailing edge.

Leading edge shift

Data is shifted on the leading edge of the serial clock (on the falling edge of the SCK pin input/output).

Trailing edge shift

Data is shifted on the trailing edge of the serial clock (on the rising edge of the SCK pin input/output).

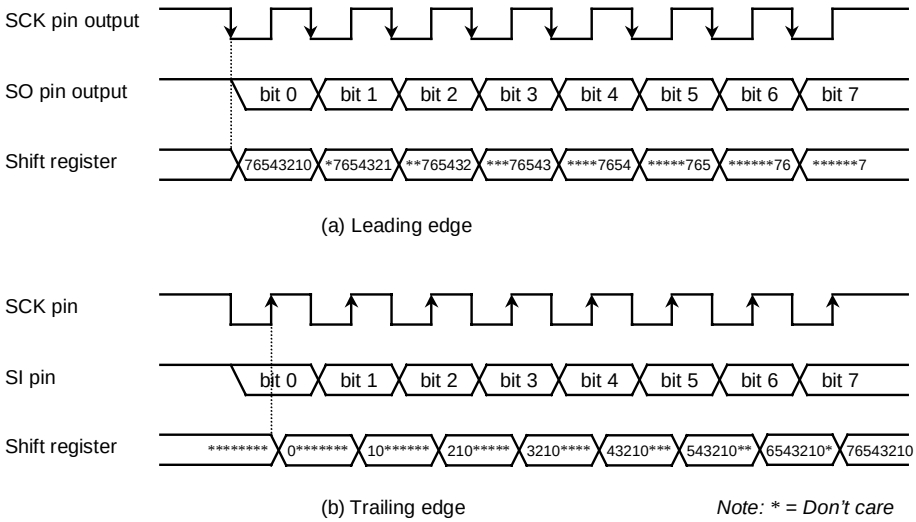

Figure 3.10.24 Shift edge

(2) Transfer modes

The SBI0CR1<SIOM1 to SIOM0> is used to select a transmit, receive or transmit / receive mode.

① 8-Bit Transmit Mode

Set a control register to a transmit mode and write transmit data to the SBI0DBR.

After the transmit data is written, set the SBI0CR1<SIOS> to "1" to start data transfer. The transmitted data is transferred from SBI0DBR to the Shift Register and output to the SO pin in synchronized with the serial clock, starting from the least significant bit (LSB), When the transmission data is transferred to the Shift Register, the SBI0DBR becomes empty. An INTS2 (buffer empty) interrupt request is generated to request new data.

When the internal clock is used, the serial clock will stop and automatic-wait function will be initiated if new data is not loaded to the data buffer register after the specified 8-bit data is transmitted. When new transmit data is written, automatic-wait function is canceled.

When the external clock is used, data should be written to SBI0DBR before new data is shifted. The transfer speed is determined by the maximum delay time between the time when an interrupt request is generated and the time when data is written to SBI0DBR by the interrupt service program.

When the transmit is started, after the SBI0SR<SIOF> goes "1" output from the SO pin holds final bit of the last data until falling edge of the SCK.

Transmitting data is ended by clearing the <SIOS> to "0" by the buffer empty interrupt service program or setting the <SIOINH> to "1". When the <SIOS> is cleared, the transmitted mode ends when all data is output. In order to confirm if data is surely transmitted by the program, set the <SIOF> (bit 3 of SBI0SR) to be sensed. The SBI0SR<SIOF> is cleared to "0" when transmitting is complete. When the <SIOINH> is set to "1", transmitting data stops. SBI0SR<SIOF> turns "0".

When an external clock is used, it is also necessary to clear SBI0SR<SIOS> to "0" before new data is shifted; otherwise, dummy data is transmitted and operation ends.

Example: Program to stop data transmission (when an external clock is used)

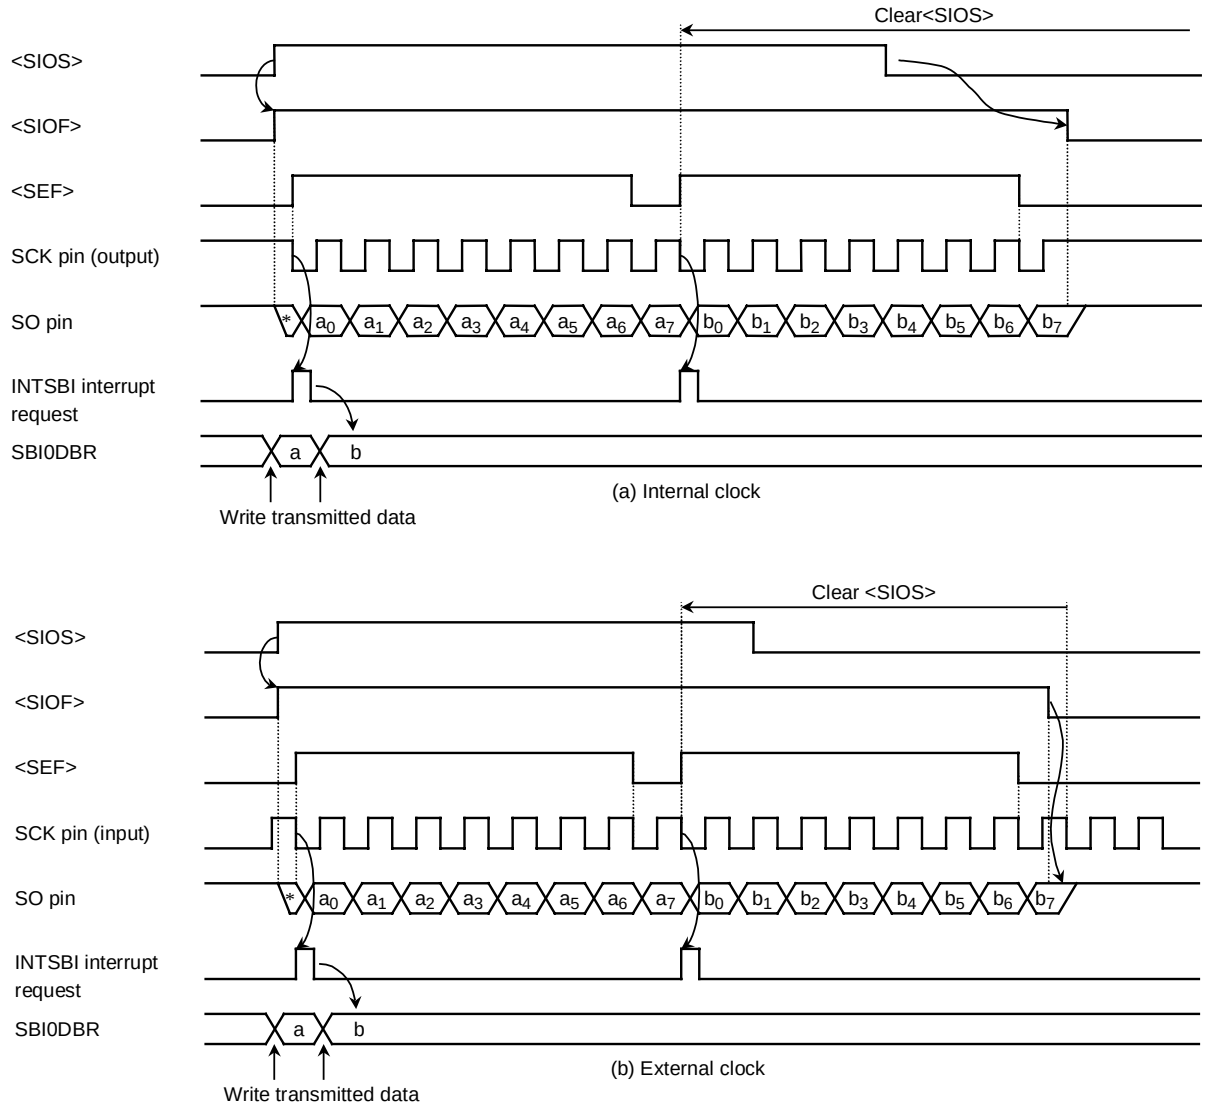

Figure 3.10.25 Transfer Mode

```
STEST1:  BIT      SEF, (SBI0SR)          ; If <SEF> = 1 then loop
         JR NZ,   STEST1
STEST2:  BIT      0, (P7)                ; If SCK = 0 then loop
         JR Z, STEST2
         LD       (SBI0CR1), 00000111B   ; <SIOS> ← 0
```

② 8-Bit Receive Mode

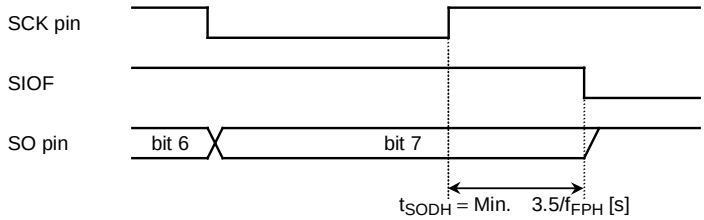

Figure 3.10.26 Transmitted data hold time at end of transmission

Set the control register to receive mode and set SBI0CR1<SIOS> to "1" for switching to receive mode. Data is received into the Shift Register via the SI pin and synchronized with the serial clock, starting from the least significant bit (LSB). When 8-bit data is received, the data is transferred from the Shift Register to SBI0DBR. An INTS2 (buffer full) interrupt request is generated to request that the received data be read. The data is then read from SBI0DBR by the interrupt service program.
When an internal clock is used, the serial clock will stop and the automatic wait function will be in effect until the received data has been read from SBI0DBR.
When an external clock is used, since shift operation is synchronized with an external clock pulse, the received data should be read from SBI0DBR before the next serial clock pulse is input. If the received data is not read, any further data, which is to be received, is canceled. The maximum transfer speed when an external clock is used is determined by the delay time between the time when an interrupt request is generated and the time when the received data is read.
Receiving of data ends when <SIOS> is cleared to "0" by the buffer full interrupt service program or when <SIOINH> is set to "1". If <SIOS> is cleared to "0", received data is transferred to SBI0DBR in complete blocks. The received mode ends when the transfer is complete. In order to confirm whether data is being received properly by the program, set SBI0SR<SIOF> to be sensed. <SIOF> is cleared to "0" when receiving has been completed. When it is confirmed that receiving has been completed, the last data is read. When <SIOINH> is set to "1", data receiving stops. <SIOF> is cleared to "0" (the received data becomes invalid, therefore no need to read it).

Note: When the transfer mode is changed, the contents of SBI0DBR will be lost. If the mode must be changed, conclude data receiving by clearing <SIOS> to "0", read the last data, then change the mode.

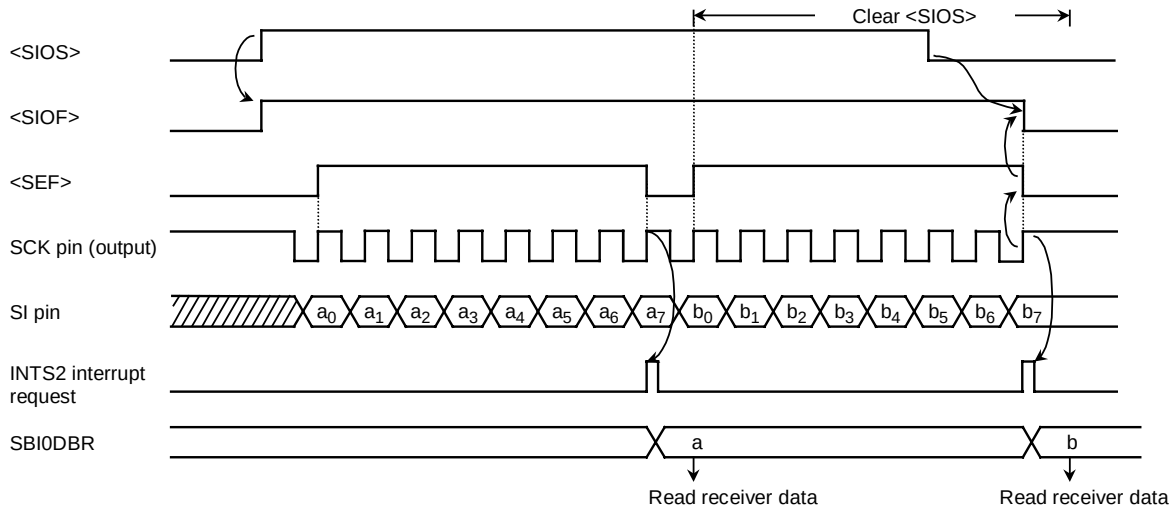

Figure 3.10.27 Receiver Mode (example: Internal clock)

③ 8-Bit Transmit/Receive Mode

Set a control register to a transmit/receive mode and write data to SBI0DBR. After the data has been written, set SBI0CR<SIOS> to "1" to start transmitting/receiving. When data is transmitted, the data is output via the SO pin, starting from the least significant bit (LSB) and synchronized with the leading edge of the serial clock signal. When data is received, the data is input via the SI pin on the trailing edge of the serial clock signal. 8-bit data is transferred from the Shift Register to SBI0DBR and an INTS2 interrupt request is generated. The interrupt service program reads the received data from the data buffer register and writes the data which is to be transmitted. SBI0DBR is used for both transmitting and receiving. Transmitted data should always be written after received data has been read.

When an internal clock is used, the automatic wait function will be in effect until the received data has been read and the next data has been written.

When an external clock is used, since the shift operation is synchronized with the external clock, received data is read and transmitted data is written before a new shift operation is executed. The maximum transfer speed when an external clock is used is determined by the delay time between the time when an interrupt request is generated and the time at which received data is read and transmitted data is written.

When the transmit is started, after the SBI0SR<SIOF> goes "1" output from the SO pin holds final bit of the last data until falling edge of the SCK.

Transmitting/receiving data ends when <SIOS> is cleared to "0" by the INTS2 interrupt service program or when SBI0CR1<SIOINH> is set to "1". When <SIOS> is cleared to "0", received data is transferred to SBI0DBR in complete blocks. The transmit/receive mode ends when the transfer is complete. In order to confirm whether data is being transmitted/received properly by the program; set SBI0SR to be sensed. <SIOF> is set to "0" when transmitting/receiving has been completed. When <SIOINH> is set to 1, data transmitting/receiving stops. <SIOF> is then cleared to 0.

Note: When the transfer mode is changed, the contents of SBI0DBR will be lost. If the mode must be changed, conclude data transmitting/receiving by clearing <SIOS> to "0", read the last data, then change the transfer mode.

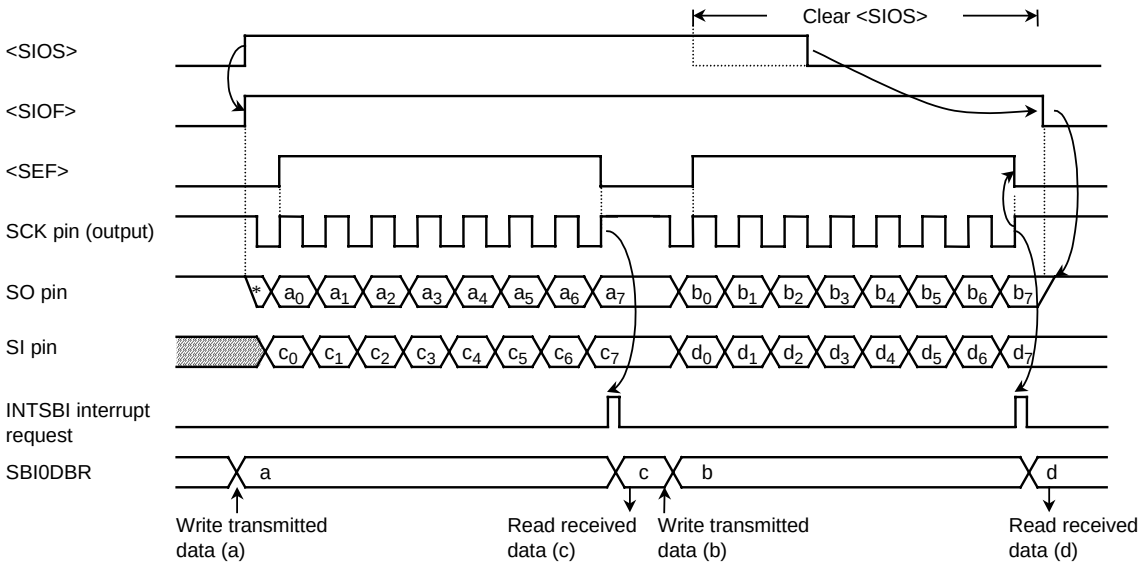

Figure 3.10.28 Transmit/Received Mode (example using internal clock)

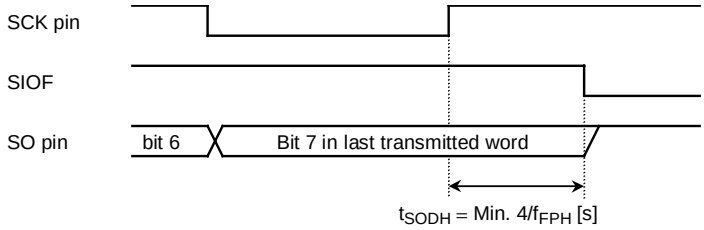

Figure 3.10.29 Transmitted data hold time at end of transmit/receive

3.11 Analog/Digital Converter

The TMP91C820A incorporates a 10-bit successive approximation-type analog/digital converter (A/D converter) with 8-channel analog input.

Figure 3.11.1 is a block diagram of the A/D converter. The 8-channel analog input pins (AN0 to AN7) are shared with the input-only port 8 and can thus be used as an input port.

Note: When IDLE2, IDLE1 or STOP Mode is selected, so as to reduce the power, with some timings the system may enter a standby mode even though the internal comparator is still enabled. Therefore be sure to check that A/D converter operations are halted before a HALT instruction is executed.

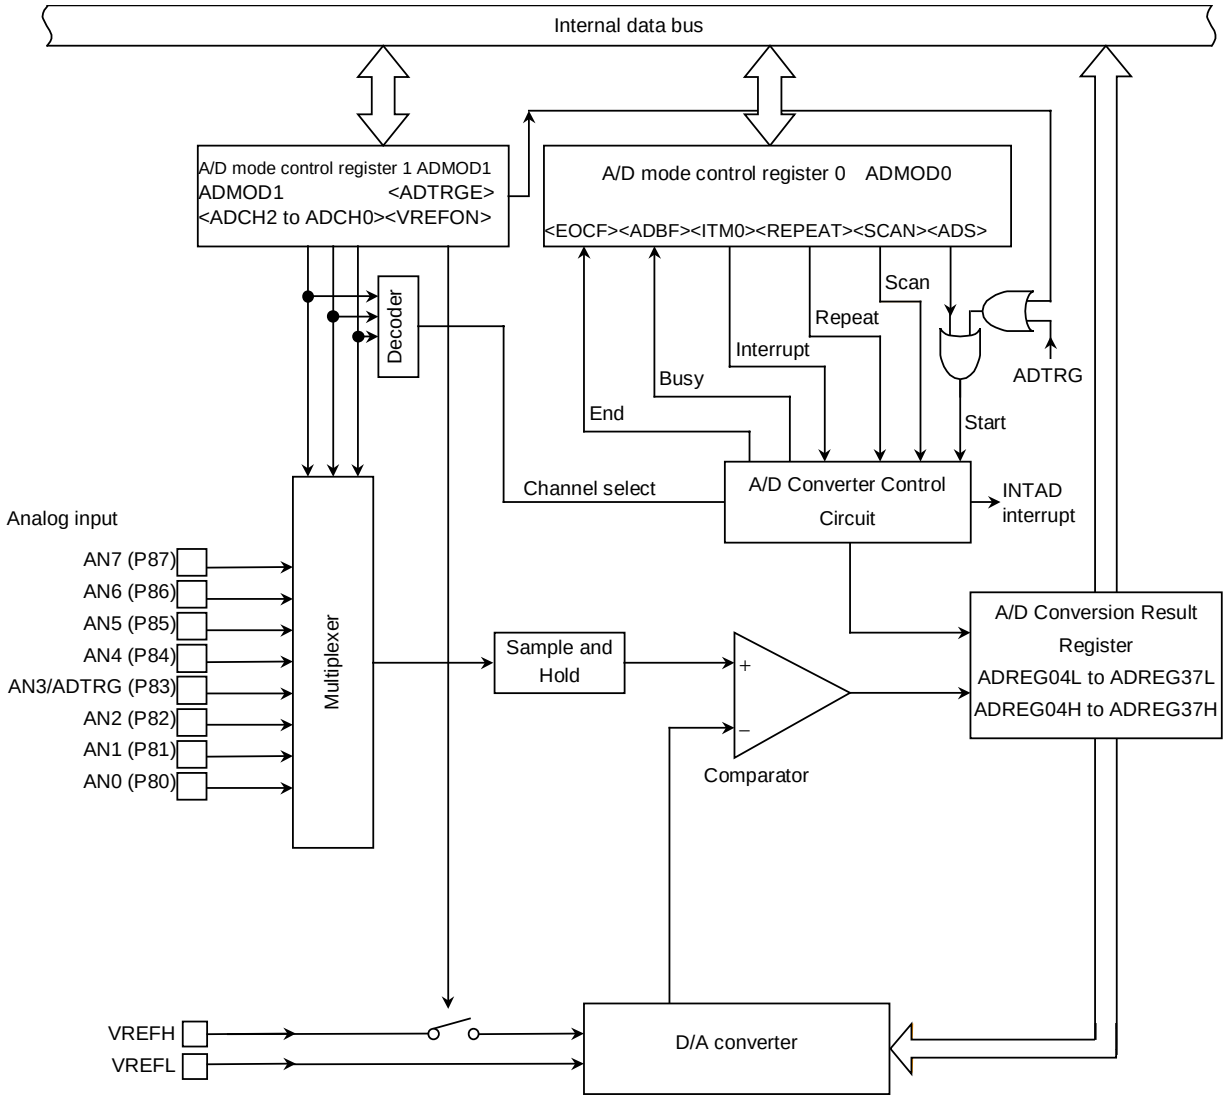

Figure 3.11.1 Block diagram of A/D converter

3.11.1 Analog/Digital converter registers

The two A/D Mode Control Registers control the A/D converter: ADMOD0 and ADMOD1. The eight A/D Conversion Data Upper and Lower Registers (ADREG04H/L, ADREG15H/L, ADREG26H/L and ADREG37H/L) store the results of A/D conversion.
Figure 3.11.2 shows the registers related to the A/D converter.

Figure 3.11.5 A/D Converter Related Registers

3.11.2 Description of operation

(1) Analog reference voltage

A High-level analog reference voltage is applied to the VREFH pin; a low-level analog reference voltage is applied to the VREFL pin. To perform A/D conversion, the reference voltage, the difference between VREFH and VREFL, is divided by 1024 using string resistance. The result of the division is then compared with the analog input voltage.

To turn off the switch between VREFH and VREFL, write a "0" to ADMOD1<VREFON> in A/D Mode Control Register 1. To start A/D conversion in the OFF state, first write a "1" to ADMOD1<VREFON>, wait 3 μs until the internal reference voltage stabilizes (this is not related to fc), then set ADMOD0< ADS> to "1".

(2) Analog input channel selection

The analog input channel selection varies depends on the operation mode of the A/D converter.

- In Analog Input Channel Fixed Mode (A/D MOD0<SCAN> = "0")
  Setting ADMOD1<ADCH2 to ADCH0> selects one of the input pins AN0 to AN7 as the input channel.
- In Analog Input Channel Scan Mode (ADMOD0<SCAN> = "1")
  Setting ADMOD1<ADCH2 to ADCH0> selects one of the eight scan modes.

Table 3.11.1 illustrates analog input channel selection in each operation mode.

On a Reset, ADMOD0<SCAN> is set to "0" and ADMOD1<ADCH2 to ADCH0> is initialized to "000". Thus pin AN0 is selected as the fixed input channel. Pins not used as analog input channels can be used as standard input port pins.

Table 3.11.1 Analog input channel selection

<ADCH2~0>	Channel fixed <SCAN> = "0"	Channel scan <SCAN> = "1"
000	AN0	AN0
001	AN1	AN0 → AN1
010	AN2	AN0 → AN1 → AN2
011	AN3	AN0 → AN1 → AN2 → AN3
100	AN4	AN4
101	AN5	AN4 → AN5
110	AN6	AN4 → AN5 → AN6
111	AN7	AN4 → AN5 → AN6 → AN7

(3) Starting A/D Conversion

To start A/D conversion, write a 1 to ADMOD0<ADS> in A/D Mode Control Register 0 or ADMOD1<ADTRGE> in A/D Mode Control Register 1, and input falling edge on $\overline{\text{ADTRG}}$ pin. When A/D conversion starts, the A/D Conversion Busy flag ADMOD0<ADBF> will be set to "1", indicating that A/D conversion is in progress.

Writing a 1 to ADMOD0<ADS> during A/D conversion restarts conversion. At that time, to determine whether the A/D conversion results have been preserved, check the value of the conversion data storage flag A/D REGxL<ADRxRF>.

During A/D conversion, a falling edge input on the $\overline{\text{ADTRG}}$ pin will be ignored.

(4) A/D conversion modes and the A/D Conversion End interrupt

The four A/D conversion modes are:

- Channel Fixed Single Conversion Mode
- Channel Scan Single Conversion Mode
- Channel Fixed Repeat Conversion Mode
- Channel Scan Repeat Conversion Mode

The ADMOD0<REPET> and ADMOD0<SCAN> settings in A/D Mode Control Register 0 determine the A/D mode setting.

Completion of A/D conversion triggers an INTAD A/D Conversion End interrupt request. Also, ADMOD0<EOCF> will be set to "1" to indicate that A/D conversion has been completed.

① Channel Fixed Single Conversion Mode

Setting ADMOD0<REPET> and ADMOD0<SCAN> to "00" selects Conversion Channel Fixed Single Conversion Mode.

In this mode data on one specified channel is converted once only. When the conversion has been completed, the ADMOD0<EOCF> flag is set to "1", ADMOD0<ADBF> is cleared to "0", and an INTAD interrupt request is generated.

② Channel Scan Single Conversion Mode

Setting ADMOD0<REPET> and ADMOD0<SCAN> to "01" selects Conversion Channel Scan Single Conversion Mode.

In this mode data on the specified scan channels is converted once only. When scan conversion has been completed, ADMOD0<EOCF> is set to "1", ADMOD0<ADBF> is cleared to "0", and an INTAD interrupt request is generated.

③ Channel Fixed Repeat Conversion Mode

Setting ADMOD0<REPET> and ADMOD0<SCAN> to "10" selects Conversion Channel Fixed Repeat Conversion Mode.

In this mode data on one specified channel is converted repeatedly. When conversion has been completed, ADMOD0<EOCF> is set to "1" and ADMOD0<ADBF> is not cleared to "0" but held at "1". INTAD interrupt request generation timing is determined by the setting of ADMOD0<ITM0>.

Setting <ITM0> to "0" generates an interrupt request every time an A/D conversion is completed.

Setting <ITM0> to "1" generates an interrupt request on completion of every fourth conversion.

④ Channel Scan Repeat Conversion Mode

Setting ADMOD0<REPET> and ADMOD0<SCAN> to "11" selects Conversion Channel Scan Repeat Conversion Mode.

In this mode data on the specified scan channels is converted repeatedly. When each scan conversion has been completed, ADMOD0<EOCF> is set to "1" and an INTAD interrupt request is generated. ADMOD0<ADBF> is not cleared to "0" but held at "1".

To stop conversion in a repeat conversion mode (i.e. in cases ③ and ④), write a "0" to ADMOD0<REPET>. After the current conversion has been completed, the repeat conversion mode terminates and ADMOD0<ADBF> is cleared to "0".

Switching to a halt state (IDLE2 Mode with ADMOD1<I2AD> cleared to "0", IDLE1 Mode or STOP Mode) immediately stops operation of the A/D converter even when A/D conversion is still in progress. In repeat conversion modes (i.e. in cases ③ and ④), when the halt is released, conversion restarts from the beginning. In single conversion modes (i.e. in cases ① and ②), conversion does not restart when the halt is released (the converter remains stopped).

Table 3.11.2 shows the relationship between the A/D conversion modes and interrupt requests.

Table 3.11.2 Relationship between A/D Conversion Modes and Interrupt Requests

Mode	Interrupt Request Generation	ADMOD0		
		<ITM0>	<REPEAT>	<SCAN>
Channel Fixed Single Conversion Mode	After completion of conversion	X	0	0
Channel Scan Single Conversion Mode	After completion of scan conversion	X	0	1
Channel Fixed Repeat Conversion Mode	Every conversion	0	1	0
	Every forth conversion	1		
Channel Scan Repeat Conversion Mode	After completion of every scan conversion	X	1	1

X: Don't care

(5) A/D conversion time

84 states (10.5 μs @ f_{FPH} = 16 MHz) are required for the A/D conversion of one channel.

(6) Storing and reading the results of A/D conversion

The A/D Conversion Data Upper and Lower Registers (ADREG04H/L to ADREG37H/L) store the results of A/D conversion. (ADREG04H/L to ADRG37H/L are read-only registers.)
In Channel Fixed Repeat Conversion Mode, the conversion results are stored successively in registers ADREG04H/L to ADRG37H/L. In other modes the AN0 and AN4, AN1 and AN5, AN2 and AN6, and AN3 and AN7 conversion results are stored in ADREG04H/L, ADREG15H/L, ADREG26H/L and ADREG37H/L respectively.
Table 3.11.3 shows the correspondence between the analog input channels and the registers, which are used to hold the results of A/D conversion.

Table 3.11.3 Correspondence between Analog Input Channels and A/D Conversion Result Registers

Analog input channel (Port A)	A/D Conversion Result Register	
	Conversion modes other than at right	Channel fixed repeat conversion mode (every 4th conversion)
AN0	ADREG04H/L	ADREG04H/L → ADREG15H/L → ADREG26H/L → ADREG37H/L → ADREG04H/L
AN1	ADREG15H/L	
AN2	ADREG26H/L	
AN3	ADREG37H/L	
AN4	ADREG04H/L	
AN5	ADREG15H/L	
AN6	ADREG26H/L	
AN7	ADREG37H/L	

<ADRxRF> bit “0” of the A/D conversion data lower register is used as the A/D conversion data storage flag. The storage flag indicates whether the A/D conversion result register has been read or not. When a conversion result is stored in the A/D conversion result register, the flag is set to “1”. When either of the A/D conversion result registers (ADREGxH or ADREGxL) is read, the flag is cleared to “0”.
Reading the A/D conversion result also clears the A/D Conversion End flag ADMOD0<EOCF> to “0”.

Setting example:

① Convert the analog input voltage on the AN3 pin and write the result, to memory address 1000H using the A/D interrupt (INTAD) processing routine.

Main routine:

```
                    7 6 5 4 3 2 1 0
INTE0AD   ← X 1 0 0 - - - -   Enable INTAD and set it to Interrupt Level 4.
ADMOD1    ← 1 1 X X 0 0 1 1   Set pin AN3 to be the analog input channel.
ADMOD0    ← X X 0 0 0 0 0 1   Start conversion in Channel Fixed Single Conversion Mode.
```

Interrupt routine processing example:

```
WA        ← ADREG37           Read value of ADREG37L and ADREG37H into 16-bit
                              general-purpose register WA.
WA        > > 6               Shift contents read into WA six times to right and zero-fill upper bits.
(1000H)   ← WA                Write contents of WA to memory address 1000H.
```

② This example repeatedly converts the analog input voltages on the three pins AN0, AN1 and AN2, using Channel Scan Repeat Conversion Mode.

```
INTE0AD   ← X 0 0 0 - - - -   Disable INTAD.
ADMOD1    ← 1 X X X 0 0 1 0   Set pins AN0 to AN2 to be the analog input channels.
ADMOD0    ← X X 0 0 0 1 1 1   Start conversion in Channel Scan Repeat Conversion Mode.
```

Note: X = Don't care; "–" = No change

3.12 Watchdog timer (runaway detection timer)

The TMP91C820A features a watchdog timer for detecting runaway.

The watchdog timer (WDT) is used to return the CPU to Normal state when it detects that the CPU has started to malfunction (runaway) due to causes such as noise. When the watchdog timer detects a malfunction, it generates a non-maskable interrupt INTWD to notify the CPU of the malfunction.

Connecting the watchdog timer output to the Reset pin internally forces a reset.

3.12.1 Configuration

Figure 3.12.1 is a block diagram of he watchdog timer (WDT).

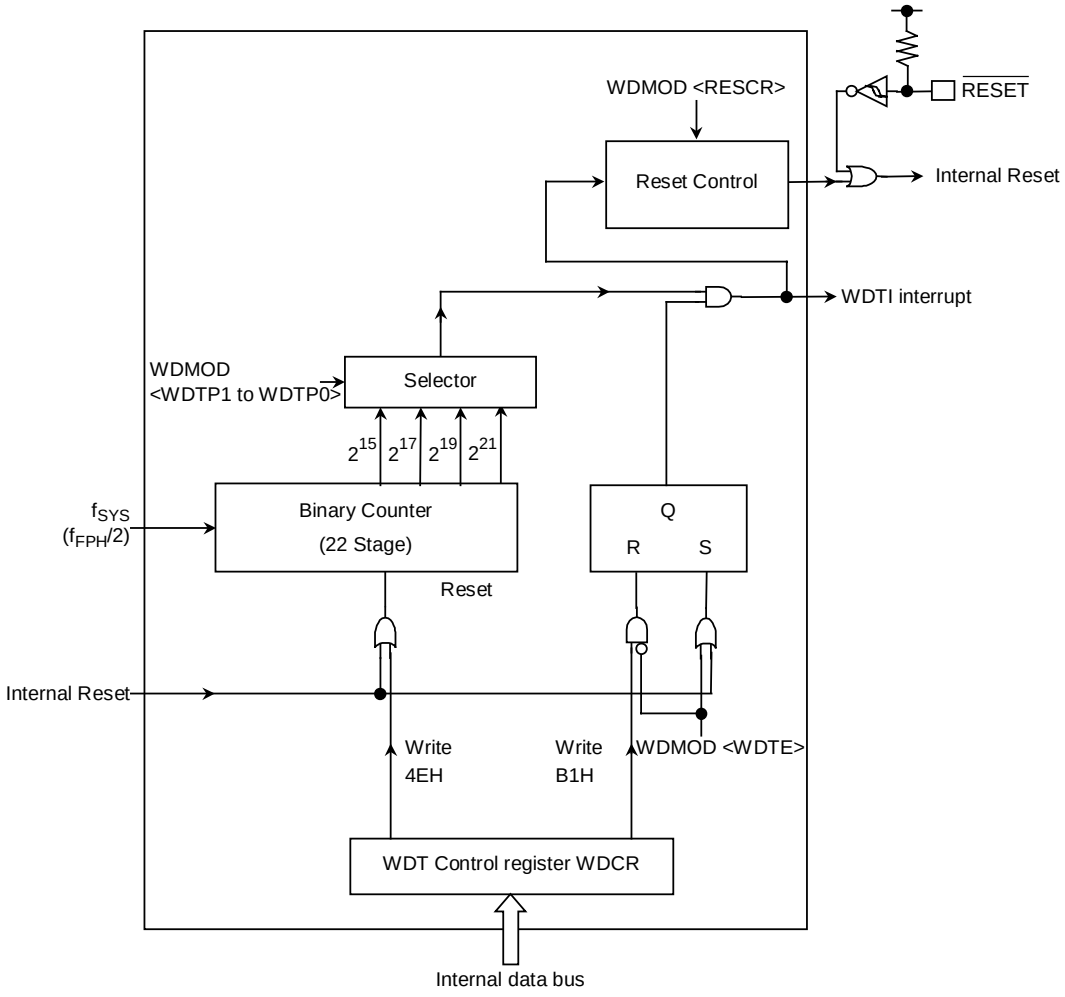

Figure 3.12.1 Block diagram of watchdog timer

The watchdog timer consists of a 22-stage binary counter which uses the system clock (f_{SYS}) as the input clock. The binary counter can output fSYS/215, fSYS/217, fSYS/219 and fSYS/221. Selecting one of the outputs using WDMOD<WDTP1, WDTP0> generates a Watchdog interrupt and outputs watchdog timer out when an overflow occurs.

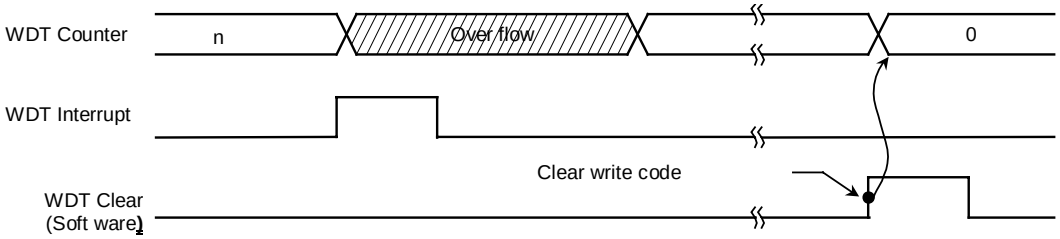

Figure 3.12.2 Normal Mode

The runaway detection result can also be connected to the Reset pin internally.
In this case, the reset time will be between 22 and 29 states as shown in Figure 3.12.3.

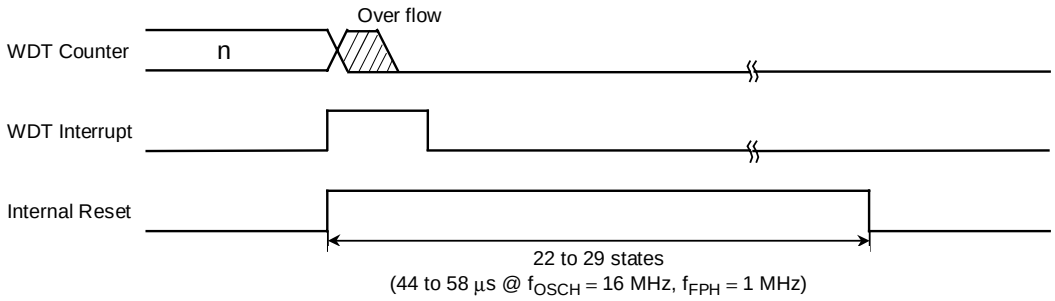

Figure 3.12.3 Reset Mode

3.12.2 Control registers

The watchdog timer WDT is controlled by two controls registers WDMOD and WDCR.

(1) Watchdog Timer Mode Register (WDMOD)

① Setting the detection time for the watchdog timer in <WDTP>

This 2-bit register is used for setting the watchdog timer interrupt time used when detecting runaway. On a Reset this register is initialized to WDMOD<WDTP1, WDTP0> = “00”.
The detection times for WDT are shown in Figure 3.12.4.

② Watchdog Timer Enable/Disable Control Register <WDTE>

On a Reset WDMOD<WDTE> is initialized to “1”, enabling the watchdog timer.
To disable the watchdog timer, it is necessary to set this bit to “0” and to write the disable code (B1H) to the Watchdog Timer Control Register WDCR. This makes it difficult for the watchdog timer to be disabled by runaway.
However, it is possible to return the watchdog timer from the disabled state to the enabled state merely by setting <WDTE> to “1”.

③ Watchdog timer out reset connection <RESCR>

This register is used to connect the output of the watchdog timer with the RESET terminal internally. Since WDMOD<RESCR>is initialized to “0” on a Reset, a Reset by the watchdog timer will not be performed.

(2) Watchdog Timer Control Register (WDCR)

This register is used to disable and clear the binary counter for the watchdog timer.

Disable control The watchdog timer can be disabled by clearing WDMOD<WDTE> to “0” and then writing the disable code (B1H) to the WDCR register.

```
WDMOD   ← 0 - - - - - X X    Clear WDMOD<WDTE>to “0”.
WDCR    ← 1 0 1 1 0 0 0 1    Write the disable code (B1H).
```

- Enable control

Set WDMOD<WDTE>to “1”.

- Watchdog timer clear control

To clear the binary counter and cause counting to resume, write the clear code (4EH) to the WDCR register.

```
WDCR    ← 0 1 0 0 1 1 1 0    Write the clear code (4EH).
```

Figure 3.12.5 Watchdog Timer Control Register

3.12.3 Operation

The watchdog timer generates an INTWD interrupt when the detection time set in the WDMOD<WDTP1, WDTP0> has elapsed. The watchdog timer must be zero-cleared in software before an INTWD interrupt will be generated. If the CPU malfunctions (i.e. if runaway occurs) due to causes such as noise, but does not execute the instruction used to clear the binary counter, the binary counter will overflow and an INTWD interrupt will be generated. The CPU will detect malfunction (runaway) due to the INTWD interrupt and in this case it is possible to return to the CPU to normal operation by means of an anti-multifunction program.

The watchdog timer does not operate in IDLE1 or STOP Mode, as the binary counter continues counting during bus release (When $\overline{\text{BUSAK}}$ goes low).

When the device is in IDLE2 Mode, the operation of WDT depends on the WDMOD<I2WDT> setting. Ensure that WDMOD<I2WDT> is set before the device enters IDLE2 Mode.

Example: ① Clear the binary counter.

```
WDCR    ← 0 1 0 0 1 1 1 0      Write the clear code (4EH).
```

② Set the watchdog timer detection time to $2^{17} / f_{SYS}$.

```
WDMOD ← 1 0 1 - - - X X
```

③ Disable the watchdog timer.

```
WDMOD ← 0 - - - - - X X      Clear WDTE to "0".
WDCR    ← 1 0 1 1 0 0 0 1    Write the disable code (B1H).
```

3.13 Real time clock (RTC)

3.13.1 Function description for RTC

1) Clock function (hour , minute , second)
2) Calendar function (month and day , day of the week , and leap year)
3) 24 or 12-hour (AM/PM) clock function
4) +/- 30 second adjustment function (by software)
5) Alarm function (Alarm output)
6) Alarm interrupt generate

3.13.2 Block diagram

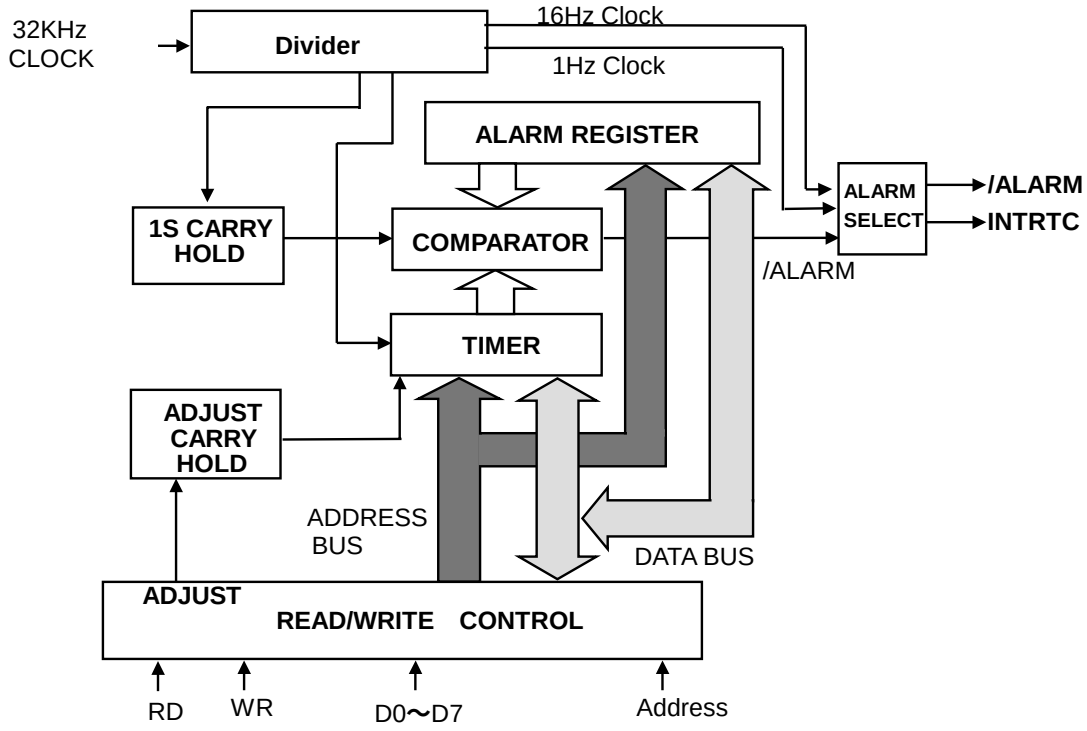

Figure 3.13(1) RTC block diagram

(Note1) The Christian era year column:
This product has year column toward only lower two columns. Therefore the next year in 99 works as 00 years. In system to use it, please manage upper two columns with the system side when handle year column in the Christian era.

(Note2) Leap year:
A leap year is the year, which is divisible with 4, but the year, which there is exception, and is divisible with 100, is not a leap year. However, the year is divisible with 400, is a leap year. But there is not this product for the correspondence to the above exception. Because there are only with the year which is divisible with 4 as a leap year, please cope with the system side if this function is problem.

0	Enable 1Hz clock (/ALARM output , INTRTC)
1	Disable 1Hz clock (/ALARM output , INTRTC)

3.13.5 Operational description

(1) Reading timer data

① There is the case, which reads wrong data when carry of the inside counter happens during the operation which timer data reads. Therefore please read two times with the following way for reading correct data.

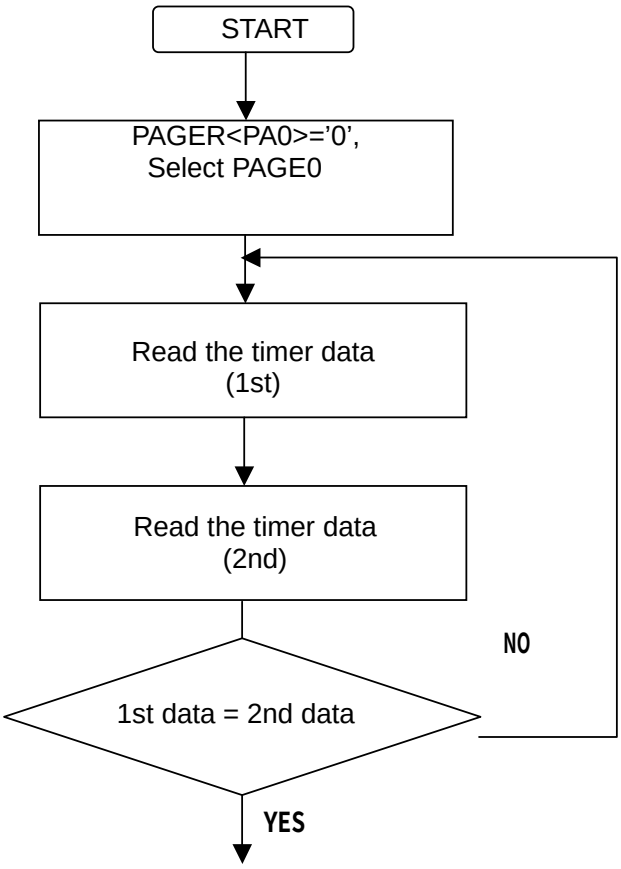

Figure 3.13(2) Flowchart of timer data read

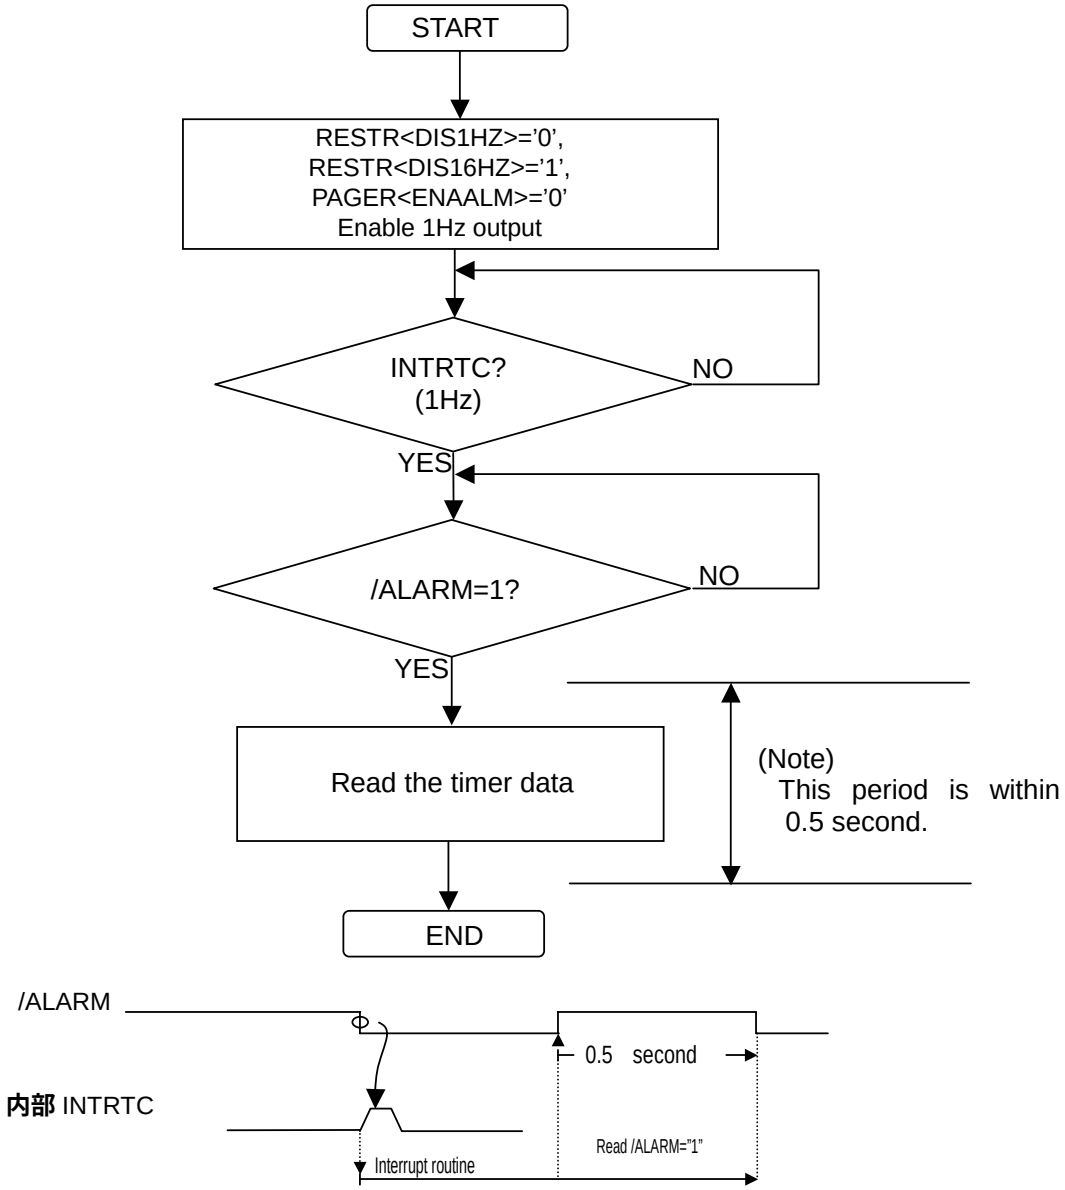
② Readout of timer data that used /ALARM output

Timer data can be read with rising edge of /ALARM output by detecting /ALARM='1' with interrupt routine of INTRTC of 1 Hz



The reason why read a timer of RTC after reading PORT in interrupt routine of /ALARM=1 is that carry of RTC timer occurs with rising edge of pulse period of 1 Hz. By reading timer during 0.5second after carry happening, right data (a timer value) can be read.

Figuire3.11(3) Readout of the timer table used /ALARM output

(2) Writing timer data

When there is carry on the way of write operation, expecting data can not be wrote exactly.

Therefore, in order to write in data exactly please follow the below way.

① Resetting a divider

In RTC inside, there are 15-stage dividers, which generates 1Hz clock from 32,768KHz. Carry of a timer is not done for one second when reset this divider. So write in data at this interval.

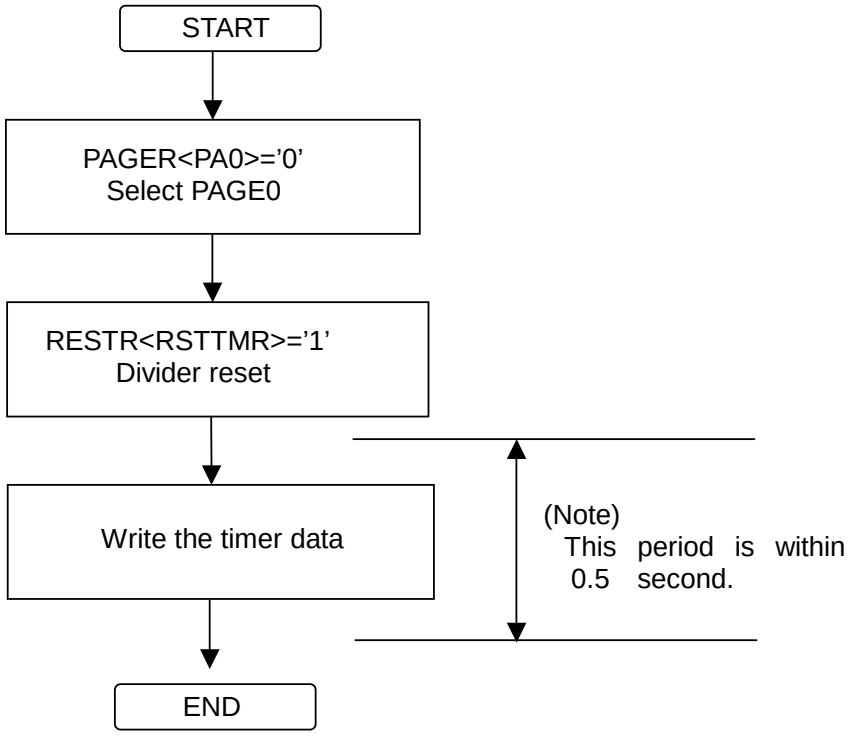


Figure 3.13(4) Flowchart of data write

② Disabling the timer

Carry of a timer is prohibited when write in '0' at PAGER<ENATMR> and can prevent malfunction by CLOCK HOLD circuit. During a timer prohibited, CLOCK HOLD circuits holds one sec. carry signal, which is generated from divider. After becoming timer enable state, output the carry signal to timer and revise time and continue operation. However, timer is late when timer-disabling state continues for one second or more. During timer disabling, pay attention with system power is downed. In this case the timer is stopped and time is delayed.

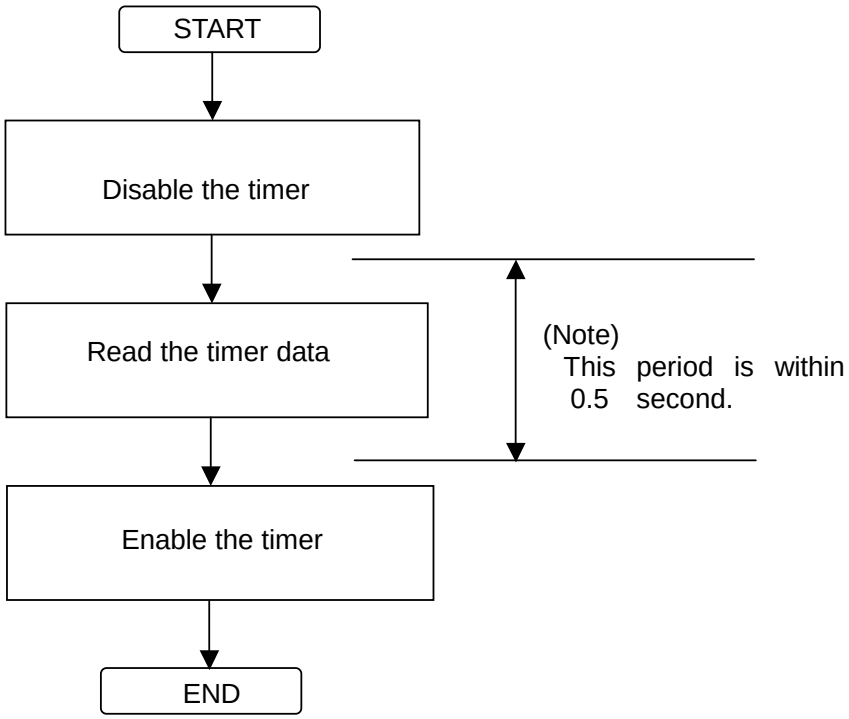

Figure 3.13(5) Flowchart of timer disable

Explanation of the alarm function

Can use alarm function by setting of register of PAGE1 and output either of three signal to /ALARM pin as follows.

(1) In accordance of alarm register and the timer, output '0'.

(2) Output clock of 1Hz.

(3) Output clock of 16Hz.

Resetting does not initialize RTC. So the case of using INTRTC, clear interrupt request flag INTERCKEY <IRC> after reset.

(1) In accordance of alarm register and a timer, output '0'.

When value of a timer of PAGE0 accorded with alarm register of PAGE1 with a state of PAGER<ENAALM>='1', output '0' to /ALARM pin and occur INTRTC.

Follows are ways using alarm.

Initialization of alarm is done by writing in '1' at RESTR<RSTALM>, setting value of all alarm becomes don't care. In this case, always accorded with value of a timer and occur INTRTC interrupt if PAGER<ENAALM> is '1'.

Setting alarm min., alarm hour, alarm day and alarm the day week is done by writing in data at each register of PAGE1.

When all setting contents accorded, RTC generates INTRTC interrupt, if PAGER<ENAALM> is '1'. However, contents (don't care state) which does not set it up is considered to always accord.

The contents, which set it up once, cannot be returned to don't care state in independence. Initialization of alarm and resetting of alarm register are necessary.

Follows are example program at outputting alarm in noon (PM12: 00) every day

```
LD      (PAGER), 09H      ; Alarm disable, setting PAGE1
LD      (RESTR), D0H      ; Alarm initialize
LD      (MONTHR), 01H     ; 24-hour clock mode
LD      (HOURR), 12H      ; setting 12 o'clock
LD      (MINR), 00H       ; setting 00 min.
LD      (PAGER), 0CH      ; Alarm enable
```

(2) When output clock of 1Hz

RTC outputs clock of 1Hz to /ALARM pin by setting up PAGER<ENAALM>='0', RESTR<DIS1HZ>='0', <DIS16HZ>='1'. And RTC generates INTRC interrupt by falling edge of the clock.

(3) When output clock of 16Hz

RTC outputs clock of 16Hz to /ALARM pin by setting up PAGER<ENAALM>='0', RESTR<DIS1HZ>='1', <DIS16HZ>='0'. And RTC generates INTRC interrupt by falling edge of the clock.

3.14 LCD controller (LCDC)

The TMP91C820A incorporates two types liquid crystal display driving circuit for controlling LCD Driver LSI. One circuit handles a RAM build-in type LCD driver that can store display data in the LCD driver itself, and the other circuit handles a shift-register type LCD driver that must serially transfer the display data to LCD driver for each display picture.

- Shift-register type LCD driver control mode (SR mode)

Set the mode of operation, start address of source data save memory and LCD size to control register before setting start register.

After set start register LCDC outputs bus release request to CPU and read data from source memory. After that LCDC transmits data of volume of LCD size to external LCD driver through data bus. At this time, control signals connected LCD driver output specified waveform synchronizes with data transmission.

After finish data transmission, LCDC cancels the bus release request and CPU will re-start.

As the DISPLAY RAM, SDRAM burst mode can be used in TMP91C820A.

- RAM built-in type LCD driver control mode (RAM mode)

Data transmission to LCD driver is executed by move instruction of CPU.

After setting mode of operation to control register, when moves instruction of CPU is executed

LCDC outputs chip select signal to LCD driver connected to the outside from control pin (D1BSCP etc.) . Therefore control of data transmission numbers corresponding to LCD size is controlled by instruction of CPU.

This section is constituted as follows.

3.14.1 Feature of LCDC of each mode

Each feature and operation of pin is as follows.

table 3.14.1Feature of LCDC of each mode

		Shift- register type LCD driver control mode	RAM built-in type LCD driver control mode
The number of picture elements can be handled		Common(row):128,160,200,240, 320,400,480 segment(column):128,160,240, 320,480,560,640	There is not a limitation
Receive data bus width		16bits fixed	Depend on the setting of CS/WAIT Controller.
Transfer data bus width		8bits fixed	
Transfer rate (at f_{FPH} =36[MHz])		55ns/1word at SDRAM/BURST 111ns/1 word at SRAM	
External pins	LCD Data Bus: (LD7 to LD0)	Data bus; Connect with DI pin of segment driver.	Exclusive Data bus for LCD; Connect with DB pin of segment/common driver.
	Bus State	not used	Bus State; Connect with /WR pin of segment/common driver.
	Address Bus: (A0)	not used	Address 0; Connect with D/I pin of segment driver. When A0=1 data bus value means display data, when A0=0 data bus means instruction data.
	Shift Clock Pulse: (D1BSCP)	Shift clock pulses; Connect with SCP pin of segment driver. LCD driver latches data bus value by falling edge of this pin.	Chip enable for segment driver 1; Connect with /CE pin of segment driver 1.
	Latch Pulse: (D2BLP)	Latch pulses output; Connect with LP pin of segment/common driver. Display data is latched in output register in LCD driver by rising edge of this pin.	Chip enable for segment driver 2; Connect with /CE pin of segment driver 2.
	Frame: (D3BFR)	LCD frame output; Connect with FR pin of segment/common driver.	Chip enable for segment driver 3; Connect with /CE pin of segment driver 3.
	Cascade Pulse: (DLEBCD)	Cascade pulses output; Connect with DIO1 pin of row driver. These pin outputs 1 shot pulse by every D3BFR pin changes.	Chip enable for common driver; Connect with /LE pin of common driver.
	Display Off: (/DOFF)	Display off output; Connect with /DSPOF terminal of segment/common driver. “L” means display off and “H” means display on.

These registers do not exist on TMP91C820A. These are image for instruction registers and display registers of external RAM built-in sequential access type LCD driver.

Address as Table 3.14.3is assigned to these registers, and the following chip enable pin becomes active when accesses corresponding address.

And, the area of these address is external area, so /RD,/WR terminal becomes active by external access .

Table 3.14.4 shows the address map in the case of controlling RAM built-in random access type LCD driver.

The explanation part of MMU circuit also explains this. This setup is performed by LCDCTL <MMULCD>.

Table 3.14.3 Memory mapping for built-in RAM sequential access type.

Register	Address	Purpose Sequential access type		Chip enable terminal	A0 terminal
LCDC1L	0FE0H	RAM built-in type driver 1	Instruction	D1BSCP	0
LCDC1H	0FE1H		Display data		1
LCDC2L	0FE2H	RAM built-in type driver 2	Instruction	D2BLP	0
LCDC2H	0FE3H		Display data		1
LCDC3L	0FE4H	RAM built-in type driver 3	Instruction	D3BFR	0
LCDC3H	0FE5H		Display data		1
LCDR1L	0FE6H	RAM built-in type driver 4	Instruction	DLEBCD	0
LCDR1H	0FE7H		Display data		1

Table 3.14.4 Memory mapping for built-in RAM random access type

Address	Purpose Random access type	Chip enable terminal
3C0000H～ 3CFFFFH	RAM built-in type driver 1	D1BSCP
3D0000H～ 3DFFFFH	RAM built-in type driver 2	D2BLP
3E0000H～ 3EFFFFH	RAM built-in type driver 3	D3BFR
3F0000H～ 3FFFFFH	RAM built-in type driver 4	DLEBCD

note1: We call built-in RAM sequential access type LCD driver that use register to access to display-ram without address.(Ex. T6B65A,T6C84 etc: mar/2000)

note2: We call built-in RAM random access type LCD driver that is same method to access to SRAM.(Ex.T6C23,T6K01 etc: mar/2000)

3.14.4 Shift- register type LCD driver control mode (SR mode)

3.14.4.1 Operation

Set the mode of operation, start address of source data save memory, gray-scale level and LCD size to control registers before setting start register.

After set start register LCDC outputs bus release request to CPU and read data from source memory. After that LCDC transmits data of volume of LCD size to external LCD driver through LD bus(LCD personal bus). At this time, control signals (DIBSCP etc.) connected LCD driver output specified waveform synchronizes with data transmission. After finish data transmission, LCDC cancels the bus release request and CPU will re-start.

NOTE: SR mode LCDC, during data reading (during DMA operation), CPU is stopped by internal BUSREQ signal. When using SR mode LCDC, programmer need to care the CPU stop time. For detail, see the Table 3.14.8.

3.14.4.2 Gray-scale mode Indication

Monochrome, 4, 8 and 16 Gray-scale mode can be selected by setting LCDGL<GRAY1: 0>.

And when SDRAM mode, you can select the size of SDRAM by setting (LCDMODE)<BULK>.

.

TMP91C820A realize gray scale display by thinning out the frame . Gray scale control palette is defined by 16bit resister (LGnL/H) shown in Table 3.14.5. Palette is selected according to the gray scale level(monochrome,4,8,16gray) for use.(cf. Table 3.14.6). ON/OFF for data of each level (i.e. each density) can modify by 16bit resister (LGnL/ H). However each resister of palette has a initial value , it is possible to adjust finely which matches to LCD driver you use and the characteristic of LCD panel.

Table 3.14.5 Gray scale control palette default setting

Level Code	Density	Data setting register (Address/ After reset)	bit0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

3.14.4.3 Memory mapping

The LCDC can display the LCD panel image which is divided horizontally into 3 parts ; upper , middle and lower. Each area calls A , B and C area that has some characteristics showing below.

Start/End address of each area in the physical memory space can be defined in the LCD Start/End address registers(see Table 3.14.2). (C area can be defined only start address.)

A and B areas are programmable visibility and they are set enable or not in LCDMODE register. When A and B area are disable , the C area take over all panel space.

When the size of A or B area is greater than LCD panel, the area of the panel is all C area because the displaying priority is A > B > C. If the A area set to enable while the panel area is defined as all C area (that is A and B area are disable) , C area is shifted to under the LCD panel and A area is inserted from the top of the LCD panel .Similarly if the B area set to enable while the panel area is defined as all C area , B area is inserted from the bottom of the C area overlapping .

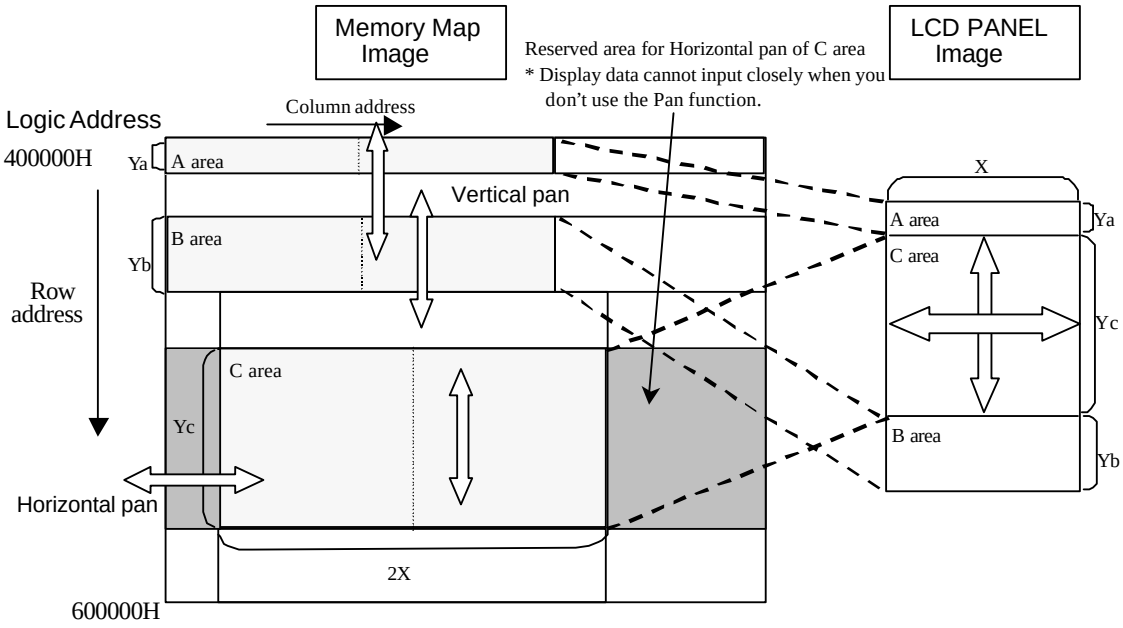

Figure 3.14.2 Memory mapping from physical memory to LCD panel

● Display memory mapping and Panning Function

LCDC can change the panel window if only you change each start address of A, B and C area. A and B area can be vertical panned by changing row address. While C area can be vertical and horizontal panned by changing row and column address.

An important thing is that display data from one line to the next line, cannot be input continuously even if you don't use the panning function. One Row address of display RAM corresponds to 1'st line of display panel. Now display data of 2'nd line cannot be set within the 1'st row address of display RAM even if the necessary data for the size you want to display do not fill the capacity of 1'st row address of display RAM. Adding the one line to display panel is equal to adding one address to row address of display RAM.

And another important thing is, this limitation is also for SRAM as display RAM without address multiplex. When you use SDRAM as display RAM, you can select the size for display RAM capacity of one line. But in case of using SRAM, display RAM capacity of one line is fixed to 512bytes.

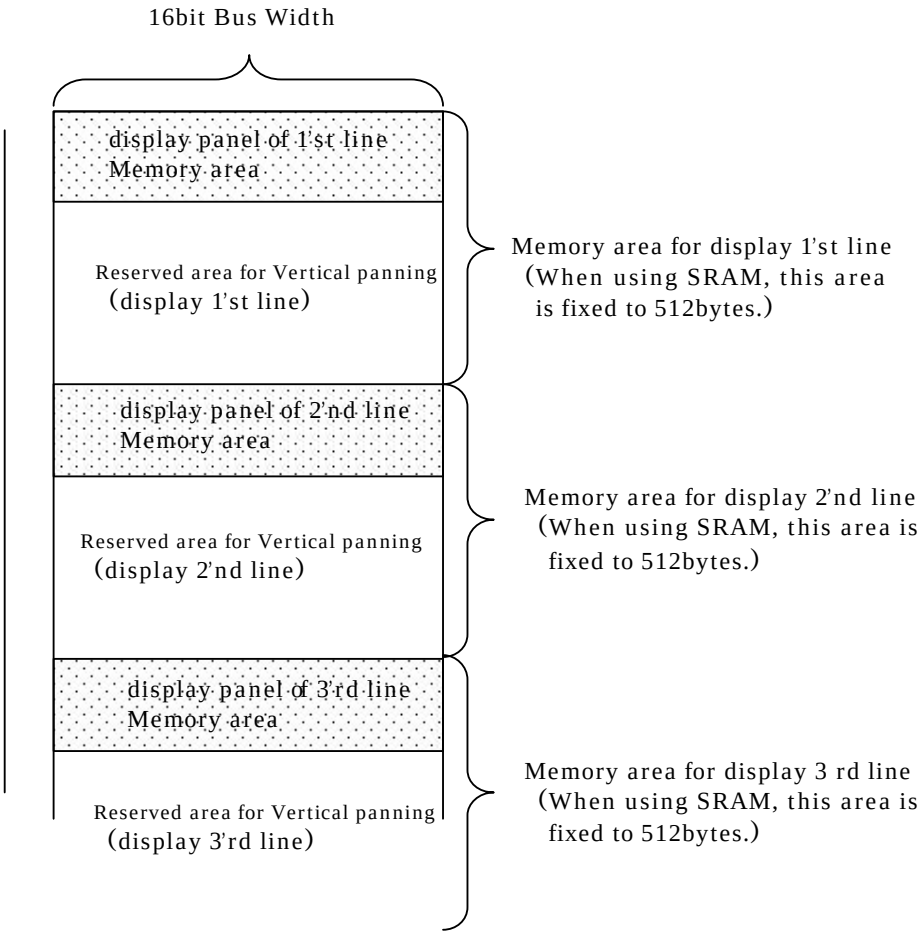

Figure 3.14.3 Memory mapping image for SRAM as display RAM

TMP91C820A can select four display scale ; monochrome , 4gray , 8gray and 16gray. With the intrinsic property of gray levels, a pixel is decoded in each gray level from different memory size.

A pixel is equal to a bit in memory for monochrome, while a pixel is equal to 2 bits in memory for 4-gray, 3 bits for 8-gray and 4 bits for 16-gray. Therefore when the 4gray mode , column address in the memory needs twice data capacity as large as dots that is displayed in the LCD panel actually showing Figure 3.14.4. Place for display data setting has some differences for each gray scale or sort of memory.

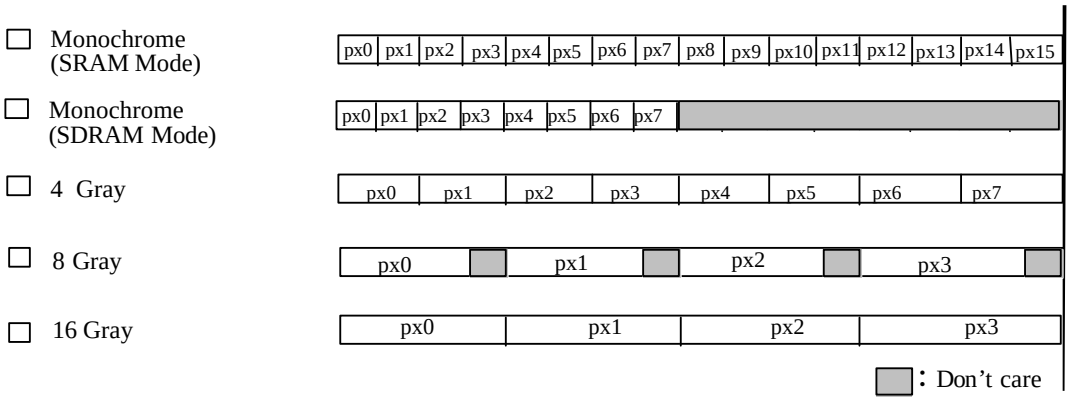

Figure 3.14.4 Memory codes for each gray level in a read cycle (16 bits)

And "px" in above Figure 3.14.4 corresponds to the image of LCD panel as below (Figure 3.14.5).But TMP91C820A outputs data of px0 from PE7(LD7), and data of px7 from PE0(LD0). Therefore PE0(LD0) should be connected to the MSB of LCD driver (e.g.DI7) according to LCD driver you use. Please note that the way TMP91C820A outputs the data differs from LCD controller built in 900/L1 Series of TOSHIBA (e.g. TMP91C815,TMP91C016,TMP91C025 etc.) .

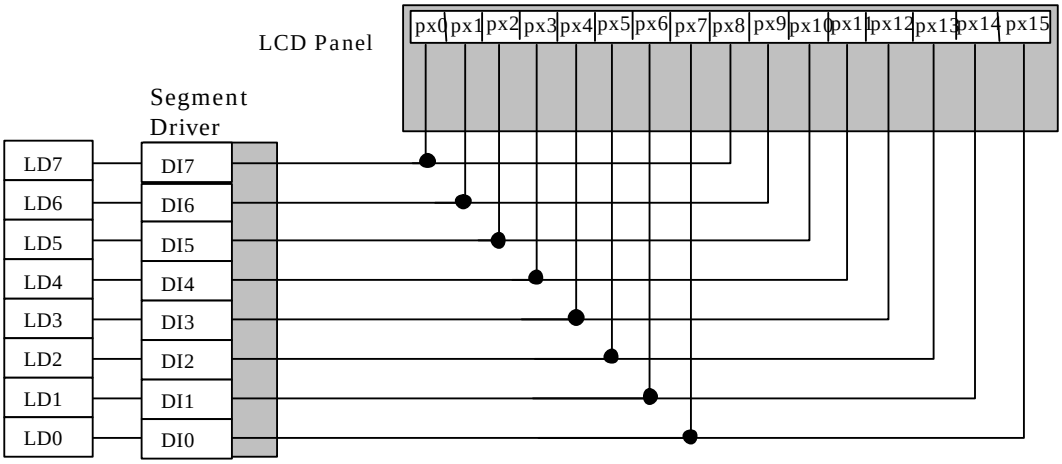

Figure 3.14.5 Connection between LCD bus of TMP91C820A and data bus of LCDD

3.14.4.4 Hardware cursor

TMP91C820A has a cursor that is blinking interval, color and size can be specified, and maximum size is 32 x 32.

A programmer can control the cursor attributes easily by filling those cursor registers, for example color (white/black) , blinking interval time , size and precise pixel location . Its space location is specified by left-up hot point. (see the Figure 3.14.6)

The precise location of the hot point is determined by memory address (LCDCPH,M,L) and bit correction number(LCDCP). For example, however 1 pixel for displaying needs 2 bits of setting data under 4gray mode, you can correct the location of Hot Point every 1 bit by setting pixel number which you want to move in the resister (LCDCP).

Cursor image is showed under the setting A,B,C area are enable , 4gray mode ,start address =410004_hex and correction bit (LCDCP)=3_hex in the following figure.

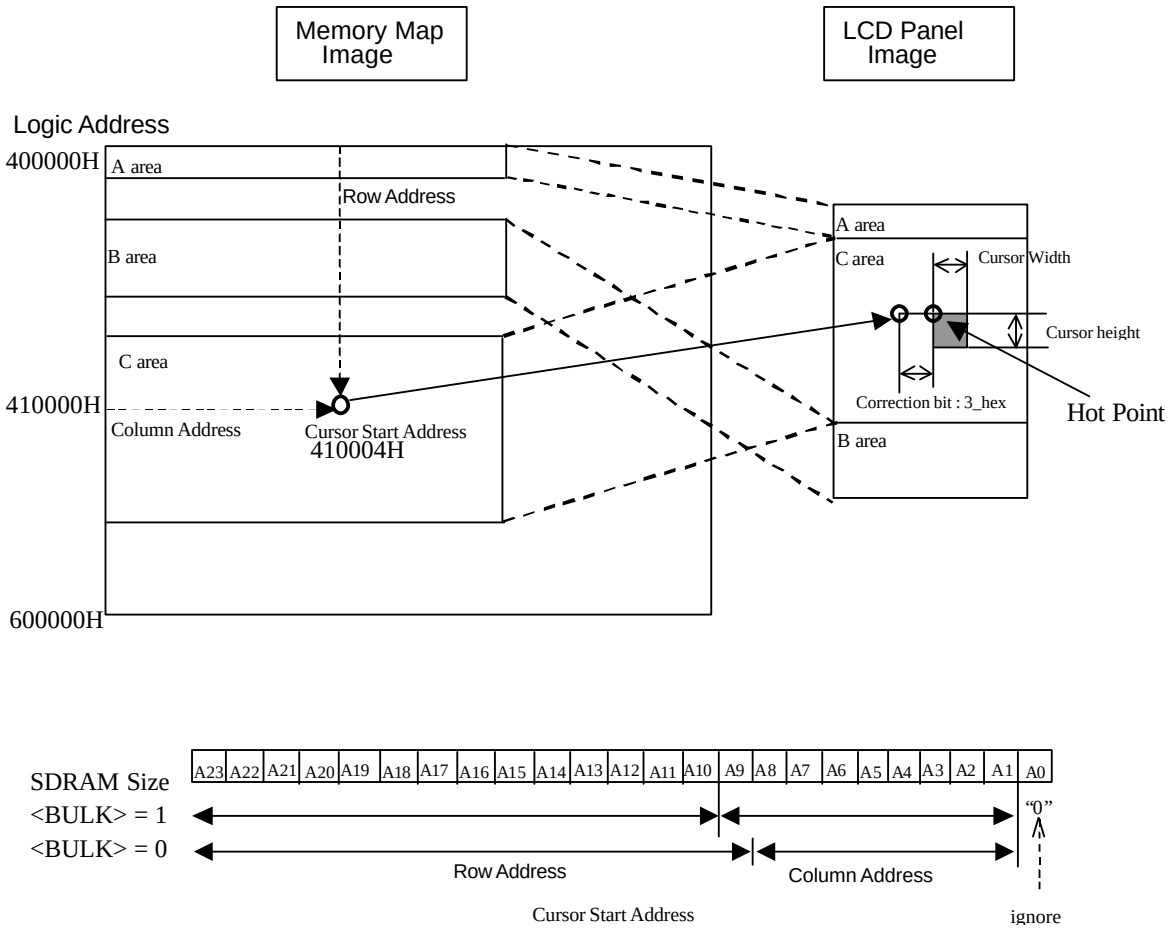

Figure 3.14.6 Cursor hot point position and size

(Note) : If panning function is set to enable during hardware cursor displaying ,the cursor moves with the data in the memory. Because TMP91C820A sets the hardware cursor in the memory address .

LCD Cursor Setting Register

After Reset					0			
Function					Setting bit3-0 of pixel for correction of Hot Point (for 1-dot correction)			

In case of monochrome (SRAM mode)	0000: 0 Pixel correct 1111: 15 Pixels correct	
In case of monochrome (SDRAM mode) and 4gray	x000: 0 Pixel correct x001: 1 Pixel correct x010: 2 Pixels correct x011: 3 Pixels correct	x100: 4 Pixels correct x101: 5 Pixels correct x110: 6 Pixels correct x111: 7 Pixels correct
In case of 8 and 16gray	xx00: 0 Pixel correct xx01: 1 Pixel correct	xx10: 2 Pixels correct xx11: 3 Pixels correct

X : don't care

Here , it is possible to correct the cursor per 1bit from the start address set before. Pixel number should be adjusted in response to the gray mode setting showing above.

For example , When 4gray and 16bit BUS mode, correction should be less than 7 because the smallest pixel is 8 pixels that can set by start address setting. Similarly correction pixel should be less than 15 at monochrome mode , 3 at 8 or 16 gray mode.

(Ex.)When Monochrome mode, correction value is (LCDCP)=011_hex,and cursor size=(8x8)

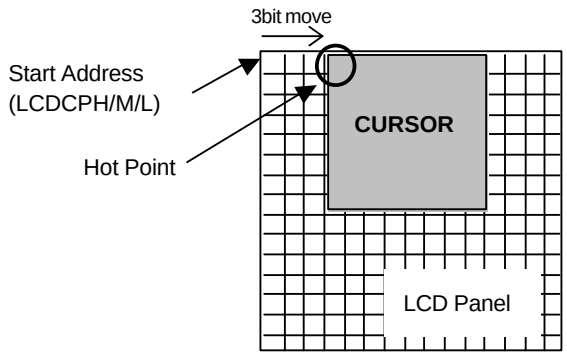

Figure 3.14.7 The location Hot Point by setting of pixel

3.14.4.5 Frame Signal Settlement

TMP91C820A defines so-called frame period (refresh interval for LCD panel) by the value set in fFP[9:0] . DLEBCD pin outputs pulse every frame period. DLEBFR pin usually outputs the signal inverts polarity every frame period.

And TMP91C820A has a special function that can set the timing of inverting frame polarity irrelevant to above frame frequency for the purpose of preventing the patches of display.

LCD Control Register

LCDCTL (04B3H)

Function	Setting DVM bit7-0							

(1) Settlement of Frame frequency function

Basic Frame period ; DLEBCD signal , is made according to the resister f_{FP}[9:0] setting mentioned before. However this f_{FP}[9:0] setting is generally equal to common number , frame period can be corrected by increasing f_{FP}[9:0] with ease. This function cannot correct frame frequency higher than that of Table 3.14.7. If it is necessary to set frame frequency higher or detailed , please refer to (3) Timer Out LCDCK .

The equation can calculate frame period .

Frame period = LCDCK / (D x f_{FP}) [Hz]

D: constant for each common(Table 3.14.7)

f_{FP}: setting of f_{FP}[9:0] resister

LCDCK: source clock of LCD

(low clock is usually selected)

Please select the value of f_{FP} [9:0] as the frame period you want to set in the Table 3.14.7.

(Note) : Please make the value set to f_{FP} [9:0] into the following range.

COM(common number) $\leqq$ FR $\leqq$ 1024

(EX.1) : In the case where frame period is set to 72.10Hz by 240coms .

f_{FP} =240(COM)+63 = 303 = 12FH (by Table 3.14.7)

Therefore, LCDCTL<FP8> = 1 and LCDFFP<FP7: 0> = 2FH are set up.

(2) Frame Invert Adjustment Function

This mode can prevent the deterioration of display (e.g. patches of display).(*Note1) If N is set in (LCDDVM) resister while this function is set to enable in resister (LCDCTL)(<FRMON> "1"), D3BFR pin outputs the signal inverted polarity every (D2BLP x N) timing.

If this function isn't necessary , D3BFR pin outputs the signal inverted polarity every frequency of DLEBCD pin after setting this function disable ((LCDCTL)<FRMON>="0").

And it is no change wave and timing for DLEBCD pin by LCDDVM setting.

(Note1) : Effects of this function have some differences as the LCD driver or LCD panel you use actually.

(3) Timer Out LCDCK

LCD source clock (LCDCK) can select low frequency (XT1,XT2 :32.768[KHz]) or timer out (TA3OUT) outputs from internal TMRA23.

(EX.2) : Here indicates the method that frame period is set 70[Hz] by selecting TA3OUT for source clock of LCD .(fc = 6[MHz] , 128COM)

The next equation calculates frame period.

Frame period = $1 / (t_{LP} \times f_{FP})$ [Hz] t_{LP} : The period of D2BLP

Source clock for LCDC defines as XT[Hz] and then this t_{LP} represents

$t_{LP} = D / XT$ D : the value is 3 at 128COM

Therefore if you set the frame period at 70[Hz] under 128 COM,

XT = 128 x 3.5 x 70

= 26880[Hz]

XT should be above value .

In order to make XT=26880[Hz] under fc= 6[MHz]with ϕT1 of timer3,

$1 / XT = T3 \times 2 \times 8 / fc$ [s] T3: the value of timer resister (TA3REG)

in short, $XT = fc / (T3 \times 2 \times 8)$ [Hz]

However T3=(TA3REG) is 13.95 after calculate , it 's impossible to set the value under a decimal point.

So if (TA3REG) is set 0DH , XT = 28846 [Hz]. And because of D=3,

Frame period = 28846 / (128 x 3)

= 75.12 [Hz]

Further if fFP is 136(COM+8) with correction,

Frame period = 28846 / (136 x 3)

= 70.70···[Hz]

(Reference) : To maintain quality for display , please refer to following value for each gray scale.

(You have to use settlement of frame frequency function , frame invert adjustment function and timer out LCDCK .)

Monochrome : Frame period =70[Hz]

4/8/16 gray : Frame period = 140[Hz]

(NOTE1) The value of the Table 3.14.8 is at f_{FPH} = 36[MHz].

(NOTE2) CPU stop time ; t_{STOP} (in the Figure 3.14.11) is the time which CPU reads the memory of transferring with 0 WAIT.

(NOTE3) The following equation can calculate t_{LP} listed below.

t_{LP} = D / 32768 [sec]

(ex) If the row is 240 and D = 1.5 by the above table

t_{LP} = 1.5 / 32768 = 45.8 [us]

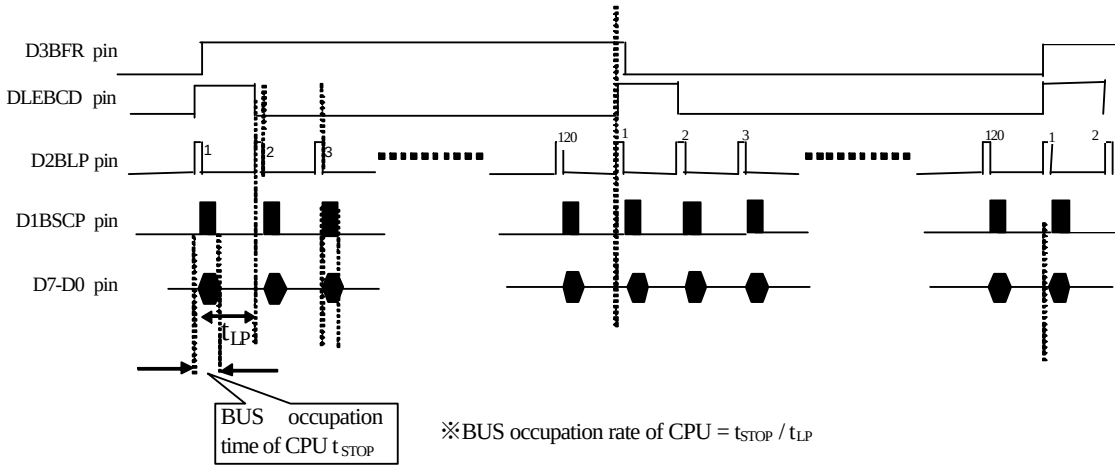

Figure 3.14.11 Stop time and BUS occupation rate of CPU

3.14.4.6 Timing Charts of Interpreting Memory Codes

TMP91C820A supports different memory accessing. They are SRAM with waits, SDRAM burst modes, and the size of SDRAM is 64 or 128Mbits. The access signals for the LCD panel are shown in Figure 3.14.12. To catch low speed LCD drivers, 3 types of SCP rates(fsys/2 ,fsys/ 4, and fsys/8) can be selected. The output data (LD7-LD0) will be issued from the built-in FIFO at the rising edge of D1BSCP when the FIFO is no-empty. The work of the FIFO is illustrated in Figure 3.14.13, where the buffer size 80 bytes. The FIFO latches BaseLD7-LD0 signal at the falling edge of BaseSCP which is shown in Figure 3.14.14 and Figure 3.14.15 for SRAM and SDRAM modes respectively. The FIFO is always reset to the empty state by the rising edge of D2BLP. In Base SCP mode (i.e. for SCPW1,0 =00), D1BCP is equal to BaseSCP , LD7-LD0 equal to BaseLD7-LD0 and no FIFO used. Generally , the data input rate of FIFO should be greater than the output one.

To make FIFO work correctly, the following condition have to be satisfied by setting SFR properly.

$$(SegNum/8+1)\times tcw + 24\times t_{FPH} < t_{LP} - t_{LPH}$$

Here, SegNum is the Segment Number, and tcw D1BSCP Clock cycle width . Referring Figure 3.14.16, we can know this relation means that the last LD7-LD0 data must be generated before the rising edge of D2BLP.

For example, in case of f_{FPH}= 36MHz, XT=32kHz, 4 gray, 240 com, 640 seg, and SDRAM burst mode, the following table can be obtained, which tells user that 8 clock mode is impossible and base,2,4 clock modes can be used.

SCPW	D1BSCP Rate (MHz)	tcw (ns)	(SegNum/8+1)×tcw +24×t_{FPH}(ns)	t_{LP}- t_{LPH} (ns)	Judgment
Base	18	55.6	5166.1	31250	OK
2clk	9	111.2	9674.4	31250	OK
4clk	4.5	222.4	18681.6	31250	OK
8clk	2.25	444.8	36696	31250	NG

(note) : The speed of BaseSCP mode is equal to 2clk mode in the 8/16GRAY mode.

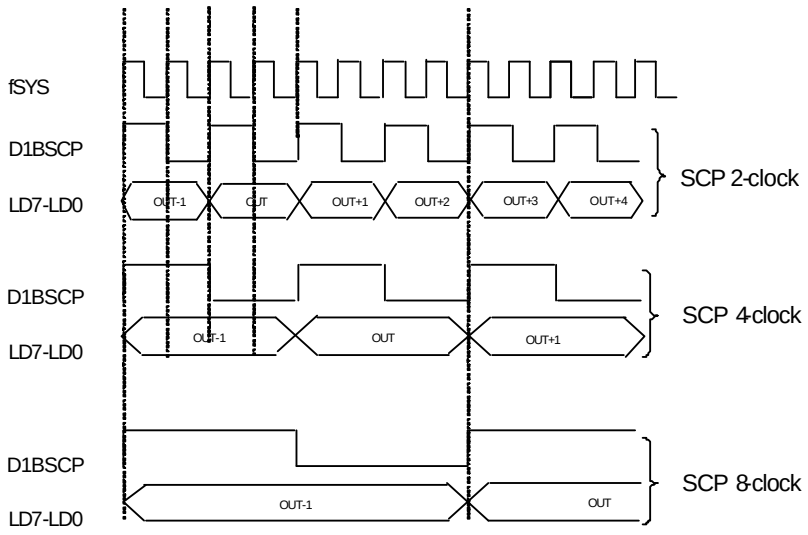

Figure 3.14.12 Timing diagram for the LCD panel access signals

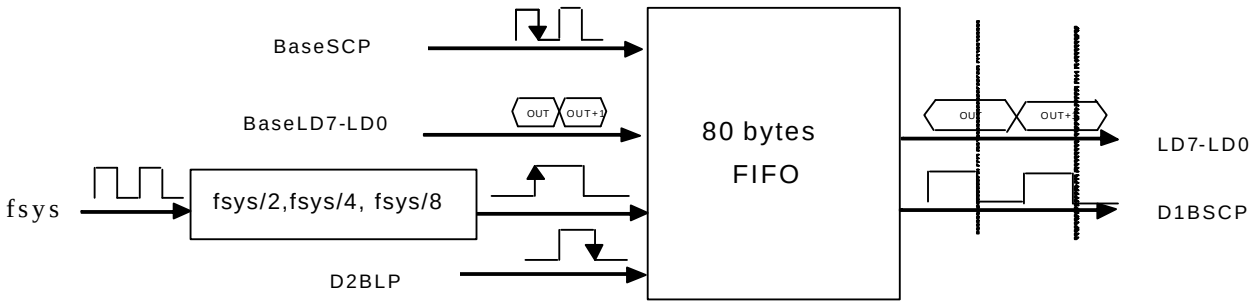

Note: D1BCP=BaseSCP and LD7-LD0=BaseLD7-LD0 in Base SCP mode (i.e. for SCPW[1:0] =00)

Figure 3.14.13 Timing diagram for FIFO

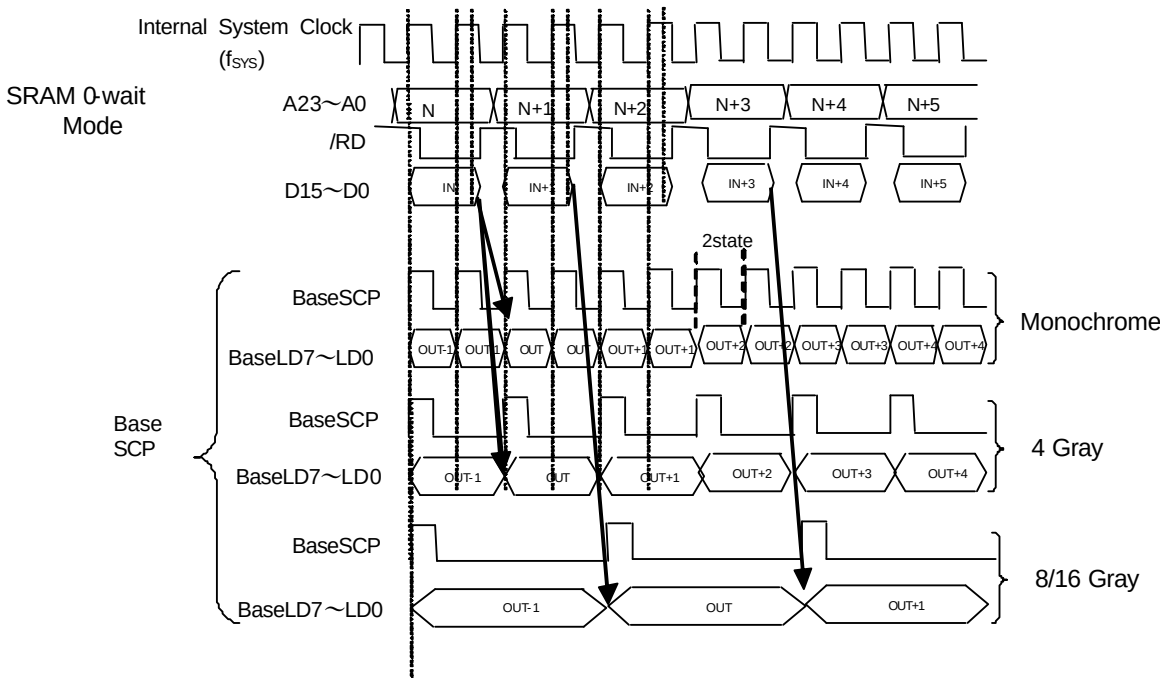

Figure 3.14.14 Timing diagram for SRAM mode with base SCP

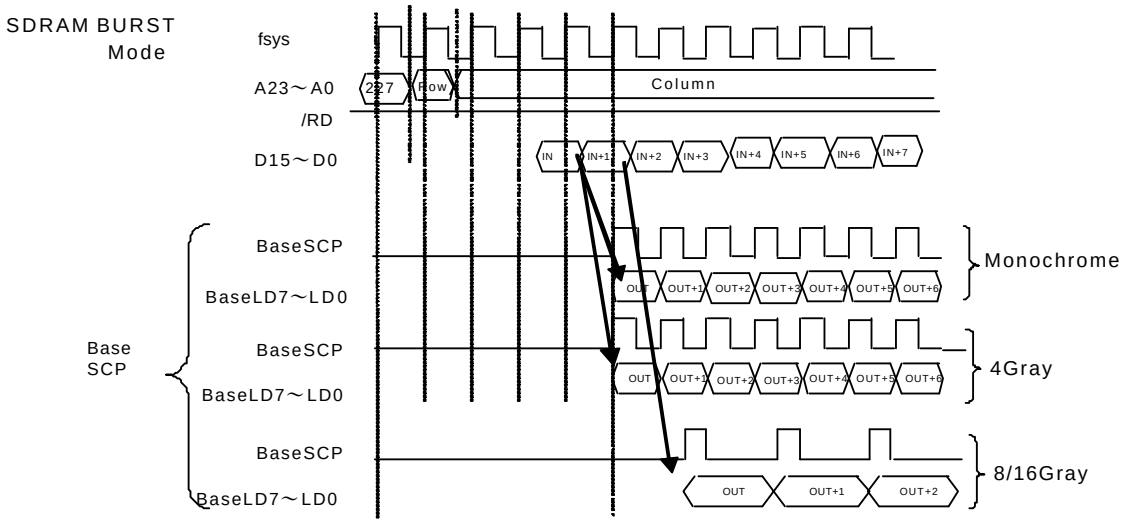

Figure 3.14.15 Timing diagram for SDRAM BURST mode with base SCP

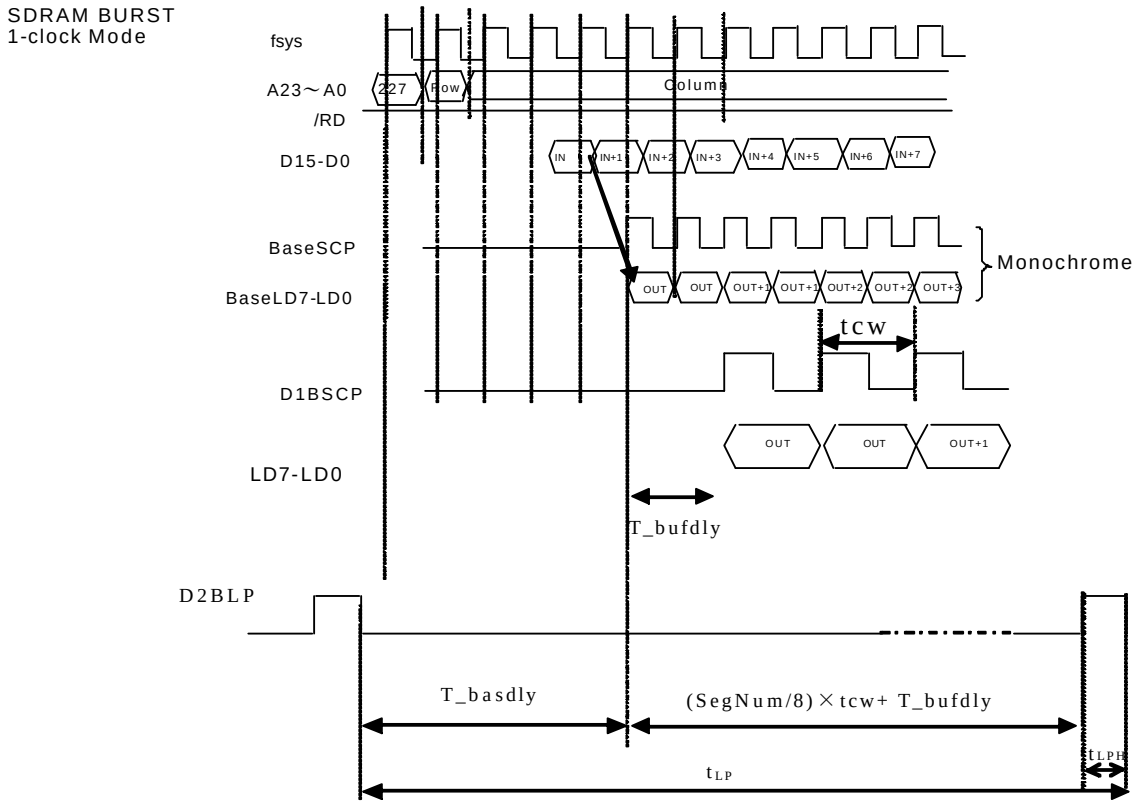
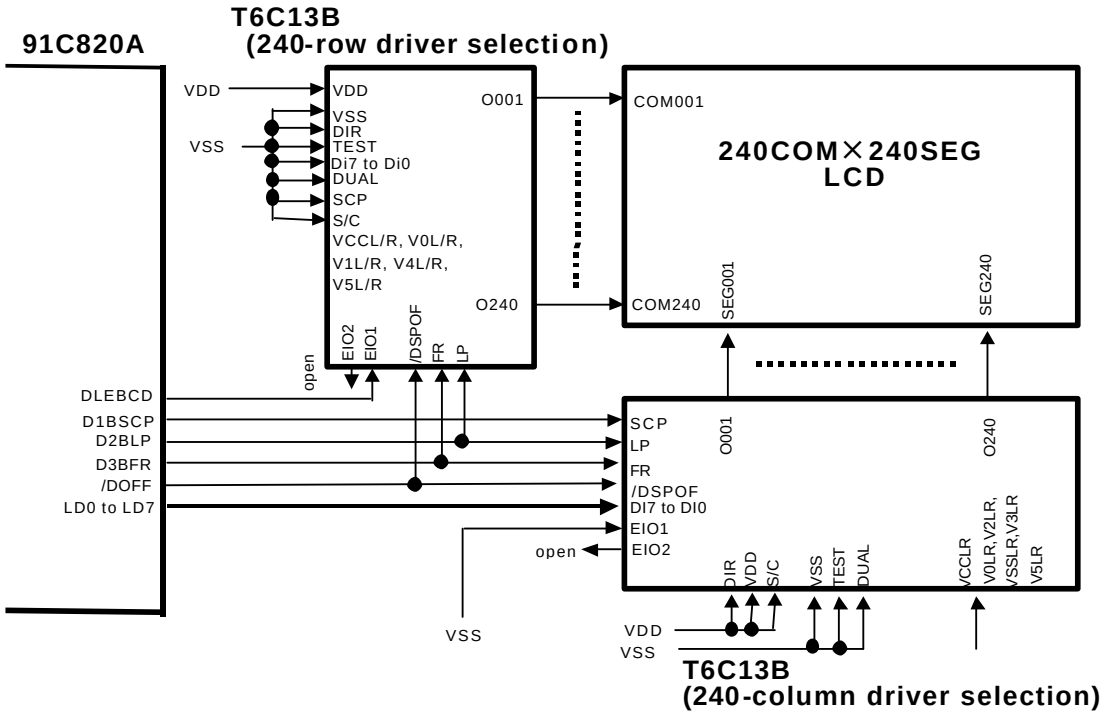


Note：1. $4t_{FPH} \leqq Tbufdly \leqq tc + 2t_{FPH}$

2. Tbasdly is about 11 times as long as f_{SYS} period (22 t_{FPH}).

Figure 3.14.16 Timing diagram for maximum FIFO delay time .

3.14.4.7 Interface Examples at SR Mode



(Note1) : Display memory should be 16bit bus.
(Note2) : Other circuit is necessary for LCD drive power supply for LCD driver display.

Figure 3.14.17 Interface example for shift register type LCD driver

【Note】 Because the connection between the line of display RAM data and output bus:LD0:7 is just the mirror reverse, please care of connection. The data LSB of display RAM is output from LD7. In the above figure , LD0 should be connected to DI7 of LCD driver , and LD1 to DI6 .
For detail information, please refer to Figure 3.14.5.

3.14.5 RAM built-in type LCD driver control mode (RAM mode)

3.14.5.1 Operation

Data transmission to LCD driver is executed by move instruction of CPU.

After setting mode of operation to control register, when move instruction of CPU is executed LCDC outputs chip select signal to LCD driver connected to the outside from control pin (D1BSCP etc.). Therefore control of data transmission numbers corresponding to LCD size is controlled by instruction of CPU. There are 2 kinds of address of LCD driver in this case, and which is chosen determines by LCDCTL <MMULCD> register.

It corresponds to LCD driver which has every 1 byte of instruction register and display data register in LCD driver at the time of <MMULCD> ="0." Please make the transmission place address at this time into either of FE0H-FE7F. **(SEQUENTIAL ACCESS TYPE: see the** Table 3.14.3**)**

It corresponds to address direct writing type LCD driver at the time of <MMULCD> ="1."

The transmission place address at this time can also assign the memory area of 3C0000H - 3FFFFF to four area for every 64 K bytes. **(RANDOM ACCESS TYPE: see the** Table 3.14.4**)**

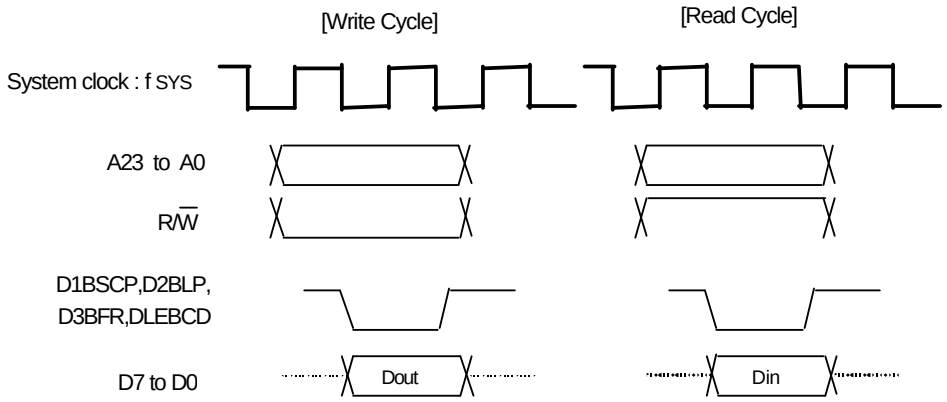

Figure 3.14.19 Example of access timing for RAM built-in type LCD driver (Wait=0)

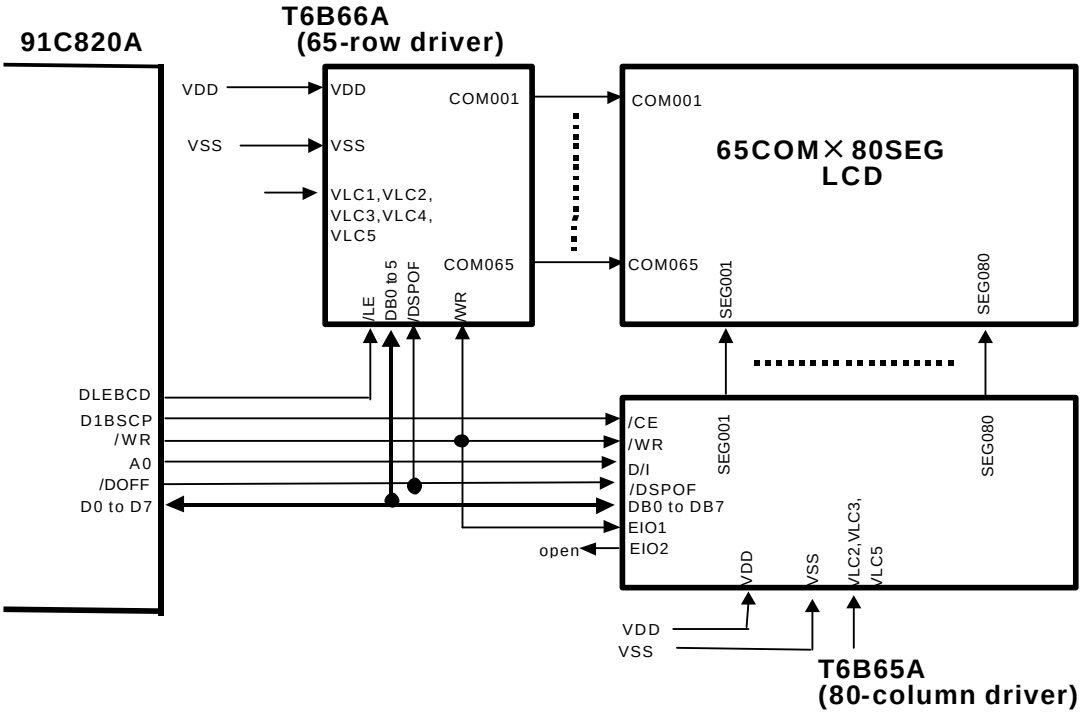
3.14.5.2 Interface Examples at Internal RAM Mode



(Note) Other circuit is necessary for LCD drive power supply for LCD driver display.

Figure 3.14.20 Interface example for RAM built-in type sequential access type LCD DRIVER

3.14.5.3 Sample Program

●Setting example : In case of use 80SEG X 65COM LCD driver.

Assign external column driver to LCDC1 and row driver to LCDC4.

This example used LD instruction in setting of instruction and used burst function of micro DMA by soft start in setting of display data.

In case of store 650 bytes transfer data to LCD driver.

```

3.15 Melody / Alarm generator(MLD)

TMP91C820A incorporates melody function and alarm function, both of which are output from the MLDALM pin. Five kind of fixed cycles INTERRUPT is generate by using 15bit counter, which is used for alarm generator.

Features are as follows.

- Melody generator

The Melody function generates signals of any frequency (4Hz- 5461Hz) based on low-speed clock (32.768KHz) and outputs the signals from the MLDALM pin.

By connecting a loud speaker outside, Melody tone can easily sound.

- Alarm generator

The Alarm function generates eight kinds of alarm waveform having a modulation frequency (4096Hz) determined by the low-speed clock (32.768KHz). And this waveform is able to invert by setting a value to a register.

By connecting a loud speaker outside, Alarm tone can easily sound.

Five kind of fixed cycles (1Hz, 2Hz, 64Hz, 512Hz, 8KHz) INTERRUPT be generated by using a counter which is used for alarm generator.

- Special mode

It is assigned <TA3LCDE> at bit0 and <TA3MLDE> at bit1, of EMCCR4 register (00E7hex). These bits are used when you want to operate LCDD and MELODY circuit without low frequency clock (XTIN,XTOUT) . After reset these two bits set to ’0’ and low clock is supplied each LCDD and MELODY circuit. If you write these bits to ‘1’, TA3OUT (generate by timer3) is supplied each LCDD and MELODY circuit. In this case, you should set 32KHz timer3 frequency. For detail, look AC specification characteristics.

This section is constituted as follows.

3.15.3 Operational Description

3.15.3.1 Melody generator

The Melody function generates signals of any frequency (4Hz- 5461Hz) based on low-speed clock (32.768KHz) and outputs the signals from the MLDALM pin.

By connecting a loud speaker outside, Melody tone can easily sound.

(Operation)

At first, MELALMC<MELALM> have to be set as 1 in order to select melody waveform as output waveform from MLDALM. Then melody output frequency has to be set to 12-bit register MELFH, MELFL.

Followings are setting example and calculation of melody output frequency.

(Formula for calculating of melody waveform frequency)

@fs = 32.768[kHz]

melody output waveform f_{MLD}[Hz] = 32768 / (2×N+4)

setting value for melody N = (16384 / f_{MLD}) – 2

(notice: N=1～4095(001H～FFFH)、0 is not acceptable)

(Example program)

In case of outputting "A" musical scale (440Hz)

```
LD      (MELALMC), --XXXXX1B    ; select melody waveform
LD      (MELFL), 23H            ; N= 16384/440 – 2 = 35.2 = 023H
LD      (MELFH), 80H            ; start to generate waveform
```

(Refer: Basic musical scale setting table)

scale	Frequency [Hz]	Register Value:N
C	264	03CH
D	297	035H
E	330	030H
F	352	02DH
G	396	027H
A	440	023H
B	495	01FH
C	528	01DH

3.15.3.2 Alarm generator

The Alarm function generates eight kinds of alarm waveform having a modulation frequency 4096Hz determined by the low-speed clock (32.768KHz). And this waveform is reversible by setting a value to a register.

By connecting a loud speaker outside, Alarm tone can easily sound.

Five kind of fixed cycles (1Hz, 2Hz, 64Hz, 512Hz, 8KHz) INTERRUPT be generate by using a counter which is used for alarm generator.

(Operation)

At first, MELALMC<MELALM> have to be set as 0 in order to select alarm waveform as output waveform from MLDALM. Then alarm pattern has to be set on 8-bit register of ALM. Finally "10" be set on MLDALMC<AC1: 0> register, and <ALMINV> be set as invert. By setting these values, counter start to generate alarm waveform.

Followings are example program, setting value of alarm pattern and waveform of each setting value.

(Setting value of alarm pattern)

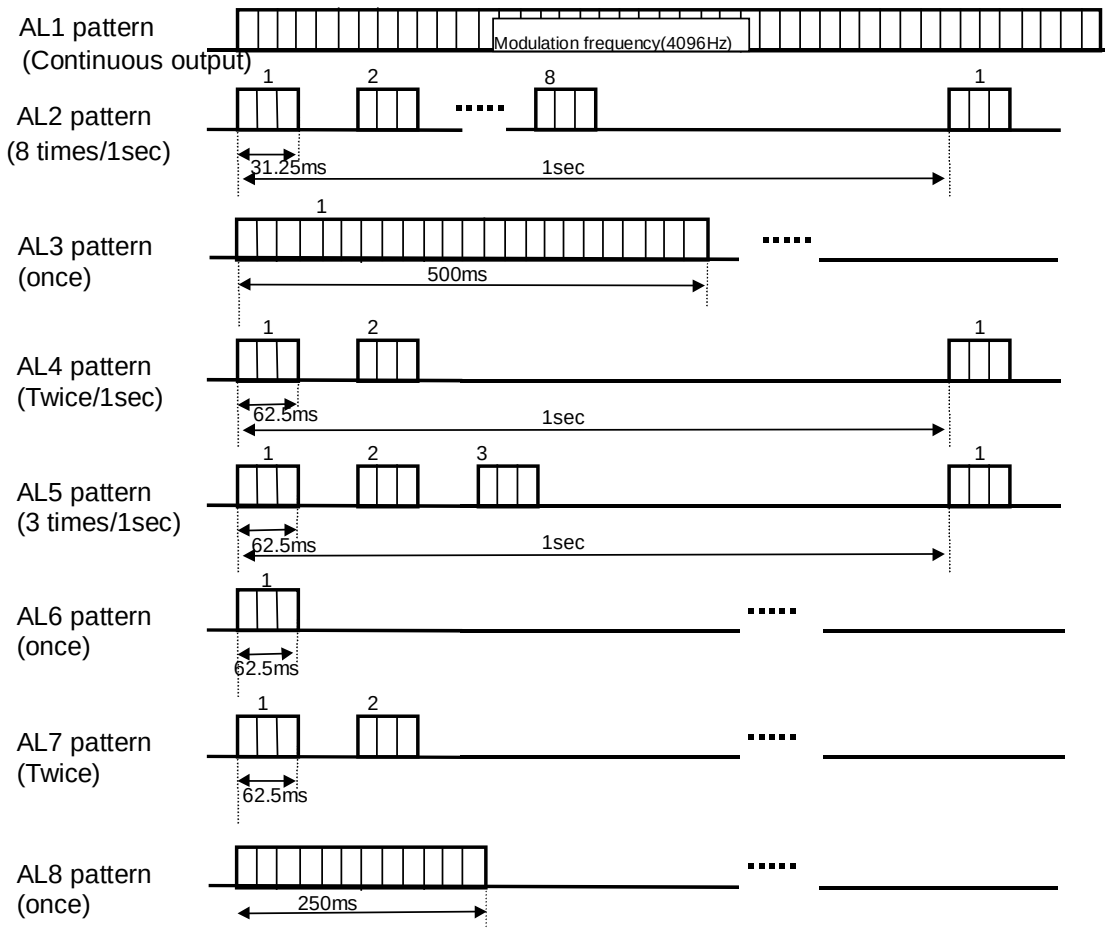
Setting value for ALM register	Alarm waveform
00H	"0" fixed
01H	AL1 pattern
02H	AL2 pattern
04H	AL3 pattern
08H	AL4 pattern
10H	AL5 pattern
20H	AL6pattern
40H	AL7 pattern
80H	AL8 pattern
Other	Undefined (do not set)

(Example program)

In case of outputting AL2 pattern (31.25ms/8 times/1sec)

```
LD      (MELALMC), C0H          ; set output alarm waveform
                                ; Free-run counter start
LD      (ALM), 02H              ; set AL2 pattern, start
```

Example: Waveform of alarm pattern for each setting value: not invert)



3.16 SDRAM Controller(SDRAMC)

TMP91C820A includes SDRAM controller which supports SDRAM access by CPU/LCDC.
The features are as follows.

(1) Support SDRAM
16M/64M/128Mbit SDRAM(×16bits×2/4Banks)

(2) Automatic Initialize Function
- All Bank Pre-charge Command Generate
- Mode Register Set Generate
- 8 times Auto Refresh

(3) Access Mode

	CPU Access	LCDC Access
Burst Length	1word	Full Page
Addressing Mode	Sequential	Sequential
CAS Latency(clock)	2	2
Write Mode	Single Write	Single Write

(4) Access Cycle
- CPU Access (Read/Write)
  Read Cycle : 4state(296ns @27MHz)
  Write Cycle : 3state(222ns @27MHz)
  Access Data Width: 8bit/16bit

- LCDC Burst Access (Read only)
  Read Cycle : 1state(74ns @27MHz)
  Over head : 4state(296ns @27MHz)
  Access Data Width: 16bit only

(5) Refresh Cycle Auto Generate
- Auto Refresh is generated during another area access.
- Refresh interval is programmable.
- Self Refresh is supported

(Notes)
- Display data has to set from the head of each page.
- Program is not operated on SDRAM.
- Condition of SDRAM area is set by CS1 setting of CHIP SELECT CONTROLLER.
- Set CS1's WAIT setting to 0-wait.

3.16.1 Control Registers

Figure 3.16.1(1) shows the SDRAMC control registers. Setting these registers controls the operation of SDRAMC.

SDACR (04F0H)

Figure 3.16.1(1) SDRAMC control registers

3.16.2 Operation description

(1) Memory access control

Access control block is enable when SDACR<SMAC>=1. And then DRAM control Signals (SDCS,SDRAS,SDCAS,SDWE,SDLDQM,SDUDQM,SDCLK and SDCKE) are output during the time CPU or LCDC accesses CS1 area.

In the access cycle, Address multiplex outputs row/column address through A1 to A12 pin. The enable/disable setting of address multiplexing is controlled by SDACR <SMUXE>. And multiplex width is decided by setting SDACR<SMUXW 0 and 1> of use memory size. The relation between multiplex width and memory size is below.

Table 3.16.2 Address mutiplex

SDRAM Address Pin Name	TMP91C820A Address Output			
	Column Address	Row Address		
		16M	64M	128M ← Memory size
—	A0	A0	A0	A0
A0	A1	A9	A9	A10

↑ TMP91C820A address pin name

effective column address

SDRAM access by CPU is performed by the 1 Word burst mode. SDRAM access by LCDC is performed by the 1 page burst mode. DRAM access cycle is shown in (6) from Fig. 3.16.2 (1).

The read cycle by CPU is the 4 State fixation, and a write cycle is the 3 State fixation.
In the burst read cycle by LCDC, a mode setup, a pre-charge cycle, and a refresh cycle are automatically inserted in a read cycle front and back.

(Note)

In SDRAM access cycle, WAIT setup by the CS/WAIT controller (CS1) is disregarded. The wait setting of CS1 should be 0 wait.

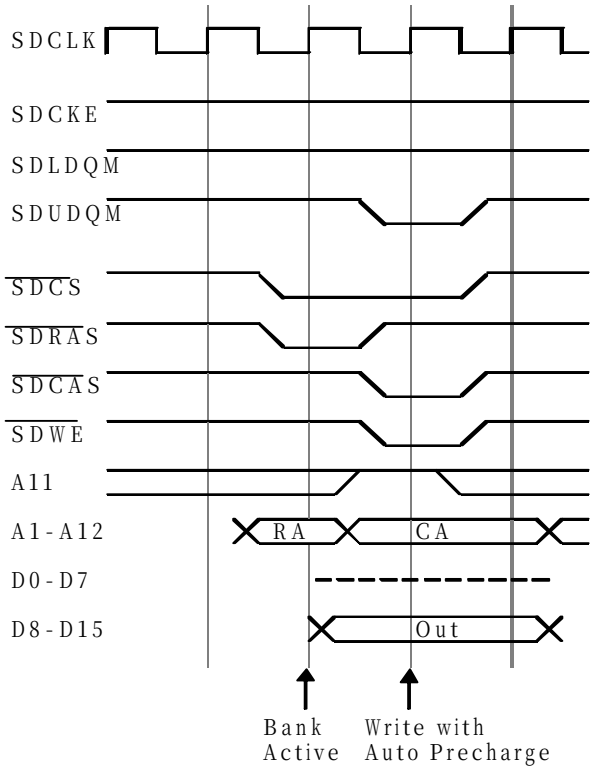

Figure 3.16.2(5) SDRAM Access Timing (CPU Uper byte Write)

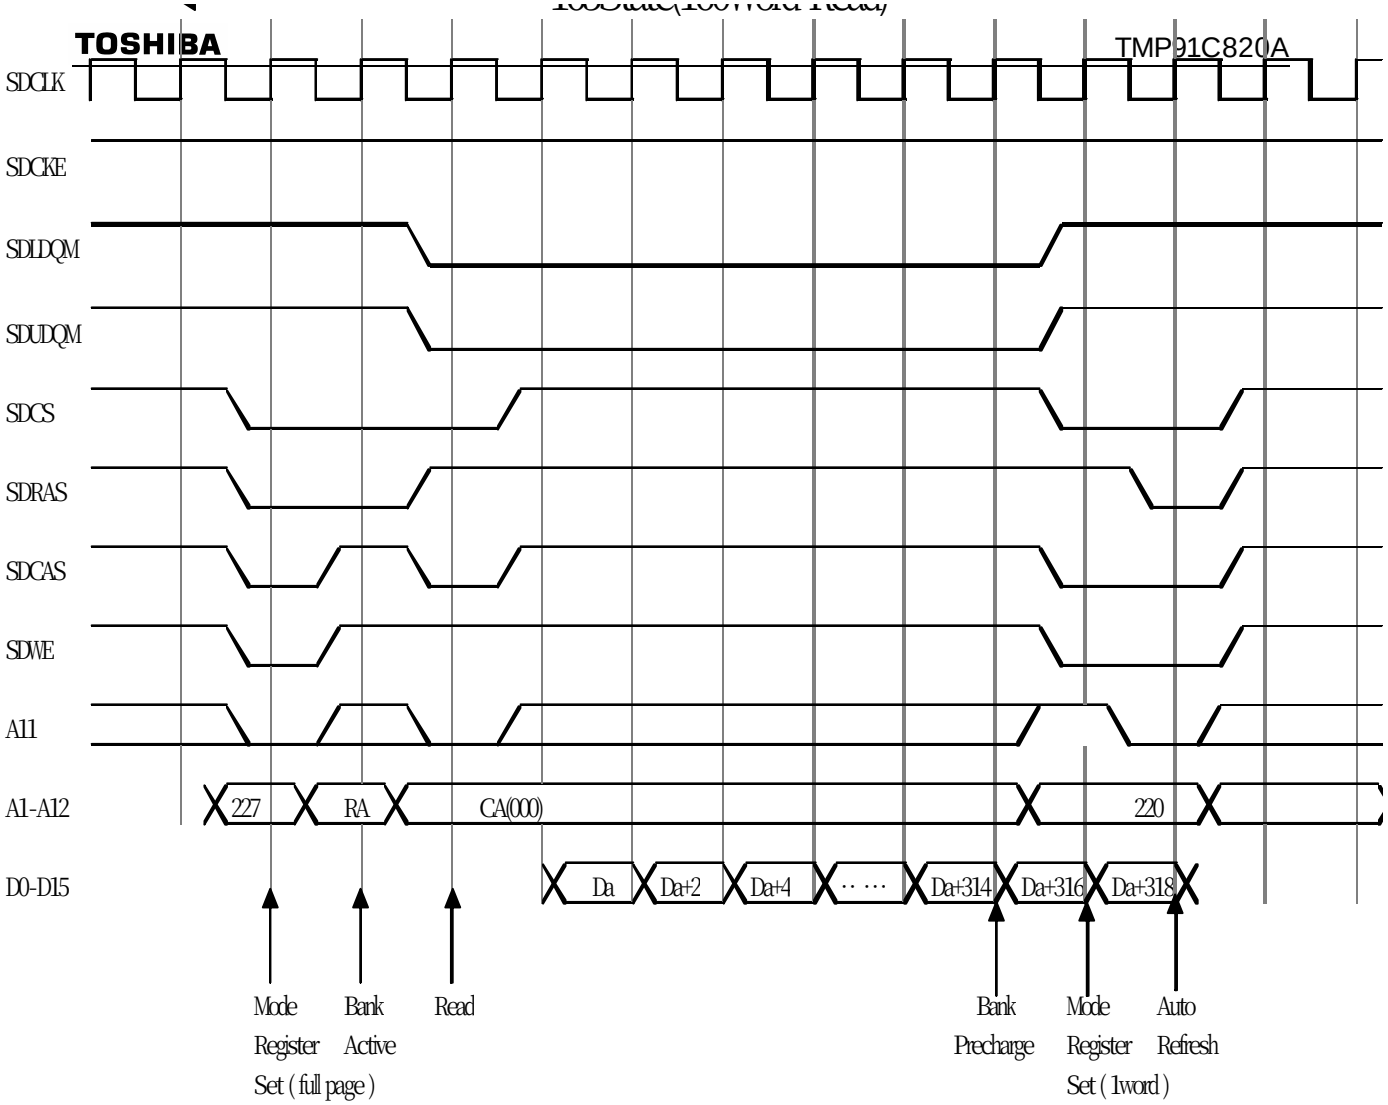

Figure 3.16.2(6) SDRAM Access Timing (LCDC Burst Read)

(2) Refresh Control

TMP91C820A can generate automatically an auto refresh cycle required for data maintenance of SDRAM. Refreshment interval can be set up by SDRCR <SR 0-2> from the 78 State to the 312 State (5.8us-23.1us @27MHz).

By setting SDRCR <SRC> to "1", a refresh cycle is generated at the interval set up by <SRS 0-2>.

The generating timing of a refresh cycle becomes into access cycles other than SDRAM area(CS1) after the interval set up by <SRS 0-2> .

The refresh cycle is shown in Fig. 3.16.2 (7). Moreover, the refreshment interval is shown in Table 3.16.2 (1).

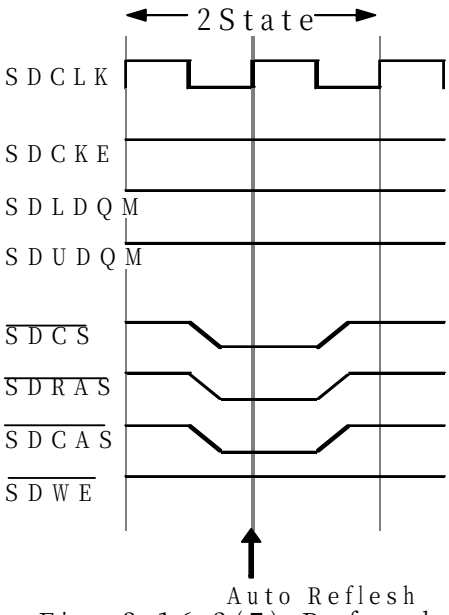

Fig. 3.16.2(7) Refresh Cycle

Table 3.16.2 (1) Auto Refresh Cycle Insertion Interval

<SRS2:0>setting			Insertion interval (state)	Frequency (fosc)					
SRS2	SRS1	SRS0		10MHz	12.5MHz	16MHz	20MHz	25MHz	27MHz
0	0	0	78	15.6	12.5	9.8	7.8	6.2	5.8
0	0	1	97	19.4	15.5	12.1	9.7	7.8	7.2
0	1	0	124	24.8	19.8	15.5	12.4	9.9	9.2
0	1	1	156	31.2	25.0	19.5	15.6	12.5	11.5
1	0	0	195	39.0	31.2	24.4	19.5	15.6	14.4
1	0	1	210	42.0	33.6	26.3	21.0	16.8	15.5
1	1	0	247	49.4	39.5	30.9	24.7	19.8	18.3
1	1	1	312	62.4	49.9	39.0	31.2	25.0	23.1

(Unit: us)

It does not generate interval refreshment during the burst access to SDRAM by LCDC. The interval refreshment demand generated in the meantime is held only once. When it returns to CPU access cycle, an interval refresh cycle is generated.

Furthermore, TMP91C820A can generate a self refresh cycle. The timing of a self refresh cycle is shown in Fig. 3.16.2 (8).

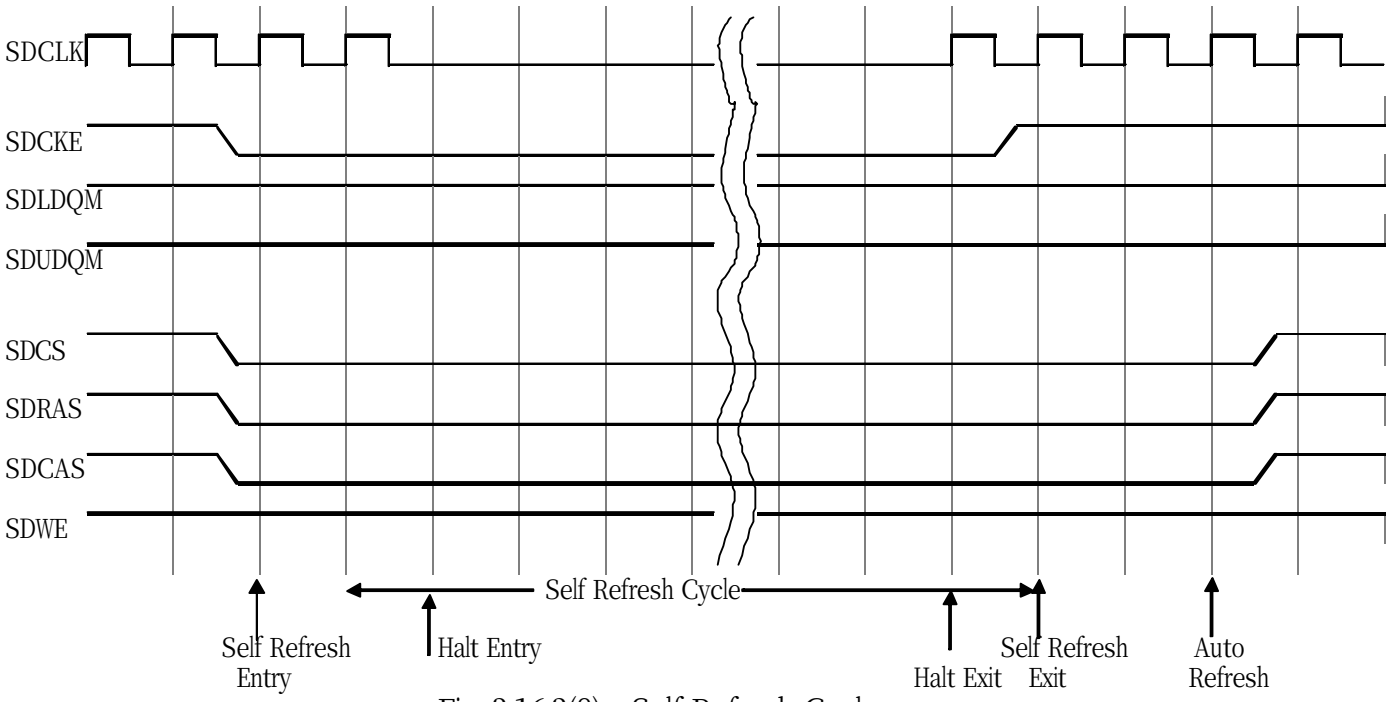

Fig. 3.16.2(8) Self Refresh Cycle

NOTE1: SDCLK is output in the IDLE2 mode . Therefore if you stop SDCLK , change PF6 pin to output port before the HALT instruction.

NOTE2: Pin condition under the IDLE1/ STOP mode depends on the setting of SYSCR2<DRVE> . However SDCKE doesn't depend on it but outputs LOW level.

If SDRCR <SFRC> is set to "1", the self-refresh cycle shown in Fig. 3.16.2 (8) will occur. The self refreshment mode is used when using the standby mode (STOP, IDLE1) which an internal clock stops. Before HALT command (STOP, IDLE1) of interval refreshment in the state of enable, please set SDRCR <SFRC> to "1."

Release of a self-refresh cycle is automatically performed by release in the standby mode. It inserts automatically one interval refreshment after self refreshment release, and returns to the interval refreshment mode.

(Note: When HALT is cancelled by a reset, the I/O registers are initialized, therefore, refresh is not performed.) .

Please do not place the command which accesses SDRAM just before the command which sets "1" to SDRCR <SFRC>. After setting SDRCR<SFRC> to "1" , make sure that the HALT instruction comes after NOP or some instruction.

(3) SDRAM Initialize

TMP91C820A can generate the cycle of the following required at the time of the power-supply injection to SDRAM. The cycle is shown in Fig. 3.16.2 (9).

1. Pre-charge of all banks
2. The initial configuration to a mode register
3. The refresh cycle of 8 cycles

The above-mentioned cycle is generated by setting "1" to SDACR <SDINI>.
Time after SDACR <SDINI> is set to "1" until an initialization cycle is performed changes with following commands.
While performing this cycle, operation (an instruction fetch, command execution) of CPU is stopped.
In addition, even before performing an initialization cycle, a port needs to be set as SDRAM control signal and an address signal (A1-A12).

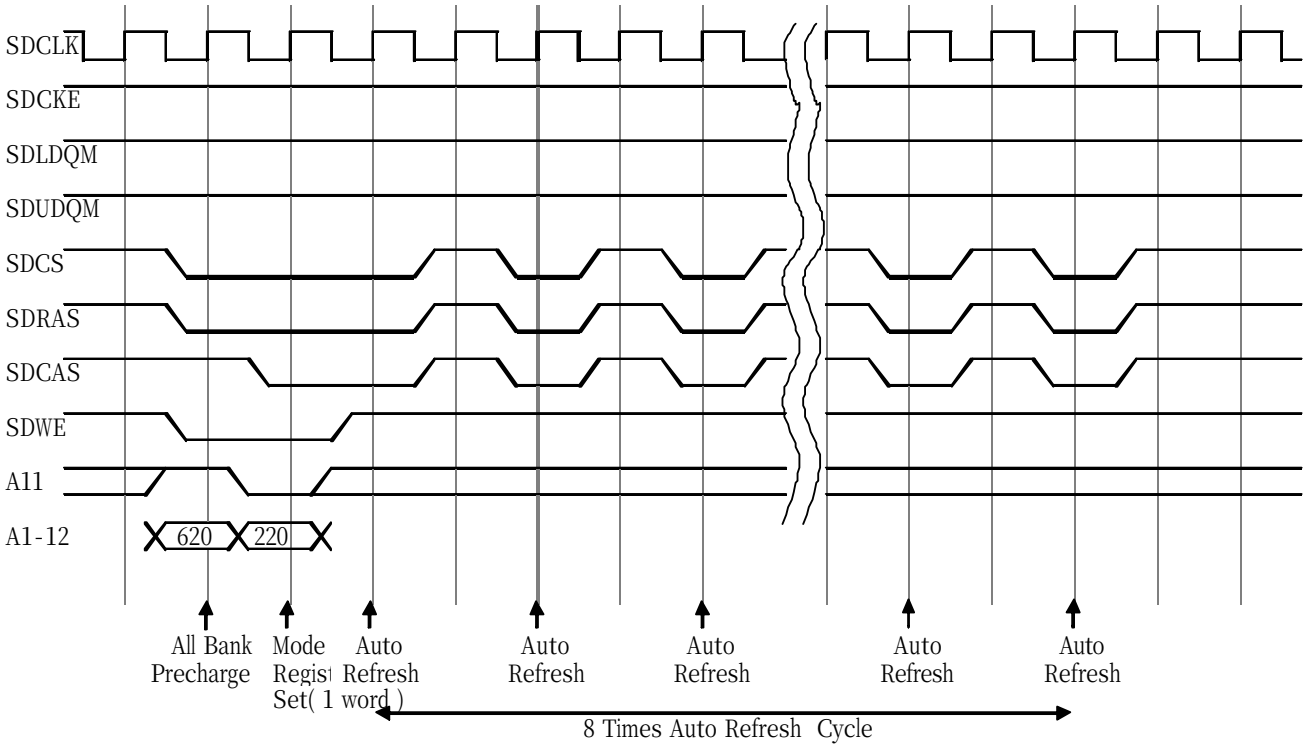

Fig. 3.16.2 (9) Initialize Cycle

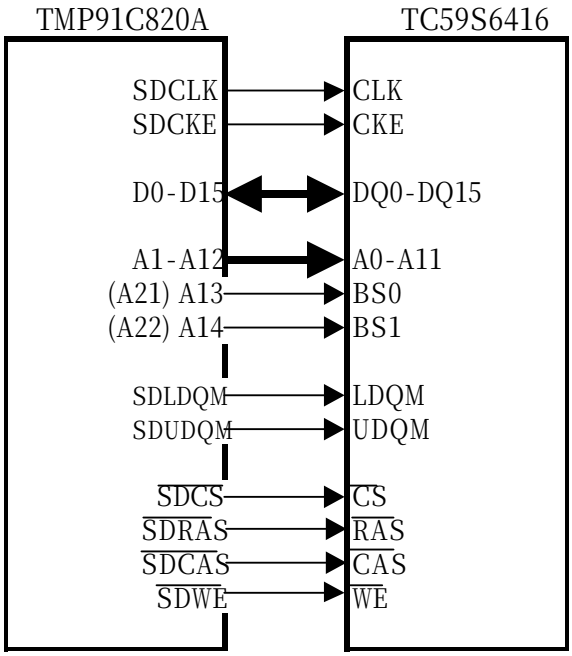
(4) Connection Example

The example of connection with SDRAM is shown in figure 3.16.2. (9).



(1Mword × 4Banks × 16bit)

Fig. 3.16.2 (10) Connection with SDRAM

3.17 16-Bit Timer/Event Counters (TMRB)

The TMP91C820A incorporates one multifunctional 16-bit timer/event counter (TMRB0) which have the following operation modes:

- 16-Bit Interval Timer Mode
- 16-Bit Event Counter Mode

16-Bit Programmable Pulse Generation (PPG) Mode
Can be used following operation modes by capture function:

- Frequency Measurement Mode
- Pulse Width Measurement Mode
- Time Differential Measurement Mode

Timer/event counter consists of a 16-bit up-counter, two 16-bit timer registers (one of them with a double-buffer structure), a 16-bit capture registers, two comparators, a capture input controller, a timer flip-flop and a control circuit.
Timer/event counter is controlled by an 11-byte control SFR.
This chapter consists of the following items:

Table 3.17.1 Pins and SFR of TMRB0

Spec \ Channel		TMRB0
External Pins	External clock / Capture trigger input pins	None
	Timer flip-flop output pins	TB0OUT0 (also used as P B6)

3.17.1 Block diagrams

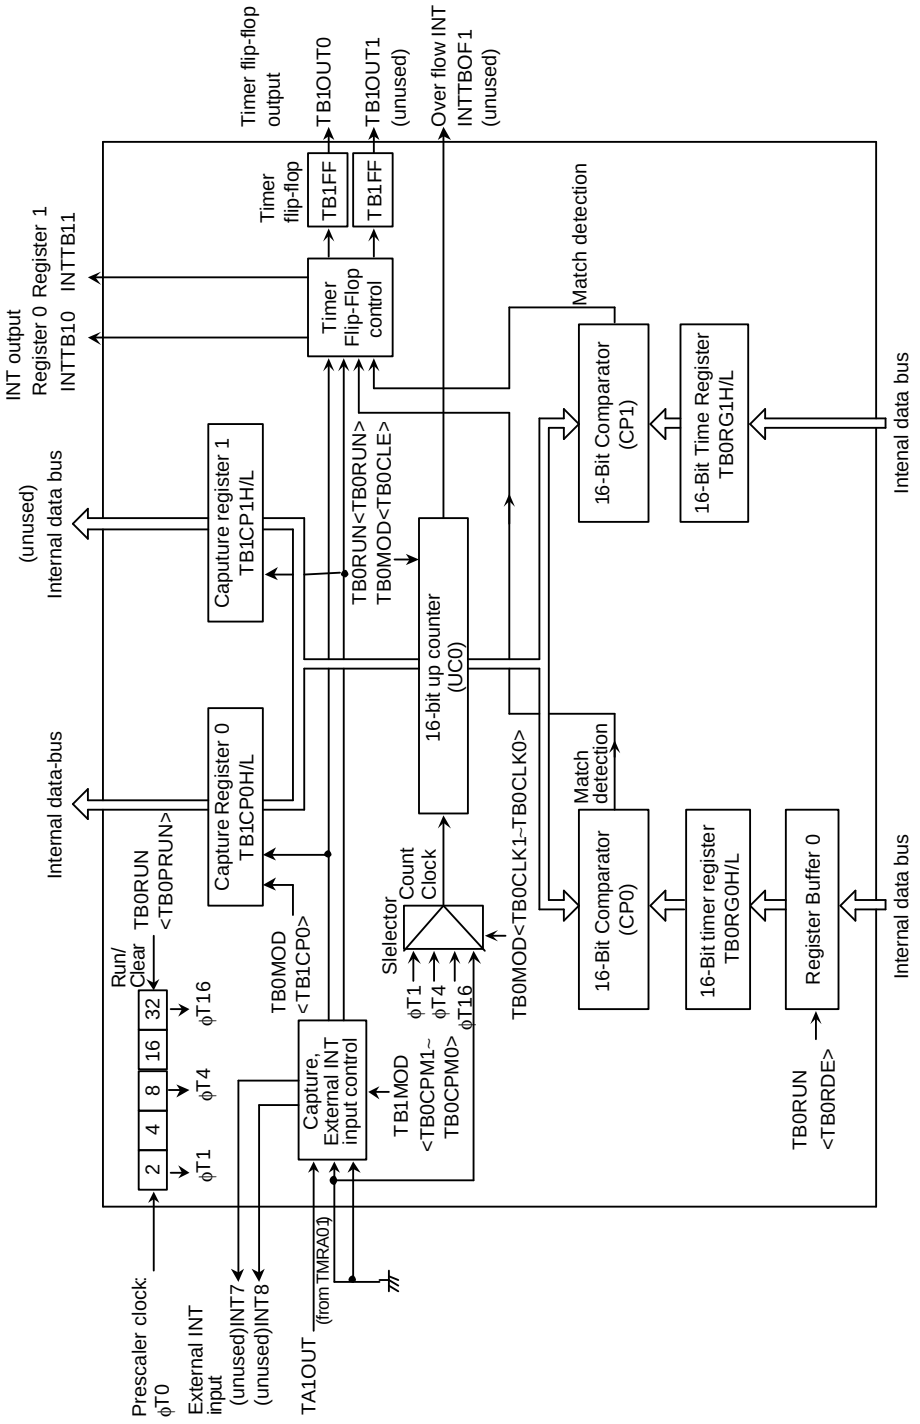

Figure 3.17.1 Block Diagram of TMRB0

3.17.2 Operation

(1) Prescaler

The 5-bit prescaler generates the source clock for TMRB0. The prescaler clock (ϕT0) is divided clock (divided by 4) from selected clock by the register SYSCR0<PRCK1~PRCK0> of clock-gear. This prescaler can be started or stopped using TB0RUN<TB0RUN>. Counting starts when <TB0RUN> is set to 1; the prescaler is cleared to zero and stops operation when <TB0RUN> is set to 0.

Table 3.17.2. Prescaler clock resolution

@fc = 16 MHz, fs = 32.768 kHz

System Clock Selection <SYSCK>	Prescaler Clock Selection <PRCK1~PRCK0>	Clock Gear Value <GEAR2~GEAR0>	Prescaler Clock Resolution		
			ϕT1	ϕT4	ϕT16
1 (fs)	00 (f_{FPH})	XXX	$fs/2^3$ (244 μs)	$fs/2^5$ (977 μs)	$fs/2^7$ (3.9 μs)
0 (fc)		000 (fc)	$fc/2^3$ (0.5 μs)	$fc/2^5$ (2.0 μs)	$fc/2^7$ (8.0 μs)
		001 ($fc_{/2}$)	$fc/2^4$ (1.0 μs)	$fc/2^6$ (4.0 μs)	$fc/2^8$ (16 μs)
		010 ($fc_{/4}$)	$fc/2^5$ (2.0 μs)	$fc/2^7$ (8.0 μs)	$fc/2^9$ (32 μs)
		011 ($fc_{/8}$)	$fc/2^6$ (4.0 μs)	$fc/2^8$ (16 μs)	$fc/2^{10}$ (64 μs)
		100 ($fc_{/16}$)	$fc/2^7$ (8.0 μs)	$fc/2^9$ (32 μs)	$fc/2^{11}$ (128 μs)
	10 ($fc_{/16}$ clock)	XXX	$fc/2^7$ (8.0 μs)	$fc/2^9$ (32 μs)	$fc/2^{11}$ (128 μs)

xxx: Don't care

(2) Up-counter (UC0)

UC0 is a 16-bit binary counter which counts up pulses input from the clock specified by TB0MOD <TB0CLK1,TB0CLK0>.

Any one of the prescaler internal clocks ϕT1, ϕTB0 and ϕT16 or an external clock input via the TB0IN0 pin can be selected as the input clock. Counting or stopping & clearing of the counter is controlled by TB0RUN<TB0RUN>.

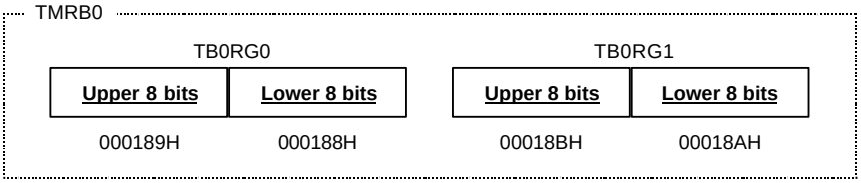
When clearing is enabled, the up-counter UC0 will be cleared to zero each time its value matches the value in the timer register TB0RG1H/L. Clearing can be enabled or disabled using TB0MOD<TB0CLE>.

If clearing is disabled, the counter operates as a free-running counter.

A Timer Overflow interrupt (INTTBOF0) is generated when UC0 overflow occurs.

(3) Timer registers (TB0RG0 and TB0RG1)

These two 16-bit registers are used to set the interval time. When the value in the up-counter UC0 matches the value set in this timer register, the Comparator Match Detect signal will go Active.
Setting data for timer register is executed using 2 byte data transfer instruction or using 1 byte date transfer instruction twice for lower 8 bits and upper 8 bits in order.
The TB0RG0 timer register has a double-buffer structure, which is paired with register buffer. The value set in TB0RUN<TB0RDE> determines whether the double-buffer structure is enabled or disabled: it is disabled when <TB0RDE> = 0, and enabled when <TB0RDE> = 1.
When the double buffer is enabled, data is transferred from the register buffer to the timer register when the values in the up-counter (UC0) and the timer register TB0RG1 match.
After a Reset, TB0RG0 and TB0RG1 are undefined. If the 16-bit timer is to be used after a Reset, data should be written to it beforehand.
On a Reset <TB0RDE> is initialized to 0, disabling the double buffer. To use the double buffer, write data to the timer register, set <TB0RDE> to 1, then write data to the register buffer as shown below.
TB0RG0 and the register buffer both have the same memory addresses (000188H & 000189H) allocated to them. If <TB0RDE> = 0, the value is written to both the timer register and the register buffer. If <TB0RDE> = 1, the value is written to the register buffer only.
The addresses of the Timer Registers are as follows:



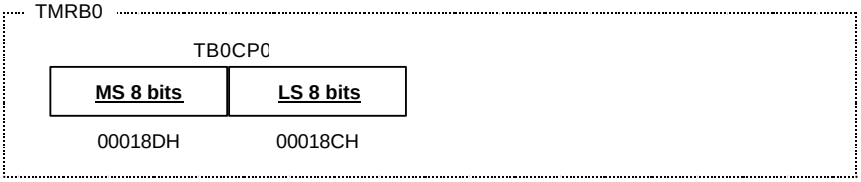
The Timer Registers are write-only registers and thus cannot be read.

(4) Capture Registers (TB0CP0H/L)

These 16-bit registers are used to latch the values in the up-counters.

Data in the Capture Registers should be read using a 2-byte data load instruction or two 1-byte data load instructions. The least significant byte is read first, followed by the most significant byte.

The addresses of the Capture Registers are as follows:



The Capture Registers are read-only registers and thus cannot be written to.

(5) Capture input control

This circuit controls the timing to latch the value of up-counter UC0 into TB0CP0, TB0CP1

The value in the up-counter can be loaded into a capture register by software. Whenever 0 is written to TB0MOD<TB0CP0>, the current value in the up-counter is loaded into capture register TB0CP0. It is necessary to keep the prescaler in Run Mode (i.e. TB0RUN<TB0PRUN> must be held at a value of 1).

(6) Comparators (CP0 & CP1)

CP0 and CP1 are 16-bit comparators which compare the value in the up-counter UC0 with the value set in TB0RG0 or TB0RG1 respectively, in order to detect a match. If a match is detected, the comparator generates an interrupt (INTTB00 or INTTB01 respectively).

(7) Timer flip-flops (TB0FF0 & TB0FF1)

These flip-flops are inverted by the match detect signals from the comparators and the latch signals to the Capture Registers. Inversion can be enabled and disabled for each element using TB0FFCR<TB0C0T1,TB0E1T1,TB0E0T1>.

After a Reset the value of TB0FF0 is undefined. If "00" is written to TB0FFCR<TB0FF0C1,TB0FF0C0> or <TB0FF1C1,TB0FF1C0>, TB0FF0 will be inverted. If "01" is written to the capture registers, the value of TB0FF0 will be set to "1".If "10" is written to the capture registers, the value of TB0FF0 will be set to "0".

The values of TB0FF0 can be output via the Timer Output pins TB0OUT0 (which is shared with PB6). Timer output should be specified using the Port B Function Register.

3.17.4 Operation in each mode

(1) 16-Bit Timer Mode

Generating interrupts at fixed intervals

In this example, the interrupt INTTB01 is set to be generated at fixed intervals. The interval time is set in the timer register TB0RG1.

		7	6	5	4	3	2	1	0	
TB0RUN	←	0	0	X	X	–	0	X	0	Stop TMRB0.
INTETB01	←	X	1	0	0	X	0	0	0	Enable INTTB01 and set Interrupt Level 4. Disable INTTB00.
TB0FFCR	←	1	1	0	0	0	0	1	1	Disable the trigger.
TB0MOD	←	0	0	1	0	0	1	*	*	Select internal clock for input and
						(** = 01, 10, 11)				disable the capture function.
TB0RG1	←	*	*	*	*	*	*	*	*	Set the interval time (16 bits).
		*	*	*	*	*	*	*	*	
TB0RUN	←	0	0	X	X	–	1	X	1	Start TMRB0.

Note: X = Don't care; "–" = No change

(2) 16-Bit Programmable Pulse Generation (PPG) Output Mode

Square wave pulses can be generated at any frequency and duty ratio. The output pulse may be either Low-active or High-active.

The PPG mode is obtained by inversion of the timer flip-flop TB0FF0 that is to be enabled by the match of the up-counter UC0 with timer register TB0RG0 or TB0RG1 and to be output to TB0OUT0. In this mode the following conditions must be satisfied.

(Value set in TB0RG0) < (Value set in TB0RG1)

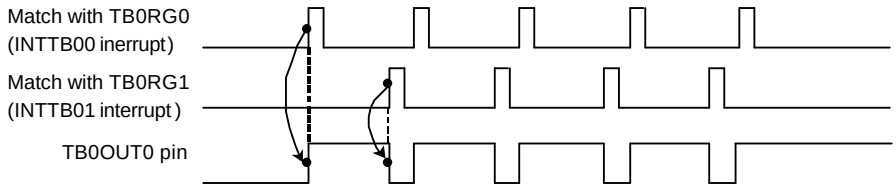

Figure 3.17.5 Programmable Pulse Generation (PPG) Output Waveforms

When the TB0RG0 double buffer is enabled in this mode, the value of Register Buffer 0 will be shifted into TB0RG0 at match with TB0RG1. This feature facilitates the handling of low-duty waves.

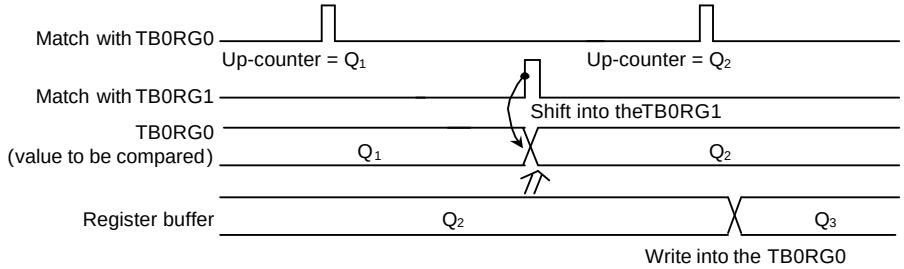

Figure 3.17.6 Operation of Register Buffer

The following block diagram illustrates this mode.

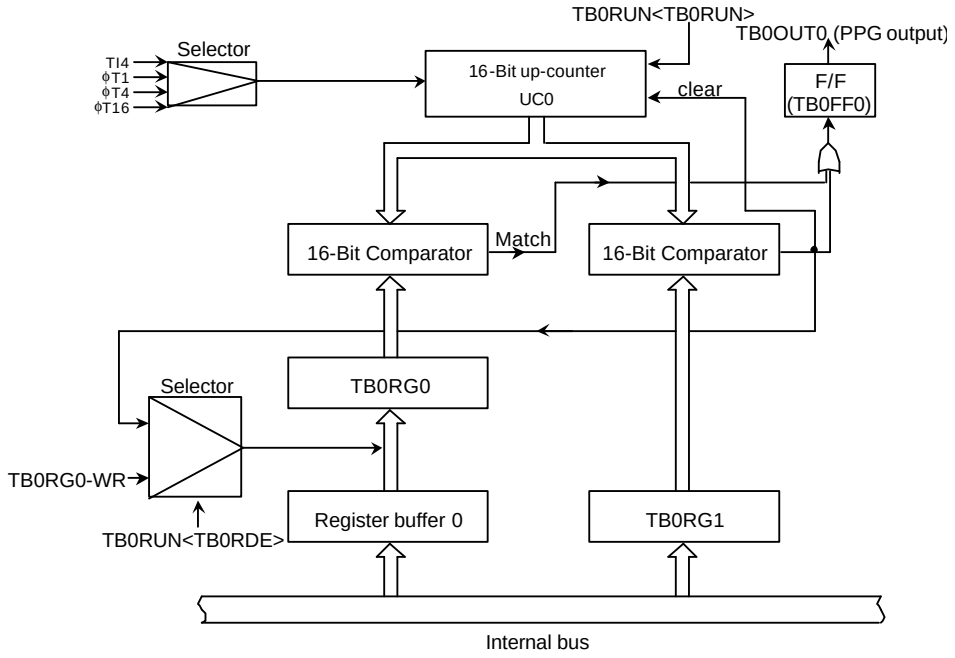

Figure 3.17.7 Block Diagram of 16-BIT Mode

The following example shows how to set 16-Bit PPG Output Mode:

		7	6	5	4	3	2	1	0	
TB0RUN	←	0	0	X	X	–	0	X	0	Disable the TB0RG0 double buffer and stop TMRB0.
TB0RG0	←	*	*	*	*	*	*	*	*	Set the duty ratio (16 bits).
TB0RG1	←	*	*	*	*	*	*	*	*	Set the frequency (16 bits).
TB0RUN	←	1	0	X	X	–	0	X	0	Enable the TB0RG0 double buffer. (The duty and frequency are changed on an INTTB01 interrupt.)
TB0FFCR	←	X	X	0	0	1	1	1	0	Set the mode to invert TB0FF0 at the match with TB0RG0/TB0RG1. Set TB0FF0 to 0.
TB0MOD	←	0	0	1	0	0	1	*	*	Select the internal clock as the input clock and disable the capture function. (** = 01, 10, 11)
P8CR	←	–	1	–	–	–	X	–	–	Set P82 to function as TB0OUT0.
P8FC	←	–	1	–	–	–	X	–	–	
TB0RUN	←	1	0	X	X	–	1	X	1	Start TMRB0.

Note: X = Don't care; "–" = No change

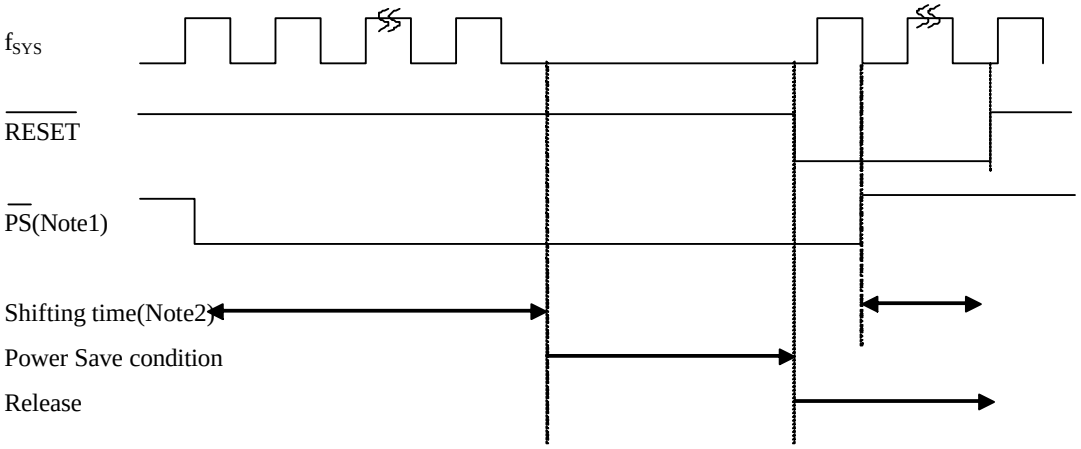
3.18 Hardware stand-by function

TMP91C820A have hardware stand-by circuit that is able to save the power consumption and protect from program runaway by supplying power voltage down. Especially, it's useful in case of battery using.

It can be shifted to "PS condition" by fixed $\overline{PS}$ pin to "LOW" level.

Figure 3.18.1 shows timing diagram of transition of PS condition below

PS condition can be released by only external RESET.



Note 1: $\overline{PS}$ pin is effective after RESET because SYSCR2<PSENV> to '0'. If you use as $\overline{NMI}$ pin , please write SYSCR2<PSENV> to '1'.

Note 2: Shifting time is 2~10-clock times of f_{SYS}.

Figure 3.18.1 hardware stand-by timing diagram

Table 3.18.1 Power Save conditions of each HALT mode

HALT mode setting	IDLE2	IDLE1	STOP
PS condition	IDLE1 mode + High frequency stop	IDLE1 mode + High frequency stop	STOP mode

Note:Settings of SYSCR2<DRVE> and <SELDRV> at HALT mode are effective as well as PS condition.

4. Electrical Characteristics

4.1 Absolute Maximum Ratings

Parameter	Symbol	Rating	Unit
Power Supply Voltage	Vcc	–0.5 to 4.0	V
Input Voltage	VIN	– 0.5 to Vcc + 0.5	V
Output Current	IOL	2	mA
Output Current	IOH	– 2	mA

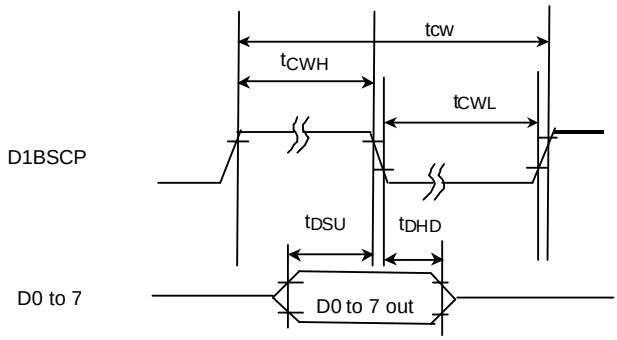
t_{INTAH}	$\overline{NMI}$, INT0 to INT3 High level width	4X + 40		188		151		ns

4.10 LCD CONTROLLER SR MODE



Vcc = 2.7～3.6 V case of f_{FPH} = 27 MHz

Vcc = 3.0～3.6 V case of f_{FPH} = 36 MHz

No.	Symbol	Parameter	Variable		fFPH=27 MHz (Case: tm=0)		fFPH=36 MHz (Case: tm=0)		Unit
			Min	Max	Min	Max	Min	Max	
1	tDSU	data Vaild ->D1BSCP Fall	x-20+tm		17		7.7		ns
2	tDHD	D1BSCP Fall->Data Hold	x -5+tm		32		22		ns
3	tCWH	D1SBCP->Clock high width	x -10+tm		27		17.7		ns
4	tCWL	D1BSCP->Clock low width	x -10+tm		27		17.7		ns
5	tcw	D1BSCP->Clock cycle	2x +2tm		27		55.4		ns

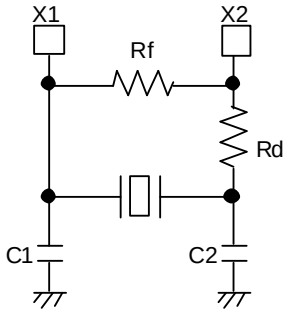
Note: tm=(2^scpw-1)x, ex. If Scpw=3 (8 clock mode) and fFPH=36 MHz, tm=(2^3-1)*27.7=193.9.

4.11 Recommended Crystal Oscillation Circuit

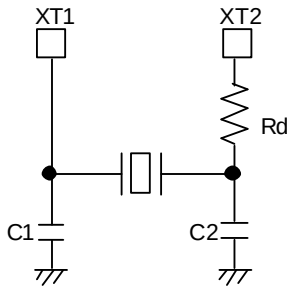
TMP91C820A is evaluated by below oscillator vender. When selecting external parts, make use of this information..

(note): Total loads value of oscillator is sum of external loads(C1 and C2) and floating loads of actual assemble board. There is a possibility of miss-operating using C1 and C2 value in below table. When designing board, it should design minimum length pattern around oscillator. And we recommend that oscillator evaluation try on your actual using board.

(1) connection example



High frequency oscillator



Low frequency oscillator

(2) TMP91C820A recommended ceramic oscillator : MURATA co. LTD; JAPAN

Circuit parameter recommended

MCU	Oscillation Frequency [MHZ]	Item of Oscillator	Parameter of elements				Running Condition	
			C1 [pF]	C2 [pF]	Rf [?]	Rd [?]	Voltage of Power [V]	Tc [℃]

NOTE: In CST ***type oscillator, Capacitance C1,C2 is built in

*After 2001/06,new products will be made, and the old products(now in production) will not be made in MURATA Co LTD ,JAPAN

*The product numbers and specifications of the resonators by Murata Manufacturing Co., Ltd. are being changed as occasion arises. For details, visit the company's home page at http://www.murata.co.jp/search/index.html

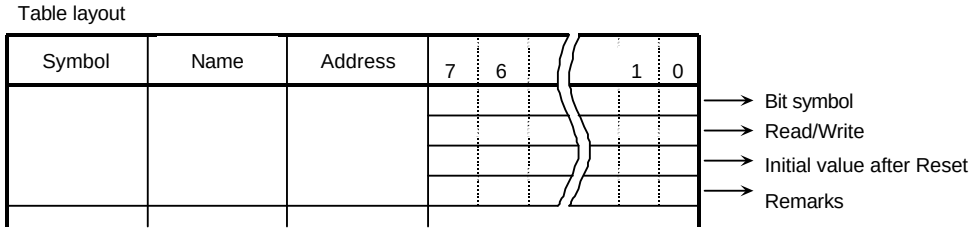
5. Table of SFRs

(SFR ; special function register)

The SFRs include the I/O ports and peripheral control registers allocated to the 4K bytes address space from 000000H to 000FFFH.

(1) I/O Port
(2) I/O Port Control
(3) Interrupt Control
(4) Chip Select / Wait Control
(5) Clock Gear
(6) DFM (Clock Doubler)
(7) 8-bit Timer
(8) UART/Serial Channel
(9) I^2CBUS/Serial Channel
(10) AD Converter
(11) Watchdog Timer
(12) RTC (Real–Time Clock)
(13) Melody/Alarm Generator
(14) MMU
(15) LCD CONTROLLER
(16) SDRAM Controller
(17) 16-bit Timer

Table layout



Note: “Prohibit RMW” in the table means that you cannot use RMW instructions on these register.

Example: When setting bit0 only of the registerP0CR, the instruction “SET 0, (0002G)” cannot be used. The LD (transfer) instruction must be used to write all eight bits.

Read/Write

R/W ; Both read and write are possible.

R; Only read is possible.

W; Only write is possible.

W*; Both read and write are possible (when this bit is read as1)

Prohibit RMW; Read-Modify-Write instructions are prohibited. (The EX, ADD, ADC, BUS, SBC, INC, DEC, AND, OR, XOR, STCF, RES, SET, CHG, TEST, RLC, RRC, RL, RR, SLA, SRA, SLL, SRL, RLD and RRD instruction are read-modify-write instructions.)

Prohibit RMW*; Read-modify-write is prohibited when controlling the pull-up resistor.

6. Points to Note and Restrictions

(1) Notation

① The notation for built-in / I/O registers is as follows register symbol <bit symbol>

e.g.) TA01RUN <TA0RUN> denotes bit TA0RUN of register TA01RUN.

② Read-modify-write instructions

An instruction in which the CPU reads data from memory and writes the data to the same memory location in one instruction.

Example 1) SET 3, (TA01RUN) ··· Set bit 3 of TA01RUN.

Example 2) INC 1, (100H) ··· Increment the data at 100H.

- Examples of read-modify-write instructions on the TLCS-900

Exchange instruction

```
EX    (mem), R
```

Arithmetic operations

```
ADD   (mem), R/#      ADC   (mem), R/#
SUB   (mem), R/#      SBC   (mem), R/#
INC   #3, (mem)       DEC   #3, (mem)
```

Logic operations

```
AND   (mem), R/#      OR    (mem), R/#
XOR   (mem), R/#
```

Bit manipulation operations

```
STCF  #3/A, (mem)     RES   #3, (mem)
SET   #3, (mem)       CHG   #3, (mem)
TSET  #3, (mem)
```

Rotate and shift operations

```
RLC   (mem)           RRC   (mem)
RL    (mem)           RR    (mem)
SLA   (mem)           SRA   (mem)
SLL   (mem)           SRL   (mem)
RLD   (mem)           RRD   (mem)
```

③ fc, fs, f_{FPH}, f_{SYS} and one state

The clock frequency input on ins X1 and 2 is called f_{OSCH}. The clock selected by DFMCR0 <ACT1~ACT0> is called fc.

The clock selected by SYSCR1 <SYSCK> is called f_{FPH}. The clock frequency give by f_{FPH} divided by 2 is called f_{SYS}.

One cycle of f_{SYS} is referred to as one state.

(2) Points to note

a) AM0 and AM1 pins

This pin is connected to the VCC or the VSS pin. Do not alter the level when the pin is active.

b) EMU0and EMU1

Open pins.

c) Reserved address areas

The TMP91C820A does not have any reserved areas.

d) Warm-up counter

The warm-up counter operates when STOP Mode is released, even if the system is using an external oscillator. As a result a time equivalent to the warm-up time elapses between input of the release request and output of the system clock.

e) Programmable pull-up resistance

The programmable pull-up resistor can be turned ON/OFF by a program when the ports are set for use as input ports. When the ports are set for use as output ports, they cannot be turned ON/OFF by a program.

The data registers (e.g. P5) are used to turn the pull-up/-down resistors ON/OFF. Consequently read-Modify-write instructions are prohibited.

f) Watchdog timer

The watchdog timer starts operation immediately after a Reset is released. When the watchdog timer is not to be used, disable it.

g) AD converter

The string resistor between the VREFH and VREFL pins can be cut by a program so as to reduce power consumption. When STOP Mode is used, disable the resistor using the program before the HALT instruction is executed.

h) CPU (micro DMA)

Only the LDC c r, r and LDC r, cr instructions can be used to access the control registers in the CPU (e.g. the Transfer Source Address Register (DMASn)).

i) Undefined SFR

The value of an undefined bit in an SFR is undefined when read.

j) POP SR instruction

Please execute the POP SR instruction during DI condition.

7. PACKAGE

Package Name：P-LQFP144-1616-0.40

Unit : mm
