INPUT/OUTPUT FUNCTIONAL DESCRIPTION

Symbol	Type	Function
CK, $\overline{\text{CK}}^{*1}$	Input	The differential system clock Input. All of the inputs are sampled on the rising edge of the clock except DQ's and DM's that are sampled on both edges of the DQS.
CKE	Input	Activates the CK signal when high and deactivates the CK signal when low. By deactivating the clock, CKE low indicates the Power down mode or Self refresh mode.
$\overline{\text{CS}}$	Input	$\overline{\text{CS}}$ enables the command decoder when low and disabled the command decoder when high. When the command decoder is disabled, new commands are ignored but previous operations continue.
$\overline{\text{RAS}}$	Input	Latches row addresses on the positive going edge of the CK with $\overline{\text{RAS}}$ low. Enables row access & precharge.
$\overline{\text{CAS}}$	Input	Latches column addresses on the positive going edge of the CK with $\overline{\text{CAS}}$ low. Enables column access.
$\overline{\text{WE}}$	Input	Enables write operation and row precharge. Latches data in starting from CAS, WE active.
DQS	Input/Output	Data input and output are synchronized with both edge of DQS.
DM0 ~ DM3	Input	Data In mask. Data In is masked by DM Latency=0 when DM is high in burst write. DM0 for DQ0 ~ DQ7, DM1 for DQ8 ~ DQ15, DM2 for DQ16 ~ DQ23, DM3 for DQ24 ~ DQ31.
DQ0 ~ DQ31	Input/Output	Data inputs/Outputs are multiplexed on the same pins.
BA0, BA1	Input	Selects which bank is to be active.
A0 ~ A11	Input	Row/Column addresses are multiplexed on the same pins. Row addresses : RA0 ~ RA11, Column addresses : CA0 ~ CA7. Column address CA8 is used for auto precharge.
VDD/VSS	Power Supply	Power and ground for the input buffers and core logic.
VDDQ/VSSQ	Power Supply	Isolated power supply and ground for the output buffers to provide improved noise immunity.
VREF	Power Supply	Reference voltage for inputs, used for SSTL interface.
MCL	Must Connect Low	Must connect Low

*1 : The timing reference point for the differential clocking is the cross point of CK and $\overline{\text{CK}}$.
For any applications using the single ended clocking, apply VREF to $\overline{\text{CK}}$ pin.

FUNCTIONAL DESCRIPTION

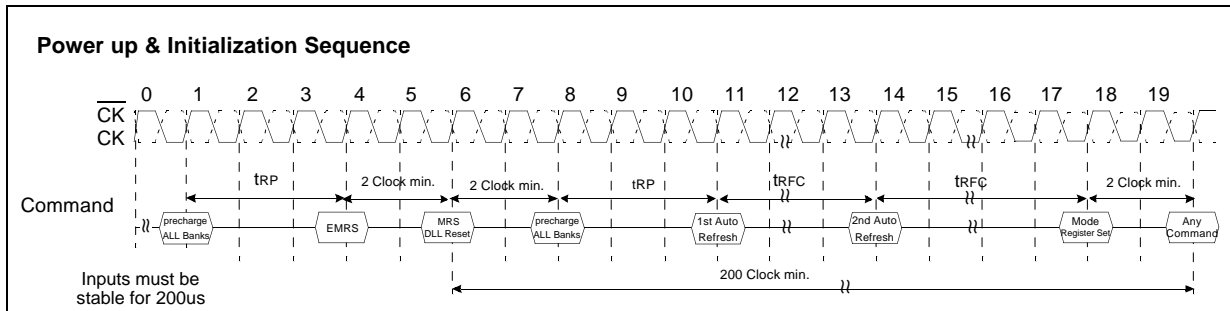

• Power-Up Sequence

DDR SDRAMs must be powered up and initialized in a predefined manner to prevent undefined operations.

1. Apply power and keep CKE at low state (All other inputs may be undefined)
 - Apply VDD before VDDQ .
 - Apply VDDQ before VREF & VTT
2. Start clock and maintain stable condition for minimum 200us.
3. The minimum of 200us after stable power and clock(CK,CK), apply NOP and take CKE to be high.
4. Issue precharge command for all banks of the device.
5. Issue a EMRS command to enable DLL
- *1 6. Issue a MRS command to reset DLL. The additional 200 clock cycles are required to lock the DLL.
- *1,2 7. Issue precharge command for all banks of the device.
8. Issue at least 2 or more auto-refresh commands.
9. Issue a mode register set command with A8 to low to initialize the mode register.

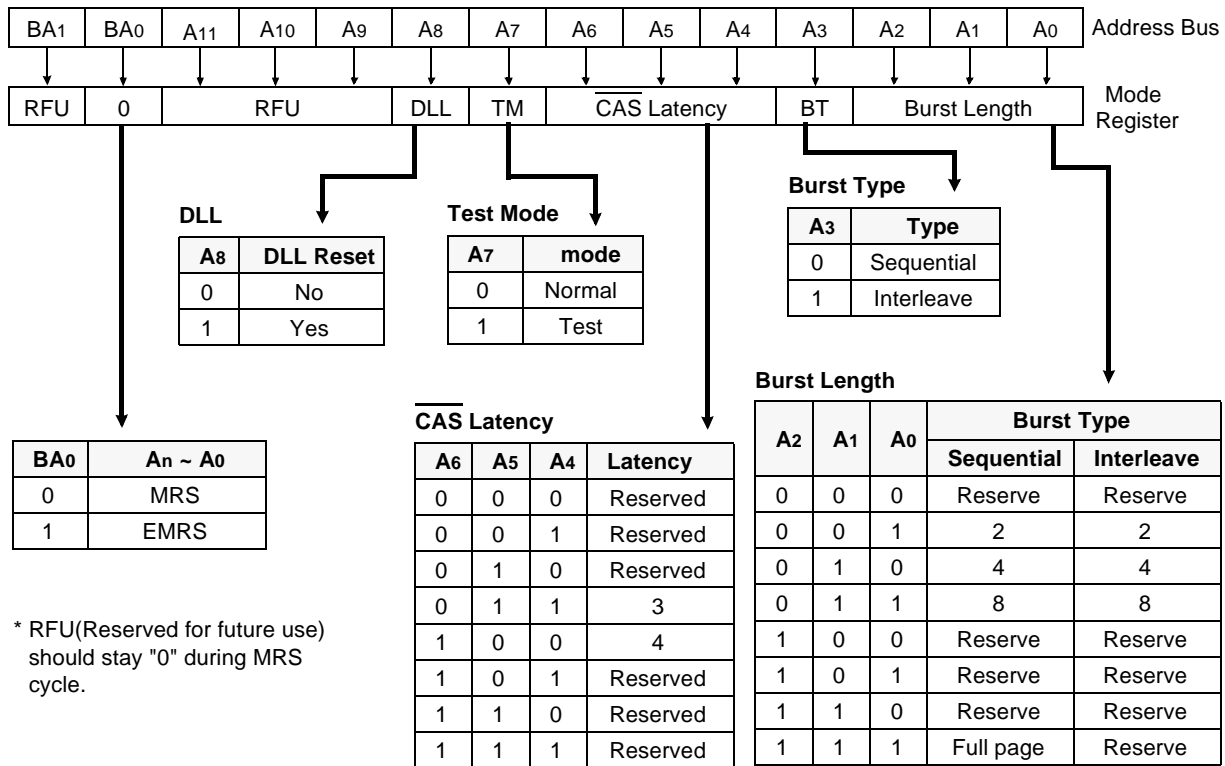

*1 The additional 200cycles of clock input is required to lock the DLL after enabling DLL.

*2 Sequence of 6&7 is regardless of the order.

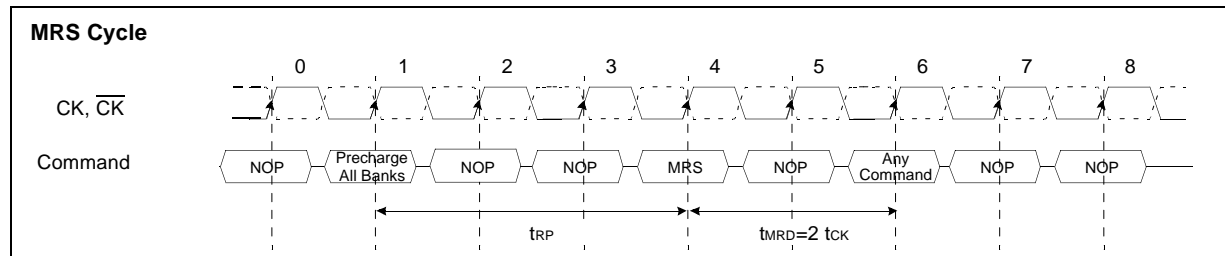

MODE REGISTER SET(MRS)

The mode register stores the data for controlling the various operating modes of DDR SDRAM. It programs $\overline{\text{CAS}}$ latency, addressing mode, burst length, test mode, DLL reset and various vendor specific options to make DDR SDRAM useful for variety of different applications. The default value of the mode register is not defined, therefore the mode register must be written after EMRS setting for proper operation. The mode register is written by asserting low on $\overline{\text{CS}}$, $\overline{\text{RAS}}$, $\overline{\text{CAS}}$ and $\overline{\text{WE}}$ (The DDR SDRAM should be in active mode with $\overline{\text{CKE}}$ already high prior to writing into the mode register). The state of address pins $\text{A}_0 \sim \text{A}_{11}$ and BA_0 , BA_1 in the same cycle as $\overline{\text{CS}}$, $\overline{\text{RAS}}$, $\overline{\text{CAS}}$ and $\overline{\text{WE}}$ going low is written in the mode register. Minimum two clock cycles are requested to complete the write operation in the mode register. The mode register contents can be changed using the same command and clock cycle requirements during operation as long as all banks are in the idle state. The mode register is divided into various fields depending on functionality. The burst length uses $\text{A}_0 \sim \text{A}_2$, addressing mode uses A_3 , $\overline{\text{CAS}}$ latency (read latency from column address) uses $\text{A}_4 \sim \text{A}_6$. A_7 is used for test mode. A_8 is used for DLL reset. A_7, A_8 , BA_0 and BA_1 must be set to low for normal MRS operation. Refer to the table for specific codes for various burst length, addressing modes and $\overline{\text{CAS}}$ latencies.

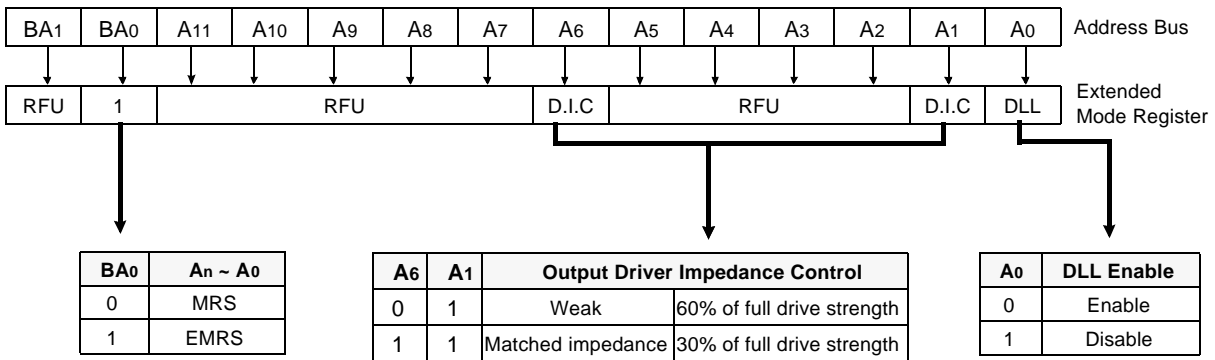

* RFU(Reserved for future use) should stay "0" during MRS cycle.

*1: MRS can be issued only at all banks precharge state.
 *2: Minimum t_{RP} is required to issue MRS command.

EXTENDED MODE REGISTER SET(EMRS)

The extended mode register stores the data for enabling or disabling DLL and selecting output driver strength. The default value of the extended mode register is not defined, therefore the extend mode register must be written after power up for enabling or disabling DLL. The extended mode register is written by asserting low on CS, RAS, CAS, WE and high on BA0(The DDR SDRAM should be in all bank precharge with CKE already high prior to writing into the extended mode register). The state of address pins A0, A2 ~ A5, A7 ~ A11 and BA1 in the same cycle as CS, RAS, CAS and WE going low are written in the extended mode register. A1 and A6 are used for setting driver strength to weak or matched impedance. Two clock cycles are required to complete the write operation in the extended mode register. The mode register contents can be changed using the same command and clock cycle requirements during operation as long as all banks are in the idle state. A0 is used for DLL enable or disable. 'High' on BA0 is used for EMRS. All the other address pins except A0,A1,A6 and BA0 must be set to low for proper EMRS operation. Refer to the table for specific codes.

* RFU(Reserved for future use) should stay "0" during EMRS cycle.

- Note :**
- Under all conditions VDDQ must be less than or equal to VDD.
 - VREF is expected to equal 0.50*VDDQ of the transmitting device and to track variations in the DC level of the same. Peak to peak noise on the VREF may not exceed $\pm 2\%$ of the DC value. Thus, from 0.50*VDDQ, VREF is allowed $\pm 25\text{mV}$ for DC error and an additional $\pm 25\text{mV}$ for AC noise.
 - V_{tt} of the transmitting device must track VREF of the receiving device.
 - V_{IH}(max.)= VDDQ +1.5V for a pulse and it which can not be greater than 1/3 of the cycle rate.
 - V_{IL}(min.)= -1.5V for a pulse width and it can not be greater than 1/3 of the cycle rate.
 - For any pin under test input of $0\text{V} \leq V_{IN} \leq V_{DD}$ is acceptable. For all other pins that are not under test V_{IN}=0V.

Simplified Timing @ BL=2, CL=3

Note 1 :

- The JEDEC DDR specification currently defines the output data valid window(t_{DV}) as the time period when the data strobe and all data associated with that data strobe are coincidentally valid.
- The previously used definition of $t_{DV}(=0.35t_{CK})$ artificially penalizes system timing budgets by assuming the worst case output valid window even then the clock duty cycle applied to the device is better than 45/55%
- A new AC timing term, t_{QH} which stands for data output hold time from DQS is defined to account for clock duty cycle variation and replaces t_{DV}
- $t_{QHmin} = t_{HP}-X$ where
 - . t_{HP} =Minimum half clock period for any given cycle and is defined by clock high or clock low time(t_{CH},t_{CL})
 - . X =A frequency dependent timing allowance account for $t_{DQSQmax}$
