

ADC12130/ADC12132/ADC12138

Self-Calibrating 12-Bit Plus Sign Serial I/O A/D Converters with MUX and Sample/Hold

General Description

NOTE: All versions of the ADC12132 are obsolete and shown here for reference only.

The ADC12130, ADC12132 and ADC12138 are 12-bit plus sign successive approximation A/D converters with serial I/O and configurable input multiplexer. The ADC12132 and ADC12138 have a 2 and an 8 channel multiplexer, respectively. The differential multiplexer outputs and A/D inputs are available on the MUXOUT1, MUXOUT2, A/DIN1 and A/DIN2 pins. The ADC12130 has a two channel multiplexer with the multiplexer outputs and A/D inputs internally connected. The ADC12130 family is tested and specified with a 5 MHz clock. On request, these A/Ds go through a self calibration process that adjusts linearity, zero and full-scale errors to typically less than ± 1 LSB each.

The analog inputs can be configured to operate in various combinations of single-ended, differential, or pseudo-differential modes. A fully differential unipolar analog input range (0V to +5V) can be accommodated with a single +5V supply. In the differential modes, valid outputs are obtained even when the negative inputs are greater than the positive because of the 12-bit plus sign output data format.

The ADC12132 is obsolete and described in this document for reference only.

The serial I/O is configured to comply with NSC MICROWIRE™. For voltage references, see the LM4040, LM4050 or LM4041.

Features

- Serial I/O (MICROWIRE, SPI and QSPI Compatible)
- Power down mode
- Programmable acquisition time
- Variable digital output word length and format
- No zero or full scale adjustment required
- 0V to 5V analog input range with single 5V power supply

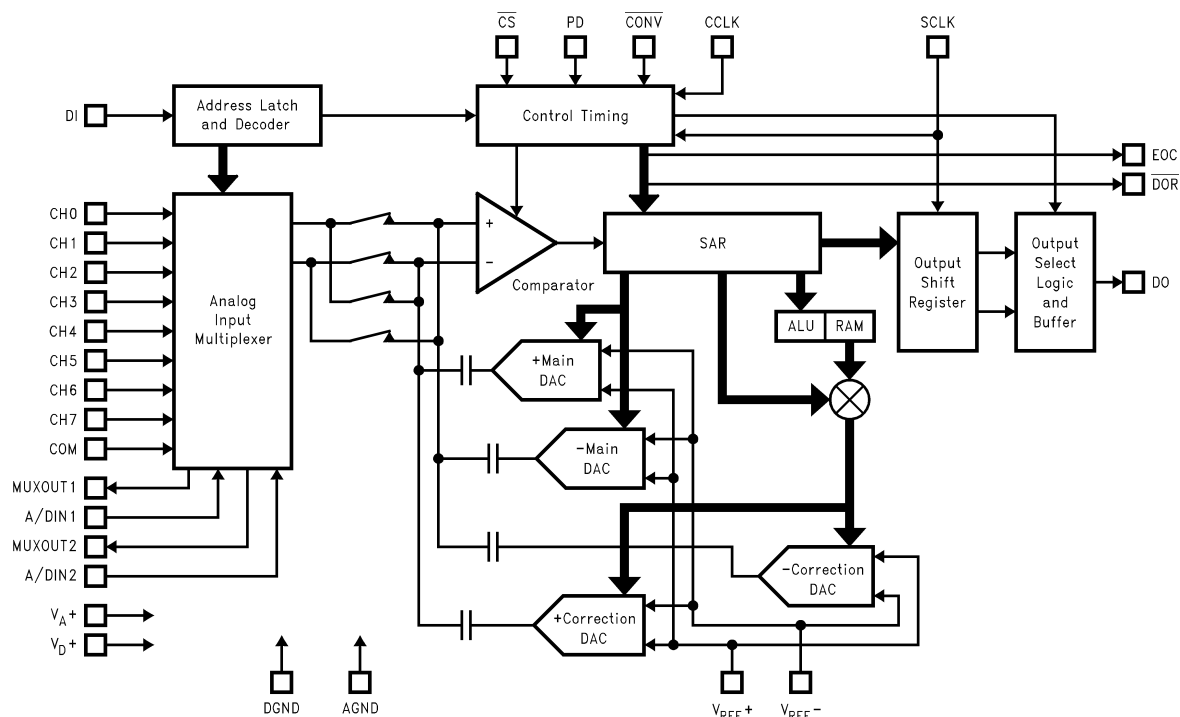

Key Specifications

Resolution	12-bit plus sign
■ 12-Bit plus sign conversion time	8.8 μ s (max)
■ 12-Bit plus sign throughput time	14 μ s (max)
■ Integral Linearity Error	± 2 LSB (max)
■ Single Supply	3.3V or 5V $\pm 10\%$
■ Power Consumption	
+3.3V	15 mW (max)
+3.3V power down	40 μ W (typ)
+5V	33 mW (max)
+5V power down	100 μ W (typ)

Applications

- Pen-based computers
- Digitizers
- Global positioning systems

* The ADC12132 is obsolete and shown in this document for reference only.

Pin Descriptions

- CCLK** The clock applied to this input controls the successive approximation conversion time interval and the acquisition time. The rise and fall times of the clock edges should not exceed 1 μs.
- SCLK** This is the serial data clock input. The clock applied to this input controls the rate at which the serial data exchange occurs. The rising edge loads the information at the DI pin into the multiplexer address and mode select shift register. This address controls which channel of the analog input multiplexer (MUX) is selected

and the mode of operation for the A/D. With \overline{CS} low, the falling edge of SCLK shifts the data resulting from the previous ADC conversion out on DO, with the exception of the first bit of data. When \overline{CS} is low continuously, the first bit of the data is clocked out on the rising edge of EOC (end of conversion). When \overline{CS} is toggled, the falling edge of \overline{CS} always clocks out the first bit of data. \overline{CS} should be brought low when SCLK is low. The rise and fall times of the clock edges should not exceed 1 μs.

Pin Descriptions (Continued)

DI	This is the serial data input pin. The data applied to this pin is shifted at the rising edge of SCLK into the multiplexer address and mode select register. <i>Table 2</i> through <i>Table 4</i> show the assignment of the multiplexer address and the mode select data.	
DO	The data output pin. This pin is an active push/pull output when \overline{CS} is low. When \overline{CS} is high, this output is TRI-STATE®. The A/D conversion result (DB0–DB12) and converter status data are clocked out at the falling edge of SCLK on this pin. The word length and format of this result can vary (see <i>Table 1</i>). The word length and format are controlled by the data shifted into the multiplexer address and mode select register (see <i>Table 4</i>).	
EOC	This pin is an active push/pull output and indicates the status of the ADC12130/2/8. When low, it signals that the A/D is busy with a conversion, auto-calibration, auto-zero or power down cycle. The rising edge of EOC signals the end of one of these cycles.	
\overline{CS}	This is the chip select pin. When a logic low is applied to this pin, the rising edge of SCLK shifts the data on DI into the address register. This low also brings DO out of TRI-STATE. With \overline{CS} low, the falling edge of SCLK shifts the data resulting from the previous ADC conversion out on DO, with the exception of the first bit of data. When \overline{CS} is low continuously, the first bit of the data is clocked out on the rising edge of EOC (end of conversion). When \overline{CS} is toggled, the falling edge of \overline{CS} always clocks out the first bit of data. \overline{CS} should be brought low when SCLK is low. The falling edge of \overline{CS} resets a conversion in progress and starts the sequence for a new conversion. When \overline{CS} is brought back low during a conversion, that conversion is prematurely terminated. The data in the output latches may be corrupted. Therefore, when \overline{CS} is brought back low during a conversion in progress the data output at that time should be ignored. \overline{CS} may also be left continuously low. In this case it is imperative that the correct number of SCLK pulses be applied to the ADC in order to remain synchronous. After the ADC supply power is applied it expects to see 13 clock pulses for each I/O sequence. The number of clock pulses the ADC expects is the same as the digital output word length. This word length can be modified by the data shifted in at the DO pin. <i>Table 4</i> details the data required.	(<i>Table 4</i>) such as 12-bit conversion, Auto Cal, Auto Zero etc. When this pin is high the ADC is placed in the read data only mode. While in the read data only mode, bringing \overline{CS} low and pulsing SCLK will only clock out on DO any data stored in the ADCs output shift register. The data on DI will be neglected. A new conversion will not be started and the ADC will remain in the mode and/or configuration previously programmed. Read data only cannot be performed while a conversion, Auto-Cal or Auto-Zero are in progress.
		PD This is the power down pin. When PD is high the A/D is powered down; when PD is low the A/D is powered up. The A/D takes a maximum of 700 μ s to power up after the command is given.
		CH0–CH7 These are the analog inputs of the MUX. A channel input is selected by the address information at the DI pin, which is loaded on the rising edge of SCLK into the address register (see <i>Table 2</i> and <i>Table 3</i>). The voltage applied to these inputs should not exceed V_{A+} or go below GND. Exceeding this range on an unselected channel will corrupt the reading of a selected channel.
		COM This pin is another analog input pin. It is used as a pseudo ground when the analog multiplexer is single-ended.
		MUXOUT1, MUXOUT2 These are the multiplexer output pins.
		A/DIN1, A/DIN2 These are the converter input pins. MUXOUT1 is usually tied to A/DIN1. MUXOUT2 is usually tied to A/DIN2. If external circuitry is placed between MUXOUT1 and A/DIN1, or MUXOUT2 and A/DIN2 it may be necessary to protect these pins. The voltage at these pins should not exceed V_{A+} or go below AGND (see <i>Figure 6</i>).
		V_{REF+} This is the positive analog voltage reference input. In order to maintain accuracy, the voltage range of V_{REF} ($V_{REF} = V_{REF+} - V_{REF-}$) is 1 V_{DC} to 5.0 V_{DC} and the voltage at V_{REF+} cannot exceed V_{A+} . See <i>Figure 5</i> for recommended bypassing.
		V_{REF-} The negative voltage reference input. In order to maintain accuracy, the voltage at this pin must not go below GND or exceed V_{A+} . (See <i>Figure 5</i>).
		V_{A+} , V_{D+} These are the analog and digital power supply pins. V_{A+} and V_{D+} are not connected together on the chip. These pins should be tied to the same power supply and bypassed separately (see <i>Figure 5</i>). The operating voltage range of V_{A+} and V_{D+} is 3.0 V_{DC} to 5.5 V_{DC} .
		DGND This is the digital ground pin (see <i>Figure 5</i>).
		AGND This is the analog ground pin (see <i>Figure 5</i>).
\overline{DOR}	This is the data output ready pin. This pin is an active push/pull output. It is low when the conversion result is being shifted out and goes high to signal that all the data has been shifted out.	
\overline{CONV}	A logic low is required on this pin to program any mode or change the ADC's configuration as listed in the Mode Programming Table	

Absolute Maximum Ratings

(Notes 1, 2)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Positive Supply Voltage ($V^+ = V_{A+} = V_{D+}$)	6.5V
Voltage at Inputs and Outputs except CH0–CH7 and COM	–0.3V to V^+ +0.3V
Voltage at Analog Inputs CH0–CH7 and COM	GND –5V to V^+ +5V
$ V_{A+} - V_{D+} $	300 mV
Input Current at Any Pin (Note 3)	±30 mA
Package Input Current (Note 3)	±120 mA
Package Dissipation at $T_A = 25^\circ\text{C}$ (Note 4)	500 mW
ESD Susceptibility (Note 5) Human Body Model	1500V
Soldering Information N Packages (10 seconds)	260°C
SO Package (Note 6): Vapor Phase (60 seconds)	215°C
Infrared (15 seconds)	220°C
Storage Temperature	–65°C to +150°C

Operating Ratings (Notes 1, 2)

Operating Temperature Range	$T_{\text{MIN}} \leq T_A \leq T_{\text{MAX}}$ –40°C ≤ T_A ≤ +85°C
Supply Voltage ($V^+ = V_{A+} = V_{D+}$)	+3.0V to +5.5V
$ V_{A+} - V_{D+} $	≤ 100 mV
$V_{\text{REF}+}$	0V to V_{A+}
$V_{\text{REF}-}$	0V to ($V_{\text{REF}+} - 1\text{V}$)
V_{REF} ($V_{\text{REF}+} - V_{\text{REF}-}$)	1V to V_{A+}
V_{REF} Common Mode Voltage Range [$(V_{\text{REF}+}) - (V_{\text{REF}-})$] / 2	0.1 V_{A+} to 0.6 V_{A+}
A/DIN1, A/DIN2, MUXOUT1 and MUXOUT2 Voltage Range	0V to V_{A+}
A/D IN Common Mode Voltage Range [$(V_{\text{IN}+}) - (V_{\text{IN}-})$] / 2	0V to V_{A+}

Package Thermal Resistance

Part Number	Thermal Resistance (θ_{JA})
ADC12130CIN	53°C/W
ADC12130CIWM	70°C/W
ADC12132CIMS *	134°C/W
ADC12132CIWM *	64°C/W
ADC121038CIN	40°C/W
ADC121038CIMS *	97°C/W
ADC12138CIWM	50°C/W

t_{RDO}	DO Rise Time, TRI-STATE to High DO Rise Time, Low to High	$R_L = 3k, C_L = 100$ pF	10 10	40 40	ns (max) ns (max)
t_{FDO}	DO Fall Time, TRI-STATE to Low DO Fall Time, High to Low	$R_L = 3k, C_L = 100$ pF	15 15	40 40	ns (max) ns (max)
t_{CD}	Delay from \overline{CS} Falling Edge to \overline{DOR} Falling Edge		45	80	ns (max)
t_{SD}	Delay from Serial Data Clock Falling Edge to \overline{DOR} Rising Edge		45	80	ns (max)
C_{IN}	Capacitance of Logic Inputs		20		pF
C_{OUT}	Capacitance of Logic Outputs		20		pF

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings indicate conditions for which the device is functional, but do not guarantee specific performance limits. For guaranteed specifications and test conditions, see the Electrical Characteristics. The guaranteed specifications apply only for the test conditions listed. Some performance characteristics may degrade when the device is not operated under the listed test conditions.

Note 2: All voltages are measured with respect to GND, unless otherwise specified.

Note 3: When the input voltage (V_{IN}) at any pin exceeds the power supplies ($V_{IN} < GND$ or $V_{IN} > V_{A+}$ or V_{D+}), the current at that pin should be limited to 30 mA. The 120 mA maximum package input current rating limits the number of pins that can safely exceed the power supplies with an input current of 30 mA to four.

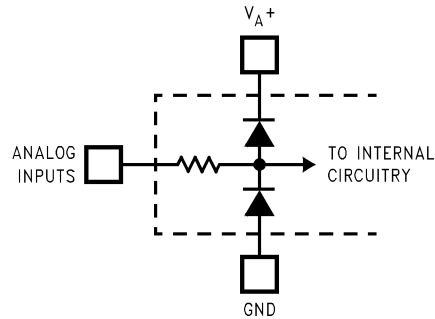

Note 4: The maximum power dissipation must be derated at elevated temperatures and is dictated by T_{Jmax} , θ_{JA} and the ambient temperature, T_A . The maximum allowable power dissipation at any temperature is $P_D = (T_{Jmax} - T_A)/\theta_{JA}$ or the number given in the Absolute Maximum Ratings, whichever is lower. For this device, $T_{Jmax} = 150^\circ C$.

Note 5: The human body model is a 100 pF capacitor discharged through a 1.5 k Ω resistor into each pin.

Note 6: See AN450 "Surface Mounting Methods and Their Effect on Product Reliability" or the section titled "Surface Mount" found in any post 1986 National Semiconductor Linear Data Book for other methods of soldering surface mount devices.

Note 7: Two on-chip diodes are tied to each analog input through a series resistor as shown below. Input voltage magnitude up to 5V above V_{A+} or 5V below GND will not damage this device. However, errors in the A/D conversion can occur (if these diodes are forward biased by more than 50 mV) if the input voltage magnitude of selected or unselected analog input go above V_{A+} or below GND by more than 50 mV. As an example, if V_{A+} is 4.5 V_{DC} , full-scale input voltage must be $\leq 4.55 V_{DC}$ to ensure accurate conversions.

AC Electrical Characteristics (Continued)

01207904

Note 8: To guarantee accuracy, it is required that the V_{A+} and V_{D+} be connected together to the same power supply with separate bypass capacitors at each V^+ pin.

Note 9: With the test condition for V_{REF} ($V_{REF+} - V_{REF-}$) given as +4.096V, the 12-bit LSB is 1.0 mV. For $V_{REF} = 2.5V$, the 12-bit LSB is 610 μV .

Note 10: Typical figures are at $T_J = T_A = 25^\circ C$ and represent most likely parametric norm.

Note 11: Tested limits are guaranteed to National's AOQL (Average Outgoing Quality Level).

Note 12: Positive integral linearity error is defined as the deviation of the analog value, expressed in LSBs, from the straight line that passes through positive full-scale and zero. For negative integral linearity error, the straight line passes through negative full-scale and zero (see *Figure 2* and *Figure 3*).

Note 13: Zero error is a measure of the deviation from the mid-scale voltage (a code of zero), expressed in LSB. It is the average value of the code transitions between -1 to 0 and 0 to +1 (see *Figure 4*).

Note 14: Total unadjusted error includes offset, full-scale, linearity and multiplexer errors.

Note 15: The DC common-mode error is measured in the differential multiplexer mode with the assigned positive and negative input channels shorted together.

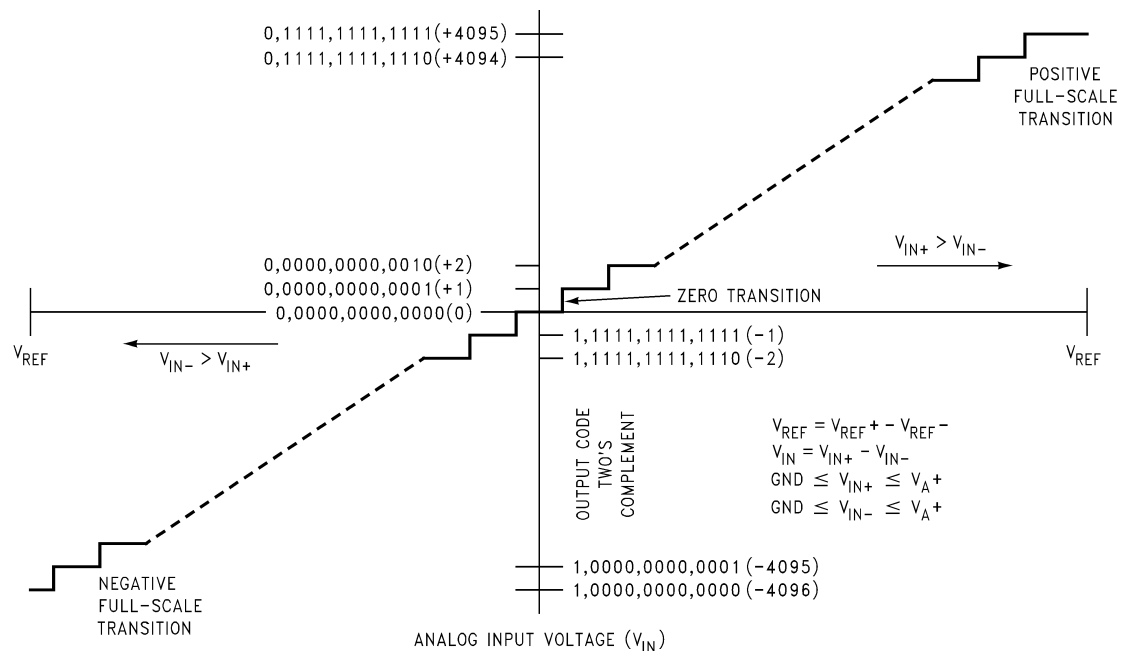

Note 16: Channel leakage current is measured after the channel selection.

Note 17: Timing specifications are tested at the TTL logic levels, $V_{OL} = 0.4V$ for a falling edge and $V_{OH} = 2.4V$ for a rising edge. TRI-STATE output voltage is forced to 1.4V.

Note 18: The ADC12130 family's self-calibration technique ensures linearity and offset errors as specified, but noise inherent in the self-calibration process will result in a maximum repeatability uncertainty of 0.2 LSB.

Note 19: If SCLK and CCLK are driven from the same clock source, then t_A is 6, 10, 18 or 34 clock periods minimum and maximum.

Note 20: The "12-Bit Conversion of Offset" and "12-Bit Conversion of Full-Scale" modes are intended to test the functionality of the device. Therefore, the output data from these modes are not an indication of the accuracy of a conversion result.

TABLE 6. Status Register

Status Bit Location	DB0	DB1	DB2	DB3	DB4	DB5	DB6	DB7	DB8
Status Bit	PU	PD	Cal		12 or 13	16 or 17	Sign	Justification	Test Mode
Function	Device Status			DO Output Format Status					
	“High” indicates a Power Up Sequence is in progress	“High” indicates a Power Down Sequence is in progress	“High” indicates an Auto-Cal Sequence is in progress	Not used	“High” indicates a 12 or 13 bit format	“High” indicates a 16 or 17 bit format	“High” indicates that the sign bit is included. When “Low” the sign bit is not included.	When “High” the conversion result will be output MSB first. When “Low” the result will be output LSB first.	When “High” the device is in test mode. When “Low” the device is in user mode.

Application Information

1.0 DIGITAL INTERFACE

1.1 Interface Concepts

The example in *Figure 7* shows a typical sequence of events after the power is applied to the ADC12130/2/8:

FIGURE 7. Typical Power Supply Power Up Sequence

The first instruction input to the A/D via DI initiates Auto Cal. The data output on DO at that time is meaningless and is completely random. To determine whether the Auto Cal has been completed, a read status instruction is issued to the A/D. Again the data output at that time has no significance since the Auto Cal procedure modifies the data in the output shift register. To retrieve the status information, an additional read status instruction is issued to the A/D. At this time the status data is available on DO. If the Cal signal in the status word, is low Auto Cal has been completed. Therefore, the next instruction issued can start a conversion. The data output at this time is again status information. To keep noise from corrupting the A/D conversion, status can not be read during a conversion. If \overline{CS} is strobed and is brought low during a conversion, that conversion is prematurely ended. EOC can be used to determine the end of a conversion or the A/D controller can keep track in software of when it would be appropriate to communicate to the A/D again. Once it has been determined that the A/D has completed a conversion, another instruction can be transmitted to the A/D. The data from this conversion can be accessed when the next instruction is issued to the A/D.

Note, when \overline{CS} is low continuously it is important to transmit the exact number of SCLK cycles, as shown in the timing diagrams. Not doing so will desynchronize the serial communication to the A/D. (See Section 1.3.)

1.2 Changing Configuration

The configuration of the ADC12130/2/8 on power up defaults to 12-bit plus sign resolution, 12- or 13-bit MSB First, 10 CCLK acquisition time, user mode, no Auto Cal, no Auto Zero, and power up mode. Changing the acquisition time and turning the sign bit on and off requires an 8-bit instruction to be issued to the ADC. This instruction will not start a conversion. The instructions that select a multiplexer address and format the output data do start a conversion. *Figure 8* describes an example of changing the configuration of the ADC12130/2/8.

During I/O sequence 1, the instruction on DI configures the ADC12130/2/8 to do a conversion with 12-bit +sign resolution. Notice that when the 6 CCLK Acquisition and Data Out without Sign instructions are issued to the ADC, I/O sequences 2 and 3, a new conversion is not started. The data output during these instructions is from conversion N which was started during I/O sequence 1. The Configuration Modification timing diagram describes in detail the sequence of events necessary for a Data Out without Sign, Data Out with Sign, or 6/10/18/34 CCLK Acquisition time mode selection. *Table 4* describes the actual data necessary to be input to

the ADC to accomplish this configuration modification. The next instruction, shown in *Figure 8*, issued to the A/D starts conversion N+1 with 16-bit format and 12 bits of resolution formatted MSB first. Again the data output during this I/O cycle is the data from conversion N.

The number of SCLKs applied to the A/D during any conversion I/O sequence should vary in accord with the data out word format chosen during the previous conversion I/O sequence. The various formats and resolutions available are shown in *Table 1*. In *Figure 8*, since 16-bit without sign MSB first format was chosen during I/O sequence 4, the number of SCLKs required during I/O sequence 5 is 16. In the following I/O sequence the format changes to 12-bit without sign MSB first; therefore the number of SCLKs required during I/O sequence 6 changes accordingly to 12.

1.3 \overline{CS} Low Continuously Considerations

When \overline{CS} is continuously low, it is important to transmit the exact number of SCLK pulses that the ADC expects. Not doing so will desynchronize the serial communications to the ADC. When the supply power is first applied to the ADC, it will expect to see 13 SCLK pulses for each I/O transmission. The number of SCLK pulses that the ADC expects to see is the same as the digital output word length. The digital output word length is controlled by the Data Out (DO) format. The DO format maybe changed any time a conversion is started or when the sign bit is turned on or off. The table below details out the number of clock periods required for different DO formats:

DO Format		Number of SCLKs Expected
12-Bit MSB or LSB First	SIGN OFF	12
	SIGN ON	13
16-Bit MSB or LSB first	SIGN OFF	16
	SIGN ON	17

If erroneous SCLK pulses desynchronize the communications, the simplest way to recover is by cycling the power supply to the device. Not being able to easily resynchronize the device is a shortcoming of leaving \overline{CS} low continuously.

The number of clock pulses required for an I/O exchange may be different for the case when \overline{CS} is left low continuously vs. the case when \overline{CS} is cycled. Take the I/O sequence detailed in *Figure 7* (Typical Power Supply Sequence) as an example. The table below lists the number of SCLK pulses required for each instruction:

Instruction	\overline{CS} Low Continuously	\overline{CS} Strobed
Auto Cal	13 SCLKs	8 SCLKs
Read Status	13 SCLKs	8 SCLKs
Read Status	13 SCLKs	8 SCLKs
12-Bit + Sign Conv 1	13 SCLKs	8 SCLKs
12-Bit + Sign Conv 2	13 SCLKs	13 SCLKs

1.4 Analog Input Channel Selection

The data input on DI also selects the channel configuration (see *Table 2*, *Table 3* and *Table 4*). In *Figure 8* the only times when the channel configuration could be modified would be during I/O sequences 1, 4, 5 and 6. Input channels are reselected before the start of each new conversion. Shown

Application Information (Continued)

below is the data bit stream required on DI, during I/O sequence number 4 in *Figure 8*, to set CH1 as the positive input and CH0 as the negative input for the different versions of ADCs:

Part Number	DI Data							
	DI0	DI1	DI2	DI3	DI4	DI5	DI6	DI7
ADC12130 and ADC12132 *	L	H	L	L	H	L	X	X
ADC12138	L	H	L	L	L	L	H	L

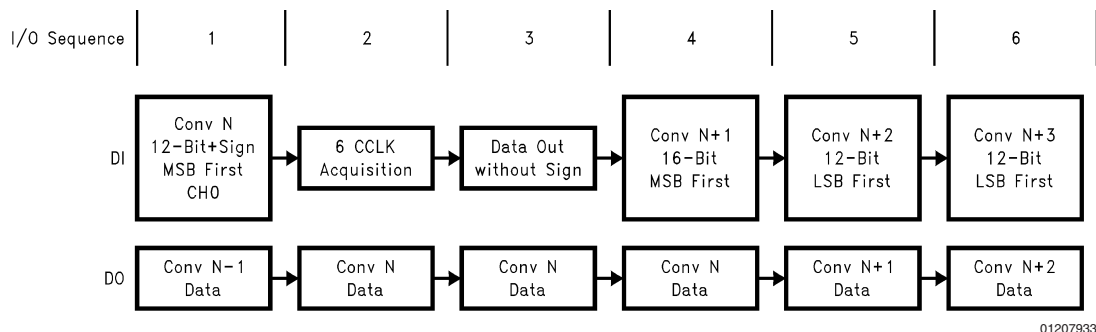

Where X can be a logic high (H) or low (L).

* ADC12132 is obsolete; shown for reference only.

1.5 Power Up/Down

The ADC may be powered down by taking the PD pin HIGH or by the instruction input on DI (see *Table 4* and *Table 5*, and the Power Up/Down timing diagrams). When the ADC is

powered down in this way, the A/D conversion circuitry is deactivated but the digital I/O circuitry is kept active. Hardware power up/down is controlled by the state of the PD pin. Software power-up/down is controlled by the instruction issued to the ADC. If a software power up instruction is issued to the ADC while a hardware power down is in effect (PD pin high) the device will remain in the power-down state. If a software power down instruction is issued to the ADC while a hardware power up is in effect (PD pin low), the device will power down. When the device is powered down by software, it may be powered up by either issuing a software power up instruction or by taking PD pin high and then low. If the power down command is issued during an A/D conversion, that conversion is interrupted, so the data output after power up cannot be relied upon.

01207933

FIGURE 8. Changing the ADC's Conversion Configuration

1.6 User Mode and Test Mode

An instruction may be issued to the ADC to put it into test mode, which is used by the manufacturer to verify complete functionality of the device. During test mode CH0–CH7 become active outputs. If the device is inadvertently put into the test mode with \overline{CS} continuously low, the serial communications may be desynchronized. Synchronization may be regained by cycling the power supply voltage to the device. Cycling the power supply voltage will also set the device into user mode. If \overline{CS} is used in the serial interface, the ADC may be queried to see what mode it is in. This is done by issuing a “read STATUS register” instruction to the ADC. When bit 9 of the status register is high, the ADC is in test mode; when bit 9 is low the ADC, is in user mode. As an alternative to cycling the power supply, an instruction sequence may be used to return the device to user mode. This instruction sequence must be issued to the ADC using \overline{CS} . The following table lists the instructions required to return the device to user mode. Note that this **entire sequence**, including both Test Mode and User Mode values, should be sent to recover from the test mode.

Instruction	DI Data							
	DI0	DI1	DI2	DI3	DI4	DI5	DI6	DI7
TEST MODE	H	X	X	X	H	H	H	H
Reset	L	L	L	L	H	H	H	L
Test Mode	L	L	L	L	H	L	H	L
Instructions	L	L	L	L	H	L	H	H
USER MODE	L	L	L	L	H	H	H	H
Power Up	L	L	L	L	H	L	H	L
Set DO with or without Sign	H or L	L	L	L	H	H	L	H
Set Acquisition Time	H or L	H or L	L	L	H	H	H	L
Start a Conversion	H or L	H or L	H or L	H or L	L	H or L	H or L	H or L

X = Don't Care

The power up, data with or without sign, and acquisition time instructions should be resent after returning to the user mode. This is to ensure that the ADC is in the required state before a conversion is started.

Application Information (Continued)

1.7 Reading the Data Without Starting a Conversion

The data from a particular conversion may be accessed without starting a new conversion by ensuring that the $\overline{\text{CONV}}$ line is taken high during the I/O sequence. See the Read Data timing diagrams. *Table 5* describes the operation of the $\overline{\text{CONV}}$ pin.

2.0 DESCRIPTION OF THE ANALOG MULTIPLEXER

For the ADC12138, the analog input multiplexer can be configured with 4 differential channels or 8 single ended channels with the COM input as the zero reference or any

combination thereof (see *Figure 9*). The difference between the voltages on the V_{REF}^+ and V_{REF}^- pins determines the input voltage span (V_{REF}). The analog input voltage range is 0 to V_A^+ . Negative digital output codes result when $V_{\text{IN}}^- > V_{\text{IN}}^+$. The actual voltage at V_{IN}^- or V_{IN}^+ cannot go below AGND.

FIGURE 9.

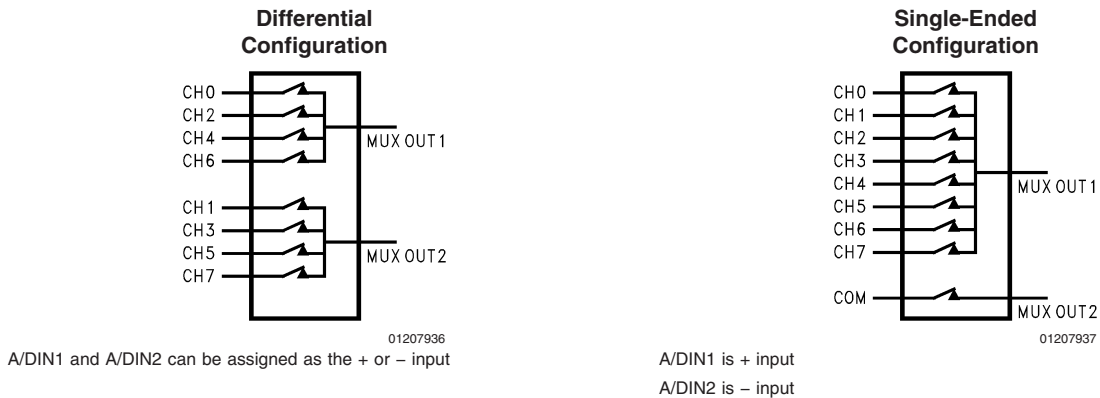

FIGURE 10.

CH0, CH2, CH4, and CH6 can be assigned to the MUXOUT1 pin in the differential configuration, while CH1, CH3, CH5, and CH7 can be assigned to the MUXOUT2 pin. In the differential configuration, the analog inputs are paired as follows: CH0 with CH1, CH2 with CH3, CH4 with CH5 and CH6 with CH7. The A/DIN1 and A/DIN2 pins can be assigned positive or negative polarity.

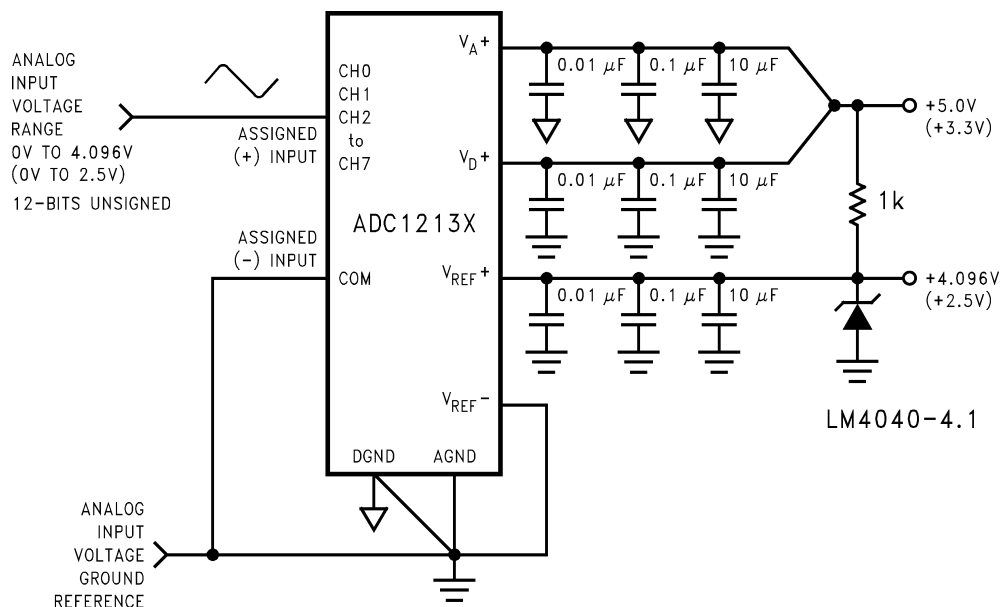

With the single-ended multiplexer configuration CH0 through CH7 can be assigned to the MUXOUT1 pin. The COM pin is always assigned to the MUXOUT2 pin. A/DIN1 is assigned as the positive input; A/DIN2 is assigned as the negative input. (See *Figure 10*).

The Multiplexer assignment tables for the ADC12130/2/8 (*Table 2* and *Table 3*) summarize the aforementioned functions for the different versions of A/Ds.

2.1 Biasing for Various Multiplexer Configurations

Figure 11 is an example of biasing the device for single-ended operation. The sign bit is always low. The digital output range is 0 0000 0000 0000 to 0 1111 1111 1111. One LSB is equal to 1 mV (4.1V/4096 LSBs).

Application Information (Continued)

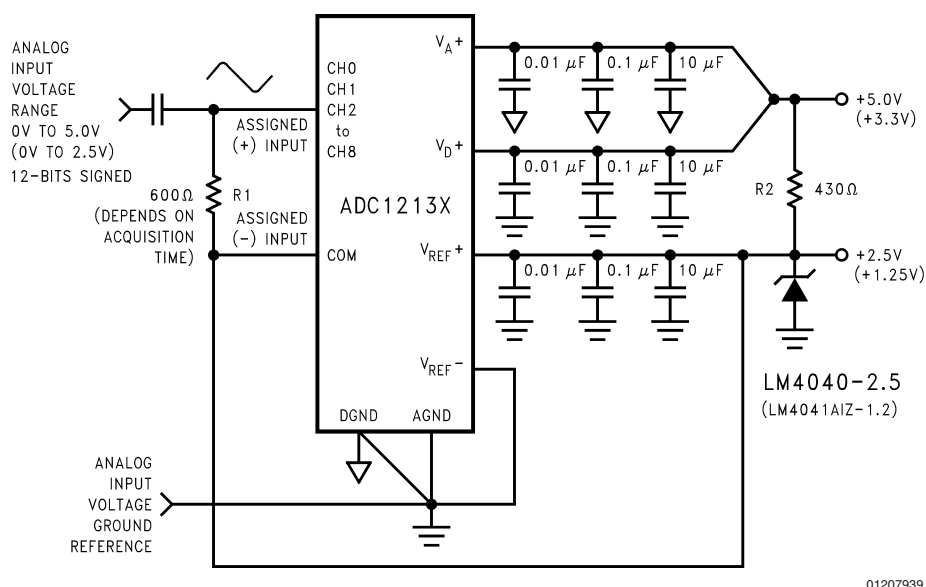

01207938

FIGURE 11. Single-Ended Biasing

For pseudo-differential signed operation, the biasing circuit shown in *Figure 12* shows a signal AC coupled to the ADC. This gives a digital output range of -4096 to $+4095$. With a 2.5V reference, 1 LSB is equal to $610\text{ }\mu\text{V}$. Although, the ADC is not production tested with a 2.5V reference, when V_{A+} and V_{D+} are $+5.0\text{V}$ linearity error typically will not change more than 0.1 LSB (see the curves in the Typical Electrical Characteristics Section). With the ADC set to an acquisition time

of 10 clock periods, the input biasing resistor needs to be 600Ω or less. Notice though that the input coupling capacitor needs to be made fairly large to bring down the high pass corner. Increasing the acquisition time to 34 clock periods (with a 5 MHz CCLK frequency) would allow the 600Ω to increase to $6\text{ k}\Omega$, which with a $1\text{ }\mu\text{F}$ coupling capacitor would set the high pass corner at 26 Hz . Increasing R_2 to $6\text{ k}\Omega$ would allow R_2 to be $2\text{ k}\Omega$.

3.0 REFERENCE VOLTAGE

The difference in the voltages applied to the V_{REF}^+ and V_{REF}^- defines the analog input span (the difference between the voltage applied between two multiplexer inputs or the voltage applied to one of the multiplexer inputs and analog ground), over which 4095 positive and 4096 negative codes exist. The voltage sources driving V_{REF}^+ or V_{REF}^- must have very low output impedance and noise. The circuit in Figure 16 is an example of a very stable reference appropriate for use with the device.

*Tantalum

01207943

FIGURE 16. Low Drift Extremely Stable Reference Circuit

The ADC12130/2/8 can be used in either ratiometric or absolute reference applications. In ratiometric systems, the analog input voltage is proportional to the voltage used for the ADC's reference voltage. When this voltage is the system power supply, the V_{REF}^+ pin is connected to V_A^+ and V_{REF}^- is connected to ground. This technique relaxes the system reference stability requirements because the analog input voltage and the ADC reference voltage move together. This maintains the same output code for given input conditions. For absolute accuracy, where the analog input voltage

varies between very specific voltage limits, a time and temperature stable voltage source can be connected to the reference inputs. Typically, the reference voltage's magnitude will require an initial adjustment to null reference voltage induced full-scale errors.

Below are recommended references along with some key specifications.

Part Number	Output Voltage Tolerance	Temperature Coefficient
LM4041CI-Adj	±0.5%	±100ppm/°C
LM4040AI-4.1	±0.1%	±100ppm/°C
LM4050AI-4.1	±0.1%	±50ppm/°C
Circuit of Figure 16	Adjustable	±2ppm/°C

The reference voltage inputs are not fully differential. The ADC12130/2/8 will not generate correct conversions or comparisons if V_{REF}^+ is taken below V_{REF}^- . Correct conversions result when V_{REF}^+ and V_{REF}^- differ by 1V and remain, at all times, between ground and V_A^+ . The V_{REF} common mode range, $(V_{REF}^+ + V_{REF}^-)/2$ is restricted to $(0.1 \times V_A^+)$ to $(0.6 \times V_A^+)$. Therefore, with $V_A^+ = 5V$ the center of the reference ladder should not go below 0.5V or above 3.0V. Figure 17 is a graphic representation of the voltage restrictions on V_{REF}^+ and V_{REF}^- .

Application Information (Continued)

FIGURE 17. V_{REF} Operating Range

4.0 ANALOG INPUT VOLTAGE RANGE

The ADC12130/2/8's fully differential ADC generate a two's complement output that is found by using the equation shown below:

for (12-bit) resolution the Output Code =

$$\frac{(V_{IN}^{+} - V_{IN}^{-}) (4096)}{(V_{REF}^{+} - V_{REF}^{-})}$$

Round off to the nearest integer value between -4096 to 4095 if the result of the above equation is not a whole number.

Examples are shown in the table below:

V_{REF}^{+}	V_{REF}^{-}	V_{IN}^{+}	V_{IN}^{-}	Code Output Digital
+2.5V	+1V	+1.5V	0V	0,1111,1111,1111
+4.096V	0V	+3V	0V	0,1011,1011,1000
+4.096V	0V	+2.499V	+2.500V	1,1111,1111,1111
+4.096V	0V	0V	+4.096V	1,0000,0000,0000

5.0 INPUT CURRENT

At the start of the acquisition window (t_A) a charging current flows into or out of the analog input pins (A/DIN1 and A/DIN2) depending on the input voltage polarity. The analog input pins are CH0-CH7 and COM when A/DIN1 is tied to MUXOUT1 and A/DIN2 is tied to MUXOUT2. The peak value of this input current will depend on the actual input voltage applied, the source impedance and the internal multiplexer switch on resistance. With MUXOUT1 tied to A/DIN1 and MUXOUT2 tied to A/DIN2 the internal multiplexer switch on resistance is typically 1.6 k Ω . The A/DIN1 and A/DIN2 mux on resistance is typically 750 Ω .

6.0 INPUT SOURCE RESISTANCE

For low impedance voltage sources (<600 Ω), the input charging current will decay, before the end of the S/H's acquisition time of 2 μ s (10 CCLK periods with $f_{CK} = 5$ MHz), to a value that will not introduce any conversion errors. For high source impedances, the S/H's acquisition time can be increased to 18 or 34 CCLK periods. For less ADC accuracy and/or slower CCLK frequencies the S/H's acquisition time may be decreased to 6 CCLK periods. To determine the number of clock periods (N_C) required for the acquisition time with a specific source impedance for the various resolutions the following equations can be used:

$$12 \text{ Bit} + \text{Sign} \quad N_C = [R_S + 2.3] \times f_{CK} \times 0.824$$

Where f_{CK} is the conversion clock (CCLK) frequency in MHz and R_S is the external source resistance in k Ω . As an example, operating with a resolution of 12 Bits + sign, a 5 MHz clock frequency and maximum acquisition time of 34 conversion clock periods the ADC's analog inputs can handle a source impedance as high as 6 k Ω . The acquisition time may also be extended to compensate for the settling or response time of external circuitry connected between the MUXOUT and A/DIN pins.

An acquisition is started by a falling edge of SCLK and ends with a rising edge of CCLK (see timing diagrams). If SCLK and CCLK are asynchronous one extra CCLK clock period may be inserted into the programmed acquisition time for synchronization. Therefore, with asynchronous SCLK and CCLK, the acquisition time will change from conversion to conversion.

7.0 INPUT BYPASS CAPACITANCE

External capacitors (0.01 μ F–0.1 μ F) can be connected between the analog input pins, CH0-CH7, and analog ground to filter any noise caused by inductive pickup associated with long input leads. These capacitors will not degrade the conversion accuracy.

8.0 NOISE

The leads to each of the analog multiplexer input pins should be kept as short as possible. This will minimize input noise and clock frequency coupling that can cause conversion errors. Input filtering can be used to reduce the effects of the noise sources.

9.0 POWER SUPPLIES

Noise spikes on the V_A^{+} and V_D^{+} supply lines can cause conversion errors; the comparator will respond to the noise. The ADC is especially sensitive to any power supply spikes that occur during the auto-zero or linearity correction. The minimum power supply bypassing capacitors recommended are low inductance tantalum capacitors of 10 μ F or greater paralleled with 0.1 μ F monolithic ceramic capacitors. More or different bypassing may be necessary depending on the overall system requirements. Separate bypass capacitors should be used for the V_A^{+} and V_D^{+} supplies and placed as close as possible to these pins.

10.0 GROUNDING

The ADC12130/2/8's performance can be maximized through proper grounding techniques. These include the use of separate analog and digital areas of the board with analog and digital components and traces located only in their respective areas. Bypass capacitors of 0.01 μ F and 0.1 μ F surface mount capacitors and a 10 μ F are recommended at

Application Information (Continued)

each of the power supply pins for best performance. These capacitors should be located as close to the bypassed pin as practical, especially the smaller value capacitors.

11.0 CLOCK SIGNAL LINE ISOLATION

The ADC12130/2/8's performance is optimized by routing the analog input/output and reference signal conductors as far as possible from the conductors that carry the clock signals to the CCLK and SCLK pins. Maintaining a separation of at least 7 to 10 times the height of the clock trace above its reference plane is recommended.

12.0 THE CALIBRATION CYCLE

A calibration cycle needs to be started after the power supplies, reference, and clock have been given enough time to stabilize after initial turn-on. During the calibration cycle, correction values are determined for the offset voltage of the sampled data comparator and any linearity and gain errors. These values are stored in internal RAM and used during an analog-to-digital conversion to bring the overall full-scale, offset, and linearity errors down to the specified limits. Full-scale error typically changes ± 0.4 LSB over temperature and linearity error changes even less; therefore it should be necessary to go through the calibration cycle only once after power up if the Power Supply Voltage and the ambient temperature do not change significantly (see the curves in the Typical Performance Characteristics).

13.0 THE AUTO-ZERO CYCLE

To correct for any change in the zero (offset) error of the A/D, the auto-zero cycle can be used. It may be desirable to do an auto-zero cycle whenever the ambient temperature or the power supply voltage change significantly. (See the curves titled "Zero Error Change vs. Ambient Temperature" and "Zero Error Change vs. Supply Voltage" in the Typical Performance Characteristics.)

14.0 DYNAMIC PERFORMANCE

Many applications require the A/D converter to digitize AC signals, but the standard DC integral and differential nonlinearity specifications will not accurately predict the A/D converter's performance with AC input signals. The important specifications for AC applications reflect the converter's abil-

ity to digitize AC signals without significant spectral errors and without adding noise to the digitized signal. Dynamic characteristics such as signal-to-noise (S/N), signal-to-noise + distortion ratio (S/(N + D)), effective bits, full power bandwidth, aperture time and aperture jitter are quantitative measures of the A/D converter's capability.

An A/D converter's AC performance can be measured using Fast Fourier Transform (FFT) methods. A sinusoidal waveform is applied to the A/D converter's input, and the transform is then performed on the digitized waveform. S/(N + D) and S/N are calculated from the resulting FFT data, and a spectral plot may also be obtained. Typical values for S/N are shown in the table of Electrical Characteristics, and spectral plots of S/(N + D) are included in the typical performance curves.

The A/D converter's noise and distortion levels will change with the frequency of the input signal, with more distortion and noise occurring at higher signal frequencies. This can be seen in the S/(N + D) versus frequency curves. These curves will also give an indication of the full power bandwidth (the frequency at which the S/(N + D) or S/N drops 3 dB).

Effective number of bits can also be useful in describing the A/D's noise and distortion performance. An ideal A/D converter will have some amount of quantization noise, determined by its resolution, and no distortion, which will yield an optimum S/(N + D) ratio given by the following equation:

$$S/(N + D) = (6.02 \times n + 1.76) \text{ dB}$$

where "n" is the A/D's resolution in bits.

Since the ideal A/D converter has no distortion, the effective bits of a real A/D converter, therefore, can be found by:

$$n(\text{effective}) = \text{ENOB} = (S/(N + D) - 1.76) / 6.02$$

As an example, this device with a differential signed 5V, 1 kHz sine wave input signal will typically have a S/N of 77 dB, which is equivalent to 12.5 effective bits.

15.0 AN RS232 SERIAL INTERFACE

Shown on the following page is a schematic for an RS232 interface to any IBM and compatible PCs. The DTR, RTS, and CTS RS232 signal lines are buffered via level translators and connected to the ADC12138's DI, SCLK, and $\overline{\text{DO}}$ pins, respectively. The D flip-flop is used to generate the $\overline{\text{CS}}$ signal.

LIFE SUPPORT POLICY

NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT AND GENERAL COUNSEL OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

BANNED SUBSTANCE COMPLIANCE

National Semiconductor manufactures products and uses packing materials that meet the provisions of the Customer Products Stewardship Specification (CSP-9-111C2) and the Banned Substances and Materials of Interest Specification (CSP-9-111S2) and contain no "Banned Substances" as defined in CSP-9-111S2.

Leadfree products are RoHS compliant.
