

# ADSP-2141L

## APPLICATIONS

Security Coprocessor for High Speed Networking Products (Routers, Switches, Hubs)  
 Cryptographic Core for Firewalls, Hardware Encryptors, and More  
 Crypto Peripheral for Implementing Secure NIC Adapters (10/100 Ethernet, Token Ring, ISDN)  
 Secure Modem-on-a-Chip (V.34, ADSL)

## FEATURES

### DES CRYPTO BLOCK

640 Mbps Sustained Performance—Single DES  
 214 Mbps Sustained Performance—Triple DES  
 Supports All Modes: ECB; CBC; 64-Bit OFB; and 1-, 8-, 64-Bit CFB. Includes Automatic Padding  
 Implements IPsec ESP Transforms Autonomously at OC-3 (155 Mbps) Rates (3-DES, SHA-1)

### HASH BLOCK

Hardware-Based SHA-1 and MD-5 Hashing  
 253 Mbps Sustained Performance—SHA-1  
 315 Mbps Sustained Performance—MD-5  
 Implements IPsec AH and HMAC Transforms

## SECURE KERNEL CONTROL

Tamper-Resistant Isolation of Cryptographic Functions Enforces Security Perimeter Around Crypto Functions and Crypto Storage Locations  
 Anticlone Protection  
 Secure Algorithm Download

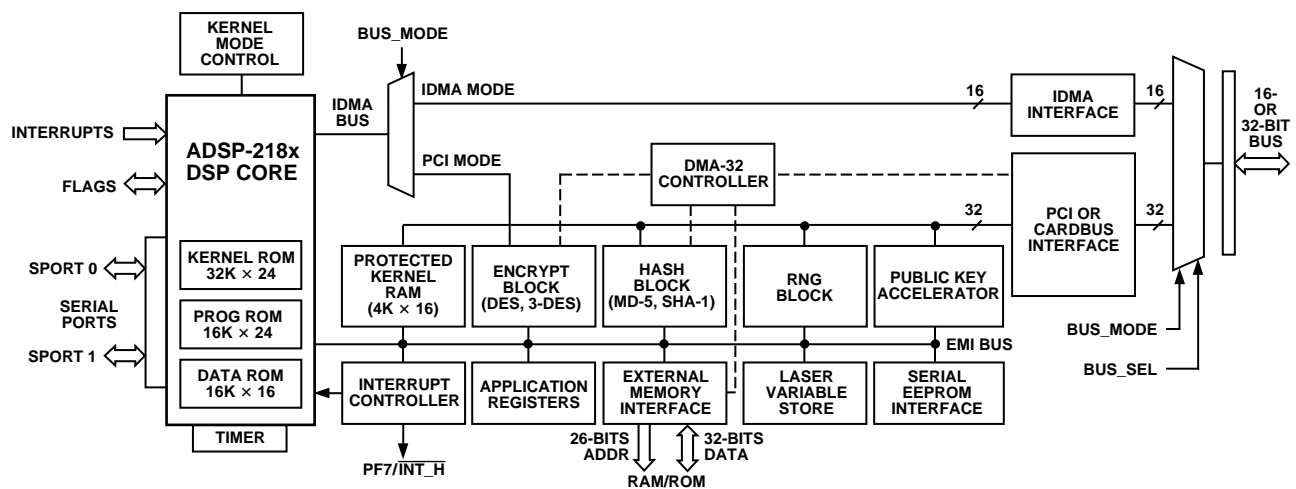

## SafeNet CGX LIBRARY

On-Chip SafeNet CGX Crypto Library with Flexible CGX API  
 Includes *Chained* and *Parallel Execution* Commands Such as Hash-and-Encrypt  
 Embodied as 32K Words (32K × 24) Kernel Program Mask-Programmed into On-Chip ROM  
 On-Chip Protected 4K × 16 Security Scratchpad RAM

## RANDOM NUMBER GENERATOR

Hardware-Based Nondeterministic Random Number Generator  
 Generates Internal Session Keys That Are Never Exposed Outside of the SafeNet DSP  
 Redundant Fail-Safe Design  
 Up to 1.3 Mbits of Random Data Available per Second

FUNCTIONAL BLOCK DIAGRAM

SafeNet is a registered trademark of Information Resource Engineering (IRE).

# ADSP-2141L

## **PUBLIC KEY ACCELERATOR**

**Accelerator for Math-Intensive Public Key Operations**  
**Diffie-Hellman Negotiate: <29 ms (1024-Bit Modulus, 180-Bit Exponent)**

**RSA 1024-Bit Sign: <29 ms; RSA 1024-Bit Verify: 6 ms**  
**DSA Sign: <39 ms; DSA Verify: <66 ms**

## **KEY MANAGEMENT BLOCK**

**Laser-Programmed Unique Triple-DES Cryptovariable**  
**Protects Off-Chip Storage**

**Support for Secure Storage of Both Secret Keys and**  
**Public/Private Key Pairs**

**Trust-Model Rules Enforcement**

**Only Encrypted Keys May Be Exported Off the Chip**  
**Internal Key Cache for 15 Keys—Can Be Expanded to**  
**700 Keys On-Chip**

**Keys May Also Be Securely Stored Off-Chip, Allowing**  
**Unlimited Storage**

## **DSP CORE**

**40 MIPS Sustained Performance**

**Single-Cycle Instruction Execution**

**Single-Cycle Context Switch**

**Zero-Overhead Looping**

**Low Power Dissipation**

**16K Words (16K × 24) On-Chip Program RAM**

**16K Words (16K × 16) On-Chip Data RAM**

**64M Words Off-Chip Program and Data Memory**

**Programmable 16-Bit Interval Timer with Prescale**

## **PCI BUS/CARDBUS INTERFACE**

**32-Bit 3.3 V Bus Interface**

**33 MHz or 40 MHz\* Bus Speed**

**Bus Master and Target Modes**

**Can Directly DMA Between Crypto Functions and Other**  
**PCI Bus Agents**

\*66 MHz speed pending chip characterization.

## **GENERAL DESCRIPTION**

The ADSP-2141L SafeNet DSP is a highly integrated embedded security processor that incorporates a sophisticated, general purpose DSP, along with a number of high performance Cryptographic function blocks, as well as PCI, DMA and Serial EEPROM interfaces. It is fabricated in 0.35  $\mu$  CMOS triple-layer metal technology and uses a 3.3 V power supply. It is available in a 208-lead MQFP package with a commercial (0°C to 70°C) temperature range.

### **DSP Core**

The DSP is a standard Analog Devices ADSP-218x core with full ADSP-2100 family compatibility. The ADSP-218x Core combines the base DSP components from the ADSP-2100 family with the addition of two serial ports, a 16-bit internal DMA port, a byte DMA port, a programmable timer, Flag I/O, extensive interrupt capabilities, and on-chip program and data memory. The external memory interface of the 218x core has been extended to support up to 64M-words addressing for both program and data memory. Some core enhancements have been added in the ADSP-2141L, including on-chip security ROM and interrupt functions. Refer to the Analog Devices ADSP-2183 data sheet for further information.

### **SafeNet CGX Library—Secure Kernel**

The SafeNet CGX Library is a crypto library embodied as firmware (a secure kernel) that is mask-programmed into ROM within the DSP. This solution protects the library from tampering. The CGX Library provides the Application Programming Interface (API) to applications that require security services from the ADSP-2141L. Those applications may be software executing in user mode on the DSP, or they may be external host software accessing the ADSP-2141L via a PCI bus. Approximately 40 Crypto commands—called CGX (CryptoGraphic eXtensions)—are provided at the API and a simple control block structure is used to pass arguments into the secure kernel and return status. The CGX library includes integrated drivers for the various hardware crypto blocks on the chip. This allows the programmer to ignore those details and concentrate on other product design issues.

The CGX library firmware runs under a protected mode state of the DSP as described in the Kernel Mode Control section following. This guarantees the security integrity of the system during the execution of CGX processes and, for example, prevents disclosure of cryptographic key data or tampering with a security operation.

### **Kernel Mode Control**

The Kernel Mode Control subsystem is responsible for enforcing the security perimeter around the cryptographic functions of the ADSP-2141L. The device may operate in either user mode (kernel space is not accessible) or kernel mode (kernel space is accessible) at a given time. When in kernel mode, the kernel RAM and certain protected crypto registers and functions (kernel space) are accessible only to the CGX library firmware. The CGX Library executes host-requested macro-level functions and then returns control to the calling application. The kernel mode control subsystem resets the DSP should any security violation occur, such as attempting to access a protected memory location while in user mode.

**Protected Kernel RAM**

The 4K × 16 kernel RAM provides a secure storage area on the ADSP-2141L for sensitive data such as keys or intermediate calculations during public key operations. The Kernel Mode Control subsystem (above) enforces the protection by allowing only internal secure kernel mode access to this RAM. A public keyset and a cache of up to 15 secret keys may be stored in kernel RAM. Secure key storage may be expanded to 700 secret keys by assigning segments of the DSP's internal data RAM to be protected. Furthermore, a virtually unlimited number of data encryption keys may be stored in an encrypted form in off-chip memory.

**Encrypt Block**

The encrypt block performs high speed DES and Triple-DES encrypt/decrypt operations. All four standard modes of DES are supported: Electronic Code Book (ECB), Cipher Block Chaining (CBC), 64-bit Output Feedback (OFB) and 1-bit, 8-bit and 64-bit Cipher Feedback (CFB). The DES encrypt/decrypt operations are highly pipelined and execute full 16-round DES in only four clock cycles. Hardware support for padding insertion, verification and removal further accelerates the encryption operation. Context switching is provided to minimize the overhead of changing crypto keys and Initialization Vectors (IVs) to nearly zero.

**Hash Block**

The secure hash block is tightly coupled with the encrypt block and provides hardware accelerated one-way hash functions. Both the MD-5 and SHA-1 algorithms are supported. Combined operations that chain both hashing and encrypt/decrypt functions are provided in order to significantly reduce the processing time for data that needs both operations applied. For *hash-then-encrypt* and *hash-then-decrypt* operations, the ADSP-2141L can perform parallel execution of both functions from the same source and destination buffers. For *encrypt-then-hash* and *decrypt-then-hash* operations, the processing must be sequential, but minimum latency is still provided through the pipeline chaining design. An offset may be specified between the start of hashing and the start of encryption to support certain protocols such as IPsec. A 'mutable bit handler' is also provided on the hash engine to facilitate IPsec AH processing.

**Random Number Generator (RNG) Block**

The hardware random number generator provides a true, non-deterministic noise source for the purpose of generating keys, Initialization Vectors (IVs), and other random number requirements. Random numbers are provided as 16-bit words to the kernel. The CGX kernel requests random numbers as needed to perform requested CGX commands such as CGX\_Gen\_Key, and can also directly supply from 1 to 65,535 random bytes to a host application via the CGX\_Random command.

**Public Key Accelerator**

The public key accelerator module works in concert with the CGX kernel firmware to provide full public key services to the host application. The kernel provides macro-level functions to perform Diffie-Hellman key agreement, RSA encrypt or decrypt, DSA compute and verify digital signatures. The hardware accelerator block speeds computation-intensive operations such as large vector multiply, add, subtract, square.

**PCI/Cardbus Interface**

A full 40 MHz/33 MHz PCI bus interface has been added to the core DSP functions. The 32-bit PCI interface supports both bus master and target modes. The ADSP-2141L is capable of using DMA to directly access data on other PCI entities and pass that data through its encryption/hash engines.

**32-Bit DMA Controller**

The ADSP-2141L incorporates a high performance 32-bit DMA controller which can be set up to move data efficiently between Host PCI memory, the hash/encrypt blocks, and/or external memory. The DMA controller can be used with the PCI bus in master mode, thus autonomously moving 32-bit data with minimal DSP intervention. Up to 255 long words (1020 bytes) can be moved in a burst at up to 160 Mbytes per second.

**Application Registers**

The application registers are a set of memory-mapped registers that facilitate communications between the ADSP-2141L and a host processor via the PCI bus. One of the registers is a mailbox that is 44 bytes long and set up to hold the CGX command structure passed between the host and DSP processors. The application registers also provide the mechanism that allows the DSP and the external host to negotiate ownership of the hash/encrypt block.

**Serial EEPROM Interface**

The serial EEPROM interface allows an external nonvolatile memory to be connected to the ADSP-2141L for storing PCI configuration information (Plug and Play), as well as general-purpose nonvolatile storage. For example, encrypted (black) keys could be stored into EEPROM for fast recovery after a power outage.

**Interrupt Controller**

The DSP core provides support for 14 interrupt sources, including six external and eight internal. All interrupts are prioritized into 12 levels and interrupt nesting may be enabled or disabled under software control. The security block interrupt controller provides enhancements to the DSP interrupt functions.

Primarily, the interrupt controller provides a new interrupt generation capability to the DSP or to an external host processor. Under programmable configuration control, a crypto interrupt may be generated due to completion of certain operations such as encrypt complete, hash complete. The interrupt may either be directed at the DSP core (on  $\overline{\text{IRQ2}}$ ), or provided on an output line (PF7/ $\overline{\text{INT\_H}}$ ) to a host subsystem.

**Laser Variable Storage**

The laser variable storage consists of 256 bits of tamper-proof factory-programmed data that is only accessible to the internal function blocks and the security kernel. Included in these laser variable bits are:

- Local Storage Variable (master key-encryption key)
- Randomizer Seed (to supplement the true entropy fed into the RNG)
- Program Control Data (enables/disables various features and configures the ADSP-2141L)
- CRC of the Laser Data (to verify laser data integrity).

# ADSP-2141L

The Program Control Data Bits (PCDBs) include configuration for permitted key lengths, algorithm enables, Red KEK loading. Most of the PCDB settings may be overridden with a digitally signed token which may be loaded into the ADSP-2141L when it boots. These tokens are created by IRE and each is targeted to a specific ADSP-2141L using a hash of its unique identity.

## Downloadable Secure Code

The ADSP-2141L allows additional security functions to be added to the device through a secure download feature. Up to 16K words of code may be downloaded into internal memory within the DSP and this code can be given the security privileges of the CGX kernel firmware. All downloaded firmware is authenticated with a digital signature and verified with an on-chip public key. Additional functions could include new encryption, hash or public key algorithms such as IDEA, RC-4, RIPEMD, elliptic curve, or any other application that needs direct control over the protected cryptographic hardware.

## ARCHITECTURE OVERVIEW

This section provides an architecture-level description of the unique function blocks within the ADSP-2141L.

### Memory Map

The ADSP-2141L memory map is very similar to that of the ADSP-2183 DSP, except that it includes significantly more off-chip memory addressing, and has additional crypto registers which are accessible to the user.

### DSP Core

The DSP core is architecturally identical to the ADSP-218x with a few exceptions.

- The memory map includes additional external memory addressing through the PMOVLAY and DMOVLAY mechanisms. For more information, see the Memory Map section.
- Additional memory-mapped crypto registers are available in the kernel data RAM space.
- The PF7/INT\_H flag pin may be reassigned to be the host interrupt output.

Figure 1. Program Memory (MMAP = 0)

Figure 2. Program Memory (MMAP = 1)

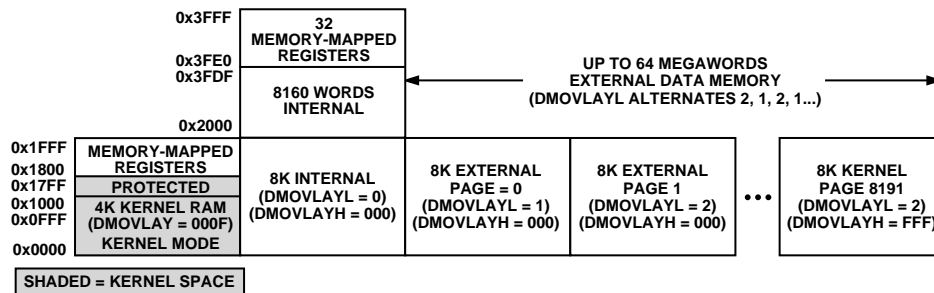

Figure 3. Data Memory

- $\overline{IRQ2}$  now can include interrupt sources from the crypto subsystem, depending on interrupt mask registers.
- A new read register has been added to indicate the state of interrupt enable and interrupt masks.
- The kernel mode control subsystem has been added to supervise the protected mode of operation of the DSP core.
- Internal RAM protection logic has been added to allow the kernel to seize increments of 1K word of internal PRAM and DRAM.
- Bus mode configuration (218x vs. PCI) pins have been added.
- 32K words of kernel program ROM have been added to the DSP memory space. (See the Memory Map section.)

### Kernel Mode Control

The kernel mode control subsystem provides the following functions which serve to enforce the security integrity of the ADSP-2141L:

- Provide a means to securely enter the kernel mode.
- Provide a means to properly exit the kernel mode.
- Prevent user mode access to protected memory and register locations.
- Manage interrupts during kernel mode executions.
- Manage the reset function to ensure that sensitive variables in DSP registers are erased.

Most of the kernel mode control functions are implemented in the hardware of the ADSP-2141L and are not directly visible to nonkernel applications (user mode). Any attempt by a user mode application program running on the DSP to access a kernel space addresses (PRAM 0x2001 – 0x3FFF, PMOVLAY 000C – 000F; or DRAM 0x0000 – 0x17FF, DMOVLAY 000F) results in an immediate chip reset and all sensitive registers and memory locations are erased. Kernel mode may only be entered via a call, jump or increment to address 0x2000 with PMOVLAY

set to 0x000F. Once in kernel mode, any branch to nonkernel space program memory causes the DSP to return to user mode. (Note: For security reasons when in kernel mode, the DSP does not respond to Emulator bus requests.)

The kernel mode can be interrupted during execution; however, during certain periods where sensitive data is being moved, all interrupts are disabled. Within the interrupt service routine, another call to the kernel (CGX call) may be made if desired, although there are limitations on which CGX commands may preempt another. (For information, see the *ADSP-2141L CGX Interface Programmer's Guide* <http://www.ire-ma.com/proddoc.htm>.) Only one level of kernel mode nesting is permitted. An interrupt to a user mode vector location while in nested kernel mode will also trigger the violation reset logic.

Once the interrupt service routine is finished, the return-from-interrupt must return control back to the kernel at the address/overlay that was originally interrupted, otherwise the protection logic will issue a chip reset.

### Hash and Encrypt Block Overview

The encrypt block is tightly coupled to the hash block in the ADSP-2141L and therefore the two are discussed together. Refer to Figure 4, *Hash/Encrypt Functional Block Diagram*, for the following description.

The algorithms implemented in the combined hash and encryption block are: DES, Triple DES, MD-5 and SHA-1. Data can be transferred to and from the module once to perform both hashing and encryption on the same data stream. The DES encrypt/decrypt operations are highly paralleled and pipelined, and execute full 16-round DES in only four clock cycles. The internal data flow and buffering allows parallel execution of hashing and encryption where possible, and allows processing of data concurrently with I/O of previous and subsequent blocks.

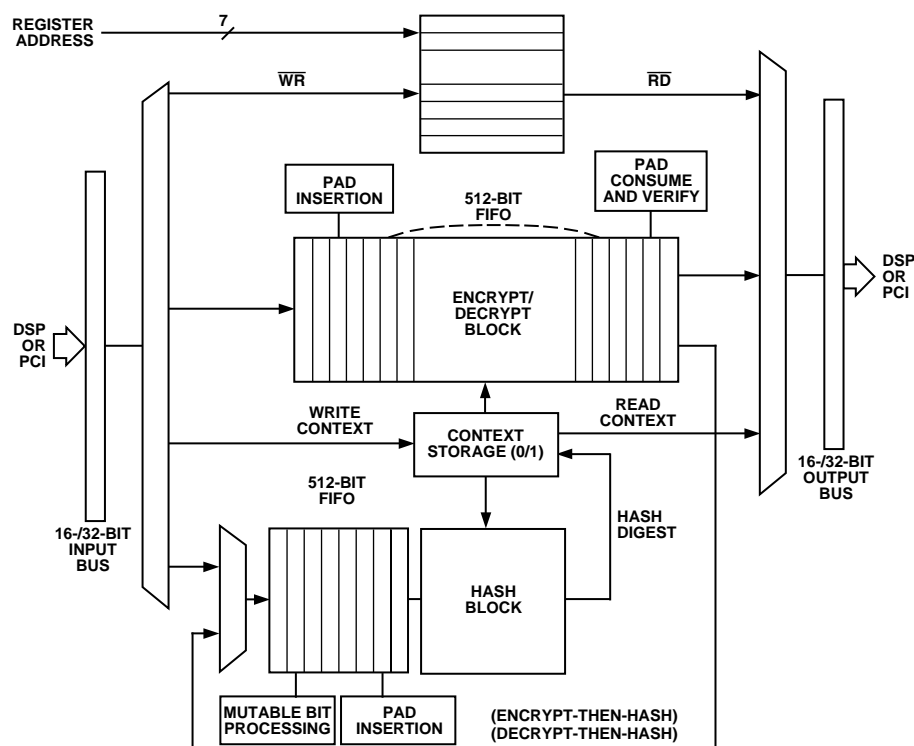

Figure 4. Hash/Encrypt Functional Block Diagram

# ADSP-2141L

Context switching is optimized to minimize the overhead of changing cryptographic keys to near zero.

The software interface to the module consists of a set of memory-mapped registers, all of which are visible to the DSP and most of which can be enabled for host access via the PCI bus. A set of five, 16-bit registers define the operation to be performed, the length of the data buffer to be processed, in bytes, the offset between the start of hashing and encryption (or vice versa), and the padding operation. If the data length is unknown at the time the encrypt/decrypt operation is started, the data length register may be set to zero, which specifies special handling. In this case, data may be passed to the hash/encrypt block indefinitely until the end of data is encountered. At that time, the operation is terminated by writing a new control word to the hash/encrypt control register (either to process the next packet or to invoke the idle state if there is no further work to do). This will close out the processing for the packet, including the addition of the selected crypto padding.

A set of seven status registers provides information on when a new operation can be started, when there is space available to accept new data, when there is data available to be read out, and the results from the padding operation.

## Crypto Contexts

There are two sets of *crypto-context* registers. Each context contains a DES or triple DES key, initialization vector, and precomputed hashes (inner and outer) of the authentication key for HMAC operations. The contexts also contain registers to reload the byte count from a previous operation (which is part of the hashing context), as well as an IV (also called *salt*) for decrypting a black key, if necessary.

Once a crypto-context has been loaded and the operation defined, data is processed by writing it to a data input FIFO. At the I/O interface, data is always written to, or read from, the same address. Internally, the hash and encryption functions have separate 512-bit FIFOs, each with their own FIFO management pointers. Incoming data is automatically routed to one or both of these FIFOs, depending on the operation in progress. Output from the encryption block is read from the data output FIFO. In encrypt-hash or decrypt-hash operations, the data is also automatically passed to the hashing data input FIFO. Output from the hash function is always read from the digest register of the appropriate crypto-context.

The initialization vector to be used for a crypto operation can be loaded as part of a crypto-context. When an operation is complete, the same context will contain the resulting IV produced at the end, which can be saved away and restored later to continue the operation with more data.

In certain packet-based applications such as IPsec, a feature is available that avoids the need for the control software to generate and load random IVs for outgoing (encrypted) packets. Effectively, the IV register can be configured to be automatically updated with new random numbers for each encrypted packet, with almost no software intervention.

## Padding

When the input data is not a multiple of eight bytes (a 64-bit DES block), the encrypt module can be configured to automatically append pad bytes. There are several options for how the padding is constructed, which are specified using the pad control word of the operation description. Options include zero padding, pad-length character padding (PKCS#7), incrementing count,

with trailing pad length and next header byte (for IPsec), or fixed character padding. Note that for the IPsec and PKCS#7 pad protocols, there are cases where the padding not only fills out the last 8-byte block, but also causes an additional 8-byte block of padding to be added.

For the hash operations, padding is automatically added as specified in the MD-5 and SHA-1 standards. When the hash final command is issued indicating the last of the input data, the algorithm-specified padding and data count bits are added to the end of the hash input buffer prior to computing the hash.

## Data Offsets

Certain security protocols, including IPsec, require portions of a data packet to be hashed while the remainder of the data is both hashed and encrypted. The ADSP-2141L supports this requirement through the OFFSET register, which allows specifying the number of 32-bit dwords of offset between the hash and encrypt/decrypt operations.

## Black Key Loads

The cryptographic keys loaded as part of a crypto-context can be stored off-chip in a *black*, or encrypted, form. If the appropriate control bit is set (HECNTL Bit 15), the DES or 3-DES key will be decrypted immediately after it is written into the context register. The hardware handles this decryption automatically. The Key Encryption Key (KEK) that covers the black keys is loaded in a dedicated write-only KEK register within the ADSP-2141L. The IV for decrypting the black secret key is called 'salt' and must be stored along with the black key (as part of the context). Note that 3-DES CBC mode is used for protecting 3-DES black keys and single DES CBC is used for single DES black keys.

When black keys are used, the key-decrypt operation adds a 6-cycle overhead (0.15  $\mu$ s @ 40 MHz) for DES keys or 36-cycle overhead (0.9  $\mu$ s @ 40 MHz) for triple DES keys each time a new crypto-context is loaded. (Note that if the same context is used for more than one packet operation, the key decryption does not need to be performed again.) Depending on the sequencing of operations, this key decryption may in fact be hidden (from a performance impact perspective) if other operations are underway. This is because the black key decryption process only requires that the DES hardware be available. For example, if the DSP is reading the previous hash result from the output FIFO, the black key decryption can be going on in parallel. Also note that the data driver firmware does NOT have to wait for the key to be decrypted before writing data to the input FIFO. The hardware automatically waits for the key to be decrypted before beginning to process data for a given packet. So, with efficient pipeline programming, it is possible to make the impact of black key essentially zero.

The KEK for key decryption is loaded via the secure kernel firmware using one of the CGX key manipulation commands. (For more information, see the Command Summary section.) This KEK is typically the same for all black keys, since it is usually protecting local storage only. It is designated the DKEK in the CGX API.

One of the laser-programmed configuration bits specifies whether red (plaintext) keys are allowed to be loaded into the ADSP-2141L from a host. If the *AllowRedKeyLoad* laser bit is not set, keys may only be loaded in their *black* form. This is useful in systems where export restrictions limit the key length that may be used or where the external storage environment is untrusted.

If the AllowRedKeyLoad bit is set, keys may be loaded either in their black form, or in the *red* or unencrypted form. Note that the laser configuration bit may be overridden with a signed enabler token. (For more information, see the Laser Variable Storage section.)

Depending on the definition of the security module boundary in a given application, FIPS 140-1 may require the use of black keys to protect key material. In other words, if the security boundary does not enclose the database where keys are stored, those keys must be protected from compromise. Black key is a satisfactory way to meet this FIPS requirement.

### Random Number Generator (RNG) Block

The random number generator is designed to provide highly random, nondeterministic binary numbers at a high delivery rate with little software intervention. The random numbers are accessible to the kernel firmware in a 16-bit register that may be read by the DSP in kernel mode. Once the register is read, the RNG immediately generates a new 16-bit value that is available within 12 microseconds.

All application-level access to random numbers should occur through the Kernels CGX\_RANDOM command (see the Command Summary section).

The random number generator is designed using a “shot noise” true entropy source which is sampled by the master 40 MHz clock of the ADSP-2141L. The entropy source then feeds a complex nonlinear combinatorial circuit that produces the final RNG output based on the interaction of the entropy source and the 40 MHz system clock. Over 200 stages of Linear Feedback Shift Register (LFSR) are incorporated into the RNG design.

In order to facilitate FIPS 140-1 compliance, an option may be selected during CGX kernel initialization to enable an ANSI X9.17 Annex C post-randomizer to be applied to the output of the RNG. This randomizer applies the DES ECB algorithm multiple times to further disperse and whiten the random source. Although this is not necessary to ensure the quality of the random numbers, it meets the criteria for a NIST-approved random number generation algorithm.

### Public Key Accelerator (PKAC)

The public key arithmetic coprocessor (otherwise known as a *BigNum* processor) is designed to support long vector calculations of the kind needed to perform RSA, Diffie-Hellman and Elliptic Curve operations.

The PKAC can perform multiplication, squaring, addition and subtraction on arbitrary length bit vectors. The CGX software is responsible for setting the address register for the operands and

result, as well as specifying the length and operation type. Once the operation type field is written, the processor polls the operation complete status while the calculation is carried out.

The PKAC utilizes the protected kernel RAM for input, output and intermediate variable storage. It may only be accessed from the secure kernel mode. Since public key computations typically take many milliseconds to complete, they may be preempted using a DSP interrupt.

Most application interaction with the public key accelerator will occur via the CGX software interface (see the Command Interface section). Both high level public key operations such as RSA Sign or Create Diffie-Hellman Key, as well as primitive operations such as Multiply Vector, Add Long Vector, etc., are presented via the CGX interface.

### PCI/Cardbus Interface

The ADSP-2141L appears as a target on the PCI Bus as a single contiguous memory space of 128k bytes. In this memory space, the host can access the following:

- The unprotected internal crypto registers of the ADSP-2141L
- IDMA access to the DSP’s internal program memory (PM) and data memory (DM)
- Paged access to external memory connected to the ADSP-2141L
- The Kernel RAM (KRAM) if it has been unprotected by an extended mode program

As a PCI Master, the ADSP-2141L can transfer data between:

- The unprotected internal crypto registers and FIFOs of the ADSP-2141L and PCI Host memory
- External memory and PCI Host memory

A 32-bit DMA engine within the ADSP-2141L facilitates these transfers and permits full PCI bandwidth use.

### Serial EEPROM Interface

The serial EEPROM interface allows the ADSP-2141L to automatically read the PCI configuration parameters at chip power-up. IRE can provide the data content for the EEPROM to properly set the chip device vendor ID, type and properties for full compliance with the PCI Plug and Play standards.

In addition to being used for storage of host bus parameters, any extra space in the EEPROM may be accessed by the DSP, either in user mode or kernel mode. Support for this function is not included in the standard CGX command set. Refer to the *ADSP-2141 User’s Manual* for the information on the data contents of the EEPROM. Refer to <http://www.analog.com/industry/dsp/ire.html>.

**Table I. Interrupt Sources**

Internal Interrupt Sources		External Interrupt Sources	
Interrupt	Notes	Interrupt	Notes
Reset	or Power-Up (PUCR = 1)	$\overline{\text{IRQ2}}$	Edge- or Level-Sensitive
Power-Down		$\overline{\text{IRQL1}}$	Level-Sensitive
SPORT0 Transmit		$\overline{\text{IRQLO}}$	Level-Sensitive
SPORT0 Receive		$\overline{\text{IRQE}}$	Edge-Sensitive
BDMA Interrupt		IRQ1	Edge- or Level-Sensitive
SPORT1 Transmit		IRQ0	Edge- or Level-Sensitive
SPORT1 Receive	Mixed with IRQ0		
Timer			

# ADSP-2141L

## Interrupt Controller

The DSP core of the ADSP-2141L provides a powerful set of interrupt sources. A total of 14 interrupt sources are available, although two pairs are multiplexed, yielding 12 simultaneous sources. Refer to Table I.

The ADSP-2141L enhances the existing interrupt controller within the ADSP-218x DSP Core with some additional functions related to the crypto functional blocks and the external host bus interfaces. Two additional interrupt controller subsystems have been added to the basic interrupt controller as shown in Figure 5.

The DSP interrupt controller allows programming between one and nine sources for the IRQ2 interrupt to the DSP. The DIMASK register provides the mask to select which interrupt source is enabled. A pair of status registers, DUMSTAT and DMSTAT, allow the DSP firmware to read the status of any interrupt source either before or after the mask is applied.

The host interrupt controller allows programming between one and five sources for the PF7/INT\_H interrupt output signal (which may be connected to the interrupt input of the host system). The HMASK register provides the mask to select which interrupt source is enabled. A pair of status registers, HUMSTAT and HMSTAT, allow the host firmware to read the status of any interrupt source either before or after the mask is applied.

## Laser Variable Storage

The laser variables are configured through 256 Fuses in the ADSP-2141L, which are programmed during IC manufacture. Each ADSP-2141L produced is programmed with a unique set of Laser Variables.

- Local Storage Variable (LSV—the Master Key-Encryption-Key)
- Internal Seed Variable

- 48-Bit Program Control Data (enables/disables various features and configures the ADSP-2141L)
- CRC of the Laser Data (to verify integrity of the laser bits)

The LSV is a unique triple DES master key-encrypting key that allows the ADSP-2141L to securely store data (primarily other keys) off-chip for later reloading. This is necessary if more storage space is needed than is available with on-chip RAM, or if keys need to be saved and restored after a power outage. Each ADSP-2141L produced is programmed with a unique, randomly generated local storage variable.

The internal seed variable is used to randomly initialize the RNG circuits before the entropy is mixed in. Each ADSP-2141L produced is programmed with a unique, randomly generated internal seed variable which is loaded into the RNG at chip boot time and cannot ever be read by software.

The 48 Program Control Data Bits (PCDBs) include configuration for permitted key lengths, algorithm enables, red KEK loading, internal IC pulse timing characteristics. The PCDBs provide configuration data that falls into three categories:

- Internal IC pulse-timing characteristics
- ADSP-2141L hardware version number field
- ADSP-2141L feature enables

The first two categories consist of data that cannot be altered once the ADSP-2141L has been fabricated.

The feature enables can be overridden using a factory token enabler which may be passed to the CGX kernel as part of the CGX\_INIT command. This token is digitally signed with an IRE private key and verified internal to the ADSP-2141L with its public key. The CGX\_INIT command is documented in the *ADSP-2141 CGX Interface Programmer's Guide* (available from <http://www.ire-ma.com/proddoc.htm>).

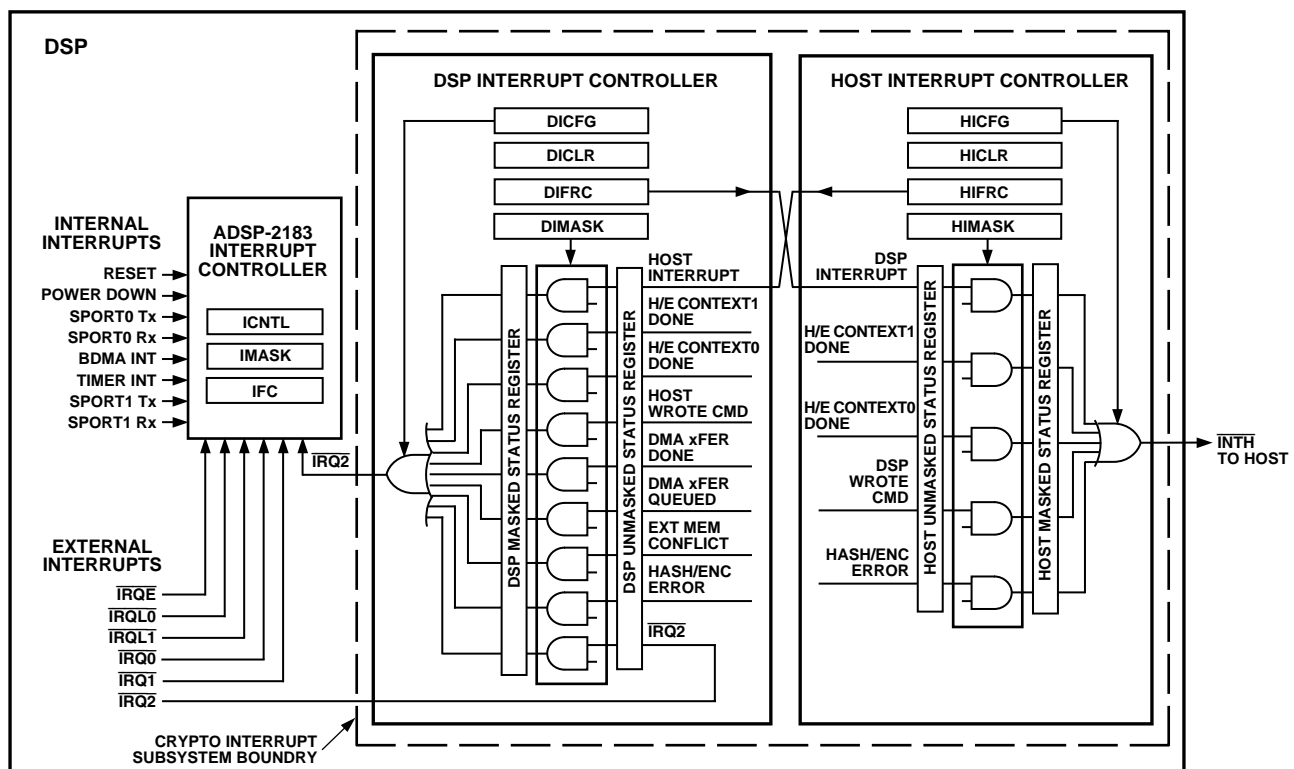

Figure 5. Interrupt Controller Block Diagram

**PIN FUNCTIONS****I/O Descriptions**

This section describes the physical I/O hardware on the ADSP-2141L.

**PIN FUNCTION DESCRIPTIONS—I/O Hardware**

Pin Name	# of Pins	Input/Output	Function
<b>External Memory Bus</b> Address [25:0]	26	O	Address Output Pins for Program, Data, Byte and I/O Spaces (13 Bits 2183, 13 Bits from Overlay Register) Note: A0 not used for 32-bit memory.
Data [31:0]	32	I/O	Data I/O Pins for Program and Data Memory Spaces D31:0 are used for wide-bus data memory. D23:0 are used for DSP Program RAM. D23:8 are used for I/O Space. D23:8 are used for DSP Data RAM. D15:8 are used for byte memory. <i>D23:16 are also used as Byte Space Addresses</i>
<b>Interrupts</b> <u>IRQ2</u>	1	I	Edge- or Level-Sensitive Interrupt Request
<u>IRQL0</u>	1	I	Level-Sensitive Interrupt Requests
<u>IRQL1</u>	1	I	Level-Sensitive Interrupt Requests
<u>IRQE</u>	1	I	Edge-Sensitive Interrupt Request
<b>Bus Signals</b> <u>BR</u>	1	I	Bus Request Input

**SYSTEM INTERFACE**

The ADSP-2141L may be integrated into a wide variety of systems, including those that already have a microprocessor and those that will use the ADSP-2141L as the main processor. The device can be configured into one of two Host Bus modes: IDMA or PCI.

**IDMA Bus Mode**

The IDMA bus mode operates the same as in a native ADSP-218x device, as described in this section.

The IDMA port provides an efficient means of communication between a host system and the ADSP-2141L. The port is used to access the on-chip program memory and data memory of the DSP with only one DSP cycle per word overhead. The IDMA port cannot, however, be used to write to the DSP's memory-mapped control registers.

The IDMA port has a 16-bit multiplexed address and data bus, and supports reading or writing 16-bit data (DM) or 24-bit program memory (PM). The IDMA port is completely asynchronous and can be written to while the ADSP-2141L is operating at full speed.

The DSP memory address is latched and then automatically incremented after each IDMA transaction. An external device can therefore access a block of sequentially addressed memory by

specifying only the starting address of the block. This increases throughput as the address does not have to be sent for each memory access.

The IDMA port access occurs in two phases. The first is the IDMA address latch cycle. When the acknowledge is asserted, a 14-bit address and 1-bit destination type can be driven onto the bus by an external device. The address specifies an on-chip memory location; the destination type specifies whether it is a DM or PM access. The falling edge of the address latch signal latches this value to the IDMAA register.

Once the address is stored, data can either be read from or written to the ADSP-2141L's on-chip memory. Asserting the select line ( $\overline{\text{IS}}$ ) and the appropriate read or write line ( $\overline{\text{IRD}}$  and  $\overline{\text{IWR}}$  respectively) signals the ADSP-2141L that a particular transaction is required. In either case, there is a one-processor-cycle delay for synchronization. The memory access consumes an additional processor cycle.

Once an access has occurred, the latched address is automatically incremented and another access can occur.

Through the IDMAA register, the ADSP-2141L can also specify the starting address and data format for DMA operation.

Figure 6 illustrates a typical system configuration for the IDMA mode.

# ADSP-2141L

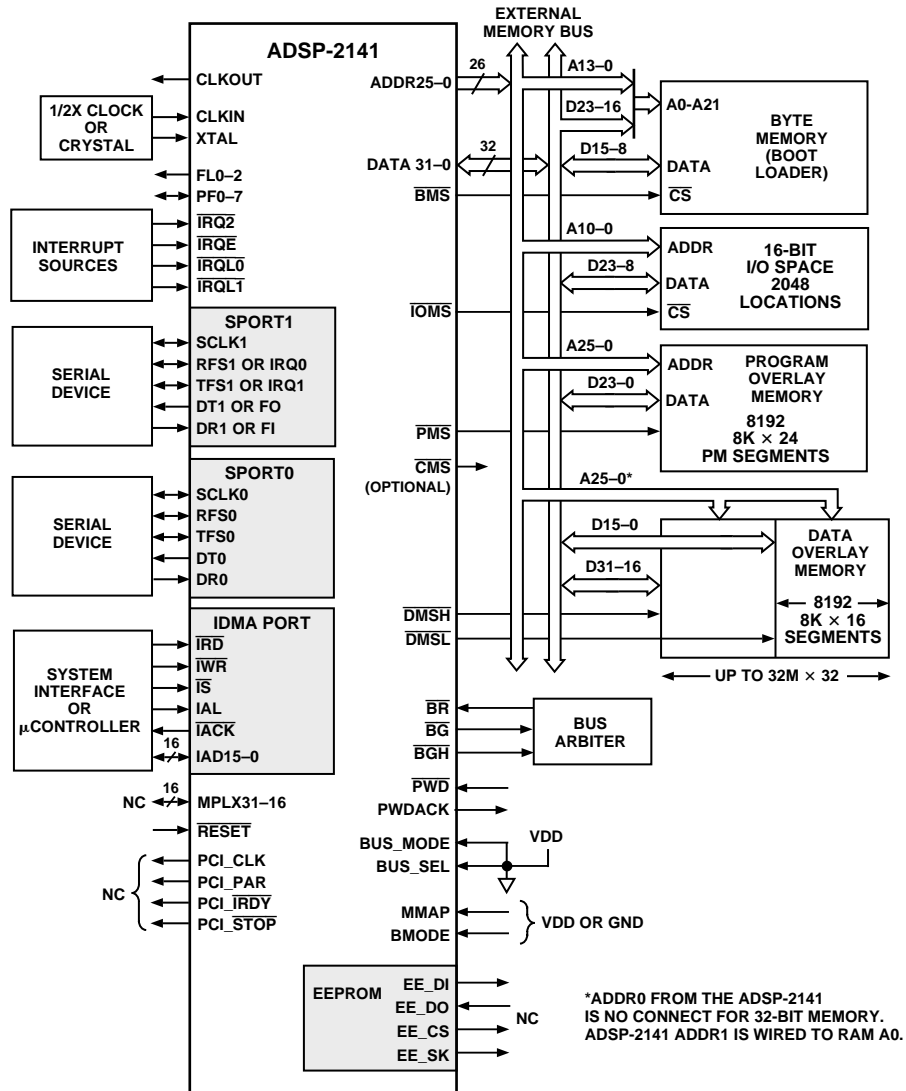

Figure 6. ADSP-2141L IDMA System Configuration

## PCI Bus Mode

Figure 7 illustrates a typical system configuration for the PCI mode.

Figure 7. ADSP-2141L PCI System Configuration

# ADSP-2141L

## DEVICE OPERATION OPERATIONAL MODES

### Security Modes

The ADSP-2141L operates in one of two security modes: kernel mode or user mode. The mode switching is performed on the fly as program execution proceeds. Kernel mode is entered via a jump or call to address 0x2000 with PMOVLAY set to 0x000F. Kernel mode will exit on its own once it has completed a requested operation (or terminates due to an error).

Special interrupt handling is performed if the DSP is executing in kernel mode. While executing a CGX command in kernel mode, it is possible to interrupt to a nonprotected vector location and then invoke the kernel again during the interrupt handler. The [IF CONDITION] RTI instruction must be used to return to the kernel from the interrupt handler. The return address and PMOVLAY page must match the interrupted address and PMOVLAY page. If not, the violation reset logic will be triggered. Only one level of kernel mode nesting is permitted. An interrupt to a nonprotected vector location while in nested kernel mode will also trigger the violation reset logic.

While in kernel mode, it is possible to interrupt to a protected vector location. In this case, the processor remains in kernel mode. The [IF CONDITION] RTI instruction must be used to return the processor from the interrupt handler. There is no imposed limit on the number of nested interrupts to a protected vector location.

### Bus Modes

The ADSP-2141L Host Bus may be configured for one of two personalities: IDMA Mode or PCI Bus Mode. The selection of mode is made with two hardware control inputs BUS\_MODE and BUS\_SEL at boot time.

**Table II. Bus Mode Selection**

Bus Mode Pins	BUS_MODE	BUS_SEL
IDMA Mode	0	0
PCI Bus Mode	1	0

This selection may not be changed after the ADSP-2141L comes out of power-up reset. It is typically expected that the bus mode signals are tied to ground or VDD on the PC Board.

### Boot Modes

The ADSP-2141L may be bootstrap-loaded from one of three sources: byte-wide memory, host processor bus, or external program memory. The selection of mode is made with two hardware control inputs BMODE and MMAP. When the host processor boot mode is selected, any one of the two bus modes may be used.

**Table III. Boot Mode Selection**

Boot Mode Pins	BMODE	MMAP
Byte-Wide (BDMA) Boot Mode	0	0
Host Bus (IDMA) Boot Mode	1	0
External Program Boot Mode	0	1

The hardware pin states are not relevant after the ADSP-2141L comes out of power-up reset. Refer to the *ADSP-2141L User's Manual* (available from IRE) for information on BDMA, IDMA and external program boot modes.

## COMMAND INTERFACE

This section provides a general overview of the software command interface to the crypto functions in the ADSP-2141L. Refer to the *ADSP-2141 CGX Interface Programmer's Guide* (available from <http://www.ire-ma.com/proddoc.htm>) for more details.

### Overview

The ADSP-2141L provides an embedded crypto library that provides a command interface API (Application Programming Interface) to outside applications. These commands are referred to as CGX (CryptoGraphic eXtensions).

The CGX API simultaneously enforces certain security policies within the ADSP-2141L and insulates applications from the details of many complex cryptographic operations. The security policy built into the ADSP-2141L has some of the following rules:

- Unencrypted (red) keys may never be retrieved from the ADSP-2141L.
- Keys within the ADSP-2141L are marked with an attributes field that specifies key type and trust level.
- A key's type field must match the use in a requested operation (i.e., cannot use a KEK to encrypt traffic).
- Keys generated internal to the ADSP-2141L (i.e., from RNG) are marked as trusted.
- Keys that are negotiated or imported from outside systems are marked untrusted (although they may still be quite secure).
- Separate trusted and untrusted key hierarchies may be maintained and customer applications may choose which trust level is required for a given command.

For most key management operations, the CGX interface must be used. However, for certain high performance encryption/ hashing applications, the CGX interface may be bypassed and either the DSP or a host processor may exercise direct control over the hash/encrypt block.

**COMMAND SUMMARY**

Approximately 40 CGX Commands are supported in the API to the ADSP-2141L.

**General Utilities**

INIT	Initializes Secure Kernel and Allow Reconfiguration of the ADSP-2141L
DEFAULT	Restores Factory Default Settings
RANDOM	Generates Random Numbers (between 1K and 64K bytes)
GET CHIPINFO	Returns ADSP-2141L System Information
SELF TEST	Runs a suite of self-tests on the hardware and CGX

**Symmetrical Key Management**

UNCOVER KEY	Loads and Decrypts a Secret Key
GEN KEY	Generates a Secret Key
GEN KEK	Generates an Internal Key Encryption Key
GEN RKEK	Generates a Key Recovery Key Encryption Key
SAVE KEY	Saves a key protected by the Recovery Key (RKEK)
LOAD KEY	Imports a Red (plaintext) User Secret Key
DERIVE KEY	Derives a Secret Key from a Pass Phrase
TRANSFORM KEY	Transforms a Secret Key using IPsec
DESTROY KEY	Removes Secret Key from the KCR
EXPORT KEY	Exports an IRE-format Secret Key
IMPORT KEY	Imports an IRE-format Secret Key

**Symmetrical Encryption**

ENCRYPT	Encrypts Data
DECRYPT	Decrypts Data
LOAD KG	Loads Secret Key into HW/SW Key Generator

**Hash**

HASH INIT	Initializes the Hash Operator
HASH DATA	Hash Customer Data
HASH ENCRYPT	Hash and Encrypt Customer Data
HASH DECRYPT	Hash and Decrypt Customer Data

**PRF Functions**

MERGE KEY	Combines two secret keys into one key
MERGE LONG KEY	Combines two secret keys into a data string (long key)
EXTRACT LONG KEY	Creates a secret key from a data string (long key)
PRF DATA	Hash multiple data items using HMAC
PRF KEY	Completes the above HMAC and create secret key

**Asymmetrical Key Management**

GEN PUBKEY	Generates a Public Keyset (Public and Private Parts)
GEN NEWPUBKEY	Generates a part of a Public Keyset
GEN NEGKEY	Generates a Diffie-Hellman Derived Secret Key
EXPORT PUBKEY	Exports an IRE-format Public Key
IMPORT PUBKEY	Imports an IRE-format Public Key

**Asymmetrical Encryption**

PUBKEY ENCRYPT	Encrypts Data using RSA Public Key
PUBKEY DECRYPT	Decrypts Data using RSA Public Key

**Digital Signatures**

SIGN	Digitally Signs a Message
VERIFY	Verifies a Digital Signature

**Math Utilities**

ADD VECTOR	Performs a Vector Add Operation
SUB VECTOR	Performs a Vector Subtract Operation
MULT VECTOR	Performs a Vector Multiply Operation
EXP VECTOR	Performs a Vector Exponentiate Operation
SHIFT VECTOR	Performs a Vector Right or Left Shift Operation

**Extended Mode**

LOAD EXTENDED	Loads/Enables Extended (Downloaded) Algorithm Block
EXECUTE EXTENDED	Executes Extended (Downloaded) Algorithm Block

# ADSP-2141L

## ABSOLUTE MAXIMUM RATINGS

Supply Voltage	-0.3 V to +4.6 V
Input Voltage	-0.5 V to $V_{DD} + 0.5$ V
Output Voltage Swing	-0.5 V to $V_{DD} + 0.5$ V
Operating Temperature Range (Ambient)	0°C to 70°C
Storage Temperature Range	-65°C to +150°C
Lead Temperature (5 sec) MQFP	280°C

## Frequency Dependency For Timing Specifications

$t_{CK}$  is defined as  $0.5t_{CKI}$ . The ADSP-2141L uses an input clock with a frequency equal to half the instruction rate: a 20.0 MHz input clock (which is equivalent to 50 ns) yields a 25 ns processor cycle (equivalent to 40 MHz).  $t_{CK}$  values within the range of  $0.5t_{CKI}$  period should be substituted for all relevant timing parameters to obtain the specification value.

Example:  $t_{CKH} = 0.5t_{CK} - 7 \text{ ns} = 0.5 (25 \text{ ns}) - 7 \text{ ns} = 8 \text{ ns}$

## CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the ADSP-2141L features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

#### NOTES

- Bidirectional pins: D0–D31, RFS0, RFS1, SCLK0, SCLK1, TFS0, TFS1, IAD0–15, PF0–PF7.
- Input only pins:  $\overline{\text{IRQ2}}$ ,  $\overline{\text{BR}}$ , MMAP, BMODE, BUS MODE, BUS SEL, DR0, DR1,  $\overline{\text{PWD}}$ ,  $\overline{\text{IRQLO}}$ ,  $\overline{\text{IRQLI}}$ ,  $\overline{\text{IRQE}}$ ,  $\overline{\text{IS}}$ ,  $\overline{\text{IRD}}$ ,  $\overline{\text{IWR}}$ , IAL.
- Input only pins: CLKIN,  $\overline{\text{RESET}}$ ,  $\overline{\text{IRQ2}}$ ,  $\overline{\text{BR}}$ , MMAP, BMODE, BUS MODE, BUS SEL, DR0, DR1,  $\overline{\text{PWD}}$ ,  $\overline{\text{IRQLO}}$ ,  $\overline{\text{IRQLI}}$ ,  $\overline{\text{IRQE}}$ ,  $\overline{\text{IS}}$ ,  $\overline{\text{IRD}}$ ,  $\overline{\text{IWR}}$ , IAL.
- Output pins:  $\overline{\text{BG}}$ ,  $\overline{\text{BGH}}$ , PMS, DMSL, DMSH, BMS, IOMS, CMS, RD,  $\overline{\text{WR}}$ ,  $\overline{\text{IACK}}$ , PWDACK, A0–A25, DT0, DT1, CLKOUT, FL2–0.
- Although specified for TTL outputs, all ADSP-2141L outputs are CMOS-compatible and will drive to V<sub>DD</sub> and GND, assuming no dc loads.
- Guaranteed but not tested.
- Output pins:  $\overline{\text{BG}}$ ,  $\overline{\text{BGH}}$ , PMS, DMSL, BMS, IOMS, DMSH, CMS, RD,  $\overline{\text{WR}}$ ,  $\overline{\text{IACK}}$ , PWDACK, A0–A25, DT0, DT1, CLKOUT, FL2–0, EE\_DI, EE\_CS, EE\_SK.
- 0 V on BR. CLKIN active (to force three-state condition).
- Three-statable pins: A0–A25, D0–D31, PMS, DMSL, DMSH, BMS, IOMS, CMS, RD,  $\overline{\text{WR}}$ , DT0, DT1, SCKL0, SCLK1, TFS0, TFS1, RFS0, RFS1, IAD0–IAD15, PF0–PF7.
- Idle refers to ADSP-2141L state of operation during execution of IDLE Instruction. Deasserted pins are driven to either V<sub>DD</sub> or GND.
- Current reflects device operating with no output loads.
- V<sub>IN</sub> = 0.4 V and 2.4 V. For typical supply currents, refer to Power Dissipation section.
- I<sub>DD</sub> measurement taken with 93% of instructions executing from internal memory and 7% from external memory. H/E operations are executing from internal memory concurrently with PCI transactions. Initialization operations are executed from external memory.
- Applies to MQFP package type.
- Output pin capacitance is the capacitive load for any three-stated output pin.

Specifications subject to change without notice.

$C_{CLK}$	PCI CLK Pin Capacitance	$T_{AMB} = 25^\circ C$	12	pF
$C_{IDSEL}$	PCI IDSEL Pin Capacitance <sup>5</sup>	$T_{AMB} = 25^\circ C$	8	pF
$L_{PIN}$	Pin Inductance		20	nH

### NOTES

<sup>1</sup>Bidirectional pins: MPLX\_BUS [31:0], MPLX1-4, MPLX7-10, MPLX12

<sup>2</sup>Input only pins: MPLX\_RESET, MPLX5, MPLX6, PCI\_CLK, PCI\_PAR, PCI\_IRDY, PCI\_STOP

<sup>3</sup>Output only pins: MPLX11

<sup>4</sup>Leakage currents include High-Z output leakage for bidirectional buffers with three-state outputs.

<sup>5</sup>Lower capacitance of IDSEL (MPLX\_5) input-only pin allows for nonresistive connection to Address/Data bus.

## TIMING PARAMETERS

### PCI Clock (Guaranteed Over Operating Temperature and Digital Supply Range)

The ADSP-2141L is targeted for use in PCI add-on I/O slave card designs. It provides a glueless interface to the PCI bus. All bus drivers are compliant with PCI interface electrical switching and drive capability specifications.

The ADSP-2141L does not implement the following signals:  $\overline{LOCK}$ ,  $\overline{INTB}$ ,  $\overline{INTC}$ ,  $\overline{INTD}$ ,  $\overline{SBO}$ ,  $\overline{SDONE}$ ,  $\overline{CLKRUN}$ , AD[64:32], C/BE[7:4], REQ64, ACK64, PAR64.

Parameter		Min	Max	Unit
<i>Timing Requirements:</i>				
$t_{CYC}$	CLK Cycle Time	25	100	ns
$t_{HIGH}$	CLK High Time	11		ns
$t_{LOW}$	CLK Low Time	11		ns
	CLK Slew Rate <sup>1</sup>	1	4	V/ns
	$\overline{RST}$ Slew Rate <sup>2</sup>	50		mV/ns

### NOTES

<sup>1</sup>Rise and fall times are specified in terms of the edge rate measured in V/ns. This slew rate must be met across the minimum peak-to-peak portion of the waveform as shown in Figure 8.

<sup>2</sup>The minimum  $\overline{RST}$  slew rate applies only to the rising (deassertion) edge of the reset signal, and ensures that system noise cannot render an otherwise monotonic signal to appear to bounce in the switching range.

Figure 8. Clock Waveform

Parameter	Min	Max	Unit
<b>PCI Bus Interface</b>			
<i>Timing Requirements:</i>			
$t_{VAL}$ CLK to Signal Valid	2	11	ns
$t_{ON}$ CLK to Low-Z Delay	2		ns
$t_{OFF}$ CLK to High-Z Delay		28	ns
$t_{SU}$ Input Setup to CLK	7		ns
$t_H$ Input Hold After CLK	1		ns
$t_{RST-OFF}$ $\overline{RST}$ Active to Outputs High-Z		40	ns

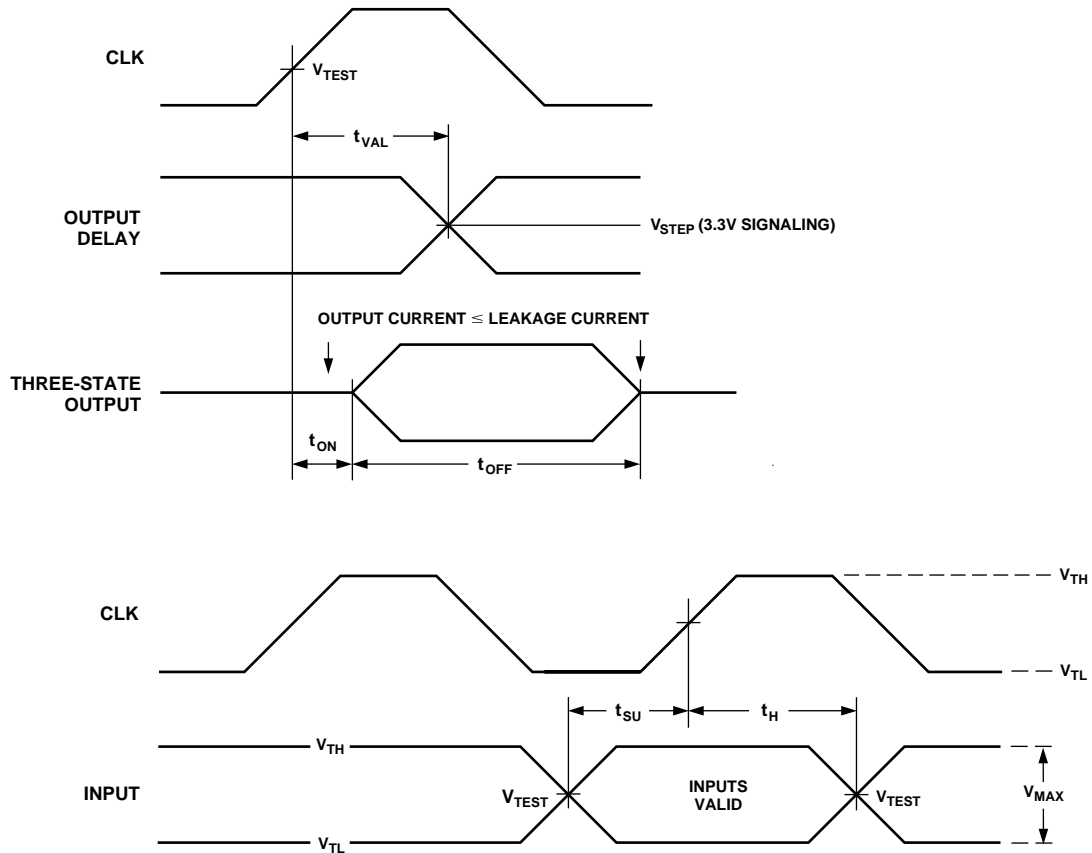

Figure 9. Output (Top) and Input Timing Measurement Conditions

# ADSP-2141L

Parameter	Min	Max	Unit
<b>Clock Signals and Reset</b>			
<i>Timing Requirements:</i>			
$t_{CKI}$ CLKIN Period	50	100	ns
$t_{CKIL}$ CLKIN Width Low	15		ns
$t_{CKIH}$ CLKIN Width High	15		ns
<i>Switching Characteristics:</i>			
$t_{CKL}$ CLKOUT Width Low	$0.5t_{CK} - 7$		ns
$t_{CKH}$ CLKOUT Width High	$0.5t_{CK} - 7$		ns
$t_{CKOH}$ CLKIN High to CLKOUT High	0	20	ns
<b>Control Signals</b>			
<i>Timing Requirement:</i>			
$t_{RSP}$ RESET Width Low <sup>1</sup>	$5t_{CK}$		ns

**NOTE**

<sup>1</sup>Applies after power-up sequence is complete. Internal phase lock loop requires no more than 2000 CLKIN cycles assuming stable CLKIN (not including crystal oscillator start-up time).

**CAPACITIVE LOADING**

Figures 23 and 24 show the capacitive loading characteristics of the ADSP-2141L.

Figure 23. Typical Output Rise Time vs. Load Capacitance,  $C_L$  (at Maximum Ambient Operating Temperature)

Figure 24. Typical Output Valid Delay or Hold vs. Load Capacitance,  $C_L$  (at Maximum Ambient Operating Temperature)

**TEST CONDITIONS**

**Output Disable Time**

Output pins are considered to be disabled when they have stopped driving and started a transition from the measured output high or low voltage to a high impedance state. The output disable time ( $t_{DIS}$ ) is the difference of  $t_{MEASURED}$  and  $t_{DECAY}$ , as shown in the Output Enable/Disable diagram. The time is the interval from when a reference signal reaches a high or low voltage level to when the output voltages have changed by 0.5 V from the measured output high or low voltage. The decay time,  $t_{DECAY}$ , is dependent on the capacitive load,  $C_L$ , and the current load,  $i_L$ , on the output pin. It can be approximated by the following equation:

$$t_{DECAY} = \frac{C_L \cdot 0.5V}{i_L}$$

from which

$$t_{DIS} = t_{MEASURED} - t_{DECAY}$$

is calculated. If multiple pins (such as the data bus) are disabled, the measurement value is that of the last pin to stop driving.

Figure 25. Voltage Reference Levels for AC Measurements (Except Output Enable/Disable)

**Output Enable Time**

Output pins are considered to be enabled when they have made a transition from a high-impedance state to when they start driving. The output enable time ( $t_{ENA}$ ) is the interval from when a reference signal reaches a high or low voltage level to when the output has reached a specified high or low trip point, as shown in the Output Enable/Disable diagram. If multiple pins (such as the data bus) are enabled, the measurement value is that of the first pin to start driving.

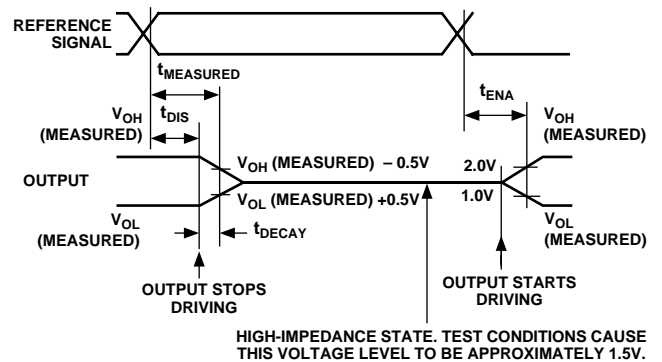

Figure 26. Output Enable/Disable

Figure 27. Equivalent Device Loading for AC Measurements (Including All Fixtures)

# ADSP-2141L

Table IV. Thermal Ratings: MQFP Package

Rating Description	Symbol	Value (MQFP Still Air)	Value (MQFP 9500 fpm)
Thermal Resistance (Case to Ambient)	$\theta_{CA}$	30.7°C/W	16.7°C/W
Thermal Resistance (Junction to Ambient)	$\theta_{JA}$	35°C/W	21°C/W
Thermal Resistance (Junction to Case)	$\theta_{JC}$	4.3°C/W	4.3°C/W

## ENVIRONMENTAL CONDITIONS

The following figures assume a four-layer JEDEC printed circuit board:

$$T_{AMB} = T_{CASE} - (PD \times \theta_{CA})$$

$$T_{CASE} = \text{Case Temperature in } ^\circ\text{C}$$

## OUTPUT DRIVE CURRENTS

Figures 28 and 29 show typical I-V characteristics for the output drivers of the ADSP-2141L. The curves represent the current drive capability of the output drivers as a function of output voltage.

Figure 28. Typical Drive Currents (PCI Pins)

Figure 29. Typical Drive Currents (Addr/Dbus/rd/wr Pins)

## POWER DISSIPATION

Total power dissipation has two components: one due to internal circuitry and one due to the switching of external output drivers. Internal power dissipation depends on the sequence in which instructions execute and the data operands involved. See  $I_{DDIN}$  calculation in Electrical Characteristics section. Internal power dissipation is calculated this way:

$$P_{INT} = I_{DDIN} \times V_{DD}$$

The external component of total power dissipation is caused by the switching of output pins. Its magnitude depends on:

- the number of output pins that switch during each cycle (O)
- the maximum frequency at which the pins can switch (f)
- the load capacitance of the pins (C)
- the voltage swing of the pins ( $V_{DD}$ ).

The external component is calculated using:

$$P_{EXT} = O \times C \times V_{DD}^2 \times f$$

The load capacitance should include the processor's package capacitance ( $C_{IN}$ ). The frequency f includes driving the load high and then back low.

**Example:**

In an application where external data memory is used and no other outputs are active, power dissipation is calculated as follows:

*Assumptions:*

- External data memory is accessed every cycle with 50% of the address pins switching.
- External data memory writes occur every other cycle with 50% of the data pins switching.
- Each address and data pin has a 10 pF total load at the pin.
- The application operates at  $V_{DD} = 3.3\text{ V}$  and  $t_{CK} = 25\text{ ns}$ .

$$Total\ Power\ Dissipation = P_{INT} + (C \times V_{DD}^2 \times f)$$

$P_{INT}$  = internal power dissipation from Power vs. Frequency graphs (Figures 30 and 31).

$(C \times V_{DD}^2 \times f)$  is calculated for each output:

	# of Pins	$\times C$	$\times V_{DD}^2$	$\times f$	=
Address, $\overline{DMS}$	8	$\times 10\text{ pF}$	$\times 3.3^2\text{ V}$	$\times 40\text{ MHz}$	= 34.8 mW
Data Output, $\overline{WR}$	9	$\times 10\text{ pF}$	$\times 3.3^2\text{ V}$	$\times 20\text{ MHz}$	= 19.6 mW
$\overline{RD}$	1	$\times 10\text{ pF}$	$\times 3.3^2\text{ V}$	$\times 40\text{ MHz}$	= 2.2 mW
CLKOUT	1	$\times 10\text{ pF}$	$\times 3.3^2\text{ V}$	$\times 20\text{ MHz}$	= 4.4 mW
					<u>61.0 mW</u>

Total power dissipation for this example is  $P_{INT} + 61\text{ mW}$ .

## PINOUT PCI Mode

## PINOUT 2183-Mode

## PACKAGE DESCRIPTION

### Package Details

The package shown below is a 208-lead metric quad flatpack. Measurements are listed in English and (metric). Because this package is designed as a metric package, Analog Devices recommends that you use these measurements for any PCB layout.

### OUTLINE DIMENSIONS

Dimensions shown in inches and (mm).

#### 208-Lead Metric Plastic Quad Flatpack (MQFP) (Nonhermetic)

**NOTE:**  
 THE ACTUAL POSITION OF EACH LEAD IS WITHIN 0.003 (0.08) FROM ITS IDEAL POSITION WHEN MEASURED IN THE LATERAL DIRECTION.  
 CENTER FIGURES ARE TYPICAL UNLESS OTHERWISE NOTED.  
 THE 208 LEAD MQFP IS A METRIC PACKAGE. ENGLISH DIMENSIONS PROVIDED ARE APPROXIMATE AND MUST NOT BE USED FOR BOARD DESIGN PURPOSES

### ORDERING GUIDE

Part Number	Ambient Temperature Range	Instruction Rate	Package Description	Package Option
ADSP-2141LKS-N1 <sup>1</sup>	0°C to +70°C	40 MHz	208-Lead MQFP	S-208
ADSP-2141LKS-E1 <sup>2</sup>	0°C to +70°C	40 MHz	208-Lead MQFP	S-208

#### NOTES

<sup>1</sup>The ADSP-2141LKS-N1 is an electrically equivalent, full function, production (non x-grade) version of the product described in this data sheet. (Full function = Triple DES enabled, full 168-bit key length, full 2048-bit public key lengths, red keys allowed.)

<sup>2</sup>The ADSP-2141LKS-E1 is an electrically equivalent, full function, production (non x-grade) version of the product described in this data sheet except for the following:  
 Encryption: DES only, with maximum 56-bit key length. Triple DES is disabled.  
 Public Key Algorithms: Public Key Algorithms limited to 1024-bit max modulus. Red keys not allowed in hardware crypto context.
