## Differential Clock Buffer/Driver DDR400/PC3200-Compliant

## Features

- Operating frequency: 60 MHz to 230 MHz
- Supports $400-M H z$ DDR SDRAM
- 10 differential outputs from one differential input
- Spread-Spectrum-compatible
- Low jitter (cycle-to-cycle): < 75
- Very low skew: < $\mathbf{1 0 0}$ ps
- Power management control input
- High-impedance outputs when input clock $<\mathbf{2 0} \mathbf{~ M H z}$
- 2.6 V operation
- Pin-compatible with CDC857-2 and -3
- 48-pin TSSOP and 40 QFN package
- Industrial temperature of $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$
- Conforms to JEDEC DDR specification

## Description

The CY2SSTV857-32 is a high-performance, low-skew, low-jitter zero-delay buffer designed to distribute differential clocks in high-speed applications. The CY2SSTV857-32 generates ten differential pair clock outputs from one differential pair clock input. In addition, the CY2SSTV857-32 features differential feedback clock outpts and inputs. This allows the CY2SSTV857-32 to be used as a zero delay buffer.
When used as a zero delay buffer in nested clock trees, the CY2SSTV857-32 locks onto the input reference and translates with near-zero delay to low-skew outputs.

| Note: <br> 1. A bypass capacitor $(0.1 \mu \mathrm{~F})$ should be placed as close as possible to each positive power pin ( $<0.2$ "). If these bypass capacitors are not close to the pins, their high-frequency filtering characteristic will be cancelled by the lead inductance of the traces. |  |  |  |  |  |

## Zero Delay Buffer

When used as a zero delay buffer the CY2SSTV857-32 will likely be in a nested clock tree application. For these applications, the CY2SSTV857-32 offers a differential clock input pair as a PLL reference. The CY2SSTV857-32 then can lock onto the reference and translate with near zero delay to low-skew outputs. For normal operation, the external feedback input, FBIN, is connected to the feedback output, FBOUT. By connecting the feedback output to the feedback input the propagation delay through the device is eliminated. The PLL works to align the output edge with the input reference edge thus producing a near zero delay. The reference frequency affects the static phase offset of the PLL and thus the relative delay between the inputs and outputs.

When VDDA is strapped LOW, the PLL is turned off and bypassed for test purposes.

## Power Management

Output enable/disable control of the CY2SSTV857-32 allows the user to implement power management schemes into the design. Outputs are three-stated/disabled when PD\# is asserted LOW (see Table 1).

## Absolute Maximum Conditions ${ }^{[2]}$

Input Voltage Relative to $\mathrm{V}_{\mathrm{SS}}: \ldots . . . . . . . . . . . . . . . . . . . . . . . . . . . . \mathrm{V}_{S S}-0.3 \mathrm{~V}$
Input Voltage Relative to $\mathrm{V}_{\mathrm{DDQ}}$ or $\mathrm{AV}_{\mathrm{DD}}$ : ........... $\mathrm{V}_{\mathrm{DDQ}}+0.3 \mathrm{~V}$
Storage Temperature: $\qquad$ $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$
Operating Temperature: ................................ $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
Maximum Power Supply: ................................................3.5V

This device contains circuitry to protect the inputs against damage due to high static voltages or electric field; however, precautions should be taken to avoid application of any voltage higher than the maximum rated voltages to this circuit. For proper operation, $\mathrm{V}_{\text {in }}$ and $\mathrm{V}_{\text {out }}$ should be constrained to the range:
$\mathrm{V}_{\mathrm{SS}}<\left(\mathrm{V}_{\text {in }}\right.$ or $\left.\mathrm{V}_{\text {out }}\right)<\mathrm{V}_{\text {DDQ }}$.
Unused inputs must always be tied to an appropriate logic voltage level (either $\mathrm{V}_{\mathrm{SS}}$ or $\mathrm{V}_{\mathrm{DDQ}}$ ).

## Notes:

2. Multiple Supplies: The voltage on any input or I/O pin cannot exceed the power pin during power-up. Power supply sequencing is NOT required.
3. Unused inputs must be held HIGH or LOW to prevent them from floating.
4. Differential input signal voltage specifies the differential voltage VTR-VCPI required for switching, where VTR is the true input level and VCP is the complementary input level. See Figure 6.
5. Differential cross-point input voltage is expected to track $V_{D D Q}$ and is the voltage at which the differential signal must be crossing.
6. For load conditions see Figure 6.
7. The value of VOC is expected to be (VTR + VCP)/2. In case of each clock directly terminated by a $120 \Omega$ resistor. See Figure 6.
8. All outputs switching load with 14 pF in $60 \Omega$ environment. See Figure 6.
9. Parameters are guaranteed by design and characterization. Not $100 \%$ tested in production.
10. PLL is capable of meeting the specified parameters while supporting SSC synthesizers with modulation frequency between 30 kHz and 50 kHz with a down spread or $-0.5 \%$.
11. While the pulse skew is almost constant over frequency, the duty cycle error increases at higher frequencies. This is due to the formula: duty $c$ cycle $=t_{W H C} / t_{C}$, where the cycle time ( t C ) decreases as the frequency goes up.
12. Refers to transition of non-inverting output.
