

# 128K x 36 Synchronous Flow-Through 3.3V Cache RAM

## Features

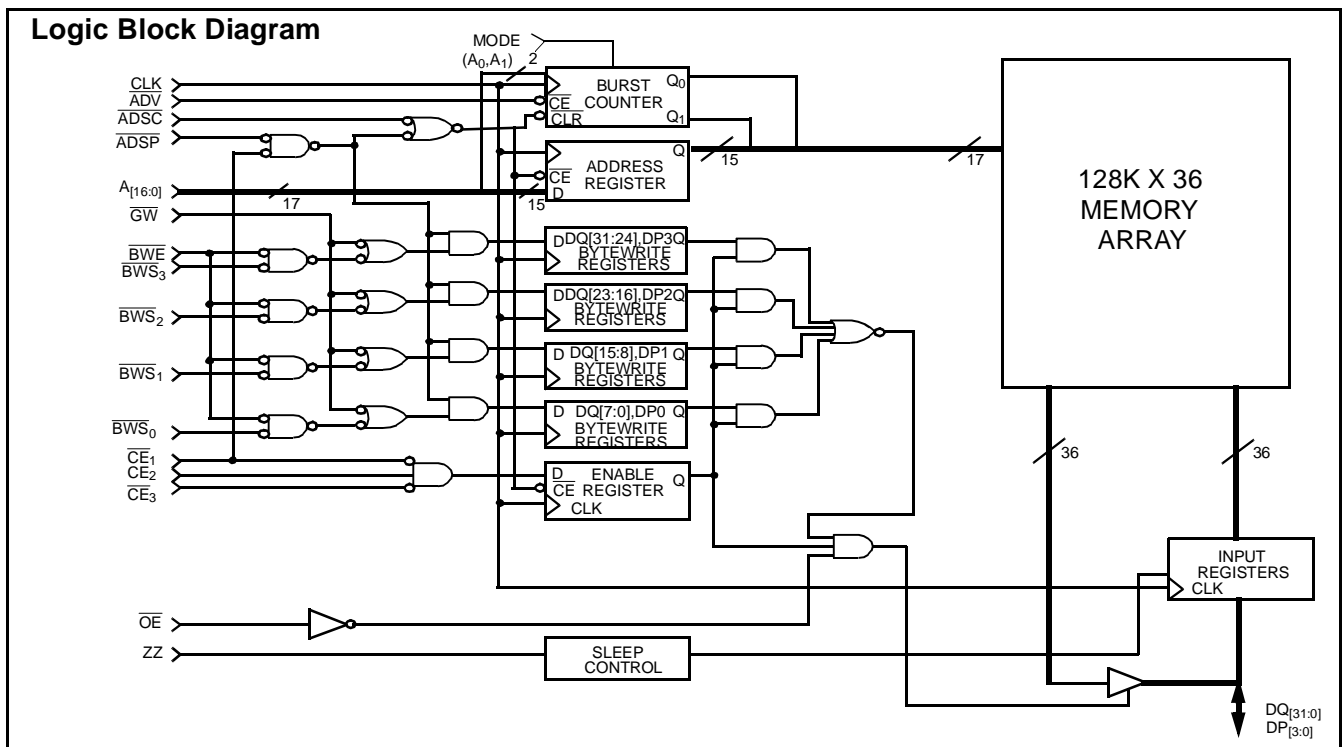

- Supports 117-MHz microprocessor cache systems with zero wait states
- 128K by 36 common I/O
- Fast clock-to-output times  
— 7.5 ns (117-MHz version)
- Two-bit wrap-around counter supporting either interleaved or linear burst sequence
- Separate processor and controller address strobes provide direct interface with the processor and external cache controller
- Synchronous self-timed write
- Asynchronous output enable
- 3.3V I/Os
- JEDEC-standard pinout
- 100-pin TQFP packaging
- ZZ “sleep” mode

## Functional Description

The CY7C1345 is a 3.3V, 128K by 36 synchronous cache RAM designed to interface with high-speed microprocessors with minimum glue logic. Maximum access delay from clock rise is 7.5 ns (117-MHz version). A 2-bit on-chip counter captures the first address in a burst and increments the address automatically for the rest of the burst access.

The CY7C1345 allows either interleaved or linear burst sequences, selected by the MODE input pin. A HIGH selects an interleaved burst sequence, while a LOW selects a linear burst sequence. Burst accesses can be initiated with the processor address strobe (ADSP) or the cache controller address strobe (ADSC) inputs. Address advancement is controlled by the address advancement (ADV) input.

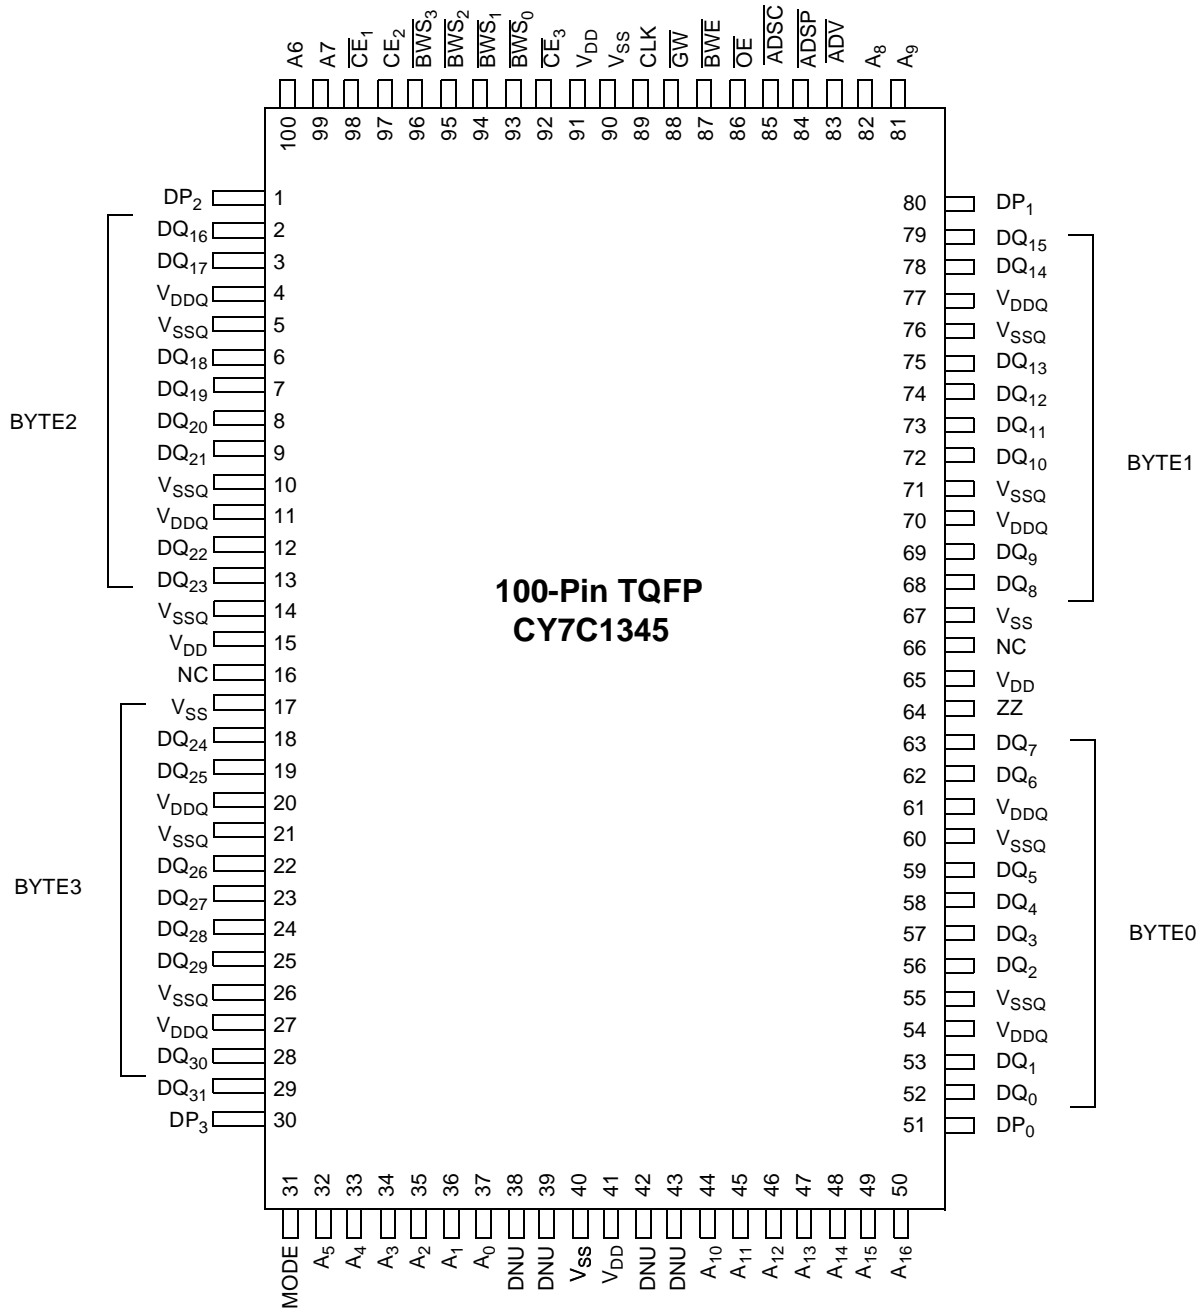

A synchronous self-timed write mechanism is provided to simplify the write interface. A synchronous chip enable input and an asynchronous output enable input provide easy control for bank selection and output three-state control.

## Selection Guide

	7C1345-117	7C1345-100	7C1345-90	7C1345-50
Maximum Access Time (ns)	7.5	8.0	8.5	11.0
Maximum Operating Current (mA)	350	325	300	250
Maximum Standby Current (mA)	2.0	2.0	2.0	2.0

Pentium is a registered trademark of Intel Corporation.

**Pin Configuration**
**100-Lead TQFP**

**Pin Descriptions**

TQFP Pin Number	Name	I/O	Description
85	$\overline{ADSC}$	Input-Synchronous	Address Strobe from Controller, sampled on the rising edge of CLK. When asserted LOW, $A_{[15:0]}$ is captured in the address registers. $A_{[1:0]}$ are also loaded into the burst counter. When $\overline{ADSP}$ and $\overline{ADSC}$ are both asserted, only $\overline{ADSP}$ is recognized.
84	$\overline{ADSP}$	Input-Synchronous	Address Strobe from Processor, sampled on the rising edge of CLK. When asserted LOW, $A_{[15:0]}$ is captured in the address registers. $A_{[1:0]}$ are also loaded into the burst counter. When $\overline{ADSP}$ and $\overline{ADSC}$ are both asserted, only $\overline{ADSP}$ is recognized. $\overline{ADSP}$ is ignored when $\overline{CE}_1$ is deasserted HIGH.
36, 37	$A_{[1:0]}$	Input-Synchronous	$A_1, A_0$ Address Inputs. These inputs feed the on-chip burst counter as the LSBs as well as being used to access a particular memory location in the memory array.
49–44, 81–82, 99–100, 32–35	$A_{[16:2]}$	Input-Synchronous	Address Inputs used in conjunction with $A_{[1:0]}$ to select one of the 64K address locations. Sampled at the rising edge of the CLK, if $\overline{CE}_1, \overline{CE}_2,$ and $\overline{CE}_3$ are sampled active, and $\overline{ADSP}$ or $\overline{ADSC}$ is active LOW.
96–93	$\overline{BW}_{[3:0]}$	Input-Synchronous	Byte Write Select Inputs, active LOW. Qualified with $\overline{BWE}$ to conduct byte writes. Sampled on the rising edge. $\overline{BW}_0$ controls $DQ_{[7:0]}$ and $DP_0, \overline{BW}_1$ controls $DQ_{[15:8]}$ and $DP_1, \overline{BW}_2$ controls $DQ_{[23:16]}$ and $DP_2,$ and $\overline{BW}_3$ controls $DQ_{[31:24]}$ and $DP_3.$ See Write Cycle Description table for further details.
83	$\overline{ADV}$	Input-Synchronous	Advance Input, used to advance the on-chip address counter. When LOW the internal burst counter is advanced in a burst sequence. The burst sequence is selected using the MODE input.
87	$\overline{BWE}$	Input-Synchronous	Byte Write Enable Input, active LOW. Sampled on the rising edge of CLK. This signal must be asserted LOW to conduct a byte write.
88	$\overline{GW}$	Input-Synchronous	Global Write Input, active LOW. Sampled on the rising edge of CLK. This signal is used to conduct a global write, independent of the state of $\overline{BWE}$ and $\overline{BW}_{[3:0]}$ . Global writes override byte writes.
89	CLK	Input-Clock	Clock Input. Used to capture all synchronous inputs to the device.
98	$\overline{CE}_1$	Input-Synchronous	Chip Enable 1 Input, active LOW. Sampled on the rising edge of CLK. Used in conjunction with $\overline{CE}_2$ and $\overline{CE}_3$ to select/deselect the device. $\overline{CE}_1$ gates $\overline{ADSP}$ .
97	$\overline{CE}_2$	Input-Synchronous	Chip Enable 2 Input, active HIGH. Sampled on the rising edge of CLK. Used in conjunction with $\overline{CE}_1$ and $\overline{CE}_3$ to select/deselect the device.
92	$\overline{CE}_3$	Input-Synchronous	Chip Enable 3 Input, active LOW. Sampled on the rising edge of CLK. Used in conjunction with $\overline{CE}_1$ and $\overline{CE}_2$ to select/deselect the device.
86	$\overline{OE}$	Input-Asynchronous	Output Enable, asynchronous input, active LOW. Controls the direction of the I/O pins. When LOW, the I/O pins behave as outputs. When deasserted HIGH, I/O pins are three-stated, and act as input data pins.
64	ZZ	Input-Asynchronous	Snooze Input. Active HIGH asynchronous. When HIGH, the device enters a low-power standby mode in which all other inputs are ignored, but the data in the memory array is maintained. Leaving ZZ floating or NC will default the device into an active state.
31	MODE	-	Mode Input. Selects the burst order of the device. Tied HIGH selects the interleaved burst order. Pulled LOW selects the linear burst order. When left floating or NC, defaults to interleaved burst order.
30–28, 25–22, 19–18, 13–12, 9–6, 3–1, 80–78, 75–72, 69–68, 63–62, 59–56, 53–51	$DQ_{[31:0]}$ , $DP_{[3:0]}$	I/O-Synchronous	Bidirectional Data I/O lines. As inputs, they feed into an on-chip data register that is triggered by the rising edge of CLK. As outputs, they deliver the data contained in the memory location specified by $A_{[16:0]}$ during the previous clock rise of the read cycle. The direction of the pins is controlled by $\overline{OE}$ in conjunction with the internal control logic. When $\overline{OE}$ is asserted LOW, the pins behave as outputs. When HIGH, $DQ_{[31:0]}$ and $DP_{[3:0]}$ are placed in a three-state condition. The outputs are automatically three-stated when a Write cycle is detected.
15, 41, 65, 91	$V_{DD}$	Power Supply	Power supply inputs to the core of the device. Should be connected to 3.3V power supply.

**Pin Descriptions** (continued)

TQFP Pin Number	Name	I/O	Description
17, 40, 67, 90	V <sub>SS</sub>	Ground	Ground for the I/O circuitry of the device. Should be connected to ground of the system.
5, 10, 14, 21, 26, 55, 60, 71, 76	V <sub>SSQ</sub>	Ground	Ground for the device. Should be connected to ground of the system.
4, 11, 20, 27, 54, 61, 70, 77	V <sub>DDQ</sub>	I/O Power Supply	Power supply for the I/O circuitry. Should be connected to a 3.3V power supply.
1, 16, 30, 50–51, 66, 80	NC	-	No connects.
38, 39, 42, 43	DNU	-	Do not use pins. Should be left unconnected or tied LOW.

**Functional Description**
**Single Write Accesses Initiated by  $\overline{\text{ADSP}}$** 

This access is initiated when the following conditions are satisfied at clock rise: (1)  $\overline{\text{CE}}_1$ ,  $\text{CE}_2$ , and  $\overline{\text{CE}}_3$  are all asserted active, and (2)  $\overline{\text{ADSP}}$  is asserted LOW. The addresses presented are loaded into the address register and the burst counter/control logic and delivered to the RAM core. The write inputs ( $\overline{\text{GW}}$ ,  $\overline{\text{BWE}}$ , and  $\overline{\text{BW}}_{[3:0]}$ ) are ignored during this first clock cycle. If the write inputs are asserted active (see Write Cycle Descriptions table for appropriate states that indicate a write) on the next clock rise, the appropriate data will be latched and written into the device. Byte writes are allowed. During byte writes,  $\overline{\text{BW}}_0$  controls  $\overline{\text{DQ}}_{[7:0]}$ ,  $\overline{\text{BW}}_1$  controls  $\overline{\text{DQ}}_{[15:8]}$ ,  $\overline{\text{BW}}_2$  controls  $\overline{\text{DQ}}_{[23:16]}$ , and  $\overline{\text{BW}}_3$  controls  $\overline{\text{DQ}}_{[31:24]}$ . All I/Os are three-stated during a byte write. Since this is a common I/O device, the asynchronous  $\overline{\text{OE}}$  input signal must be deasserted and the I/Os must be three-stated prior to the presentation of data to  $\overline{\text{DQ}}_{[31:0]}$ . As a safety precaution, the data lines are three-stated once a write cycle is detected, regardless of the state of  $\overline{\text{OE}}$ .

**Single Write Accesses Initiated by  $\overline{\text{ADSC}}$** 

This write access is initiated when the following conditions are satisfied at clock rise: (1)  $\text{CE}_1$ ,  $\text{CE}_2$ , and  $\text{CE}_3$  are all asserted active, (2)  $\overline{\text{ADSC}}$  is asserted LOW, (3)  $\overline{\text{ADSP}}$  is deasserted HIGH, and (4) the write input signals ( $\overline{\text{GW}}$ ,  $\overline{\text{BWE}}$ , and  $\overline{\text{BW}}_{[3:0]}$ ) indicate a write access.  $\overline{\text{ADSC}}$  is ignored if  $\overline{\text{ADSP}}$  is active LOW.

The addresses presented are loaded into the address register and the burst counter/control logic and delivered to the RAM core. The information presented to  $\overline{\text{DQ}}_{[31:0]}$  will be written into the specified address location. Byte writes are allowed. During byte writes,  $\overline{\text{BW}}_0$  controls  $\overline{\text{DQ}}_{[7:0]}$ ,  $\overline{\text{BW}}_1$  controls  $\overline{\text{DQ}}_{[15:8]}$ ,  $\overline{\text{BW}}_2$  controls  $\overline{\text{DQ}}_{[23:16]}$ , and  $\overline{\text{BW}}_3$  controls  $\overline{\text{DQ}}_{[31:24]}$ . All I/Os are three-stated when a write is detected, even a byte write. Since this is a common I/O device, the asynchronous  $\overline{\text{OE}}$  input signal must be deasserted and the I/Os must be three-stated prior to the presentation of data to  $\overline{\text{DQ}}_{[31:0]}$ . As a safety precaution, the data lines are three-stated once a write cycle is detected, regardless of the state of  $\overline{\text{OE}}$ .

**Single Read Accesses**

A single read access is initiated when the following conditions are satisfied at clock rise: (1)  $\overline{\text{CE}}_1$ ,  $\text{CE}_2$ , and  $\text{CE}_3$  are all as-

serted active, and (2)  $\overline{\text{ADSP}}$  or  $\overline{\text{ADSC}}$  is asserted LOW (if the access is initiated by  $\overline{\text{ADSC}}$ , the write inputs must be deasserted during this first cycle). The address presented to the address inputs is latched into the address register and the burst counter/control logic and presented to the memory core. If the  $\overline{\text{OE}}$  input is asserted LOW, the requested data will be available at the data outputs a maximum to  $t_{\text{CDV}}$  after clock rise.  $\overline{\text{ADSP}}$  is ignored if  $\overline{\text{CE}}_1$  is HIGH.

**Burst Sequences**

The CY7C1338 provides an on-chip 2-bit wraparound burst counter inside the SRAM. The burst counter is fed by  $\text{A}_{[1:0]}$ , and can follow either a linear or interleaved burst order. The burst order is determined by the state of the MODE input. A LOW on MODE will select a linear burst sequence. A HIGH on MODE will select an interleaved burst order. Leaving MODE unconnected will cause the device to default to a interleaved burst sequence.

### Sleep Mode

The ZZ input pin is an asynchronous input. Asserting ZZ HIGH places the SRAM in a power conservation “sleep” mode. Two clock cycles are required to enter into or exit from this “sleep” mode. While in this mode, data integrity is guaranteed. Accesses pending when entering the “sleep” mode are not con-

sidered valid nor is the completion of the operation guaranteed. The device must be deselected prior to entering the “sleep” mode.  $\overline{CE}_1$ ,  $CE_2$ ,  $\overline{CE}_3$ ,  $\overline{ADSP}$ , and  $\overline{ADSC}$  must remain inactive for the duration of  $t_{ZZREC}$  after the ZZ input returns LOW. Leaving ZZ unconnected defaults the device into an active state.

**Cycle Description Table**<sup>[1, 2, 3]</sup>

Cycle Description	ADD Used	$\overline{CE}_1$	$\overline{CE}_3$	$CE_2$	ZZ	$\overline{ADSP}$	$\overline{ADSP}$	$\overline{ADV}$	$\overline{WE}$	$\overline{OE}$	CLK	DQ

Write Cycle, Suspend Burst	Current	H	X	X	L	X	H	H	L	X	L-H	D

**Notes:**

1. X="Don't Care", 1=Logic HIGH, 0=Logic LOW.
2. The SRAM always initiates a read cycle when  $\overline{ADSP}$  asserted, regardless of the state of  $\overline{GW}$ ,  $\overline{BWE}$ , or  $\overline{BWS}_{[3:0]}$ . Writes may occur only on subsequent clocks after the  $\overline{ADSP}$  or with the assertion of  $\overline{ADSC}$ . As a result,  $\overline{OE}$  must be driven HIGH prior to the start of the write cycle to allow the outputs to three-state.  $\overline{OE}$  is a don't care for the remainder of the write cycle.
3.  $\overline{OE}$  is asynchronous and is not sampled with the clock rise. During a read cycle  $DQ=High-Z$  when  $\overline{OE}$  is inactive, and  $DQ=data$  when  $\overline{OE}$  is active.

t <sub>WEH</sub>	$\overline{\text{BWS}}_{[1:0]}, \overline{\text{GW}}, \overline{\text{BWE}}$ Hold After CLK Rise	0.5		0.5		0.5		0.5		ns
t <sub>ADVS</sub>	$\overline{\text{ADV}}$ Set-Up Before CLK Rise	2.0		2.0		2.0		2.0		ns
t <sub>ADVH</sub>	$\overline{\text{ADV}}$ Hold After CLK Rise	0.5		0.5		0.5		0.5		ns
t <sub>DS</sub>	Data Input Set-Up Before CLK Rise	2.0		2.0		2.0		2.0		ns
t <sub>DH</sub>	Data Input Hold After CLK Rise	0.5		0.5		0.5		0.5		ns
t <sub>CES</sub>	Chip Enable Set-Up	2.0		2.0		2.0		2.0		ns
t <sub>CEH</sub>	Chip Enable Hold After CLK Rise	0.5		0.5		0.5		0.5		ns
t <sub>CHZ</sub>	Clock to High-Z <sup>[10,11]</sup>		3.5		3.5		3.5		3.5	ns
t <sub>CLZ</sub>	Clock to Low-Z <sup>[10,11]</sup>	0		0		0		0		ns
t <sub>EOHZ</sub>	$\overline{\text{OE}}$ HIGH to Output High-Z <sup>[10,12]</sup>		3.5		3.5		3.5		3.5	ns
t <sub>EOLZ</sub>	$\overline{\text{OE}}$ LOW to Output Low-Z <sup>[10,12]</sup>	0		0		0		0		ns
t <sub>EOV</sub>	$\overline{\text{OE}}$ LOW to Output Valid		3.5		3.5		3.5		3.5	ns

**Note:**

9. Unless otherwise noted, test conditions assume signal transition time of 2.5 ns or less, timing reference levels of 1.25V, input pulse levels of 0 to 2.5V, and output loading of the specified I<sub>OL</sub>/I<sub>OH</sub> and load capacitance. Shown in (a) and (b) of AC test loads.
10. t<sub>CHZ</sub>, t<sub>CLZ</sub>, t<sub>EOHZ</sub>, and t<sub>EOLZ</sub> are specified with a load capacitance of 5 pF as in part (b) of AC Test Loads. Transition is measured ± 200 mV from steady-state voltage.
11. At any given voltage and temperature, t<sub>CHZ</sub> (max) is less than t<sub>CLZ</sub> (min).
12. This parameter is sampled and not 100% tested.

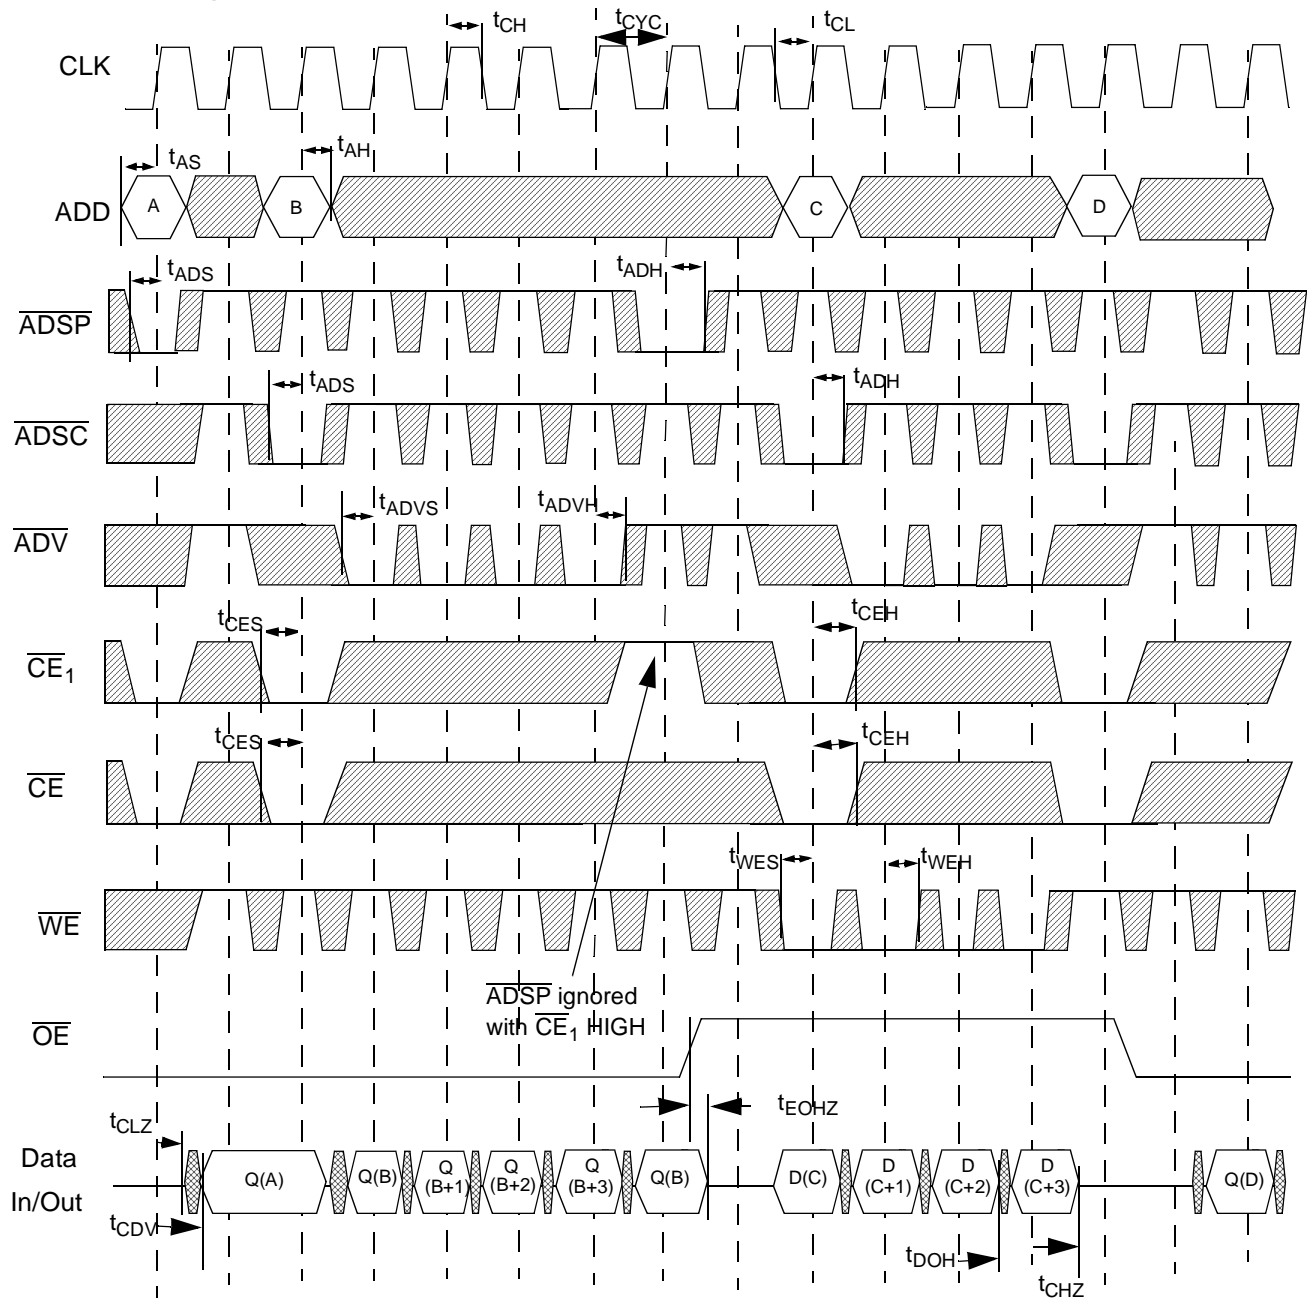

**Timing Diagrams** (continued)

**Read Cycle Timing**<sup>[13, 15]</sup>

**Note:**  
 15. RD<sub>x</sub> stands for Read Data from Address X.

**Timing Diagrams** (continued)

**Read/Write Timing**

Device originally deselected

$\overline{WE}$  is the combination of  $\overline{BWE}$ ,  $\overline{BWS}_{[1:0]}$ , and  $\overline{GW}$  to define a write cycle (see Write Cycle Descriptions table).  $\overline{CE}$  is the combination of  $CE_2$  and  $\overline{CE}_3$ . All chip selects need to be active in order to select the device. RAX stands for Read Address X, WAX stands for Write Address X, DX stands for Data-in X, Qx stands for Data-out X.

**ZZ Mode Timing** [16, 17]

**Note:**

16. Device must be deselected when entering ZZ mode. See Cycle Description Table for all possible signal conditions to deselect the device.
17. I/Os are in three-state when exiting ZZ sleep mode.
