

DATA SHEET

TDA1387T **Stereo Continuous Calibration DAC** **(CC-DAC)**

Preliminary specification
Supersedes data of September 1994
File under Integrated Circuits, IC01

1995 Dec 11

Stereo Continuous Calibration DAC (CC-DAC)

TDA1387T

FEATURES

- Low power consumption
- Low total harmonic distortion
- Wide dynamic range (16-bit resolution)
- Continuous Calibration (CC) concept
- Single 3 to 5.5 V supply rail
- Output and bias current are proportional to the supply voltage
- Fast settling time enables 2, 4 and 8 times oversampling (serial input) or double-speed operation at 4 times oversampling
- Internal bias current ensures maximum dynamic range
- Wide operating temperature range (−40 to + 85 °C)
- I²S-bus input format (time multiplex, two's complement, TTL)
- No zero-crossing distortion
- Large DC output voltage compliance
- Contained in small outline package.

APPLICATIONS

- Portable digital audio equipment.

GENERAL DESCRIPTION

The TDA1387T is a member of a generation of digital-to-analog converters which incorporates the innovative technique of Continuous Calibration. The largest bit currents are repeatedly generated from one single reference current. This duplication is based upon an internal charge storage principle and has an accuracy which is insensitive to ageing, temperature and process variations.

The TDA1387T is fabricated in a 1.0 μm CMOS process and features an extremely low power dissipation, small package size and easy application. The intrinsic high coarse current accuracy combined with the implemented symmetrical offset decoding method preclude zero-crossing distortion and ensure high quality audio reproduction. The CC-DAC is eminently suitable for use in portable digital audio equipment.

| I _{OR} | 8 | right channel output |

FUNCTIONAL DESCRIPTION

The basic operation of the continuous calibration DAC is illustrated in Fig.3 which shows the calibration and operation cycle. During calibration of the MOS current source (Fig.3a) transistor M1 is connected as a diode by applying a reference current. The voltage V_{gs} on the intrinsic gate-source capacitance C_{gs} of M1 is then determined by the transistor characteristics. After the drain current has been calibrated to the reference value I_{ref} , the switch S1 is opened and S2 is switched to the other position (Fig.3b). The gate-to-source voltage V_{gs} of M1 is not changed because the charge on C_{gs} is preserved. Therefore, the drain current of M1 will still be equal to I_{ref} and this exact duplication of I_{ref} is now available at the OUT terminal.

In the TDA1387T, 32 current sources and one spare current source are continuously calibrated (see Fig.1). The spare current source is included to allow continuous converter operation. The output of one calibrated source is connected to an 11-bit binary current divider which consists of 2048 transistors. A symmetrical offset decoding principle is incorporated and arranges the bit switching such that the zero-crossing is performed by switching only the LSB currents.

The TDA1387T (CC-DAC) accepts serial input data format of 16-bit word length. Left and right data words are time multiplexed. The input data format is shown in Figs 4 and 5.

With a HIGH level on the WS input, data is placed in the right input register, with a LOW level on the WS input, data is placed in the left input register. The data in the input registers are simultaneously latched to the output registers which control the bit switches. An internal bias current I_{bias} is added to the full scale output current I_{FS} in order to achieve maximum dynamic range at the outputs of OP1 and OP2.

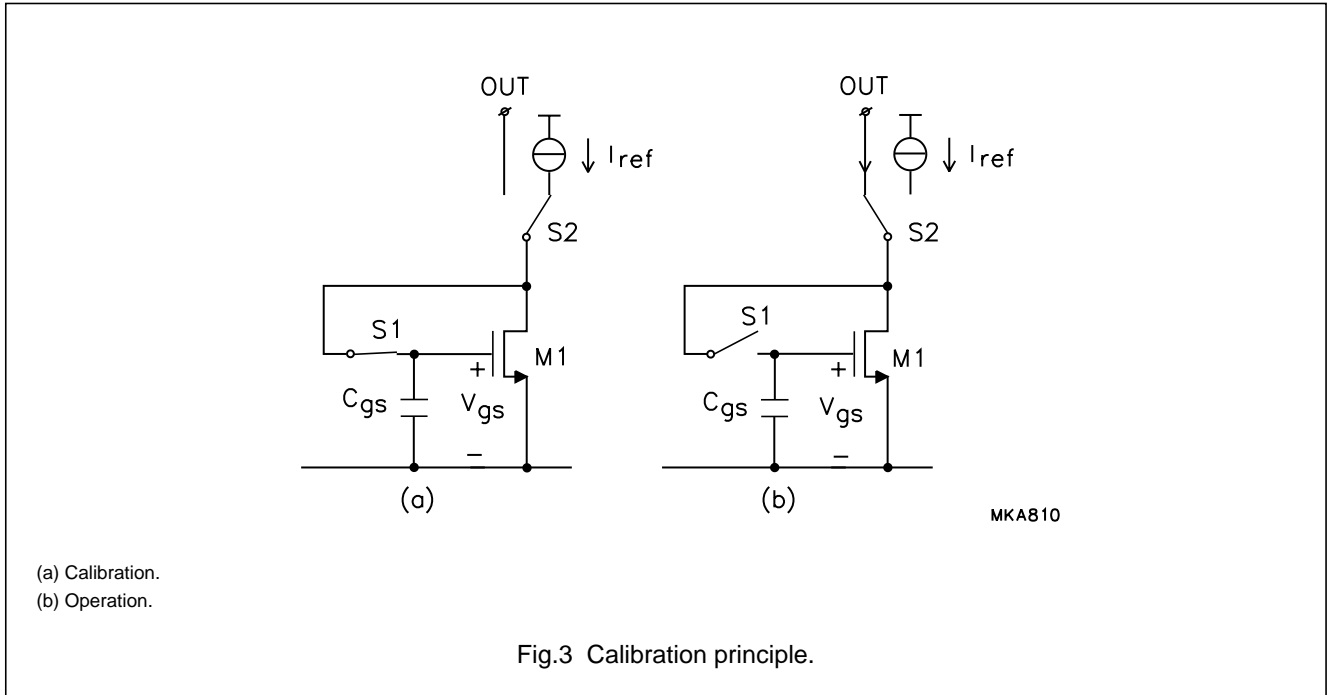

The signal current I_{FS} and the bias current I_{bias} are both proportional to the supply voltage V_{DD} , and have a fixed mutual relation A_{bias} (where $A_{bias} = I_{bias}/I_{FS}$).

It is preferred that the non-inverting input of operational amplifiers OP1 and OP2 is tied to ground to achieve a maximum dynamic range over the supply voltage range.

A decoupling capacitor C4 is recommended for enhancing the supply voltage ripple rejection of the DAC. It has no significant effect on the noise performance.

Stereo Continuous Calibration DAC (CC-DAC)

TDA1387T

LIMITING VALUES

In accordance with the Absolute Maximum Rating System (IEC 134).

| SYMBOL | DESCRIPTION | CONDITIONS | MIN. | MAX. | UNIT |
|-----------------|-------------------------------|------------|-------|-------|------|
| V_{DD} | supply voltage | | - | 6.0 | V |
| $T_{xtal(max)}$ | maximum crystal temperature | | - | +150 | °C |
| T_{stg} | storage temperature | | -55 | +150 | °C |
| T_{amb} | operating ambient temperature | | -40 | +85 | °C |
| V_{es} | electrostatic handling | note 1 | -2000 | +2000 | V |
| | | note 2 | -200 | +200 | V |

Notes

- Human body model: C = 100 pF; R = 1.5 kΩ; 3 zaps positive and 3 zaps negative.
- Machine model: C = 200 pF; L = 0.5 μH; R = 10 Ω; 3 zaps positive and 3 zaps negative.

THERMAL CHARACTERISTICS

| SYMBOL | DESCRIPTION | VALUE | UNIT |
|--------------|---|-------|------|

TDA1387T

APPLICATION INFORMATION

The TDA1387T offers great ease in designing-in to printed-circuit board due to its small size and low pin count. The TDA1387T being a mixed-signal IC in CMOS, some attention needs to be paid to layout and topology of the application PCB. The following basic rules will yield the desired performance. The most important considerations are:

1. **Supply:** care should be taken to supply the TDA1387T with a clean, noiseless supply voltage, for a good noise performance of the analog parts of the DAC. Supply purity can easily be achieved by using an RC-filtered supply.
2. **Grounding:** preferably a ground plane should be used, in order to have a low-impedance return available at any point in the layout. It is advantageous to make a partitioning of the ground plane according to the nature of the expected return currents (digital input returns separate from supply returns separate from the analog section).
3. **Topology:** the capacitor decoupling high-frequency supply interference from V_{DD} to GND should be placed as close as is physically possible to the IC body, ensuring a low-inductance path to ground. The digital input conductors may be shielded by ground leads running alongside. The placement of a passive ground plane underside the entire IC surface gives 'free' additional decoupling from the IC body to ground as well as providing a shield between the digital input pins and the analog output pins.

SOLDERING

Introduction

There is no soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and surface mounted components are mixed on one printed-circuit board. However, wave soldering is not always suitable for surface mounted ICs, or for printed-circuits with high population densities. In these situations reflow soldering is often used.

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our *"IC Package Databook"* (order code 9398 652 90011).

Reflow soldering

Reflow soldering techniques are suitable for all SO packages.

Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement.

Several techniques exist for reflowing; for example, thermal conduction by heated belt. Dwell times vary between 50 and 300 seconds depending on heating method. Typical reflow temperatures range from 215 to 250 °C.

Preheating is necessary to dry the paste and evaporate the binding agent. Preheating duration: 45 minutes at 45 °C.

Wave soldering

Wave soldering techniques can be used for all SO packages if the following conditions are observed:

- A double-wave (a turbulent wave with high upward pressure followed by a smooth laminar wave) soldering technique should be used.
- The longitudinal axis of the package footprint must be parallel to the solder flow.
- The package footprint must incorporate solder thieves at the downstream end.

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured.

Maximum permissible solder temperature is 260 °C, and maximum duration of package immersion in solder is 10 seconds, if cooled to less than 150 °C within 6 seconds. Typical dwell time is 4 seconds at 250 °C.

A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

Repairing soldered joints

Fix the component by first soldering two diagonally-opposite end leads. Use only a low voltage soldering iron (less than 24 V) applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to 300 °C. When using a dedicated tool, all other leads can be soldered in one operation within 2 to 5 seconds between 270 and 320 °C.
