## TVText Pro

## Release Note: Revision bars indicate significant changes to the previous edition.

## 1. Introduction

The Micronas SDA 55xx TV microcontroller is dedicated to 8 bit applications for TV control and provides dedicated graphic features designed for modern low class to mid range TV sets.

The SDA 55xx is a microcontroller and single chip teletext decoder for decoding World System Teletext data as well as other data services as Video Programming System (VPS), Program Delivery Control (PDC), and Wide Screen Signalling (WSS) data used for PAL plus transmissions (in line 23). The data slicer and display part of the SDA 55xx supports a wide range of TV standards including PAL, NTSC as well as the acquisition of the above mention data services as VPS, WSS, PDC, TTX and Closed Caption data.

The slicer combined with its dedicated hardware stores TTX data in a VBI buffer of 1 kByte. The Microcontroller firmware available from Micronas performs all the acquisition tasks (hamming and parity checks, page search and evaluation of header control bits) once per field. Additionally, the firmware can provide high end teletext features like Packet-26-handling, FLOF, TOP and list page mode. The Application Program Interface (API) to the user software is optimized for a minimum SW overhead.

The on-chip display unit used to display teletext data up to level 1.5 can also be used for customer defined on-screen displays (OSD). The display generator is able to handle parallel display attributes, pixel oriented displays and dynamically re-definable characters (DRCS).

The SDA 55xx provides also an integrated generalpurpose, fully 8051-compatible microcontroller with specific hardware features especially suitable in TV sets. The microcontroller core has been enhanced to provide powerful features such as memory banking, data pointers and additional interrupts, etc.

The internal XRAM consists of up to 16 kBytes. The microcontroller provides an internal ROM of up to 128 kBytes. ROMless versions can access up to 1 MByte of external RAM and ROM.

The 8-bit microcontroller runs at 33.33 MHz internal clock. SDA $55 x x$ is realized in 0.25 micron technology with 2.5 V supply voltage for the core and 3.3 V for the I/O port pins to make them TTL compatible.

Based on the SDA 55xx microcontroller the MINTS software package was developed and provides dedicated device drivers for many Micronas video \& audio
products and includes a full blown TV control SW for the PEPER application chassis. The SDA 55xx is also supported with powerful design tools like emulators from Hitex, Kleinhenz, iSystems, the Keil C51 Compiler and TEDIpro OSD development SW by Tara Systems. This support provided by Micronas leads to:

- Shorter time to market
- Re-usability of the SW also for future Micronas products
- Target independent SW development based on ANSI C.
- Verification and validation of SW before targeting and improved SW test concept
- Graphical interface design requiring a minimum effort for OSD programming and TV controlled know how.
- Complete, modular and open tool chain available and configurable by customer.

### 1.1. General Features

- 8051 compatible microcontroller with TV related special features and advanced OSD display
- Feature selection via special function register
- Simultaneous processing of TTX, VPS, PDC and WSS (line 23) data
- Supply voltage 2.5 V for core and 3.3 V for ports
- ROM version package PSDIP52-2, PMQFP64-1
- Romless version package PMQFP100-2
- 128 kByte Flash ROM version package PSDIP52-2

### 1.1.1. External Crystal and Programmable Clock Speed

- Normal mode 33.33 MHz CPU clock, power save mode 8.33 MHz
- CPU clock speed selectable via special function registers.
- Single external 6 MHz crystal, all necessary clock signals are generated internally by means of PLLs

### 1.1.2. Microcontroller Features

- 8-bit 8051 instruction set compatible CPU
- Two 16-bit timers
- Watchdog timer
- Capture compare timer for infrared remote control decoding
- Pulse width modulation unit (2 channels 14 bit, 6 channels 8 bit)
- ADC (4 channels, 8 bit)
- UART

### 1.1.3. Memory

- Non-multiplexed 8-bit data and 16...20-bit address bus (ROMless version)
- Memory banking up to 1 MByte (ROMless version)
- Up to 128 kByte on-chip program ROM
- Eight 16-bit data pointer registers (DPTR)
- 256-bytes on-chip processor internal RAM (IRAM)
- 128 bytes extended stack memory
- Display RAM and TXT/VPS/PDC/WSS Data Acquisition Buffer directly accessible via MOVX command
- Up to 16 kByte on-chip extended RAM (XRAM) consisting of
- 1 kByte on-chip ACQ buffer RAM (access via MOVX)
- 1 kByte on-chip extended RAM (XRAM, access via MOVX) for user software
- 3 kByte display memory

### 1.1.4. Display Features

- ROM character set supports all east and west European languages in a single device
- Mosaic graphic character set
- Parallel display attributes
- Single/double width/height of characters
- Variable flash rate
- Programmable screen size ( 25 rows $\times 33 \ldots 64$ columns)
- Flexible character matrixes ( $\mathrm{H} \times \mathrm{V}$ ) $12 \times 9 \ldots 16$
- Up to 256 dynamically re-definable characters in standard mode; 1024 dynamically re-definable characters in enhanced mode
- CLUT with up to 4096 color combinations
- Up to 16 colors per DRCS character
- One out of eight colors for foreground and background colors for 1-bit DRCS and ROM characters
- Shadowing \& contrast reduction
- Pixel by pixel shiftable cursor with up to 4 different colors
- Support of progressive and 100 Hz double scan
$-3 \times 4$ bits RGB-DACs on chip
- Free programmable pixel clock from 10 MHz to 32 MHz
- Pixel clock independent from CPU clock
- Multinorm H/V-display synchronization in master or slave mode

### 1.1.5. Acquisition Features

- Multistandard digital data slicer
- Parallel multinorm slicing (TTX, VPS, WSS, CC, G+)
- Four different framing codes available
- Data caption only limited by available memory
- Programmable VBI-buffer
- Full channel data slicing supported
- Fully digital signal processing
- Noise measurement and controlled noise compensation
- Attenuation measurement and compensation
- Group delay measurement and compensation
- Exact decoding of echo disturbed signals

### 1.1.6. Ports

- One 8-bit I/O-port with open drain output and optional $\mathrm{I}^{2} \mathrm{C}$ bus emulation support (Port 0)
- Two 8-bit multifunction I/O-ports (Port 1, Port 3)
- One 4-bit port working as digital or analog inputs for the ADC (Port 2)
- One 2-bit I/O-port with secondary functions (P4.2, 4.3, 4.7)
- One 4-bit I/O-port with secondary function (P4.0, 4.1, 4.4) Not available in PSDIP52-2)

Fig. 1-1: Logic Symbol

Fig. 1-2: Block Diagram

### 1.2. Overview of Current Versions and Packages for SDA 55xx

Table 1-1: TVText Pro versions and packages overview

| Version | Type | Package |
| :---: | :---: | :---: |
| SDA 5550M | - ROMless version <br> - 16 kByte RAM | PMQFP100-1 |
| SDA 5550 | - ROMless version <br> - 16 kByte RAM | PLCC84-1 |
| SDA 555xFL | - 128 kByte Flash memory on chip (re-programmable) <br> - 16 kByte RAM | PSDIP52-2 |
| $\begin{aligned} & \text { SDA } 555 x \\ & x=1 \ldots 5 \end{aligned}$ | - 32-128 kByte user ROM <br> - 8-16 kByte RAM | PMQFP64-1, PSDIP52-1, PSDIP52-2 <br> See note |
| SDA 5521 | - OSD-only version <br> - 32 kByte user ROM on chip <br> - 8 kByte RAM | PSDIP52-1, PSDIP52-2 See note |
| SDA 5522 | - OSD-only version <br> - 64 kByte user ROM on chip <br> - 8 kByte RAM | PSDIP52-1, PSDIP52-2 <br> See note |

Note: Micronas delivers two types of PSDIP52 packages (-1, -2 ).
The packages have slightly different outline dimensions, but are considered identical.
See Outline Dimensions for PSDIP52-1 Package on page 144 and Outline Dimensions for PSDIP52-1 Package on page 144.
For logistics reasons, the customer cannot choose the package to be delivered.

## 2. Functional Description

### 2.1. Clock System

### 2.1.1. General Function

The on-chip clock generator provides the TVTpro with its basic clock signal. The oscillator runs with an external crystal and the appropriate internal oscillator circuitry (see Fig. on page 174).

For applications with lower timing accuracy requirements (and if the RTC is not used) an external ceramic resonator can be used. The usage of a ceramic resonator is not recommended for Teletext applications as depending on the absolute tolerance of the ceramic resonator the data slicer may not work correctly. Additional this might also require that display timing parameters and the baud rate prescaler have to be adapted. In timing critical applications the horizontal frequency of the incoming CVBS signal can be used to measure the actual timing deviation and to re-program the clock PLL.

The 6 MHz clock signal is used to generate the internal 300 MHz display reference clock by means of an onchip phase locked loop (PLL). The PLL can be bypassed to reduce the power consumption. If an immediate wake up from power down is not required the PLL can also be switched off in this mode.

From the output frequency of the main clock PLL two clock systems are derived.

### 2.1.2. System Clock

The 33.33 MHz system clock ( $\mathrm{f}_{\mathrm{CPU}}$ ) is provided to the microcontroller core, all microcontroller related peripherals, the sync timing logic, the $A / D$ converters, the slicer, the display generator and the color lookup tables CLUT.

It is possible to use $8.33 \mathrm{MHz}(1 / 4$ of 33.33 MHz ) for the system clock domain (slow down mode). Setting SFR-bit PLLS = 1 the user is able to send the PLL into a power save mode.

Note: Before the PLL is switched to power save mode (PLLS = 1), the software has to switch the clock source from 200 MHz PLL clock to the 3 MHz oscillator clock (SFR bit CLK_src = 1). In this mode the slicer, acquisition, DAC and display generator are switched off.

To switch back to full frequency operation, the software has to end the PLL power save mode (SFR-bit PLLS = 0), reset the PLL for $10 \mu \mathrm{~s}$ (3 machine cycles, SFR bit PLL_res = '1', then ' 0 ' again), wait for $150 \mu \mathrm{~s}$ ( 38 machine cycles) and switch back to the PLL clock (SFR-bit SCR_src = 0).

If the power down mode is activated, PLL and oscillator are send to sleep mode (SFR bit PDS =1). Furthermore, there are additional possibilities to disable the clocks for the peripherals - See Section 2.3.17. on page 44.

Fig. 2-1: Clock System of TVText Pro

### 2.1.3. Pixel Clock

The second clock system is the pixel clock ( $\mathrm{f}_{\text {PIX }}$ ), which is programmable in a range from $10 \ldots 32 \mathrm{MHz}$. It serves the output part of the display FIFO and the D/A converters. The pixel clock is derived from the high frequent output of the PLL and line by line phase shifted to the positive edge of the horizontal sync signal (normal polarity). Because the final display clock is derived from a DTO (digital time oscillator) it has no equidistant clock periods although the average frequency is exact. This pixel clock generation system has several advantages:

- The frequency of the pixel clock can be programmed independently from the horizontal line period.
- Because the input of the PLL is already a signal with a relative high frequency, the resulting pixel frequency has an extremely low jitter.
- The resulting pixel clock follows the edge of the Hsync impulse without any delay and has always the same quality than the sync timing of the deflection controller.

### 2.1.4. Related Registers

Table 2-1: Related registers and bits

| Register Name | Bit Name |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| PCLK1 |  |  |  |  |  | PF[10:8] |  |  |
| PCLKO | PF[7:0] |  |  |  |  |  |  |  |

| PSAVEX |  |  |  |  |  | CLK_src | PLL_res | PLLS |
| See Section 3. on page 110 for detailed register description. |  |  |  |  |  |  |  |  |

### 2.2. Slicer and Data Acquisition

### 2.2.1. General Function

TVTPro provides a full digital data slicer including digital H - and V -sync separation and digital sync processing. The acquisition interface is capable to process all known data services transmitted in the Vertical Blanking Interval VBI of a CVBS signal (Teletext, VPS, CC, G+, WSS). Four different framing codes (two of them freely programmable for each field) are available for each field. Digital signal processing algorithms are applied to compensate various disturbing influences as there are:

- Noise measurement and compensation.
- Attenuation measurement and compensation.
- Group delay measurement and compensation.

Note: TVTPro is optimized for precise data clock recovery and error free reception of data. Thus, the reception of data services is widely unaffected by noise and the actual transmission channel characteristics.

The CVBS input contains an on chip clamping circuit.
The integrated A/D converter has a 7 bit resolution. The sampling frequency is 33.33 MHz .

The sliced data are synchronized to the data clock frequency given by the clock-run-in. The framing code will define the start of the data stream. The resulting valid data will be written to the VBI data buffer. After line 23 is received an interrupt will be issued to the microcontroller. The microcontroller starts processing the buffered data. That means, a SW module will check the data for errors and store them in an assigned memory area.

To improve the data signal quality the slicer control logic generates horizontal and vertical windows during which the reception of the framing code is allowed. The framing code can be programmed individually for each line, so that in each line a different data service can be received. For VPS and WSS the framing code is hardwired. All following acquisition tasks are performed by the internal controller, so in principal the data of any data service can be acquired.

### 2.2.2. Slicer Architecture

The slicer consists of three main blocks:

- The slicer
- The H/V synchronization for the slicer
- The acquisition interface

Fig. 2-2: Block Diagram of Digital Slicer and Acquisition Interface

### 2.2.2.1. Distortion Processing

After A/D conversion the digital CVBS bit stream is applied to internal circuitry which corrects the input signal for distortions created in the transmission channel. In order to apply the right algorithm for the correction, a signal measurement is done in parallel. This measurement unit can detect the following distortions.

### 2.2.2.1.1. Noise

The noise measurement unit incorporates two different algorithms. Both algorithms use the value between two equalizing pulses, which corresponds to the black level. As the system knows the black level, a window is placed between this two equalizing pulses (located in line 4).

The first algorithm compares successive the amplitude samples inside that window. The difference between these samples is measured and a flag is set as soon as this difference over several TV lines is greater than a specified value. This algorithm is able to detect higher frequency noise (e.g. white noise).

The second algorithm measures the difference between the black value and the actual sampled value inside this window. As soon as this difference over several TV lines is greater than a specified value a second flag is set. This algorithm is sensitive against low frequency noise as it is known from co-channel distortion.

Both flags can be used to optimize the response of the compensation circuits in order to achieve best reception performance.

### 2.2.2.1.2. Frequency Attenuation

During signal transmission the CVBS signal can severely be attenuated. This attenuation normally is frequency depending. That means that the higher the frequency the stronger the attenuation. As the clock run-in (from now on referred to as CRI) for teletext represents the highest possible frequency ( 3.5 MHz ) it can be used to measure the attenuation. Only strong negative attenuation causes problems during data slicing. A flag is needed to notify highly negative attenuation to the SW. If this flag is set a special peaking filter is switched on in the data-path.

### 2.2.2.1.3. Group Delay

Quite often the data stream is corrupted because of group delay distortion introduced by the transmission channel. The teletext framing code ( $\mathrm{E} 4_{\mathrm{H}}$ ) is used as a measurement reference. The delay of the edges inside this code can be used to measure the group delay dis-
tortion. The measurement is done during every teletext line and filtered over several lines.

It can be detected whether the signal has positive, negative or no group delay distortions. Two flags are set accordingly. By means of these two flags, an allpass contained in the compensation circuit is configured to compensate positive or negative group delay.

All of the above mentioned filters can be individually be disabled, set to forced mode, or automatic mode via control registers.

### 2.2.2.2. Data Separation

Parallel to signal analysis and distortion compensation another filter is calculating the required slicing level. The slicing level is the mean value of the clock run-in CRI. As teletext is coded using the NRZ format, the slicing level can not be calculated outside the CRI timing window and is therefore frozen after CRI. Using the found slicing level the data are sliced from the digitized CVBS signal. The result is a stream of zeros and ones. In order to find the logical zeros and ones which have been transmitted, the data clock needs to be recovered. Therefore during the CRI timing window a digital data PLL (D-PLL) is synchronized to the transitions in the sliced data stream which represent the original data clock. The frequency of the D-PLL is also frozen after the CRI timing window.

Timing information to freeze the slicing level, the DPLL and to control other actions are generated by the timing circuit. It generates also all control signals which have to be synchronized to the data start.

### 2.2.3. H/V-Synchronization

Data slicer and acquisition interface require different control signals which have to be synchronized to the incoming CVBS (e.g. line number, field sequence or line start of a TV line). Therefore a slicing level for the sync pulses is calculated and the sync signal is sliced from the filtered digital CVBS signal.

Using a digital integrator vertical and horizontal sync pulses are separated. The horizontal pulses are fed into a digital H-PLL which has flywheel functionality. The H-PLL includes a counter which is used to generate all the necessary horizontal control signals. The vertical sync pulse is used to synchronize the line counter, which generates the required vertical control signals.

The synchronization block includes a watchdog for supervision of the actual lock condition of the H-PLL. The watchdog can produce an interrupt (CC_IR) if synchronization has been lost. It could therefore be an indication for a channel change or missing input signal.

### 2.2.4. Acquisition Interface

The acquisition interface manages the data transfer from between slicer and memory. From slicer to memory first of all a bit synchronization is performed (Framing Code (FC) check). Following this, the data is serial/ parallel converted. 8 bit wide words will be shifted into the memory. The data acquisition supports several features. The FC check is able to handle four different framing codes for one field. Two of this framing codes are programmable and could therefore be changed from field to field. The acquisition can be switched from normal mode (line 6 to 23) to full channel mode (line 6 to the end of a field).

In the other direction parameters are loaded from the memory to the slicer. This parameter down loading takes place after the vertical sync and after the horizontal sync. These parameters are used for the slicer configuration.

### 2.2.4.1. Framing Code Check

There are four Framing Codes FC implemented which are compared with the FC of the incoming signal.

- The first one is 8 -bit wide and is loaded down with the field parameters.
- The second one is 16 -bit wide and fixed to the FC of VPS.
- The third one is 16-bit wide as well, but can be loaded with the field parameters. If the third one is used, the user can specify not only the FC but also a "don't-care" mask.
- The fourth FC is reserved for WSS. The actual FC can be changed line by line.

### 2.2.4.1.1. Framing Code FC1

This FC should be used for all services with 8-bit framing codes (e.g. for TTX). The actual framing code is loaded down each field. The check can be done without any bit error tolerance or with a tolerance of one bit.

### 2.2.4.1.2. Framing Code FCVPS

This FC is fixed to that of VPS. Only an error-free signal will enable the reception of the VPS data line.

Note: If VPS should be sliced in field 1 and TTX in field 2 , the appropriate line parameters for line 16 have to be changed dynamically from field to field.

### 2.2.4.1.3. Framing Code FC3

This 16 -bit FC is loaded with the field parameters as well as a "don't care" mask. The incoming signal is compared with both, the framing code and the "don't care" mask. Further reception is enabled if all bits which are not "don't care" match the incoming data stream.

### 2.2.4.1.4. Framing Code FCWSS

This FC is pre-programmed to that of WSS. Only an error-free signal will enable the reception of the WSS data line.

### 2.2.4.1.5. FC Check Select

There is a two bit line parameter called FCSEL. By means of this parameter the user is able to select which FC check is used for the actual line. If NORM is set to WSS the WSS FC check is used independently of FCSEL.

### 2.2.4.2. Interrupts

Some events which occur inside the slicer, sync separation or acquisition interface should cause an interrupt. They are summarized in register CISRO and CISR1. The slicer hardware sets the related interrupt flag which must be reset by the application software before the next interrupt can be accepted.

### 2.2.4.3. VBI Buffer and Memory Organization

The implemented SW has to provide configuration parameters for the slicer and the acquisition interface. Both circuits will produce status information for the CPU.

Some of these parameters and status bits are constant during the duration of a field. Those parameters are called field parameters. They are downloaded after the vertical sync.

Other parameters and status bits may change from line to line (e.g. data service depending values). Those parameters are called line parameters. They are downloaded after each horizontal sync impulse.

The start address of the VBI buffer can be configured with a special function register 'STRVBI'. 9 Bytes are needed for the field parameter. 47 Bytes should be reserved for every sliced data line. If 18 lines of data (in full channel mode 314) have been send to memory no further data acquisition will take place until the next vertical pulse appears and the H-PLL is still locked.

That means if at least 855 Bytes (14767 Bytes in full channel mode) are reserved for the VBI buffer size in the RAM no VBI overflow will occur. The controller can start or stop the VBI data acquisition using bit 'ACQON' of register STRVBI. The acquisition is stopped as soon as this bit is changed to ' 0 '. If the bit is changed back to ' 1 ' the acquisition starts again with the next V-pulse (only if STAB = 1). The start address (Bit $3 \ldots 0$ of register STRVBI) of the VBI buffer should only be changed if the acquisition is switched off.

| STRVBI $\longrightarrow$ ACQFPO | 7 | Field Pa | ameters |  | 0 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Send to slicer after V-pulse |  | Field Pa | ameters |  |  |
|  |  | Field Pa | ameters |  |  |
|  |  | Field Pa | ameters |  |  |
|  |  | Field Pa | ameters |  |  |
|  |  | Field Pa | ameters |  |  |

|  |  | Field Status | Informati | ion |  |
|  |  | Field Status | Informati | ion |  |

Fig. 2-3: VBI Buffer: General Structure

### 2.2.5. Related Registers

The acquisition interface has only three SFR Registers. The line and field parameters are stored in the RAM (RAM registers). They have to be initialized by software before starting the data acquisition.

Table 2-2: Related registers

| Register Name | Bit Name |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| STRVBI | ACQON | Reserved | ACQSTA |  | VBIADR |  |  |  |
| CISRO <br> bit addressable | L24 | ADC | WTmr | AVS | DVS | PWtmr | AHS | DHS |
| CISR1 <br> bit addressable | CC | ADW |  |  |  |  | IEX[1:0] |  |
| See Section 3. on page 110 for detailed register description. |  |  |  |  |  |  |  |  |

### 2.2.5.1. RAM Registers

See Section 3. on page 110 for detailed register description.

### 2.2.5.1.1. Field Parameters

All field parameters are updated once in a field. That means the status information written from the acquisition interface to the memory represents only a snapshot of the status.

Table 2-3: Field parameters

| Register Name | Bit Name |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

### 2.2.7. Microcontroller

### 2.2.8. Architecture

Every CPU machine cycle consists of 12 internal CPU clock periods.

The CPU manipulates operands in two memory spaces: The program memory space, and the data memory space. The program memory address space is provided to accommodate relocatable code.

The data memory address space is divided into the 256-Byte internal data RAM, XRAM (extended data memory, accessible with MOVX instructions) and the 128-Byte Special Function Register (SFR) address space.

Four register banks (each bank has eight registers), 128 addressable bits, and the stack reside in the internal data RAM. The stack depth is limited only by the available internal data RAM. Its location is determined by the 8-bit stack pointer. All registers except the program counter and the four 8 -register banks reside in the special function register address space.

These memory mapped registers include arithmetic registers, pointers, l/O-ports, registers for the interrupt system, timers, pulse width modulator, capture control unit, watchdog timer, UART, display, acquisition control etc. Many locations in the SFR address space are bitwise addressable.

Note: Reading from unused locations within data memory will yield undefined data.

Conditional branches are performed relative to the 16 bit program counter. The register indirect jump permits branching relative to a 16-bit base register with an offset provided by an 8-bit index register. Sixteen-bit jumps and calls permit branching to any location in the memory address space.

The microcontroller has five methods for addressing source operands: Register, direct, register-indirect, immediate, and base register plus index register-indirect addressing.

The first three methods can be used for addressing destination operands. Most instructions have a "destination, source" field that specifies the data type, addressing methods and operands involved. For operations other than moves, the destination operand is also a source operand.

Registers in the four 8-register banks can be accessed through register, direct, or register-indirect addressing. The lower 128 Bytes of internal data RAM can be accessed through direct or register-indirect address-
ing, the upper 128 Bytes of internal data RAM through register-indirect addressing; and the special function registers through direct addressing. Look-up tables resident in program memory can be accessed through base register plus index register-indirect addressing.

### 2.2.8.1. CPU Hardware

### 2.2.8.1.1. Instruction Decoder

Each program instruction is decoded by the instruction decoder. This unit generates the internal signals that control the functions of each unit within the CPU section. These signals control the sources and destination of data, as well as the function of the Arithmetic/Logic Unit (ALU).

### 2.2.8.1.2. Program Control Section

The program control section controls the sequence in which the instructions stored in the program memory are executed. The conditional branch logic enables conditions internal and external to the microcontroller to cause a change in the sequence of program execution. The 16-bit program counter holds the address of the instruction to be executed. It is manipulated with the control transfer instructions listed in Section 2.2.10..

### 2.2.8.1.3. Internal Data RAM

The internal data RAM provides a 256-Byte scratch pad memory, which includes four register banks and 128 direct addressable software flags. Each register bank contains registers R0... R7. The addressable flags are located in the 16-Byte locations starting at Byte address $20_{\mathrm{H}}$ and ending with Byte location $2 \mathrm{~F}_{\mathrm{H}}$ of the RAM address space.

In addition to this standard internal data RAM the microcontroller contains an extended internal RAM. It can be considered as a part of an external data memory. It is referenced by MOVX instructions (MOVX A, @DPTR), the memory organization is explained in Section 2.5. on page 47.

### 2.2.8.1.4. Arithmetic/Logic Unit (ALU)

The arithmetic section of the microcontroller performs many data manipulation functions and includes the Arithmetic/Logic Unit (ALU) and the ACC, B, and PSW registers. The ALU accepts 8 -bit data words from one or two sources and generates an 8-bit result under the control of the instruction decoder. The ALU performs the arithmetic operations of add, subtract, multiply, divide, increment, decrement, BCD-decimal-add adjust and compare, and the logic operations like and, or,
exclusive-or, complement and rotate (right, left, or nibble swap).

The register $\mathbf{A C C}$ is the accumulator, the register $\mathbf{B}$ is dedicated during multiply and divide and serves as both source and destination. During all other operations the register $\mathbf{B}$ is simply another location of the special function register space and may be used for any purpose.

### 2.2.8.1.5. Boolean Processor

The Boolean processor is an integral part of the microcontroller architecture. It is an independent bit processor with its own instruction set, its own accumulator (the carry flag) and its own bit-addressable RAM and I/ O. The bit manipulation instructions allow the direct addressing of 128 bits within the internal data RAM and several bits within the special function registers. The special function registers which have addresses exactly divisible by eight contain directly addressable bits.

The Boolean processor can perform, on any addressable bit, the bit operations of "set", "clear", "complement", "jump-if-set", "jump-if-not-set", "jump-if-set thenclear" and "move to/from carry". Between any addressable bit (or its complement) and the carry flag it can perform the bit operation of logical AND or logical OR with the result returned to the carry flag.

### 2.2.8.1.6. Program Status Word Register (PSW)

The PSW flag bits record microcontroller status information and control the operation of the microcontroller. The carry (CY), auxiliary carry (AC), two user flags (F0 and F1), register bank select (RS0 and RS1), overflow $(\mathrm{OV})$ and parity $(\mathrm{P})$ flags reside in the program status word register. These flags are bit-memory-mapped within the Byte-memory-mapped PSW. The CY, AC,
and OV flags generally reflect the status of the latest arithmetic operations. The CY flag is also the Boolean accumulator for bit operations. The P-flag always reflects the parity of the register ACC. F0 and F1 are general purpose flags which are pushed onto the stack as part of a PSW save (see Table 2-7).

The two register bank select bits (RS1 and RS0) determine which one of the four register banks is selected as show in Table 2-6.

See Section 3. on page 110 for detailed register description.

### 2.2.8.1.7. Stack Pointer (SP)

The 8-bit stack pointer contains the address at which the last Byte was pushed onto the stack. This is also the address of the next Byte that will be popped. The $\mathbf{S P}$ is incremented during a push. SP can be read or written to under software control. The stack may be located anywhere within the internal data RAM address space and may be as large as 256 Bytes.

Note: For memory above 64k, the memory extension stack is used, refer to Section 2.5.3. on page 49.

Table 2-6: Register banks

| RS1 | RS0 | Register Bank | Register Location |
| :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | $00_{\mathrm{H}} \ldots 07_{\mathrm{H}}$ |
| 0 | 1 | 1 | $08_{\mathrm{H}} \ldots 0 \mathrm{~F}_{\mathrm{H}}$ |
| 1 | 0 | 2 | $10_{\mathrm{H}} \ldots 17_{\mathrm{H}}$ |
| 1 | 1 | 3 | $18_{\mathrm{H}} \ldots 1 \mathrm{~F}_{\mathrm{H}}$ |

Table 2-7: Related register

| Register Name | Bit Name |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| PSW | CY | AC | F0 | RS[1:0] |  | OV | F1 | P |
| See Section 3. on page 110 for detailed register description. |  |  |  |  |  |  |  |  |

### 2.2.8.1.8. Data Pointer Register (DPTR).

Table 2-8: Related registers

| Register Name | Bit Name |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| DPL | DPL[7:0] |  |  |  |  |  |  |  |
| DPH | DPH[7:0] |  |  |  |  |  |  |  |
| DPSEL |  |  |  |  |  | DPSEL[2:0] |  |  |
| See Section 3. on page 110 for detailed register description. |  |  |  |  |  |  |  |  |

The 16-bit Data Pointer Register DPTR is the concatenation of registers DPH (high-order Byte) and DPL (low-order Byte). The DPTR is used in register-indirect addressing to move program memory constants and to access the extended data memory. DPTR may be manipulated as one 16-bit register or as two independent 8-bit registers DPL and DPH.

Eight data pointer registers are available, the active one is selected by a special function register (DPSEL)

### 2.2.8.2. CPU Timing

Timing generation is completely self-contained, except for the frequency reference which can be a crystal or external clock source. The on-board oscillator is a parallel anti-resonant circuit. The XTAL2 pin is the output of a high-gain amplifier, while XTAL1 is its input. A crystal connected between XTAL1 and XTAL2 provides the feedback and phase shift required for oscillation.

In slowdown mode, the microcontroller runs at one fourth the normal frequency. This mode is useful when power consumption needs to be reduced. Slow down mode is entered by setting the bit SD in PCON register.

Note: Any slow-down mode should only be used if teletext reception and the display are disabled. Otherwise processing of the incoming text data might be incomplete and the display structure will be corrupted. For disabling acquisition and display generator see Section 2.3.17.

### 2.2.8.3. Addressing Modes

There are five general addressing modes operating on Bytes. One of these five addressing modes, however, operates on both Bytes and bits:

- Register
- Direct (both Bytes and bits)
- Register indirect
- Immediate
- Indirect, using base register plus index-register

The following list summarizes, which memory spaces may be accessed by each of the addressing modes:

## Register Addressing

R0 ... R7
ACC, B, CY (bit), DPTR

## Direct Addressing

RAM (low part)
Special Function Registers

## Register-indirect Addressing

RAM (@R1, @R0, SP)

Immediate Addressing
Program Memory

## Base Register plus Index-Register Indirect Addressing

Program Memory (@DPTR + A, @PC + A)

### 2.2.8.3.1. Register Addressing

Register addressing accesses the eight working registers ( $R 0 \ldots \mathrm{R} 7$ ) of the selected register bank. The PSW register flags RS1 and RSO determine which register bank is enabled. The least significant three bits of the instruction opcode indicate which register is to be used. ACC, B, DPTR and CY, the Boolean processor accumulator, can also be addressed as registers.

### 2.2.8.3.2. Direct Addressing

Direct Byte addressing specifies an on-chip RAM location (only low part) or a special function register. Direct addressing is the only method of accessing the special function registers. An additional Byte is appended to the instruction opcode to provide the memory location address. The highest order bit of this Byte selects one of two groups of addresses: Values between $00_{H} \ldots 7 \mathrm{~F}_{\mathrm{H}}$ access internal RAM locations, while values between $80_{\mathrm{H}} \ldots 0 \mathrm{FF}_{\mathrm{H}}$ access one of the special function registers.

### 2.2.8.3.3. Register Indirect Addressing

Register indirect addressing uses the contents of either R0 or R1 (in the selected register bank) as a pointer to locations in the 256 Bytes of internal RAM. Note that the special function registers are not accessible by this method.

Execution of PUSH and POP instructions also use reg-ister-indirect addressing. The stack pointer may reside anywhere in internal RAM.

### 2.2.8.3.4. Immediate Addressing

Immediate addressing allows constants to be part of the opcode instruction in program memory.

An additional Byte is appended to the instruction to hold the source variable. In the assembly language and instruction set, a number sign (\#) precedes the value to be used, which may refer to a constant, an expression, or a symbolic name.

### 2.2.8.3.5. Base Register plus Index Register Indirect Addressing

Base register plus index register indirect addressing allows a Byte to be accessed from program memory via an indirect move from the location whose address is the sum of a base register (DPTR or PC) and index register, ACC. This mode facilitates accessing to lookup table resident in program memory.

### 2.2.9. Ports and I/O-Pins

There are 34 Port pins available, out of which 24 are I/ O pins configured as three 8 -bit wide ports P0, P1, and P3. Port 4 consists of 6 I/O bits, out of which only 3 are available in the PSDIP52-2 package. All 6 port pins are only available in the other packages with higher pin count. Each pin can be individually and independently programmed as input or output and each can be configured dynamically. One 4-bit-port P2 is input only.

An instruction that uses a port's bit/Byte as a source operand reads a value that is the logical AND of the last value written to the bit/Byte and the polarity being applied to the pin/pins by an external device (this assumes that none of the microcontroller's electrical specifications are being violated).

An instruction that reads a bit/Byte, operates on the content, and writes the result back to the bit/Byte, reads the last value written to the bit/Byte instead of the logic level at the pin/pins.

Pins of a single port can be individually configured as inputs and outputs by writing a 'one' to each pin that is to be an input. Each time an instruction uses a complete port as destination, the SW has to make sure that 'ones' are written to those bits that correspond to the pins used as inputs. An external input signal to a port pin needs not to be synchronized to the internal clock.

All the port latches have 'one's written to them by the reset function. If a 'zero' is subsequently written to a port latch, it can be reconfigured as an input by writing a 'one' to it.

The instructions that perform a read of, operation on, and write to a port's bit/Bytes are INC, DEC, CPL, JBC, SETB, CLR, MOV P.X, CJNE, DJNZ, ANL, ORL, and XRL. The data read by these instructions is the last value that was written to the port, without regard to the levels being applied at the pins. This insures that bits written to a 'one' (for use as inputs) are not inadvertently cleared.

Port 0 has an open-drain output. Writing a 'one' to the bit latch leaves the output transistor off, so the pin floats.

In that condition it can be used as a high-impedance input. Port 0 is considered 'true bidirectional', because when configured as an input it floats.

Ports 1, 3 and 4 have 'quasi-bidirectional' output drivers.

In ports P1, P3 and P4 the output drivers provide source current for one system clock period if, and only if, software updates the bit in the output latch from a 'zero' to an 'one'. Sourcing current only on 'zero to one' transition prevents a pin, programmed as an input,
from sourcing current into the external device that is driving the input pin.

It is not allowed to drive Port 3.6 to logic low level while reset state changes from the active to inactive state otherwise a special test mode is activated.

Secondary functions can be selected individually and independently for the pins of Port 1 and 3. Further information on Port 1's secondary functions is given in Section 2.9. on page 59. P3 generates the secondary control signals automatically as long as the pin corresponding to the appropriate signal is programmed as an input, i. e. if the corresponding bit latch in the P3 special function register contains a 'one'.

Table 2-9: Ports and I/O-pins

| Port | I/O | Default Function | Alternate Function 2 |  | Alternate Function 3 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Toggle | Function | Toggle | Function |
|  |  |  | Control bit | Function | Control bit | Function |
| P0(0...7) | I/O | Port pin | - | - | - | - |
| P1(0) | I/O | Port pin | PWME(E0) | PWM 8 bit channel 0 | - | - |
| P1(1) | I/O | Port pin | PWME(E1) | PWM 8 bit channel 1 | - | - |
| P1(2) | I/O | Port pin | PWME(E2) | PWM 8 bit channel 2 | - | - |
| P1(3) | I/O | Port pin | PWME(E3) | PWM 8 bit channel 3 | - | - |
| P1(4) | I/O | Port pin | PWME(E4) | PWM 8 bit channel 4 | - | - |
| P1(5) | I/O | Port pin | PWME(E5) | PWM 8 bit channel 5 | - | - |
| P1(6) | I/O | Port pin | PWME(E6) | PWM 14 bit channel 0 | - | - |
| P1(7) | I/O | Port pin | PWME(E7) | PWM 14 bit channel 1 | - | - |
| P2(0) | I | Port pin | CADCCO(ADO) | ADC channel 0 | - | - |
| P2(1) | I | Port pin | CADCCO(AD1) | ADC channel 1 | - | - |
| P2(2) | I | Port pin | CADCCO(AD2) | ADC channel 2 | - | - |
| P2(3) | I | Port pin | CADCCO(AD3) | ADC channel 3 | - | - |
| P3(0) | I/O | Port pin | CSCR0(O_E_P3_0) | ODD/Even indicator | - | - |
| P3(1) | I/O | Port pin | Port input mode | External extra Int 0 | Port output mode | TXD |
| P3(2) | I/O | Port pin | Port input mode | External interrupt 0 | - | - |
| P3(3) | I/O | Port pin | Port input mode | External interrupt 1 | - | - |
| P3(4) | I/O | Port pin | Port input mode | Timer/counter 0 input | - | - |
| P3(5) | I/O | Port pin | Port input mode | Timer/counter 1 input | - | - |
| P3(6) | I/O | Port pin | - | - | - | - |
| P3(7) | I/O | Port pin | Port input mode | External extra Int 1 | Port input mode | RXD |
| $\mathrm{P} 4(0)^{1)}$ | 1/O | A17 | CSCR1( $\overline{\text { A17_P4_0) }}$ | Port pin | - | - |
| ${ }^{1)}$ Not available in PSDIP52-2 |  |  |  |  |  |  |

Table 2-9: Ports and I/O-pins, continued

| Port | I/O | Default Function | Alternate Function 2 |  | Alternate Function 3 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Toggle | Function | Toggle | Function |
|  |  |  | Control bit | Function | Control bit | Function |
| $\mathrm{P} 4(1)^{1)}$ | I/O | A18 | CSCR1( $\overline{\text { A18_P4_1) }}$ | Port pin | - | - |
| P4(2) | I/O | Port pin | CSCR1(ENARW) | Read signal | - | - |
| P4(3) | I/O | Port pin | CSCR1(ENARW) | Write signal | - | - |
| $\mathrm{P} 4(4)^{1)}$ | I/O | A19 | CSCR1( $\overline{\text { 119_P4_4) }}$ | Port pin | - | - |
| P4(7) | I/O | Port/VS in | CSCRO(VS_OE, P4_7_ALT) | VS output | $\begin{aligned} & \text { CSCR0 } \\ & \text { (VS_OE, } \\ & \text { P4_7_ALT) } \end{aligned}$ | OddEven output |
| ${ }^{1)}$ Not available in PSDIP52-2 |  |  |  |  |  |  |

### 2.2.9.1. Read Modify Write Feature

'Read-modify-write' commands are instructions that read a value, possibly change it, and then rewrite it to the latch. The read-modify-write instructions are listed in Table 2-10.

If the destination operand is a port or a port bit, these instructions read the information stored in the latch rather than the status of the pin. The read-modify-write instructions are directed to the latch rather than to the pin in order to avoid a possible misinterpretation of the
voltage level at the pin. For example, a port bit might be used to drive the base of a transistor. If a 'one' is written to the bit, the transistor is turned on.

If the CPU would read back the status of the same port bit from the pin rather than the latch, it would read the base-emitter voltage of the transistor and interpret it as a logic ' 0 '. Reading the latch rather than the pin will return the correct value of logic ' 1 '.

Table 2-10: Read-modify-write instructions

| Mnemonic | Description | Example |
| :--- | :--- | :--- |
| ANL | Logical AND | ANL P1, A |
| ORL | Logical OR | ORL P2, A |
| XRL | Logical EX - OR | XRL P3, A |
| JBC | Jump if bit =1 and clear bit | JBC P1.1, LABEL |
| CPL | Complement bit | CPL P3.0 |
| INC | Increment | DEC P1 |
| DEC | Decrement | DJNZ P3, LABEL |
| DJNZ | Decrement and jump if not zero | MOV P1.7, C |
| MOV PX.Y, $C^{1) ~}$ | Move carry bit to bit Y of Port X | CLR P2.6 |
| CLR PX.Y |  |  |
| SET PX. ${ }^{11)}$ | Clear bit Y of Port X | SET P3.5 |
| 1) The instruction reads the port Byte (all 8 bits), modifies the addressed bit, then writes the new Byte back to the |  |  |
| latch. | Set bit Y of Port X |  |

### 2.2.10. Instruction Set

The assembly language uses the same instruction set and the same instruction opcodes as the 8051 microcomputer family.

### 2.2.10.1. Notes on Data Addressing Modes

Rn - Working register R0-R7.
direct - 128 internal RAM-locations, any I/Oport, control or status register.
$@ \mathrm{Ri}$ - Indirect internal RAM-location addressed by register R0 or R1.
\#data $\quad$ - 8-bit constant included in instruction.
\#data 16 - 16-bit constant included as Bytes 2 \& 3 of instruction.
bit - 128 software flags, any I/O-pin, control or status bit in special function registers.

Operations working on external data memory (MOVX ...) are used to access the extended internal data RAM (XRAM).

### 2.2.10.2. Notes on Program Addressing Modes

addr 16 - Destination address for LCALL \& LJMP may be anywhere within the program memory address space.
addr 11 - Destination address for ACALL \& AJMP will be within the same 2 KByte of the following instruction.
rel - SJMP and all conditional jumps include an 8-bit offset Byte. Range is $+127 /-128$ Bytes relative to first Byte of the following instruction.

### 2.2.10.3. Instruction Set Description

Table 2-11: Arithmetic operations

| Mnemonic | Description | Byte |  |
| :--- | :--- | :--- | :--- |
| ADD | A, Rn | Add register to Accumulator | 1 |
| ADD | A, direct | Add direct Byte to Accumulator | 2 |
| ADD | A, @Ri | Add indirect RAM to Accumulator | 1 |
| ADD | A, \#data | Add immediate data to Accumulator | 2 |
| ADDC | A, Rn | Add register to Accumulator with Carry flag | 1 |
| ADDC | A, direct | Add direct Byte to A with Carry flag | 2 |
| ADDC | A, @Ri | Add indirect RAM to A with Carry flag | 1 |
| ADDC | A, \#data | Add immediate data to A with Carry flag | 2 |
| SUBB | A, Rn | Subtract register from A with Borrow | 1 |
| SUBB | A, direct | Subtract direct Byte from A with Borrow | 2 |
| SUBB | A, @Ri | Subtract indirect RAM from A with Borrow | 1 |
| SUBB | A, \#data | Subtract immediate data from A with Borrow | 2 |
| INC | A | Increment Accumulator | 1 |
| INC | Rn | Increment register | 1 |
| INC | direct | Increment direct Byte | 2 |
| INC | @Ri | Increment indirect RAM | 1 |
| DEC | A | Decrement Accumulator | 1 |
| DEC | Rn | Decrement register | 1 |
| DEC | direct | Decrement direct Byte | 2 |
| DEC | @ Ri | Decrement indirect RAM | 1 |
| INC | DPTR | Increment Data Pointer | 1 |
| MUL | AB | Multiply A \& B | 1 |
| DIV | AB | Decimal Adjust Accumulator |  |
| DA | A |  | 1 |
|  |  |  | 1 |

Table 2-12: Logical operations

| Mnemonic |  | Description <br> AND register to Accumulator |  |
| :---: | :---: | :---: | :---: |
| ANL | A, Rn |  |  |
| ANL | A, direct | AND direct Byte to Accumulator | 2 |
| ANL | A, @ Ri | AND indirect RAM to Accumulator | 1 |
| ANL | A, \#data | AND immediate data to Accumulator | 2 |
| ANL | direct, A | AND Accumulator to direct Byte | 2 |
| ANL | direct, \#data | AND immediate data to direct Byte | 3 |
| ORL | A, Rn | OR register to Accumulator | 1 |
| ORL | A, direct | OR direct Byte to Accumulator | 2 |
| ORL | A, @ Ri | OR indirect RAM to Accumulator | 1 |
| ORL | A, \#data | OR immediate data to Accumulator | 2 |
| ORL | direct, A | OR Accumulator to direct Byte | 2 |
| ORL | direct, \#data | OR immediate data to direct Byte | 3 |
| XRL | A, Rn | Exclusive-OR register to Accumulator | 1 |
| XRL | A, direct | Exclusive-OR direct Byte to Accumulator | 2 |
| XRL | A, @ Ri | Exclusive-OR indirect RAM to Accumulator | 1 |
| XRL | A, \#data | Exclusive-OR immediate data to Accumulator | 2 |
| XRL | direct, A | Exclusive-OR Accumulator to direct Byte | 2 |
| XRL | direct, \#data | Exclusive-OR immediate data to direct | 3 |
| CLR | A | Clear Accumulator | 1 |
| CPL | A | Complement Accumulator | 1 |
| RL | A | Rotate Accumulator left | 1 |
| RLC | A | Rotate A left through the Carry flag | 1 |
| RR | A | Rotate Accumulator right | 1 |
| RRC | A | Rotate A right through Carry flag | 1 |
| SWAP | A | Swap nibbles within the Accumulator | 1 |

Table 2-13: Boolean variable manipulation

| Mnemonic | Description | Byte |  |
| :--- | :--- | :--- | :--- |
| CLR | C | Clear Carry flag | 1 |
| CLR | bit | Clear direct bit | 2 |
| SETB | C | Set Carry flag | 1 |
| SETB | bit | Set direct bit | 2 |
| CPL | C | Complement Carry flag | 1 |
| CPL | bit | Complement direct bit | 2 |
| ANL | C, bit | AND direct bit to Carry flag | 2 |
| ANL | C, /bit | AND complement of direct bit to Carry | 2 |
| ORL | C, bit | OR direct bit to Carry flag | 2 |
| ORL | C, /bit | OR complement of direct bit to Carry | 2 |
| MOV | C, bit | Move direct bit to Carry flag | 2 |
| MOV | bit, C | Move Carry flag to direct bit | 2 |

Table 2-14: Data transfer operations

| Mnemonic |  | Description <br> Move register to Accumulator |  |
| :---: | :---: | :---: | :---: |
| MOV | A, Rn |  |  |
| MOV | A, direct | Move direct Byte to Accumulator | 2 |
| MOV | A, @ Ri | Move indirect RAM to Accumulator | 1 |
| MOV | A, \#data | Move immediate data to Accumulator | 2 |
| MOV | Rn, A | Move Accumulator to register | 1 |
| MOV | Rn, direct | Move direct Byte to register | 2 |
| MOV | Rn, \#data | Move immediate data to register | 2 |
| MOV | direct, A | Move Accumulator to direct Byte | 2 |
| MOV | direct, Rn | Move register to direct Byte | 2 |
| MOV | direct, direct | Move direct Byte to direct | 3 |
| MOV | direct, @ Ri | Move indirect RAM to direct Byte | 2 |
| MOV | direct, \#data | Move immediate data to direct Byte | 3 |
| MOV | @Ri, A | Move Accumulator to indirect RAM | 1 |
| MOV | @ Ri, direct | Move direct Byte to indirect RAM | 2 |
| MOV | @ Ri, \#data | Move immediate data to indirect RAM | 2 |
| MOV | DPTR, \#data 16 | Load Data Pointer with a 16-bit constant | 3 |
| MOVC | A@ A + DPTR | Move Code Byte relative to DPTR to Accumulator | 1 |
| MOVC | A@A+PC | Move Code Byte relative to PC to Accumulator | 1 |
| MOVX | A, @ Ri | Move External RAM (8-bit addr) to Accumulator ${ }^{1}{ }^{\text {( }}$ | 1 |
| MOVX | A, @DPTR | Move External RAM (16-bit addr) to Accumulator | 1 |
| MOVX | @Ri, A | Move A to External RAM (8-bit addr) ${ }^{1)}$ | 1 |
| MOVX | @DPTR, A | Move A to External RAM (16-bit addr) | 1 |
| PUSH | direct | Push direct Byte onto stack | 2 |
| POP | direct | Pop direct Byte from stack | 2 |
| XCH | A, Rn | Exchange register with Accumulator | 1 |
| XCH | A, direct | Exchange direct Byte with Accumulator | 2 |
| XCH | A, @ Ri | Exchange indirect RAM with Accumulator | 1 |
| XCHD | A, @ Ri | Exchange low-order digital indirect RAM with $A^{1)}$ | 1 |
| 1) not applicable |  |  |  |

Table 2-15: Program and machine control operations

| Mnemonic | Description | Byte |  |
| :--- | :--- | :--- | :--- |
| ACALL | addr 11 | Absolute subroutine call | 2 |
| LCALL | addr 16 | Long subroutine call | 3 |
| RET | Return from subroutine | 1 |  |
| RETI | Return from interrupt | 1 |  |
| AJMP | addr 11 | Absolute jump | 2 |
| LJMP | addr 16 | Long jump | 3 |
| SJMP | rel | Short jump (relative addr | 2 |
| JMP | @A + DPTR | Jump indirect relative to the DPTR | 2 |
| JZ | rel | Jump if Accumulator is zero | 2 |
| JNZ | rel | Jump if Accumulator is not zero | 2 |
| JC | rel | Jump if Carry flag is set | 2 |
| JNC | rel | Jump if Carry flag is not set | 2 |
| JB | bit, rel | Jump if direct bit set | 3 |
| JNB | bit, rel | Jump if direct bit not set | 3 |
| JBC | bit, rel | Jump if direct bit is set and clear bit | 3 |
| CJNE | A, direct rel | Compare direct to A and jump if not equal | 3 |
| CJNE | A, \#data, rel | Compare immediate to A and jump if not equal | 3 |
| CJNE | Rn, \#data, rel | Compare immediate to register and jump if not equal | 3 |
| DJNZ | direct, rel | Ri, \#data, rel | Compare immediate to indirect and jump if not equal |

2.2.10.4. Instruction Opcodes in Hexadecimal Order
Table 2-16: Instruction opcodes in hexadecimal order

| Hex Code | Number of Bytes | Mnemonic | Operands |

### 2.3. Interrupt

### 2.3.1. Interrupt System

External events and the real-time operation of on-chip peripherals require CPU service asynchronous to the execution of any particular section of code. To couple the asynchronous activities of these functions to normal program execution, a sophisticated multiplesource, four-priority-level, nested interrupt system is provided.

### 2.3.2. Interrupt Sources

The TVT microcontroller core is capable of handling up to 24 interrupt sources. In Type<Default If Font> 17 interrupts are implemented. The rest are reserved for future use. The microcontroller acknowledges interrupt requests from these 17 sources. Two external sources via the INT0 and INT1 pins and two additional external interrupts INTX0 (P3.1) and INTX1 (P3.7) are provided. On-chip peripherals also use interrupts: one from each of the two internal counters, one from the analog digital converter and one from UART. In addition there are four Data Acquisition related interrupts, two display related interrupts and one interrupt indicat-
ing change of channel, two interrupts are generated by the WDT and PWM overflow in timer mode.

Timer 0 and Timer 1 overflows are indicated by TCON(TF0) and TCON.(TF1). Interrupts are generated following a rollover in their respective registers (except in Mode 3 when $\operatorname{TCON}(\mathrm{THO})$ controls the Timer 1 interrupt).

The external interrupts $\overline{\mathrm{INTO}}$ and $\overline{\mathrm{INT}}$ are either level or edge triggered depending on bits in TCON and IRCON. Other external interrupts are level sensitive and active high. Any edge triggering will need to be taken care of by individual peripherals.

INTX0 and INTX1 can be programed to be either negative or positive edge triggered.

The analog digital converter interrupt is generated on completion of the analog digital conversion.

### 2.3.3. Overview

A simple overview of the interrupt handling is shown in Fig. 2-4.

Fig. 2-4: Interrupt Handling Overview

### 2.3.4. Enabling Interrupts

Interrupts are enabled through a set of Interrupt Enable registers (IEN0, IEN1, IEN2, IEN3).

Bits 0 to 5 of the Interrupt Enable registers each individually enable/disable a particular interrupt source. Overall control is provided by bit 7 of IENO (EAL). When EAL is set to ' 0 ', all interrupts are disabled: when EAL is set to ' 1 ', interrupts are individually enabled or disabled through the other bits of the Interrupt Enable Registers. EAL may however be overridden by the DISINT signal which provides a global disable signal for the interrupt controller.

### 2.3.4.1. Interrupt Enable Registers (IEN0, IEN1, IEN2, IEN3)

The microcontroller has 4 Interrupt Enable registers. For each bit in these registers, a ' 1 ' enables the corresponding interrupt and a ' 0 ' disables it.See Table 217.

### 2.3.5. Interrupt Source Registers

All the interrupts except for timer0, timer1, external interrupt0, external interrupt1, external extra interrupt0 and external extra interrupt1 are generated by the respective blocks and are positive edge triggered. They are sampled in a central interrupt source register, the corresponding bit must be cleared by the software after entering the interrupt service routine.

Table 2-17: Interrupt enable registers

| Register Name | Bit Name |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

### 2.3.6. Interrupt Priority

For the purposes of assigning priority, the 24 possible interrupt sources are divided into groups determined by their bit position in the Interrupt Enable Registers. Their respective requests are scanned in the order as shown in Table 2-19.

Each interrupt group may individually be assigned to one of four priority levels by writing to the IP0 and IP1 Interrupt Priority registers at the corresponding bit position.

An interrupt service routine may only be interrupted by an interrupt of higher priority level. If two interrupts of
different priority occur at the same time, the higher level interrupt will be serviced first. An interrupt cannot be interrupted by another interrupt of the same or a lower priority level.

If two interrupts of the same priority level occur simultaneously, the order in which the interrupts are serviced is determined by the scan order shown below.

Table 2-19: Interrupt priority

| Interrupt Group | Interrupts in Group High Priority |  |  |  | Group Priority |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | External Interrupt 0 | External Interrupt 6 ${ }^{1 \text { }}$ | External Interrupt 12 ${ }^{1 \text { ) }}$ | External Interrupt 18 ${ }^{1 \text { ) }}$ | High Priority |

| External Interrupt 18 | IEN3 | EX18 | 00A3 | Reserved |
| External Interrupt 19 | IEN3 | EX19 | 00AB | Reserved |
| External Interrupt 20 | IEN3 | EX20 | 00B3 | Reserved |
| External Interrupt 21 | IEN3 | EX21 | 00BB | Reserved |
| Line 24 Start | IEN3 | E24 | 00C3 | L24(CISR0.7) |
| A to D Wake up | IEN3 | EADW | 00CB | ADW(CISR1.6) |

### 2.3.8. Interrupt and Memory Extension

When an interrupt occurs, the Memory Management Unit (MMU) carries out the following sequence of actions:

1. The MEX1 register bits are made available on SDATAO[7:0].
2. The MEXSP register bits are made available on SADD[7:0].
3. The Stack read and write signals are set for a write operation.
4. A write is performed to External memory.
5. The MEXSP Stack Pointer is incremented.
6. The Interrupt Bank bits IB19-IB16 (MEX2.3-

MEX2.0) are copied to both the NB19 - NB16 and the CB19-CB16 bits in the MEX1.

Then on return from the interrupt service routine:

1. The MEXSP Stack Pointer is decremented.
2. The MEXSP register bits are made available on SADD [7:0].
3. The Stack read and write signals are set for a read operation.
4. A read is performed on External memory.
5. SDATAI [7:0] is copied to the MEX1 register.

This action allows the user to place interrupt service routines on specific banks.

### 2.3.9. Interrupt Handling

External interrupt0, external interrupt1, timer0, timer1 and UART interrupt are handled as follows:

- Interrupts are sampled at Step5 Phase2 in each machine cycle and the sampled interrupt information is polled during the following machine cycle. If an interrupt is active when it is sampled, it will be serviced provided:
- An interrupt of an equal or higher priority is not currently being serviced.
- The polling cycle is not the final cycle of a multicycle instruction, and
- The current instruction is neither a RETI nor a write either to one of Interrupt Enable registers or to one of the Interrupt Priority registers.

Note: Active interrupts are only stored for one machine cycle. As a result, if an interrupt was active for one or more polling cycles but not serviced for one of the reasons given above, the interrupt will not be processed.

For all other interrupts the interrupt request is stored as an interrupt flag in registers CISR0 and CISR1. These request bits must be cleared by user software while servicing the interrupt. The interrupts always get serviced once raised regardless of the number of polling cycles required to service them.

### 2.3.10. Interrupt Latency

The response time in a single interrupt system is between 3 and 9 machine cycles.

### 2.3.11. Interrupt Flag Clear

In case of external interrupt0 and external interrupt1, if the external interrupts are edge triggered, the interrupt flag is cleared when entering into the interrupt service routine but if they are level triggered, the flag follows the signal applied to the port pin. Timer/counter flags are cleared when entering into the interrupt service routine. All other interrupt flags, including IEXO and IEX1 are not cleared by hardware. They must be cleared by software.

### 2.3.12. Interrupt Return

For the proper operation of the interrupt controller it is necessary that all interrupt routines end with a RETI instruction.

### 2.3.13. Interrupt Nesting

The process whereby a higher-level interrupt request interrupts a lower-level interrupt service routine is called "nesting".

In this case the address of the next instruction in the lower-priority service routine is pushed onto the stack, the stack pointer is incremented by two and the microcontroller will continue the SW program execution from the memory location of the first instruction of the higher-level service routine. The last instruction of the higher-priority interrupt service program must be a RETI-instruction. This instruction clears the higher 'pri-ority-level-active' flip-flop. The RETI command also makes that the microcontroller executes the next instruction of the lower-level interrupt service routine. Since the lower 'priority-level-active' flip-flop has remained set, higher priority interrupts are re-enabled while further lower-priority interrupts remain disabled.

### 2.3.14. External Interrupts

The external interrupt request inputs (INT0 and $\overline{\mathrm{NT} 1}$ ) can be programmed for either transition- activated or level-activated operation. Control of the external interrupts is provided in the TCON register.

Table 2-22: Related register

| Register Name | Bit Name |  |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :---: |
|  | $\mathbf{7}$ | $\mathbf{6}$ | $\mathbf{5}$ | $\mathbf{4}$ | $\mathbf{3}$ | $\mathbf{2}$ | 1 |  |  |
| TCON | TF1 | TR1 | TF0 | TR0 | IE1 | IT1 | IE0 |  |  |
| See Section 3. on page 110 for detailed register description. |  |  |  |  |  |  |  |  |  |

### 2.3.15. Extension of Standard 8051 Interrupt Logic

For more flexibility, SDA 55xx family provides a new feature for the status detection of external extra interrupts EXO and EX1 in an edge-triggered mode. Now there is the possibility to trigger an interrupt on the falling and/or rising edge at the dedicated Port 3 Pin. In order to use this feature respective IT0 and IT1 bits in the TCON register must be set to activate edge triggering mode. Table 2-23 shows combination for Interrupt0, however description is also true for interrupt1.

Table 2-23: Interrupt combinations

| ITO | EXOR | EXOF | Interrupt |
| :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | Disabled |
| 0 | 0 | 1 | Low level |
| 0 | 1 | 0 | High level |
| 0 | 1 | 1 | Disabled |
| 1 | 0 | 0 | Disabled |
| 1 | 0 | 1 | Negative edge triggered |
| 1 | 1 | 0 | Positive edge triggered |
| 1 | 1 | 1 | Positive and negative edge <br> triggered |

Table 2-24: Related register

| Register Name | Bit Name |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| IRCON | EXX1R | EXX1F | EXXOR | EXXOF | EX1R | EX1F | EXOR | EXOF |
| See Section 3. on page 110 for detailed register description. |  |  |  |  |  |  |  |  |

Note: If both EXXxR and EXXxF are set then both rising and falling edges would generate an interrupt. Minimum delay between the interrupts should be ensured by the software.
If both the EXXxR and EXXxF are reset to 0 , interrupt is disabled.

External extra interrupts EX1 and EX2 are edge triggered interrupts only.

### 2.3.16. Interrupt Task Function

The microcontroller records the active priority level(s) by setting internal flip-flop(s). Each interrupt level has its own flip-flop. The flip-flop corresponding to the interrupt level being serviced is reset when the microcontroller executes a RETI-instruction.

The sequence of events for an interrupt is:

- A source provokes an interrupt by setting its associated interrupt request bit to let the microcontroller know an interrupt condition has occurred.
- The interrupt request is conditioned by bits in the interrupt enable and interrupt priority registers.
- The microcontroller acknowledges the interrupt by setting one of the four internal 'priority-level active' flip-flops and performing a hardware subroutine call. This call pushes the PC (but not the PSW) onto the stack and, for some sources, clears the interrupt request flag.
- The service program is executed.
- Control is returned to the main program when the RETI-instruction is executed. The RETI- instruction also clears one of the internal 'priority-level active' flip-flops.

The interrupt request flags IE0, IE1, TF0 and TF1 are cleared when the microcontroller transfers control to the first instruction of the interrupt service program.

### 2.3.17. Power Saving Modes

The controller provides four modes in which power consumption can be significantly reduced.

- Idle mode: The CPU is gated off from the oscillator. All peripherals except WDT (in watch dog mode) are still provided with the clock and are able to work.
- Power-down mode: Operation of the controller is turned off. This mode is used to save the contents of internal RAM with a very low standby current.
- Power-save mode: In this mode display generator, Slicer_acq_sync, VADC, CADC, ADC_wakeup, PWM, CRT, WDT, DAC, PLL, and Display (display, pixel clock and D sync) can be turned off.
- Slow-down mode: In this mode the system frequency is reduced by one fourth.

All modes are entered by software. Special function register is used to enter one of these modes.

### 2.3.18. Power-Save Mode Registers.

The Table 3-25 lists the respective registers which control or reflect the Power-Save Modes. A description is given below.

Table 2-25: Related registers

| Register Name | Bit Name |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| PSAVE |  |  |  | CADC | WAKUP | SLI_ACQ | DISP | PERI |
| PSAVEX <br> bit addressable |  |  |  |  |  | Clk_src | PLL_res | PLLS |
| PCON | SMOD | PDS | IDLS | SD | GF1 | GF0 | PDE | IDLE |

### 2.3.19. Idle Mode

Entering the idle mode is done by two consecutive instructions immediately following each other. The first instruction has to set bit IDLE (PCON.0) and must not set bit IDLS (PCON.5). The following instruction has to set bit IDLS (PCON.5) and must not set bit IDLE (PCON.0). Bits IDLE and IDLS will automatically be cleared after having been set. This double-instruction sequence is implemented to minimize the chance of unintentionally entering the idle mode. The following instruction sequence may serve as an example:

ORL PCON, \#00000001B ;Set bit IDLE, bit IDLS must not be set.

ORL PCON,\#00100000 ${ }_{B}$;Set bit IDLS, bit IDLE must not be set.

The instruction that sets bit IDLS is the last instruction executed before going into idle mode.

Concurrent setting of the enable and the start bits does not set the device into the respective power saving mode.

The idle mode can be terminated by activation of any enabled interrupt (or a hardware reset). The CPUoperation is resumed, the interrupt will be serviced and the next instruction to be executed after RETI-instruction will be the one following the instruction that set the bit IDLS. The port state and the contents of SFRs are held during idle mode.

Entering Idle mode disables, VADC, Acquisition, Slicer, Display, CADC and DAC. However note that CADC Wake up unit is still operational. Leaving idle mode brings them to their original power save configuration (See Section 2.3.21.).

### 2.3.20. Power-down Mode

Entering the power-down mode is done by two consecutive instructions immediately following each other. The first instruction has to set bit PDE (PCON.1) and must not set bit PDS (PCON.6). The following instruction has to set bit PDS (PCON.6) and must not set bit PDE (PCON.1). Bits PDE and PDS will automatically be cleared after having been set.

This double-instruction sequence is implemented to minimize the chance of unintentionally entering the power-down mode. The following instruction sequence may serve as an example:

[^0]The instruction that sets bit PDS is the last instruction executed before going into power-down mode.

Concurrent setting of the enable and the start bits does not set the device into the respective power saving mode.

If idle mode and power-down mode are invoked simultaneously, the power-down mode takes precedence.

The only exit from power-down mode is a hardware reset. The reset will redefine all SFRs, but will not change the contents of internal RAM.

### 2.3.21. Power-save Mode

Bits in the PSAVE register individually enable and disable different major blocks in the IC. Note that power-save mode is independent of Idle and power-down mode. In case of idle mode, blocks which are in power save mode remain in power-save mode.

Entering the power down mode with power-save mode is possible. However leaving the power down mode (reset) would initialize all the power save register bits.

Note that power-save mode has a higher priority then idle mode.

### 2.3.22. Slow-Down Mode

SD bit in PCON register when sets divides the system frequency by 4. During the normal operation TVT Pro is running with 33.33 MHz and in SD mode TVT Pro runs with 8.33 MHz . In slow-down mode the slicer, Acquisition and display are disabled regardless of power-save mode or other modes. All the pending request to the bus by these blocks are masked off. Leaving slow-down mode restores the original status of these blocks.

### 2.4. Reset

### 2.4.1. Reset Sources

TVText Pro can be reset by two sources:

1. Externally by pulling down the reset pin RST.
2. Internally by Watch dog timer reset.

Please note that both reset signals use the same signal path however a Watchdog reset does not reset the clock PLL.

### 2.4.2. Reset Filtering

The RST pin uses a filter with a delay element, which suppresses jitter and spikes in the range of 25 ns to 75 ns .

### 2.4.3. Reset Duration

With the active edge of the $\overline{\text { RST }}$ an internal signal resets all the flip flops asynchronously. The internal signal is released synchronously to the internal clock when it is stable as described below.

The minimum duration of the external reset signal depends on the time required for the SDA55xx internal crystal oscillator to reach it's full amplitude swing and is dependent on the crystal used.

During the period when the RST pin is held low, the PLL is initialized and it gets locked. The high going reset pulse then initiates a sequence which requires one machine cycle ( 12 clock cycles) to initialize the microcontroller and all other registers and peripherals.

### 2.4.4. Registers

Upon reset, all the registers are initialized to the values as defined in Section 3. on page 110.

### 2.4.5. Functional Blocks

After reset all the functional blocks will be in a defined known state. Microcontroller, acquisition and display will not have any pending bus requests after reset.

### 2.4.6. RAMs

The HW reset and its related logic does not initialize any RAMs.

### 2.4.7. Analog Blocks

After the power up reset the DAC will output a fixed value. ADC and the ADC wake up unit do not generate any interrupts till the 12 cycle long reset sequence is completed.

### 2.4.8. Microcontroller

After the reset sequence the program counter initializes to $0000_{\mathrm{H}}$ and starts execution from this location in the ROM. Location 0000 H to 0002 H are reserved for the a jump instruction to the initialization routine.

### 2.4.9. Ports

With the reset all ports are set in to the input mode. Exception are Port 4.0, 4.1 and 4.4, which by default after reset are assigned as data outputs for the address lines A17, A18, A19.

### 2.4.10. Initialization Phase

### 2.4.10.1. Acquisition

After the reset the Acquisition will not generate any memory accesses to the RAM, due to the fact that the Acq_start bit is initialized to ' 0 '. The microcontroller should then initialize the VBI buffer and set the ACQ_start bit (by software). The Acquisition will not generate any accesses to the RAM if the H/V synchronization is not achieved.

### 2.4.10.2. Display

After reset the DACs will output a fix value as defined by En_DGOut, which is reset to ' 0 '. COR_BL is reset to a level indicating COR $=$ ' 0 ' and BLank $=$ ' 1 '.

The microcontroller should initialize the display memory and set the En_DGOut (OCD_Ctrl) bit.

### 2.5. Memory Organization

The microcontroller has separate Program and Data memory spaces. Memory spaces can be further classified as:

- Program Memory
- Internal Data Memory of 256 Bytes (CPU RAM)
- Internal Extended Data Memory (XRAM)

A 16-bit program counter and a dedicated banking logic provide the microcontroller with 1 MByte addressing capability (with the ROM-less versions, up to 20 address lines are available).

The program counter allows the user to execute calls and branches to any location within the program memory space.

Data pointers allow to move data to and from Extended Data RAM.

There are no instructions that permit program execution to move from the program memory space to any data memory space.

### 2.5.1. Program Memory

Program ROM consists of 128 KByte on chip ROM for mask programmed versions.

Locations ' 0000 ' through ' 0002 ' are reserved for the Long Jump instruction to the initialization routine. Following reset, the CPU always begins execution at location '0000'. Locations '0003' through '00CB' are can be reserved for the interrupt-request service routines if required.

Table 2-26: Program memory

| Interrupt Source | Vector Address |
| :--- | :--- |
| External Interrupt 0 | 0003 |
| Timer 0 Overflow | 000 B |
| External Interrupt 1 | 0013 |
| Timer 1 Overflow | 001 B |
| UART | 0023 |
| ADC | 002 B |
| Reserved | 0033 |
| ExternalX Interrupt 0 | 003 B |
| Watchdog timer | 0043 |
| External X Interrupt 1 | 004 B |
| Acquisition V Sync | 0053 |
| Display V sync | 005 B |
| Reserved | 0063 |
| Reserved | 006 B |
| Reserved | 0073 |
| Reserved | 007 B |
| PWM in timer mode | 0083 |
| Channel Change | 008 B |
| Acq H Sync | 0093 |
| Display H Sync | 009 B |
| Reserved | 00 AB |
| Reserved | 00 AB |
| Reserved | 00 B 3 |
| Reserved | 00 BB |
| Line 24 start | 00 C 3 |
| A to D wake up | 00 CB |
|  |  |
|  |  |

### 2.5.2. Internal Data RAM

Internal Data RAM is split into CPU RAM and XRAM

### 2.5.2.1. CPU RAM

### 2.5.2.1.1. Address Space

The internal CPU RAM (IRAM) occupies address space $00_{H}$ to $\mathrm{FF}_{\mathrm{H}}$. This space is further split into two regions.

The lower 128 Bytes $\left(00_{H}-7 \mathrm{~F}_{\mathrm{H}}\right)$ can be accessed using both direct and indirect register addressing method.

The upper half of 128 Bytes $\left(80_{H}-F_{H}\right)$ can be accessed using the "register indirect method" only. Register direct method for this address space $\left(80_{H^{-}}\right.$ $\mathrm{FF}_{\mathrm{H}}$ ) is reserved for Special function register access.

### 2.5.2.1.2. Registers

Controller registers are also located in IRAM. Four banks of eight registers each occupy locations 0 through 31. Only one of these banks may be enabled at a time through a two-bit field in the PSW.

### 2.5.2.1.3. Bit Addressable RAM Area

128-bit locations of the on-chip RAM are accessible through direct addressing. These bits reside in internal data RAM at Byte locations 32 through 47.

### 2.5.2.1.4. Stack

The stack can be located anywhere in the internal data RAM address space. The stack depth is limited only by the available internal data RAM, thanks to an 8-bit relocatable stack pointer. The stack is used for storing the program counter during subroutine calls and may also be used for passing parameters. Any Byte of internal data RAM or special function registers accessible through direct addressing can be pushed/popped. By default Stack Pointer always has a reset value of $07_{\mathrm{H}}$.

### 2.5.2.2. Extended Data RAM (XRAM)

An additional on-chip RAM space called 'XRAM' extends the capacity of the internal RAM. Up to 16 KiloBytes of XRAM are accessed by MOVX @ DPTR. The XRAM is located in the upper area of the 64 K address space.

1 KByte of the XRAM, called VBI Buffer, is reserved for storing teletext data. 1 KByte of address space can be allocated as CPU work space. Three KiloByte of RAM are reserved as Display RAM. The rest of the RAM can be configured either as Teletext page memory or DRCS (Dynamically Redefinable Character Set) memory.

### 2.5.2.2.1. Extended Data Memory Address Mapping

The XRAM is mapped in the address space from $\mathrm{COOO}_{\mathrm{H}}$ to $\mathrm{FFFF}_{\mathrm{H}} .16$ KBytes are implemented as onchip memory. The address space of the 16 K block is decoded starting from $\mathrm{COOO}_{\mathrm{H}}$. Note that this decoding is done independent of the memory banking. That means that in all 16 available banks of 64 K , the upper 16KByte long address space is reserved for internal Extended data memory. This decoding method has the advantage, that when copying data back and forth between on-chip RAM and off-chip RAM, there is no need to switch the memory banks.

### 2.5.3. Memory Extension

The controller provides four additional address lines A16, A17, A18 and A19. These additional address lines are used to access program and data memory space of up to 1 MByte. The extended memory space is split into 16 banks of 64 KByte each.

A16 is available as a dedicated pin, A17, A18 and A19 however work as alternate function to port pins P4.0, P 4.1 and P4.4 respectively. Refer to register CSCR1 ( $\overline{\mathrm{A} 19}$ _P4_4, $\overline{\mathrm{A} 18} \_\mathrm{P} 4 \_1, \overline{\mathrm{~A} 17}$-P4_0).

The functionality for memory extension is provided by a Memory management Unit (MMU) which includes the four SFR registers MEX1, MEX2, MEX3 and MEXSP.

These registers can be read and written through MOV instructions like any other SFR register. Except for the CB bits in MEX1 - which are read only - and can be written only by the MMU. During normal operation user must not write to the MEXSP register.

### 2.5.3.2. Reset Value

In order to insure proper 8051 functionality all the bits in SFR MEX1, MEX2, MEX3 and MEXSP are initialized to ' 0 '

### 2.5.3.1. Memory Extension Registers

The following registers are present in the Memory management unit.

Table 2-27: Related registers

| Register Name | Bit Name |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| MEX1 | CB[19:16] |  |  |  | NB[19:16] |  |  |  |
| MEX2 | MM | MB[18:16] |  |  |  |  |  |  |
| MEX3 | MB19 | UB3 | UB4 | MX19 | MXM | MX[18:16] |  |  |
| MEXSP | Reserved | SP[6:0] |  |  |  |  |  |  |
| See Section 3. on page 110 for detailed register description. |  |  |  |  |  |  |  |  |

### 2.5.4. Instructions on which Memory Extension would act

The following instruction are used to access the extended memory space:

- LJMP
- MOVC
- MOVX
- LCALL
- ACALL
- RET
- RETI

### 2.5.4.1. Program Memory Banking (LJMP)

After reset the bits for current bank (CB) and next bank (NB) are set to zero. This insures that the microcontroller starts like a standard 8051 microcontroller at address $00000_{H}$.

When a jump to another bank is required, software changes the bits NB16 ... 19 to the appropriate bank address (before LJMP instruction).

When a LJMP is encountered in the code, the MMU copies the NB16 ... 19 (next bank) bits to CB16 ... 19 (current bank). Note that the NB bits are not destroyed.

Bits related the Extended Memory address would appear at the pins A16... A19. These address line have the same timing requirements compared to normal address lines A0...A15 and must be stable at the same time.

Only with LJMP above mentioned action is performed, other jmp instructions have no effect.

CB bits are read only.

### 2.5.4.2. MOVC Handling

There are two modes for MOVC instructions. The mode is selected by MM bit in MEX2.

### 2.5.4.2.1. MOVC with Current Bank

When MM bit = ' 0 ', MOVC will access the current bank. The CB16... CB19 bits would appear as addresses A16 ... A19 during MOVC instructions.

### 2.5.4.2.2. MOVC with Memory Bank

When MM bit ='1', MOVC will access the Memory bank. The MB16 ... MB19 bits would appear as
addresses A16 ... A19 during MOVC instructions. Note: MEX1 is not destroyed.

### 2.5.4.2.3. MOVX Handling

There are two modes for MOVX instructions. The mode is selected by MXM bit in MEX3.

### 2.5.4.2.4. MOVX with Current Bank

When MXM bit = ' 0 ', MOVX will access the current bank. The CB16 ... CB19 bits would appear as addresses A16 ... A19 during MOVX instructions.

### 2.5.4.2.5. MOVX with Data Memory Bank

When MXM bit = '1', MOVX will access the Data memory bank. The MX16 .. MX19 bits would appear as address A16 ... A19 during MOVX instructions.
Note: MEX1 is not destroyed.

### 2.5.4.3. CALLs and Interrupts

### 2.5.4.3.1. Memory Extension Stack

For Interrupts and Calls the Memory extension Stack is required. Stack pointer MEXSP provides the stack depth of up to 128 Bytes. Stack width is 1 Byte. In TVTPro 128 Bytes stack is implemented.

### 2.5.4.4. Stack Full

No indication for stack full is provided. The user is responsible to read MEXSP SFR to determine the status of the MEXSP stack.

### 2.5.4.5. Timing

The MMU outputs the address bits A19 ... A16 at the same time as the normal addresses A15 ... A0.

Stack operation signals, SAdd[6:0], SDatal[7:0], SDataO[7:0], SRd and SWr have the same timing as internal RAM signals.

### 2.5.4.6. Interfacing Extended Memory

The address bits A19, A18, A17, A16 are used to decode extended memory.

### 2.5.4.7. Application Examples

MOVC

Fig. 2-5: PC and DPTR on different banks

### 2.5.4.7.1. Sample Code

Fig. 2-6 shows an assembler program run, performing the following actions:

1. Start at bank 0 at 00000 .
2. Set ISR-page to bank 2.
3. Jump to bank 1 at address 25.
4. Being interrupted to bank 2 ISR.
5. Call a subprogram at bank 2 address 43 .
6. After return read data from bank 2.

### 2.5.4.8. ROM and ROMless Version

The XROM pin determines whether the on-chip or the off-chip ROM is accessed.

If no internal ROM is to be used, then the XROM pin (in ROMless version) should be driven 'low'. The controller then accesses the External ROM only. In the ROM version this pin is internally pulled high, indicating that no external ROM is available.

Fig. 2-6: Program Code

### 2.6. UART

The serial port is full duplex, meaning it can transmit and receive simultaneously. It is also receive-buffered, meaning it can commence reception of a second Byte before a previously received Byte has been read from the receive register (however, if the first Byte still hasn't been read by the time the reception of the second Byte is complete, one of the Bytes will be lost). The serial port receive and transmit registers are both accessed at special function register SBUF. Writing to SBUF loads the transmit register, and reading SBUF accesses a physically separate receive register.

The frequencies and baud rates depend on the internal system clock used by the serial interface.

### 2.6.1. Operation Modes of the UART

The serial port can operate in 4 different modes. In all four modes, transmission is initiated by any instruction that uses SBUF as a destination register. Reception is initiated in mode 0 by the condition $\mathrm{RI}=0$ and REN $=1$. Reception is initiated in the other modes by the incoming start bit if REN $=1$.

### 2.6.1.1. Mode 0

Serial data enter and exit through pin RxD (P3.7). TxD (P3.1) outputs the shift clock.

### 2.6.1.2. Mode 1

10 bits are transmitted (through TxD) or received (through RxD): a start bit (0), 8 data bits (LSB first), and a stop bit (1). On reception, the stop bit goes into bit RB8 in special function register SCON. The baud rate is variable.

### 2.6.1.3. Mode 2

11 bits are transmitted (through TxD) or received (through RxD): a start bit (0), 8 data bits (LSB first), a programmable $9^{\text {th }}$ data bit, and a stop bit (1). On transmission, the $9^{\text {th }}$ data bit (TB8 in SCON) can be assigned the value of 0 or 1 . Or, for example, the parity bit ( P , in the PSW) could be moved into TB8. On reception, the $9^{\text {th }}$ data bit goes into RB8 in the special function register SCON, while the stop bit is ignored. The baud rate is programmable via SFR-Bit SMOD.

### 2.6.1.4. Mode 3

11 bits are transmitted (through TxD) or received (through RxD): a start bit (0), 8 data bits (LSB first), a programmable $9^{\text {th }}$ data bit and a stop bit (1). In fact, mode 3 is the same as mode 2 in all respects except the baud rate. The baud rate in mode 3 is variable.

Table 2-28: Select Mode 0-3 for UART

| SM0 | SM1 | Mode | Description | Baud Rate <br> (CDC = 0) |
| :--- | :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | Shift Reg. | $\mathrm{f}_{\text {system/12 }}$ |
| 0 | 1 | 1 | 8-bit UART | Variable |
| 1 | 0 | 2 | 9-bit UART | $\mathrm{f}_{\text {system/64 }}$ <br> $\mathrm{f}_{\text {system/32 }}$ |
| 1 | 1 | 3 | 9-bit UART | Variable |

### 2.6.2. Multiprocessor Communication

Modes 2 and 3 of the serial interface of the controller have a special provision for multiprocessor communication. In these two modes, 9 data bits are received. The 9th bit goes into register SCON bit RB8. Then comes a stop bit. The port can be programmed such that when the stop bit is received, the serial port interrupt will be activated only if $\mathrm{RB} 8=1$. This feature is enabled by setting bit SM2 in SCON. A way to use this feature in multiprocessor communications is as follows:

When the master microcontroller wants to transmit a block of data to one of the several slaves, it first sends out an address Byte which identifies the target slave. In an address Byte the 9th bit is a ' 1 ', a data Byte is identified with a ' 0 ' as 9 th. bit.

If the SCON register bit SM2 is set to ' 1 ', no slave will be interrupted by a data Byte. An address Byte however, will interrupt all slaves, so that each slave can examine the received Byte and see if it is being addressed. The addressed slave will clear its SM2 bit and prepare to receive the data Bytes that will be transmitted by the master. The slaves that were not addressed leave their SM2 bits set to 1 and go on with the execution of the currently running program and ignore the data Byte transmission on the bus.
the bit SM2 has no effect in mode 0, and in mode 1 the SM2 bit can be used to check the validity of the stop bit. In a mode 1 reception, if $S M 2=1$, the receive interrupt will not be activated unless a valid stop bit is received.

Table 2-29: Related register

| Register Name | Bit Name |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| SCON | SMO | SM1 | SM2 | REN | TB8 | RB8 | Ti | RI |
| See Section 3. on page 110 for detailed register description. |  |  |  |  |  |  |  |  |

### 2.7. General Purpose Timers/Counters

Two independent general purpose 16-bit timer/ counters are integrated for use to measure time intervals, pulse widths, counting events, and causing periodic (repetitive) interrupts. Both can be configured to operate as timer or event counter.

In the 'timer' function, the registers TLx and/or THx ( $x=0,1$ ) are incremented once every machine cycle. As one machine cycle has a length of 12 cycles of the oscillator the counting frequency is fcrystal /12.

In the 'counter' function, the registers TLx and/or THx ( $x=0,1$ ) are incremented in response to a 1-to-0 transition at its corresponding external input pin, T0 or T1. In this function, the external input is sampled during every machine cycle. If the samples taken show a ' 1 ' in one cycle and a ' 0 ' in the next cycle, the count is incremented. The new count value appears in the register during the cycle following the one in which the transition was detected. Since it takes 2 machine cycles (24 oscillator periods) to recognize a '1'-to-'0' transition, the maximum count rate is $1 / 24$ of the oscillator frequency. There are no restrictions on the duty cycle of the external input signal, but to ensure that a given level is sampled at least once before it changes, it should be held for at least one full machine cycle.

### 2.7.1. Timer/Counter 0: Mode Selection

Timer/counter 0 can be configured in one of four operating modes, which are selected by bit-pairs (M1, M0) in TMOD register. See Section 2.7.1. on page 53.

### 2.7.1.1. Mode 0

Putting timer/counter 0 into mode 0 makes it looks like an 8048 timer, which is an 8 -bit counter with a divide-by-32 prescaler. Table $2-32$ shows the mode 0 operation as it applies to timer 0.

In this mode, the timer register is configured as a 13-bit register. As the count rolls over from all ' 1 ' to all ' 0 ', it sets the timer interrupt flag TFO. The timer input is enabled if TRO $=1$ and either GATE $=0$ or $\overline{\mathrm{NTO}}=1$. (Setting GATE $=1$ allows the timer to be controlled by external input INTO, to facilitate pulse width measurements.) TRO is a control bit in the special function register TCON (see Section 2.8.5. on page 57). GATE is contained in register TMOD (see Section 2.7.4. on page 54).

The 13-bit register consists of all 8 bits of THO and the lower 5 bits of TLO. The upper 3 bits of TLO are not valid and should be ignored. Setting the run flag TR0 does not clear the registers.

### 2.7.1.2. Mode 1

Mode 1 is the same as mode 0 , except that all 16 bits of the timer/counter 0 register are being used.

### 2.7.1.3. Mode 2

Mode 2 configures the timer/counter 0 register as an 8 -bit counter TLO with automatic reload. The High Byte THo is used as storage for the Reload value. Overflow from TLO not only sets TF0, but also reloads TLO with the contents of THO, which is preset by software. The reload leaves TH0 unchanged.

### 2.7.1.4. Mode 3

Timer/counter 0 in mode 3 establishes TLO and THO as two separate counters. TLO uses the timer 0 control bits: C/T, GATE, TRO, INTO and TFO. THO is locked into a timer function (counting machine cycles) and takes over the use of TR1 and TF1 from timer 1. Thus, THO now controls the 'timer 1' interrupt.

Mode 3 is provided for applications requiring an extra 8 -bit timer or counter. With timer 0 in mode 3, the microcontroller can operate as if it has three timers/ counters. When timer 0 is in mode 3, timer 1 can be turned on and off by switching it out of and into its own mode 3, or can still be used in any application not requiring an interrupt.

### 2.7.2. Timer/Counter 1: Mode Selection

Timer/counter 1 can also be configured in one of four modes, which are selected by its own bitpairs (M1, MO) in TMOD register.

The serial port receives a pulse each time that timer/ counter 1 overflows. This pulse rate is divided to generate the transmission rate of the serial port.

Modes 0 and 1 are the same as for counter 0 .

### 2.7.2.1. Mode 2

The 'reload' mode is reserved to determine the frequency of the serial clock signal (not implemented).

### 2.7.2.2. Mode 3

When counter 1's mode is reprogrammed to mode 3 (from mode 0,1 or 2 ), it disables the increment counter. This mode is provided as an alternative to using the TR1 bit (in TCON register) to start and stop timer/counter 1.

### 2.7.3. Configuring the Timer/Counter Input

The use of the timer/counter is determined by two 8-bit registers, TMOD (timer mode) and TCON (timer control). The input to the counter circuitry is from an external reference (for use as a counter), or from the onchip oscillator (for use as a timer). The operation mode depends on whether TMOD's C/T-bit is set or cleared, respectively. When used as a time base, the on-chip oscillator frequency is divided by twelve or six before being used as the counter input. When TMOD's GATE bit is set (1), the external reference input (T1, T0) or the oscillator input is gated to the counter conditional upon a second external input (INTO) or (INT1) being high. When the GATE bit is zero (0), the external reference, or oscillator input, is unconditionally enabled. In either case, the normal interrupt function of INTO and INT1 is not affected by the counter's operation. If enabled, an interrupt will occur when the input at INTO or INT1 is low. The counters are enabled for incrementing when TCON's TR1 and TR0 bits are set. When the counters overflow, the TF1 and TF0 bits in TCON get set, and interrupt requests are generated.

The counter circuitry counts up to all 1's and then overflows to either 0's or the reload value. Upon overflow, TF1 or TF0 is set. When an instruction changes the timer's mode or alters its control bits, the actual change occurs at the end of the instruction's execution.

### 2.7.4. Timer/Counter Mode Register

Table 2-30: TMOD

| Register Name | Bit Name |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| TMOD | GATE | C/T | M1 | M0 | GATE | C/T | M1 | M0 |
|  | Timer 1 |  |  |  | Timer 0 |  |  |  |
| See Section 3. on page 110 for detailed register description. |  |  |  |  |  |  |  |  |

Table 2-31: TCON

| Register Name | Bit Name |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| TCON | TF1 | TR1 | TFO | TR0 | IE1 | IT1 | IE0 | ITO |

### 2.8. Capture Reload Timer

The capture control timer is a 16 bit up counter, with special features suited for easier infrared decoding by measuring the time interval between two successive trigger events. Trigger events can be positive, negative or both edges of a digital input signal (Port 3.2 or 3.3). A built in Spike Suppression Unit (SSU) can be used for suppressing pulses with obviously too small or too long time duration at the beginning of an expected telegram, thereby relieving the FW of processing corrupted telegrams. This is especially useful in idle mode.

### 2.8.1. Input Clock

The input clock is $f_{C C T}$ and is same as the system clock frequency divided by two. In normal mode the system frequency is $33.33 \mathrm{MHz}\left(\mathrm{f}_{\mathrm{CCT}}=16.66 \mathrm{MHz}\right.$ ) and in slow down mode (SD mode) it is 8.33 MHz $\left(\mathrm{f}_{\mathrm{CCT}}=4.16 \mathrm{MHz}\right)$.

PR prescaler bit: when set the input clock is further divided by 2 , setting PR1 divides further by 8 .

If the operation is changed to the SD mode the frequency is adjusted accordingly so that maximum time resolution of 15.73 ms or 251.66 ms is achieved depending on Prescaler PR bits.

### 2.8.2. Reset Values

All the eight 8 bit registers CRT_rell, CRT_relh, CRT_capl, CRT_caph, CRT_mincapl, CRT_mincaph, CRT_con0 and CRT_con1 are reset to $00_{\mathrm{H}}$.

### 2.8.3. Functional Description

### 2.8.3.1. Port Pin

Either Port P3.3 or P3.2 can be selected as capture input via SEL bit. Capture event can be programmed to occur on rising or falling edge or both using the bits RISE and FALL bits.

### 2.8.3.2. Slow Down Mode

SD bit when set, reduces the system frequency to 8.33 MHz. However the clk to the counter has a fix frequency (for a particular prescaler value). This is achieved by a divide by 4 chain, which divides the incoming frequency by 4 when $\mathrm{SD}=0$ and feeds the incoming signal directly to the counter when $\mathrm{SD}=1$.

### 2.8.3.3. Run

When the counter is started (RUN), a 16 bit reload value is automatically loaded into the 16 bit counter. (Note: REL bit is irrelevant in case of RUN function). Setting run bit resets the First and OV bit.

All the control bits PR, PLG, REL, RUN, RISE, FALL, SEL, Start, Int_Src, SD can be changed anytime during the operation. These changes take immediate effect. There is no protected mode when the counter is running.

### 2.8.3.4. Overflow

In case no capture event occurs, the counter keeps on counting till it overflows from $\mathrm{FFFF}_{\mathrm{H}}$ to $0000_{\mathrm{H}}$. At this transition the OV bit is set. After the overflow the counter keeps on counting. Overflow does not reload the reload value. Note that the OV bit is set by the counter and can be reset by software.

### 2.8.3.5. Modes

There are three different modes in which the counter can be used.

- Normal Capture mode
- Polling mode
- Capture mode with spike suppression at the start of an IR telegram

Table 2-32: Timer/Counter mode selection

| Mode | START | PLG |
| :--- | :--- | :--- |
| Normal capture mode | 0 | 0 |
| Capture mode with spike <br> suppression | 1 | 0 |
| Polling mode | X | 1 |

For each change in the mode selection it is recommended to reset the RUN bit (if it is not already at 0), set the appropriate mode bit and then re-start the counter by setting the RUN bit again.

For each of the capture modes the event is captured based on the CRTCON0 (bit RISE) and CRTCON0 (bit FALL).

### 2.8.3.6. Normal Capture Mode

Normal capture mode is started by setting the RUN bit ( 0 --> 1 ) and PLG $=0$, start $=0$. Setting RUN bit will reload the counter with reload value and reset the overflow bit and counter will start to count.

Upon event on the selected port pin, contents of the counter are copied to the capture registers CRT_caph and CRT_capl.

In capture mode if REL bit is set counter is automatically reloaded upon occurrence of the event with the reload value and starts to count. If however REL bit is not set then the counter continues to count from the current value.

OV bit is not effected by the capture event.

Note: Min_cap register has no functionality in this mode.
Interrupt would be generated from CRT, however it will only be registered in the int source register if Intsrc bits in the CSCR1 are appropriately set. It is not required to use the CRT generated interrupt in this mode. Direct pin interrupt can be used.

### 2.8.3.7. Polling Mode

The polling mode is started by setting the PLG bit to ' 1 ' (START bit is in don't care for this mode). Setting the RUN bit will reload the counter with the reload value and reset the overflow bit and start the counting.

In the timer polling mode, the capture register mirrors the current timer value, note that in this mode any event at the selected port pin is ignored. Upon overflow the OV bit is set.

Note: Interrupts are not generated as events are not recognized.

### 2.8.3.8. Capture Mode with Spike Suppression at the Start of an Infrared Telegram

This mode is specially been implemented to prevent false interrupt from being generated specially in idle mode while waiting for a new infrared telegram.

This mode is entered by setting the START bit ( $\mathrm{PLG}=0$ ). The software sets the Start bit to indicate it is expecting a new telegram. Setting the RUN bit will reload the counter with the reload value and reset the overflow bit and start the counting.

### 2.8.3.9. First Event

On occurrence of the capture event, the counter value is captured and the comparator then sets the First bit. The Interrupt is suppressed. The OV bit is reset and the counter reloads the reload value (regardless of the status of REL bit) and starts counting again.

### 2.8.3.10. Second Event

On occurrence of second capture event, the counter value is captured and the interrupt is triggered if the capture value exceeds the value in the Min_Cap register and the OV bit is not set. First bit is reset. The counter will now continue in the normal capture mode. Software may reset the START bit if the capture value is detected as a valid pulse of an IR telegram.

If the pulse was invalid then software must stop the counter and start again (Run bit \& First reset and then SET) with start bit set to wait for a new telegram.

If Capture value is less then or equal to min_cap value or OV bit has been set, that is spike has been detected and Interrupt is suppressed. OV bit would be reset counter would be reloaded with reload value (regardless of REL bit).

In this case if either RISE or FALL bit were set then counter will wait for the second event (First = 1), if RISE and FALL both were set then counter will wait for the first event (First = 0 ).

### 2.8.3.11. Capture Reload TImer CRT Interrupt

The Capture Reload Timer CRT can generate an interrupt if the Spice Suppression Unit SSU is employed.

The CRT unit uses the same interrupt line as INT1 and $\overline{\mathrm{INTO}}$. The interrupt line is selected by the SEL bit.

Note that when using CRT to generate an interrupt, the direct interrupt source from Port 3.2 or 3.3 (which ever is selected) should be switched to CRT (CSCR1(IntSrc0), CSCR1(IntSrc1)). If the application uses port pins directly to generate interrupts, then these bits should be reset. Note that by default INT1 and INTO are mapped to P3.3 and P3.2.

The SSU generates an interrupt signal as a pulse, which is captured in the interrupt source register TCON (IE1 or IEO). While using this mode TCON (ITO or IT1) must be set to 1 (edge triggered) and IRCON (EX1R or EXOR) must be set to 1 and IRCON(EX1F or EXOF) must be set to 0 .

For further information on interrupts please refer to Section 2.3. on page 37.

### 2.8.3.12. Counter Stop

The counter can be stopped any time by resetting the RUN bit. If the counter is stopped and started again (reset and set the RUN bit), the counter reloads with the RELOAD value and reset the OV bit.

### 2.8.4. Idle and Power-down Mode

In idle mode the Capture Reload Timer CRT continues to function normally, unless it has been explicitly shut down via the PSAVEX (PERI) bit.

In power down mode the Capture Reload Timer CRT is shut off.

### 2.8.5. Registers

The CRT_rell and CRT_relh are the reload registers (SFR address $B 7_{\mathrm{H}}$ and $B 9_{\mathrm{H}}$ ), CRT_caph and CRT_capl are the corresponding capture registers
(SFR address $\mathrm{BA}_{\mathrm{H}}$ and $\mathrm{BB}_{\mathrm{H}}$ ). CRT_mincapl and CRT_mincaph (SFR Address $\mathrm{BC}_{\mathrm{H}}, \mathrm{BD}_{\mathrm{H}}$ ) are minimum capture registers. CRT_con0 (E5H) and CRT_con1 are the control registers.

Table 2-33: Related registers

| Register Name | Bit Name |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| CRT_rell | RelL[7:0] |  |  |  |  |  |  |  |
| CRT_relh | RelH[7:0] |  |  |  |  |  |  |  |
| CRT_capl | CapL[7:0] |  |  |  |  |  |  |  |
| CRT_caph | CapH[7:0] |  |  |  |  |  |  |  |
| CRT_mincapl | MinL[7:0] |  |  |  |  |  |  |  |
| CRT_mincaph | [7:0] |  |  |  |  |  |  |  |
| CRT_con0 | OV | PR | PLG | REL | RUN | RISE | FALL | SEL |
| CRT_con1 | Reserved | Reserved | Reserved | Reserved | Reserved | PR1 | First | Start |
| See Section 3. on page 110 for detailed register description. |  |  |  |  |  |  |  |  |

Table 2-34: Time resolution

| SD | $\mathrm{f}_{\text {sys }}$ | PR1 | PR | $\mathrm{f}_{\text {ctr }}$ | $f_{\text {ctr }}$ | Time Res. | Max Pulse Width |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 33.33 MHz | 0 | 0 | $\mathrm{f}_{\text {sys }} / 8 \mathrm{MHz}$ | 4.17 MHz | 240 ns | 15.73 ms |
|  |  | 0 | 1 | $\mathrm{f}_{\text {sys }} / 16 \mathrm{MHz}$ | 2.083 MHz | 480 ns | 31.46 ms |
|  |  | 1 | 0 | $\mathrm{f}_{\text {sys }} / 64 \mathrm{MHz}$ | . 5208 MHz | 1920 ns | 125.83 ms |
|  |  | 1 | 1 | $\mathrm{f}_{\text {sys }} / 128 \mathrm{MHz}$ | . 2604 MHz | 3840 ns | 251.66 ms |
| 1 | 8.33 MHz | 0 | 0 | $\mathrm{f}_{\text {sys }} / 8 \mathrm{MHz}$ | 4.17 MHz | 240 ns | 15.73 ms |
|  |  | 0 | 1 | $\mathrm{f}_{\text {sys }} / 16 \mathrm{MHz}$ | 2.083 MHz | 480 ns | 31.46 ms |
|  |  | 1 | 0 | $\mathrm{f}_{\text {sys }} / 64 \mathrm{MHz}$ | . 5208 MHz | 1920 ns | 125.83 ms |
|  |  | 1 | 1 | $\mathrm{f}_{\text {sys }} / 128 \mathrm{MHz}$ | . 2604 MHz | 3840 ns | 251.66 ms |

Fig. 2-7: Block Diagram

### 2.9. Pulse Width Modulation Unit

The Pulse Width Modulation unit consists of 6 channels with 8 bit resolution and 2 channels with 14 bit resolution PWM channels. PWM channels are programmed via special function registers and each channel can be enabled and disabled individually.

### 2.9.1. Reset Values

All the PWM unit registers as there are: PWME, PWCOMP8 0-5, PWCOMP14 0-1, PWMCOMPEXT14 $0-1, \mathrm{PWML}$ and PWMH by default are reset to $00_{\mathrm{H}}$.

### 2.9.2. Input Clock

The input clock fpwm to the PWM unit PWMU is derived from $f_{\text {sys }} f_{\text {sys }}$ is 33.33 MHz in normal mode and in slowdown mode 8.33 MHz.

In normal mode $f_{\text {sys }}$ is divided by 2 and in slow down mode it is directly fed to the PWMU. Therefore PWM unit is counting at 16.5 MHz in normal mode and 8.25 MHz in slow down mode. If the PR bit PCOMPEXT14 0 (bit 0 ) is set the then the counting frequency is half of that.

In addition the PWM_direct bit makes it possible to run the PWM counter at system frequency, ignoring the PR bit and the built in divide by 2 prescaler.

To reduce noise radiation, the different PWM-channels are not switched 'on' simultaneously with the same counter value. The channels are switching on with one clock cycle delay to the next channel: Channel 0: 0 clock cycles delayed, Channel 1: 1 clock cycle delayed, ..., Channel 5: 5 clock cycles, ..., PWM14_0: 6 clock cycles, PWM14_1: 7 clock cycles delayed.

### 2.9.3. Port Pins

Port 1 is a dual function port. Under normal mode it works as standard Port 1, in the alternate function mode it outputs the PWM channels.

P1.0 ... P1.5 corresponds to the six 8 bit resolution PWM channels PWM8_0 ... PWM8_5. P1.6 and P1.7 corresponds to the two 14 bit resolution PWM channels PWM14_0 and PWM14_1. PWM channels can be individually enabled by corresponding bits in the PWME register provided the PWM_Tmr bit is not set (timer mode start bit).

### 2.9.4. Functional Description

### 2.9.4.1. 8-bit PWM

The base frequency of a 8 bit resolution DA converter channel is derived from the overflow of a six bit counter.

On every counter overflow, the enabled PWM lines would be set to 1. Except in the case it the compare value is set to zero.

In case the comparator bits (7 $\ldots 2$ ) are set to 1 , the high time of the base cycle is 63 clock cycles. In case all the comparator bits ( $7 \ldots 0$ ) including the stretching bits are set to 1 , the high time of the full cycle ( 4 base cycles) is 255 clock cycles.

The corresponding PWCOMP8x register determines the duty cycle of the channel. If the counter value is equal to or greater than the compare value then the output channel is set to zero. The duty cycle can be adjusted in steps of fpwm as mentioned in Table 2-36.

In order to achieve the same resolution as 8-bit counter, the high time is stretched periodically by one clock cycle. The stretching cycle is determined based on the two least significant bits in the corresponding PWCOMP8x register.

The relationship for the stretching cycle can be seen in Table 2-35 and the example below.

Table 2-35: 8-bit PWM stretching cycle relationship

| PWCOMP8X | Cycle Stretched |
| :--- | :--- |
| Bit 1 | 1,3 |
| Bit 0 | 2 |

Fig. 2-8: 8-bit PWM and the Stretching Cycles

### 2.9.4.2. 14-bit PWM

The base frequency of a 14 bit resolution channel is derived from the overflow of a eight bit counter.

On every counter overflow, the enabled PWM lines would be set to 1 - except in the case where the compare value is set to zero.

The corresponding PWCOMP14x register determines the duty cycle of the channel. When the counter value
is equal to or greater than the compare value then the output channel is set to zero. The duty cycle can be adjusted in steps of fpwm as mentioned in Table 2-36.

In order to achieve the same resolution as 14bit counter, the high time is stretched periodically by one clock cycle. Stretching cycle is determined based on the bit $7 \ldots 1$ in the corresponding PWCOMPEXT14x register.

Table 2-36: 14-bit PWM stretching cycle relationship

| PWCOMPEXT14X | Cycle Stretched |
| :--- | :--- |
| Bit 7 | $1,3,5,7, \ldots, 59,61,63$ |
| Bit 6 | $2,6,10, \ldots, 54,58,62$ |
| Bit 5 | $4,12,20, \ldots, 52,60$ |
| Bit 4 | $8,24,40,56$ |
| Bit 3 | 16,48 |
| Bit 2 | 32 |

### 2.9.5. Cycle Time

Table 2-37: Cycle time

| PWM Resolution | Slow Down (SD) | $\begin{aligned} & \text { PWM_ } \\ & \text { PR } \end{aligned}$ | PWM direct | $f_{\text {sys }}$ [MHz] | Counting Rate [MHz] | Base Cycle Time [ $\mu \mathbf{s}$ ] | Full Cycle Time [ $\mu \mathrm{s}$ ] |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 8 Bit | 0 | 0 | 0 | 33.33 | 16.66 | 3.84 | 15.37 |
|  | 1 | 0 | 0 | 8.33 | 8.33 | 7.68 | 30.73 |
|  | 0 | 1 | 0 | 33.33 | 8.33 | 7.68 | 30.73 |
|  | 1 | 1 | 0 | 8.33 | 4.16 | 15.37 | 61.46 |
|  | 0 | X | 1 | 33.33 | 33.33 | 1.92 | 7.68 |
|  | 1 | X | 1 | 8.33 | 8.33 | 7.68 | 30.73 |
| 14 Bit | 0 | 0 | 0 | 33.33 | 16.66 | 15.37 | 983.4 |
|  | 1 | 0 | 0 | 8.33 | 8.33 | 30.7 | 1967 |
|  | 0 | 1 | 0 | 33.33 | 8.33 | 30.7 | 1967 |
|  | 1 | 1 | 0 | 8.33 | 4.16 | 61.4 | 3934 |
|  | 0 | X | 1 | 33.33 | 33.33 | 7.68 | 492 |
|  | 1 | X | 1 | 8.33 | 8.33 | 30.7 | 1967 |

### 2.9.6. Power-Down, Idle and Power-save Mode

In idle mode the pulse width modulation unit PWMU continues to function normally, unless it has been explicitly shut down by PSAVE(PERI). Note that in PSAVE mode all channels are frozen and the pins are switched to port output mode making it possible to use the port lines.

In power-down mode the pulse width modulation unit PWMU is shut off.

### 2.9.7. Timer

The pulse width modulation unit PWM unit uses a single 14 bit timer to generate signals for all 8 channels. The timer is mapped into the SFR address space and hence is readable by the controller. Timer is enabled (running) if one of the PWM channels is enabled in PWME. If all the channels are disabled counter is stopped. Enabling one of the channels will reset the timer to 0 and start. Note that this reset is done for the first enabled channel. All other channels enabled later will drive the output from the current value of the counter.

If all the channels are disabled then it can be used as a general purpose timer, by enabling it with PWM_Tmr bit in PWCH.

Setting PWM_Tmr bit switches to timer mode and starts the timer. The timer always starts from a reset value of 0 ( OV also reset to 0 ). Timer can be stopped any time by turning off the PWM_Tmr bit.

If the timer overflows it sets an over flow bit OV (bit 6) PWCH and interrupt bit CISR0 (PWtmr) in the central interrupt register. If the corresponding interrupt enable bit IEN2(EPW) is set the interrupt will be serviced. OV bit and PWtmr bits must be reset by the software.

[^1]
### 2.9.8. Control Registers

All control registers for the PWM are mapped in the SFR address space. Their address and bit description are given below.

Note that the controller can write any time into these registers. However registers PWM_COMP8_X, PWM_CPMP14_X and PWM_CPMPEXT14_X, including the bits PWM_direct and PWM_PR are double buffered and values from shadow registers are only
loaded into the main register in case timer overflows or timer is stopped ( $\mathrm{PWME}=00_{\mathrm{H}}$ ) of 8 bit counter.

Overflow for 8 bit PWM occurs at the overflow of 6 bit counter and overflow for 14 bit counter occurs at the overflow.

When any of the PWM channels is not used associated compare register can be used as general purpose registers, except PWM_En and PWCOMPEXT14_0 bit 0 and 1.

Table 2-38: Related registers

| Register Name | Bit Name |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| PWM_EN | PE[7:0] |  |  |  |  |  |  |  |
| PWM_comp8_0... | PC80_[7:0] |  |  |  |  |  |  |  |
| PWM_comp8_1 | PC81_[7:0] |  |  |  |  |  |  |  |
| PWM_comp8_2 | PC82_[7:0] |  |  |  |  |  |  |  |
| PWM_comp8_3 | PC83_[7:0] |  |  |  |  |  |  |  |
| PWM_comp8_4 | PC84_[7:0] |  |  |  |  |  |  |  |
| PWM_comp8_5 | PC85_[7:0] |  |  |  |  |  |  |  |
| PWM_comp14_0 | PC140_[7:0] |  |  |  |  |  |  |  |
| PWM_comp14_1 | PC141_[7:0] |  |  |  |  |  |  |  |
| PWM_compext14_0 | PCX140_[7:0] |  |  |  |  |  |  |  |
| PWM_compext14_1 | PCX141_[7:0 |  |  |  |  |  |  |  |
| PWM_cl | PWC_[7:0] |  |  |  |  |  |  |  |
| PWM_ch | PWM_Tmr | OV | PWC_[13:8] |  |  |  |  |  |
| See Section 3. on page 110 for detailed register description. |  |  |  |  |  |  |  |  |

### 2.10. Watchdog Timer

The Watchdog timer is a 16 bit up counter which can be programed to clock by $f_{w d t} / 2$ or $f_{w d t} 128$. The current count value of the watchdog timer is contained in the watchdog timer register WDT_high and WDT_low. which are read-only register. Control and refresh function of the WDT are controlled by WDT_refresh and WDT_ctrl.

Additionally the counter can be used as a general purpose timer in timer mode. The associated load register can be used either as load register or independently as a scratch pad register by the user.

### 2.10.1. Input Clock

The input clock $f_{\text {wdt }}$ is the same as the CPU clock $f_{\text {sys }}$ divided by 12 (i.e. machine cycle). It is fed to the WDT either as divide-by-2 or divide-by-128 clock signal. The divider factor is determined by WDT_in (WDT_ctrl) equal 0 and 1 respectively. WDT_in has the same functionality in both watch dog mode and timer mode.

### 2.10.2. Starting

The watch dog timer WDT can be started if the WDT unit is in the Watch dog mode (WDT_tmr = 0 ).

WDT is started by setting the bit WDT_start in the WDT_ctrl register. Immediately after the start (1 clock cycle) the reload value from the WDT_rel register is copied to the WDT_high. WDT_low is always reset to 0 upon start.

Data can be written to WDT_rel any time during normal controller operation. Data are only loaded to the counter upon start, refresh or watchdog reset (if WDT_narst is set).

Note that the counter registers are read only and cannot be directly written to by the controller.

### 2.10.3. Refresh

Once the watch dog timer WDT is started it cannot be stopped by software. (Note that while the WDT is running any change to WDT_tmr bit would be ignored.) A refresh to the WDT is required before the counter overflows. Refreshing the WDT requires two instruction sequences whereby first instruction sets WDT_ref bit and the next instruction sets the WDT_start bit. (For example if there is a NOP between these two instructions, a refresh would be ignored). This double instruction refresh minimize the chances of an unintentional reset of the watchdog timer. Once set, the WDT_ref bit is reset by the hardware after three machine cycles.

A refresh causes WDT_low to reset to $00_{\mathrm{H}}$ and loads the reload value to from WDT_rel to WDT_high.

### 2.10.4. WDT Reset

If the software fails to refresh the WDT before the counter overflows after $\mathrm{FFFF}_{\mathrm{H}}$, an internally generated watchdog reset is performed.

The watchdog timer reset differs only from the normal reset in that during normal reset all the WDT relevant bits in the three registers WDT_rel, WDT_refresh, WDT_control are reset to $00_{\mathrm{H}}$. The counter gets initialized to $0000_{\mathrm{H}}$.

In case of a watchdog reset, WDT_start and WDT_narst are not reset. The bit WDT_rst (read only) is set to indicate the source of the reset. In addition the WDT reset does not reset the PLL and clock generator.

If the WDT_narst bit is set then the values in the WDT_rel are retained after the WDT reset. The counter starts with the same pre-scaler (WDT_in) and reload configuration as before reset. If WDT_narst is not set then upon watchdog reset, WDT_rel is reset to OOh and WDT_in to 0.

After the WDT reset the counter starts again and must be refreshed by the microcontroller in order to avoid further WDT resets.

Duration of the WDT reset is sufficient to ensure the proper reset sequence.

### 2.10.5. Power-down Mode

The WDT is shut off during power down mode along with the rest of the peripherals.

In idle mode the WDT (in watchdog mode) is frozen, in timer mode it continues it's operation. In power save mode PSAVE (PERI) the watchdog continues it's operation. Any write access to this bit is ignored. If in timer mode the timer can be frozen by setting this bit.

### 2.10.6. Time Period

The period between refreshing the watchdog timer and the next overflow can be determined by the following formula.

PWDT $=\left[2(1+(\right.$ WDT_in $) \times 6) \times\left(216-\left(W D T \_r e l\right) \times\right.$ 28)] / [FWDT]

Based on 33.33 MHz system clock minimum time period and maximum time period are as defined below.

Table 2-39: Maximum and minimum WDT overflow time period

|  | $\mathbf{f}_{\text {system }}$ | WDT_in | WDT_rel | P $_{\text {WDT }}$ |
| :--- | :--- | :--- | :--- | :--- |
| Min. | 33.33 MHz | 0 | FF $_{\mathrm{H}}$ | $184.3 \mu \mathrm{~s}$ |
| Max. | 33.33 MHz | 1 | $00_{\mathrm{H}}$ | 3.02 s |

Fig. 2-9: Block Diagram

### 2.10.7. WDT as General Purpose Timer

The watch dog timer WDT counter can be used as a general purpose timer in timer mode. The associated load register can be used either as load register or independent scratch pad register for the programmer. This is achieved by setting WDT_tmr bit.

WDT_tmr bit can only be set before starting the WDT timer. Once the watchdog timer is started it is not possible to switch to general purpose timer mode.

If WDT_tmr bit is set then timer can be started using WTmr_strt bit.

When the timer is started it

- Resets the WTmr_ov overflow flag.
- Loads the preload value from WDT_rel and starts counting up.

Upon overflow the WDT_rst bit is not set neither is internal watchdog reset initiated. Overflow is indicated by the bit WTmr_ov (r/w). Overflow also sets the interrupt source bit CISRO (WTmr). Both of these bits are set by hardware and must be cleared by software. If the corresponding watchdog timer interrupt enable IE1 (EWT) bit is set then upon overflow the interrupt is initiated.

After an overflow the timer starts to count from WDT_rel. It is possible for the microcontroller to stop the timer by resetting the WTmr_strt bit any time.

While the timer is running, the WDT_tmr bit cannot be toggled. Any write access to this bit is ignored. To reset the WDT_tmr bit, either timer is stopped (WTmr_strt). However it is possible to stop the timer (WTmr_strt) and toggle the bit (WDT_tmr) with the same instruction.

### 2.11. Analog Digital Converter (CADC)

TVTpro includes a four channel 8-bit ADC for control purposes. By means of these four input signals the controller is able to supervise the status of up to four analog signals and take actions if necessary.

This analog signals can be connected to the Port 2 inputs without any special configuration. If the port pins of Port 2 are used as digital input, make sure that the input high level never exceeds VDDA.

The input range of the ADC is fixed to the analog supply voltage range ( 2.5 V nominal).

The conversion is done continuously on all four channels the results are stored in the SFRs CADCO ... CADC3 and updated automatically every $46 \mu \mathrm{~s}$. An interrupt can be used to inform the microcontroller about new available results.

### 2.11.1. Power-down and Wake-up

During idle mode it is required to reduce the power consumption dramatically. In order to do this for the controller ADC a special wake-up unit has been included.

During this mode only the signal on input channel 1 is supervised. As soon as the input signal has fallen below a predefined level an interrupt is triggered and the system wakes up.T wo different levels are available. The first one corresponds to (fullscale-4 LSB) the second one to (fullscale-16 LSB). The actual level can be selected by a control bit (ADWULE).

Nevertheless it is possible to send even this wake-up unit into power-down (for detailed description refer to Section 2.3.20. on page 45).

### 2.11.2. Registers

Table 2-40: Related registers

| Register Name | Bit Name |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| CADCO | CADCO[7:0] |  |  |  |  |  |  |  |
| CADC1 | CADC1[7:0] |  |  |  |  |  |  |  |
| CADC2 | CADC2[7:0] |  |  |  |  |  |  |  |
| CADC3 | CADC3[7:0] |  |  |  |  |  |  |  |
| CADCCO |  |  |  | ADWULE | AD[3:0] |  |  |  |
| CISRO bit addressable | L24 | ADC | WTmr | AVS | DVS | PWtmr | AHS | DHS |
| CISR1 bit addressable | CC | ADW |  |  |  |  | IEX1 | IEXO |
| PSAVE bit addressable |  |  |  | CADC | WAKUP | SLI_ACQ | DISP | PERI |
| PCON | SMOD | PDS | IDLS | SD | GF1 | GFO | PDE | IDLE |
| See Section 3. on page 110 for detailed register description. |  |  |  |  |  |  |  |  |

### 2.12. Sync System

### 2.12.1. General Description

The display sync system is completely independent from the acquisition sync system (CVBS timing) and can either work as a sync master or as a sync slave system.

Talking about 'H/V-Syncs' in this chapter and in Section 2.13. on page 69 always refers to display related H/V Syncs and never to CVBS related sync timing.

In sync slave mode TVTpro receives the synchronization information from two independent pins which deliver separate horizontal and vertical signals or a sandcastle impulse from which the horizontal and vertical sync signals are separated internally. Due to the not line locked pixel clock generation it can process any possible horizontal and vertical sync frequency.

In sync master mode TVTpro delivers separate horizontal and vertical signals with the same flexibility in the programming of these periods as in sync slave mode.

### 2.12.1.1. Screen Resolution

The number of displayable pixels on the screen is defined by the pixel frequency (which is independent from horizontal frequency), the line period and number of lines within a field. The screen is divided in three different regions:

### 2.12.1.1.1. Blacklevel Clamping Area

During horizontal and vertical blacklevel clamping, the black value $(R G B=000)$ is delivered on output side of TVTPro. Inside this area the BLANK pin and COR pin are set to the same values which are defined as transparency for subCLUT0 (see also Section 2.13.7.5. on page 88). This area is programmable in vertical direction (in terms of lines) and in horizontal direction in terms of 33.33 MHz clock cycles.

### 2.12.1.1.2. Border Area

The size of this area is defined by the sync delay registers (SDH and SDV) and the size of the character display area. The color and transparency of this area is defined by a color look up vector. See Section 2.13.7. on page 79).

Fig. 2-10: TVTPro's Display Timing

### 2.12.1.1.3. Character Display Area

Characters and their attributes which are displayed inside this area are free programmable according to the specifications of the display generator (see also Section 2.13.2. on page 69). The start position of that area can be shifted in horizontal and vertical direction by programming the horizontal and vertical sync delay registers (SDH and SDV). The size of that area is defined by the instruction FSR in the display generator.

Registers which allow to set up the screen and sync parameters are given in Table 2-41.

The user has to take care of setting PFR and SDH so that SDH/PFR is greater than $2 \mu \mathrm{~s}$.

Table 2-42 lists some of the possible display modes.

Note that the Pixel clock (Pclk) must be appropriately selected to the nearest value in the registers Pclk 0 and Pclk 1.

Table 2-42 serves as an example,. The freely programmable Pixel clock between 10 to 32 MHz makes it possible to adjust and fine tune the display as per application requirement.

### 2.12.1.2. Sync Interrupts

The sync unit delivers interrupts (Horizontal and vertical interrupt) to the controller to support the recognition of the frequency of an external sync source. These interrupts are related to the positive edge of the non delayed horizontal and vertical impulses which can be seen at pins HSYNC and VSYNC.

Table 2-41: Overview on sync register settings

| Parameters | Register | Min. Value | Max. Value | Step | Default |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Sync Control Register | SCR | No min/max general setup |  |  |  |
| VL - Lines / Field | VLR | 1 line | 1024 lines | 1 line | 625 lines |
| $\mathrm{T}_{\mathrm{h} \text {-period }}$ - Horizontal Period | HPR | $15 \mu \mathrm{~s}$ | 122.8 ¢ | 30 ns | $64 \mu \mathrm{~s}$ |
| $\mathrm{F}_{\text {pixel }}$ - Pixel Frequency | PCIk | 10 MHz | 32 MHz | 73.25 kHz | 12.01 MHz |
| T vsync_delay ${ }^{\text {- Sync Delay }}$ | SDV | 4 lines | 1024 lines | 1 line | 32 lines |
| Thsync_delay - Sync Delay | SDH | 32 pixel | 2048 pixel | 1 pixel | 72 pixel |
| BVCR - Beginning of Vertical Clamp Phase | BVCR | 1 line | 1024 lines | 1 line | line 0 |
| EVCR - End of Vertical Clamp Phase | EVCR | 1 line | 1024 lines | 1 line | line 4 |
| Th_clmp_b - Beginning of Horizontal Clamp Phase | BHCR | $0 \mu s$ | 122.8 ¢ | 480 ns | $0 \mu s$ |
| Th_clmp_e - End of Horizontal Clamp Phase | EHCR | $0 \mu \mathrm{~s}$ | 122.8 ¢ | 480 ns | $4.8 \mu \mathrm{~s}$ |

Table 2-42: Possible display modes

| $\mathbf{5 0 ~ H z} / 100 \mathrm{~Hz}$ | Character Display Mode | Pclk | $\mathbf{T}_{\text {Character display area }}$ |
| :--- | :--- | :--- | :--- |
| 50 Hz | $40 \times 25$ | 12 MHz | $40 \mu \mathrm{~s}$ |
| 50 Hz | $64 \times 25$ | 16 MHz | $48 \mu \mathrm{~s}$ |
| 100 Hz | $40 \times 25$ | 24 MHz | $20 \mu \mathrm{~s}$ |
| 100 Hz | $64 \times 25$ | 32 MHz | $24 \mu \mathrm{~s}$ |

### 2.12.1.3. Related Registers

Table 2-43: Related registers

| Register Name | Bit Name |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| SCR1 |  | RGB_G_[1:0] |  | COR_BL | VSU[3:0] |  |  |  |
| SCRO | RGB_D_[1:0] |  | HP | VP | INT | SNC | VCS | MAST |
| CISRO bit addressable | L24 | ADC | WTmr | AVS | DVS | PWtmr | AHS | DHS |
| VLR1 |  | ODD_Ev | vsu[3:0) |  |  |  | VLR[9:8] |  |
| VLRO | VLR[7:0] |  |  |  |  |  |  |  |
| HPR1 |  |  |  |  | HPR[11:8] |  |  |  |
| HPRO | HPR[7:0] |  |  |  |  |  |  |  |
| SDV1 |  |  |  |  |  |  | SDV |  |
| SDVO | SDV[7:0] |  |  |  |  |  |  |  |
| SDH1 |  |  |  |  | SDH[11:8] |  |  |  |
| SDHO | SDH[7:0] |  |  |  |  |  |  |  |
| HCR1 | EHCR[7:0] |  |  |  |  |  |  |  |

| EVCR1 |  |  |  |  |  |  | EVCR[9:8] |  |
| EVCRO | EVCR[7:0] |  |  |  |  |  |  |  |
| SNDCSTL |  | HYS | SND_V[2:0] |  |  | SND_H[2:0] |  |  |
| CSCRO |  |  | ENETCLK | ENERCLK | PA_7_Alt | VS_OE | O_E_P3_0 | O_E_Pol |

See Section 3. on page 110 for detailed register description.
DHS is used as an interface from H input pin to software interrupt routines.
DVS is used as an interface from V input pin to software interrupt routines.
These interrupt routines can be used for detection of the frequency of an external sync source. It is set by the HW and must be reset by the SW. The clamp phase area has higher priority than the screen background area or the character display area and can be shifted independent from any other register.

Fig. 2-11: Priority of Clamp Phase, Screen Background and Pixel Layer Area.

### 2.13. Display

The display is based on the requirements for a Level 1.5 Teletext and powerful additional enhanced OSD features.

The display circuit reads the contents and attribute settings of the display memory and generates the RGB data for a TV back-end signal processing unit.

The display can be synchronized to external H/V sync signals (slave mode) or can generate the synchronization signals by itself (master mode). The display can be synchronized to 50 Hz as well as to 60 Hz systems. Interlaced display is supported for interlaced sync sources and non-interlaced ones.

### 2.13.1. Display Features

- Teletext Level 1.5 feature set
- ROM Character Set to Support all European Languages in Parallel
- Mosaic Graphic Character Set

Table 2-44: Display memory organization of TVTpro

| Row No. | Address | $\mathbf{i}=\mathbf{0 d}$ | $\ldots$ | $\mathbf{i}=39 \mathrm{~d}$ |
| :---: | :---: | :---: | :---: | :---: |
| 0 | $\begin{aligned} & \text { DISPOINT }_{\mathrm{H}} \\ & +0_{\mathrm{H}} \\ & +\mathrm{i} \times 3_{\mathrm{H}} \end{aligned}$ | Character Display Area |  |  |
| 1 | DISPOINT $_{h}$ $\begin{aligned} & +78_{\mathrm{H}} \\ & +\mathrm{i} \times 3_{\mathrm{H}} \end{aligned}$ |  |  |  |
| 2 | $\begin{aligned} & \text { DISPOINT }_{h} \\ & +\mathrm{FO}_{\mathrm{H}} \\ & +\mathrm{i} \times 3_{\mathrm{H}} \end{aligned}$ |  |  |  |
| ... | ... |  |  |  |
| 23 | $\begin{aligned} & \text { DISPOINT }_{H} \\ & +\mathrm{ACB}_{\mathrm{H}} \\ & +\mathrm{i} \times 3_{\mathrm{H}} \end{aligned}$ |  |  |  |
| 24 | $\begin{aligned} & \mathrm{DISPOINT}_{\mathrm{H}} \\ & +{\mathrm{B} 40_{\mathrm{H}}}^{+\mathrm{i} \times 3_{\mathrm{H}}} \end{aligned}$ |  |  |  |

### 2.13.3. Display Memory

The display memory is located inside the internal XRAM.

The start address of the display memory is at memory address DISPOINT ${ }_{H}$. This memory address is defined by the user due to a pointer. For each character position three Bytes in the display memory are reserved. These three Bytes are stored in a serial incremental order for each character and used to define the display attributes of each single character position. The complete amount of allocated display memory depends on the display resolution. In vertical direction the character display area is fixed to 25 rows. In horizontal direction the character display area can be adjusted from 33 up to 64 columns. Table 2-44 is an example for a character display area resolution of 25 rows and 40 columns.

### 2.13.4. Parallel Character Attributes

The character display area content of each character position is defined by a 3 Byte character display word (CDW; see also Section 2.13.9.1. on page 102) in display memory.

Following formula helps to calculate a memory address of a character position $\left(\mathrm{X}_{\mathrm{CH}}, \mathrm{Y}_{\mathrm{CH}}\right)$ depending on the count of characters in horizontal direction (defined in the binary parameters (DISALH4 ... DISALH0) ${ }_{\mathrm{H}}$ ) and a display start address DISPOINT $_{H}$ :

$$
\text { CHARADDRESS }_{H}=\text { DISPOINT }_{H}+\left(Y_{C H} \times\left((\text { DISALH } 4 \ldots \text { DISALH } 0)_{H}+21_{H}\right)+X_{C H} \times 3_{H}\right)
$$

Table 2-45: Character display word: RAM location: Display memory

| Byte <br> Pos. | Bit | Name | Function | Remark |
| :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | CHAR0 | Used to choose a ROM or DRCS character | DRCS characters are defined by the user. Up to 16 different colors can be used within one DRCS; see also see Section 2.13.4.1. |
|  | 1 | CHAR1 |  |  |
|  | 2 | CHAR2 |  |  |
|  | 3 | CHAR3 |  |  |
|  | 4 | CHAR4 |  |  |
|  | 5 | CHAR5 |  |  |
|  | 6 | CHAR6 |  |  |
|  | 7 | CHAR7 |  |  |
| 1 | 8 | CHAR8 |  |  |
|  | 9 | CHAR9 |  |  |
|  | 10 | FLASH | Control of flash modes | See also Section 2.13.4.4. |
|  | 11 | UH | Upper half double height | See also Section 2.13.4.5. |
|  | 12 | DH | Double height | See also Section 2.13.4.5. |
|  | 13 | DW | Double width | See also Section 2.13.4.6. |
|  | 14 | BOX | Control for Boxes | See also Section 2.13.7.4. |
|  | 15 | CLUTO | Bit0/CLUT select | See also Section 2.13.7.5. |

Table 2-45: Character display word: RAM location: Display memory, continued

| Byte Pos. | Bit | Name | Function | Remark |
| :---: | :---: | :---: | :---: | :---: |
| 2 | 16 | CLUT1 | Bit1/CLUT select | See also Section 2.13.7.5. |
|  | 17 | CLUT2 | Bit2/CLUT select | See also Section 2.13.7.5. |
|  | 18 | FG0 | Foreground color vector | Only used for ROM characters and 1-bit DRCS characters; Foreground-color is chosen if bit inside ROM-mask/RAM is set to ' 1 ' <br> See also Section 2.13.7.5. |
|  | 19 | FG1 |  |  |
|  | 20 | FG2 |  |  |
|  | 21 | BGO | Background color vector | Used for ROM characters and 1-bit DRCS characters; <br> For 2-bit and 4-bit DRCS characters only used in flash mode; Background color is chosen if bit inside ROM-mask/RAM is set to ' 0 '; See also Section 2.13.7.5.and Section 2.13.4.4. |
|  | 22 | BG1 |  |  |
|  | 23 | BG2 |  |  |

### 2.13.4.1. Access of Characters

The DRCS characters and ROM characters are accessed by a 10-bit character address inside the character display word (CDW; see also Section 2.13.9.1. on page 102).

### 2.13.4.2. Address Range from $\mathbf{0}_{\mathrm{d}}$ to $\mathbf{7 6 7}_{\mathrm{d}}$

This address range can either be used to access ROM characters or to access 1-bit DRCS characters.

See also Section 2.13.5. on page 75 Global Display Word (GDW).

Table 2-46: Definition of character access mode

| CHAAC | Description |
| :--- | :--- |
| 0 | Normal mode: <br> Address range $0_{d}-767_{d}$ is used to <br> access ROM characters. |
| 1 | Enhanced mode: <br> Address range $0_{d}-767_{d}$ is used to <br> access 1-bit DRCS characters. |

### 2.13.4.3. Address Range from $\mathbf{7 6 8}_{\mathrm{d}}$ to $\mathbf{1 0 2 3}_{\mathrm{d}}$

The address range from $768_{d}$ to $1023_{d}$ is reserved to address the DRCS characters. This range is split into three parts for 1-bit DRCS, 2-bit DRCS and 4-bit DRCS. The boundary between 1-bit DRCS and 2-bit DRCS as well as the boundary between 2-bit DRCS and 4-bit DRCS are defined by two boundary pointers inside the global display word (GDW) (see also Section 2.13.5.)

Table 2-47: Boundary pointer 1

| DRCS <br> B1_3 | DRCS <br> B1_2 | DRCS <br> B1_1 | DRCS <br> B1_0 | Description |
| :--- | :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | 0 | Boundary1 set to $768_{d}$ |
| 0 | 0 | 0 | 1 | Boundary1 set to $784_{d}$ |
| 0 | 0 | 1 | 0 | Boundary1 set to $800_{d}$ |
| 0 | 0 | 1 | 1 | Boundary1 set to $816_{d}$ |
| $\ldots$ | 1 | 1 | 0 | Boundary1 set to $992_{d}$ |
| 1 | 1 | 1 | 1 | Boundary1 set to $1008_{d}$ |
| 1 | 1 |  |  |  |

Table 2-48: Boundary pointer 2

Below some examples can be found to show how the character addressing depends on the boundary definitions:

### 2.13.4.3.1. Example 1

Boundary Pointer 1 set to $848_{d}$
Boundary Pointer 2 set to $928_{d}$

| Character Address |  | Description |
| :--- | :--- | :--- |
| From | To |  |
| $768_{d}$ | $847_{d}$ | 1-bit DRCS characters |
| $848_{d}$ | $991_{d}$ |  |
| $928_{d}$ | $1023_{d}$ | 4-bit DRCS characters |

### 2.13.4.3.2. Example 2

Boundary Pointer1 set to $848_{d}$
Boundary Pointer2 set to 848d

| Character Address |  | Description |
| :--- | :--- | :--- |
| From | To |  |
| $768_{d}$ | $847_{d}$ | 1-bit DRCS characters |
| $848_{d}$ | $1023_{d}$ | 4-bit DRCS characters |

### 2.13.4.3.3. Example 3

Boundary Pointer 1 set to $768_{d}$
Boundary Pointer 2 set to $9288_{d}$

| Character Address |  | Description |
| :--- | :--- | :--- |
| From | To |  |
| $768_{d}$ | $927_{d}$ | 2-bit DRCS characters |
| $928_{d}$ | $1023_{d}$ | 4-bit DRCS characters |

### 2.13.4.4. Flash

The bit FLASH inside the character display word (CDW; see also Section 2.13.4.) is used to enable flash for a character.

| FLASH | Description |
| :--- | :--- |
| 0 | Steady (flash disabled) |
| 1 | Flash |
| See also Section 2.13.4. on page $70 /$ Character <br> Display Word (CDW) |  |

The meaning of the flash attribute is different for ROM characters and 1-bit DRCS characters in comparison to the meaning of flash for 2-bit and 4-bit DRCS characters.

For flash rate control see also the global attribute "FLRATE1 ... FLRATE0" in Section 2.13.7.3..

### 2.13.4.4.1. Flash for ROM Characters and 1-Bit DRCS Characters

For ROM characters and 1-bit DRCS characters the enabled flash mode causes the foreground pixels to alternate between the foreground and background color vector.

### 2.13.4.4.2. Flash for 2-Bit and 4-Bit DRCS Characters

For these characters the enabled flash mode causes the DRCS pixels to alternate between the 2-bit/ 4-bit color vector and the background color vector which is defined by the parameters BG2 ... BG0 inside character display word (CDW; see also Section 2.13.4. on page 70 ).

### 2.13.4.5. Character Individual Double Height

Bit UH (Upper half, double height) marks the upper part of a double height character. It is only active, if the DH bit (Double Height) is set to ' 1 '.

Table 2-49 shows the influence of the DH bit and the UH bit on the character ' $A$ '.

Table 2-49: Character individual double height

| DH | UH | Display |
| :--- | :--- | :--- |
| 0 | X |  |
| 1 | 1 | 0 |
| 1 |  |  |

### 2.13.4.6. Character Individual Double Width

The bit DW (double width) marks the left half of a character with double width.

The character to its right will be overwritten by the right half.

If the DW bit of the following character (here the ' $X$ ') is also set to ' 1 '; the right half of the ' $A$ ' is overwritten by the left half of the ' $X$ '.

If a character is displayed in double width mode the attribute settings of the left character position are used to display the whole character.

Table 2-50: Character individual double width

| DW Bit |  | Display |  |
| :--- | :--- | :--- | :--- |
| Left <br> Character | Right <br> Character |  |  |
| 0 | 0 |  |  |
| 1 | 0 |  |  |
| 1 |  |  |  |
| 0 | 1 |  |  |

### 2.13.5. Global OSD Attributes

Next to the parallel attributes stored inside character display word there are global attributes. The settings of the global attributes affect the full screen.

The settings of the global OSD attributes are stored in the global display word (GDW; see also Section 2.13.5.) within 10 Bytes in the XRAM. The location of the GDW is defined by a programmable pointer (See also Section 2.13.9. on page 100).

Table 2-51: Global OSD attributes

| Byte Pos. | Bit | Name | Function | Cross Reference |
| :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | DISALH0 | Count of display columns in horizontal direction | See also Section 2.13.6. on page 79 |
|  | 1 | DISALH1 |  |  |
|  | 2 | DISALH2 |  |  |
|  | 3 | DISALH3 |  |  |
|  | 4 | DISALH4 |  |  |
|  | 5 | PROGRESS | Used to enable progressive scan mode. | See also <br> Section 2.13.7.8. on page 96 |
|  | 6 | --- | Reserved. | --- |
|  | 7 | --- | Reserved. | --- |
| 1 | 0 | CURSEN | Enables cursor function. | See also Section 2.13.7. on page 79 |
|  | 1 | CURHORO | Horizontal pixel shift of cursor to character position |  |
|  | 2 | CURHOR1 |  |  |
|  | 3 | CURHOR2 |  |  |
|  | 4 | CURHOR3 |  |  |
|  | 5 | CURVERO | Vertical pixel shift of cursor to character position |  |
|  | 6 | CURVER1 |  |  |
|  | 7 | CURVER2 |  |  |

Table 2-51: Global OSD attributes, continued

| Byte Pos. | Bit | Name | Function | Cross Reference |
| :---: | :---: | :---: | :---: | :---: |
| 2 | 0 | CURVER3 | Vertical pixel shift of cursor to character position | See also Section 2.13.7. on page 79 |
|  | 1 | POSHOR0 | Horizontal character position of cursor |  |
|  | 2 | POSHOR1 |  |  |
|  | 3 | POSHOR2 |  |  |
|  | 4 | POSHOR3 |  |  |
|  | 5 | POSHOR4 |  |  |
|  | 6 | POSHOR5 |  |  |
|  | 7 | POSVER0 | Vertical character position of cursor |  |
| 3 | 0 | POSVER1 |  |  |
|  | 1 | POSVER2 |  |  |
|  | 2 | POSVER3 |  |  |
|  | 3 | POSVER4 |  |  |
|  | 4 | GLBT0_BOX1 | Used to enable transparency of Box1. CLUT transparency of subCLUT0 can be overruled for destined pixels inside Box1. | See also <br> Section 2.13.7.4. on page 86 |
|  | 5 | GLBT1_BOX1 |  |  |
|  | 6 | GLBT2_BOX1 |  |  |
|  | 7 | --- | Reserved. | --- |

Table 2-51: Global OSD attributes, continued

| Byte <br> Pos. | Bit | Name | Function | Cross Reference |
| :--- | :--- | :--- | :--- | :--- |
|  | 0 | SHEN | Enables shadow. |  |
|  | 1 | SHEAWE | Defines if east or west shadow is processed. |  |

### 2.13.6. Character Display Area Resolution

Table 2-52: Character display area resolution

| DISALH4 | DISALH3 | DISALH2 | DISALH1 | DISALHO | Description |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 0 | 0 | 33 columns |
| 0 | 0 | 0 | 0 | 1 | 34 columns |
| 0 | 0 | 0 | 1 | 0 | 35 columns |
| $\ldots$ |  |  |  |  | ... |
| 0 | 1 | 1 | 1 | 1 | 48 columns |
| 1 | 0 | 0 | 0 | 0 | 49 columns |
| $\ldots$ |  |  |  |  | ... |
| 1 | 1 | 1 | 1 | 0 | 63 columns |
| 1 | 1 | 1 | 1 | 1 | 64 columns |
| See also Section 2.13.5. / Global Display Word (GDW) |  |  |  |  |  |

The count of rows of the character display area can be adjusted in a range from 33 to 64 columns in horizontal direction. In vertical direction the character display area is fixed to 25 rows. It depends on the settings for synchronization mode, pixel frequency and character matrix if all these columns are visible on the tube.

The programmable parameters DISALH4 to DISALH0 are the binary representation of an offset value. This offset value plus $33_{d}$ gives the count of columns:

Table 2-52 shows some examples for the settings.

### 2.13.7. Cursor

The 2-bit color vector matrix of the cursor is stored in the XRAM. A programmable pointer is used, so that the matrix can be stored at any location inside the XRAM (see also Section 2.13.9.3. on page 102).

The cursor matrix has the same resolution as the character matrix (see also Section 2.13.7.6. on page 94).

If the Global Display Double Height (see also Section 2.13.7.2. on page 83) is set to double height, the rows which are displayed in double height the cursor is also displayed in double height. For rows which are displayed in normal height, the cursor is also displayed in normal height. If cursor is displayed over two rows and one of these rows is displayed in double height, and the other is displayed in normal height, cursor is also partly displayed in double height and partly in normal height. Cursor-Pixels which are shifted to a non-visible row are also not displayed on the screen.

The cursor can be shifted in horizontal and vertical direction pixel by pixel all over the character display area.

Table 2-53: Setting of CURSEN to enable cursor mode

| CURSEN | Description |
| :--- | :--- |
| 0 | Cursor mode disabled |
| 1 | Cursor mode enabled |
| See also Section 2.13.5. on page $75 /$ Global Dis- <br> play Word (GDW) |  |

The display position of the cursor is determined by a display column value, a display row value and on pixel level by a pixel shift in horizontal and vertical direction.

The cursor can not be shifted more than one character height and one character width on pixel level. The cursor is clipped at the border of the display area. In full screen double height mode (See also Section 2.13.7.2. on page 83) the cursor is also displayed in double height.

The pixel shift value is always related to a south-east shift. The pixel shift is determined by the parameters shown in Table 2-54 and Table 2-55 on page 80.

Table 2-54: Horizontal cursor pixel offset within character matrix

| CURHOR3 | CURHOR2 | CURHOR1 | CURHOR0 | Description |
| :--- | :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | 0 | Horizontal shift of 0 |
| 0 | 0 | 0 | 1 | Horizontal shift of 1 |
| 0 | 0 | 1 | 0 | Horizontal shift of 2 |
| 0 | 0 | 1 | Horizontal shift of 3 |  |
| $\ldots$ | 0 | 1 | $\ldots$ |  |
| 1 | 1 | X | Horizontal shift of 11 |  |
| 1 | See also Section 2.13.5. on page 75-Global Display Word (GDW) |  |  |  |

Table 2-55: Vertical cursor pixel offset within character matrix

| CURVER3 | CURVER2 | CURVER1 | CURVER0 | Description |  |
| :--- | :--- | :--- | :--- | :--- | :---: |
| 0 | 0 | 0 | 0 | Vertical shift of 0 |  |
| 0 | 0 | 0 | 1 | Vertical shift of 1 |  |
| 0 | 0 | 1 | 0 | Vertical shift of 2 |  |
| 0 | 0 | 1 | Vertical shift of 3 |  |  |
| $\ldots$ | 1 | 1 | $\ldots$ |  |  |
| 1 | 1 | 1 | Vertical shift of 14 |  |  |
| 1 |  |  |  |  |  |
| See also Section 2.13.5. on page 75-Global Display Word (GDW) |  |  |  |  |  |

The character position of the cursor is determined by the parameters shown in Table 2-56 and Table 2-57.

Character position and pixel position have to be changed in parallel. Otherwise it may appear that the character position already has been changed to a new position, but the pixel position is still set to the former value. This may cause a "jumping" cursor.

To avoid this "jumping" cursor there is a EN_LD_GDW (enable load GDW) bit in the SFR bank. If this bit is set to ' 0 ' the global display word can be changed without any effect on the screen and in consequence the cursor position can be changed without any effect on the screen. To bring the effect to character display area, the LOAD bit has to be set to 1 for at least one V period (approximately 50 ms ).

The cursor is handled as a layer above the character display area. Pixels of the 2-bit cursor bit plane which are set to '00' are transparent to the OSD/Video layer below. So the cursor can be transparent to the OSD (in case of no transparency of OSD) or to video (in case of transparency of OSD).

Table 2-56: Horizontal character position of the cursor within the character matrix

| POS <br> HOR5 | POS <br> HOR4 | POS <br> HOR3 | POS <br> HOR2 | POS <br> HOR1 | POS <br> HOR0 | Description |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | 0 | 0 | 0 | Horizontal character column 0 |
| 0 | 0 | 0 | 0 | 0 | 1 | Horizontal character column 1 |
| $\ldots$ | 1 | 1 | 1 | 1 | 0 | Horizontal character column 62 |
| 1 | 1 | 1 | 1 | 1 | 1 | Horizontal character column 63 |
| 1 | 1 |  |  |  |  |  |
| See also Section 2.13.5. on page 75-Global Display Word (GDW) |  |  |  |  |  |  |

Table 2-57: Vertical character position of the cursor within the character matrix

| POS <br> VER4 | POS <br> VER3 | POS <br> VER2 | POS <br> VER1 | POS <br> VER0 | Description |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | 0 | 0 | Vertical character row 0 |
| 0 | 0 | 0 | 0 | 1 | Vertical character row 1 |
| 0 | 0 | 0 | 1 | 0 | Vertical character row 2 |
| 0 | 0 | 0 | 1 | Vertical character row 3 |  |
| $\ldots$ | 1 | 1 | 1 | Vertical character row 30 |  |
| 1 | 1 | 1 | 1 | Vertical character row 31 |  |
| 1 |  |  |  |  |  |

## Example:

DRCS-character
stored at $896_{d}$ :

character-row/column:
horizontal: $5_{d}$
vertical: $\quad 10_{d}$

Fig. 2-12: Positioning of HW Cursor

One out of 8 subCLUTs is used to display the cursor. The parameters CURCLUT2 ... CURCLUT0 are used to define the subCLUT to be used.

Table 2-58: CURCLUT2, CURCLUT1, CURCLUTO

| CUR <br> CLUT2 | CUR <br> CLUT1 | CUR <br> CLUTO | Description |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | Used to select the subCLUT which is used for color look up of the cursor (0... 7) |
| 0 | 0 | 1 |  |
| 0 | 1 | 0 |  |
| 0 | 1 | 1 |  |
| ... |  |  |  |
| 1 | 1 | 0 |  |
| 1 | 1 | 1 |  |
| See also Section 2.13.5. on page 75-Global Display Word (GDW) |  |  |  |

For detailed information of CLUT access see Section 2.13.7.5. on page 88

### 2.13.7.1. Border Color

Table 2-59: Border color settings

| BRDCOL5 | BRDCOL4 | BRDCOL3 | BRDCOL2 | BRDCOL1 | BRDCOLO | Description |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 0 | 0 | 0 | Defines a color vector for the border; see also Section 2.13.7.5. on page 88 |
| 0 | 0 | 0 | 0 | 0 | 1 |  |
| 0 | 0 | 0 | 0 | 1 | 0 |  |
| 0 | 0 | 0 | 0 | 1 | 1 |  |
| ... |  |  |  |  |  |  |
| 1 | 1 | 1 | 1 | 1 | 0 |  |
| 1 | 1 | 1 | 1 | 1 | 1 |  |

Next to the character display area in which the characters are displayed there is an area which is surrounding the character display area. The visibility of this border area depends on the width and height of the character display area. The user is free to define the color vector of this border.

### 2.13.7.2. Full Screen Double Height

If double height is enabled for the full screen each line of the OSD is repeated twice at the RGB output. As a result, characters which are normally displayed in normal height, are now displayed in double height and characters which are normally displayed in double height are now displayed in quadruple height.

Row 0 and 24 are handled in a special way. If double height is selected for the full screen these two rows can be fixed to normal display (each line of these rows is repeated only once).

In double height mode the user may want to start the processing of the display at row 12 and not at row 0 . To decide this, three bits are used as a global attribute.

Table 2-60: Full screen double height

| GDDH2 | GDDH1 | GDDH0 | Display Area |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | Full Screen Normal Height: |
| 0 | 0 | 1 | Full Screen Double Height: <br> Rows $0-11$ are displayed in double height. <br> Row 24 is settled on bottom of display in normal height. <br> Memory organization: |
| 0 | 1 | 0 | Full Screen Double Height: <br> Rows 12-23 are displayed in double height. <br> Row 24 is settled on bottom of display in normal height. |
| 0 | 1 | 1 | Full Screen Double Height: <br> Rows 13-24 are displayed in double height. <br> Row 0 is settled on top of display in normal height. <br> Memory organization: <br> Display Appearance: |
| 1 | X | X | Full Screen Double Height: <br> Rows 1-12 are displayed in double height. <br> Row 0 is settled on top of display in normal height. <br> Memory organization: |
| See also Section 2.13.5. on page 75-Global Display Word (GDW) |  |  |  |

### 2.13.7.3. Flash Rate Control

This attribute is used to control the flash rate for the full screen. All the characters on the screen for which flash is enabled are flashing with same frequency and in same phase.

Table 2-61: Flash rate control

| FLRATE1 | FLRATE0 | Description |
| :--- | :--- | :--- |
| 0 | 0 | Slow flash rate. <br> The flash rate is derived from display V pulse. <br> For 50 Hz systems Flash rate is approximately 0.5 Hz. <br> Duty cycle is approximately $50 \%$. |
| 0 | 1 | Medium flash rate. <br> The flash rate is derived from the V pulse. <br> For 50 Hz systems Flash rate is approximately 1.0 Hz. <br> Duty cycle is approximately $50 \%$. |
| 1 | Fast flash rate. <br> The flash rate is derived from the V pulse. <br> For 50 Hz systems Flash rate is approximately 2.0 Hz. <br> Duty cycle is approximately $50 \%$. |  |
| See also Section 2.13.5. on page 75-Global Display Word (GDW) |  |  |

### 2.13.7.4. Transparency of Boxes

For characters which are using subCLUTO the transparency which is defined for the whole CLUT (see also Section 2.13.7.5. on page 88) can be overruled for foreground or background pixels. There are two different definitions for two box areas to define this overruling. Which of these two box transparencies is used, is selected character individual inside the bit BOX in CDW (character display word; See also Section 2.13.4.)

Transparency definition for characters for BOXO:
The cursor (see also Section 2.13.7. on page 79) is not affected by these bits.

Table 2-62: Transparency mode of BOXO

| GLBT2_BOXO | GLBT1_BOXO | GLBTO_BOXO | Description |
| :---: | :---: | :---: | :---: |
| X | 0 | 0 | Box transparency is disabled for BOXO. <br> For all pixels the global defined transparency of subCLUTO is used. |
| 0 | 0 | 1 | Box transparency is enabled for BOXO for following pixels: Foreground pixels of ROM characters |
| 0 | 1 | 0 | Box transparency is enabled for BOXO for following pixels: Foreground pixels of 1 -bit DRCS characters |
| 0 | 1 | 1 | Box transparency is enabled for BOXO for following pixels: Foreground pixels of ROM characters Foreground pixels of 1 -bit DRCS characters |
| 1 | 0 | 1 | Box transparency is enabled for BOXO for following pixels: Background pixels of ROM characters |
| 1 | 1 | 0 | Box transparency is enabled for BOXO for following pixels: Background pixels of 1-bit DRCS characters |
| 1 | 1 | 1 | Box transparency is enabled for BOXO for following pixels: Background pixels of ROM characters Background pixels of 1 -bit DRCS characters |
| See also Section 2.13.5. on page 75-Global Display Word (GDW) |  |  |  |

To decide the levels of COR and BLANK for BOXO two global parameters are used.

Table 2-63: COR/BLANK polarity of BOXO

| COR_BOXO | BLA_BOXO | Description |
| :--- | :--- | :--- |
| 0 | 0 | Box transparency levels of COR and BLANK are overruled by: <br> COR $=0 ;$ BLANK $=0$ |
| 0 | 1 | Box transparency levels of COR and BLANK are overruled by: <br> COR $=0 ;$ BLANK $=1$ |
| 1 | 0 | Box transparency levels of COR and BLANK are overruled by: <br> COR $=1 ;$ BLANK $=0$ |
| 1 | 1 | Box transparency levels of COR and BLANK are overruled by: <br> COR $=1 ;$ BLANK $=1$ |
| See also Section 2.13.5. on page 75-Global Display Word (GDW) |  |  |

For characters which are using subCLUTO there are two types of transparency which can be defined. Which of these two box transparencies is used is defined character individual inside the bit BOX in CDW (character display word; see also Section 2.13.4. on page 70).

Transparency definition for characters for which BOX is set to 1 and which are using subCLUTO.

Table 2-64: Transparency mode of BOX1

| GLBT2_BOX1 | GLBT1_BOX1 | GLBT0_BOX1 | Description |
| :--- | :--- | :--- | :--- |
| X | 0 | 0 | Box transparency is disabled for BOX1. |\(\left|\begin{array}{l}Box transparency is enabled for BOX1 for following pixels: <br>

Foreground pixels of ROM characters\end{array}\right|\)| 0 | 0 | 1 | Box transparency is enabled for BOX1 for following pixels: <br> Foreground pixels of 1-bit DRCS characters |
| :--- | :--- | :--- | :--- |
| 0 | 1 | 1 | Box transparency is enabled for BOX1 for following pixels: <br> Foreground pixels of ROM characters <br> Foreground pixels of 1-bit DRCS characters |
| 0 | 0 | 0 | Box transparency is enabled for BOX1 for following pixels: <br> Background pixels of ROM characters |
| 1 | 1 | 1 | Box transparency is enabled for BOX1 for following pixels: <br> Background pixels of 1-bit DRCS characters |
| 1 | 1 | Box transparency is enabled for BOX1 for following pixels: <br> Background pixels of ROM characters <br> Background pixels of 1-bit DRCS characters |  |
| See also Section 2.13.5. on page 75-Global DisplayWord (GDW) |  |  |  |

To decide the levels of COR and BLANK for BOX1 two global parameters are used.

Table 2-65: COR/BLANK polarity of BOX1

| COR_BOX1 | BLA_BOX1 | Description |
| :--- | :--- | :--- |
| 0 | 0 | Box transparency levels of COR and BLANK for BOX1 are overruled by: <br> COR $=0 ;$ BLANK $=0$ |
| 0 | 1 | Box transparency levels of COR and BLANK coming from CLUT0 inside BOX1 are <br> overruled by: <br> COR $=0 ;$ BLANK $=1$ |
| 1 | 0 | Box transparency levels of COR and BLANK coming from CLUT0 inside BOX1 are <br> overruled by: <br> COR $=1 ;$ BLANK $=0$ |
| 1 | 1 | Box transparency levels of COR and BLANK coming from CLUT0 inside BOX1 are <br> overruled by: <br> COR $=1 ;$ BLANK $=1$ |
| See also Section 2.13.5. on page 75-Global Display Word (GDW) |  |  |

### 2.13.7.5. CLUT

Table 2-66: COR/BLANK polarity setup for hardware CLUT during black clamp phase

| HDWCLUTCOR | HDWCLUTBLANK | Description |
| :--- | :--- | :--- |
| 0 | 0 | Decides the polarity for COR and BLANK output for the hardwired CLUT <br> entries 0-15 and the polarity of COR and BLANK during black clamp <br> phase (See also Section 2.12.1. on page 66): <br> COR = 0 <br> BLANK $=0$ |
| 0 | 1 | Decides the polarity for COR and BLANK output for the hardwired CLUT <br> entries 0-15 and the polarity of COR and BLANK during black clamp <br> phase (See also Section 2.12.1. on page 66): <br> COR $=0$ <br> BLANK =1 |
| 1 | 0 | Decides the polarity for COR and BLANK output for the hardwired CLUT <br> entries 0-15 and the polarity of COR and BLANK during black clamp <br> phase (See also Section 2.12.1. on page 66): <br> COR $=1$ <br> BLANK = 0 |
| 1 | 1 | Decides the polarity for COR and BLANK output for the hardwired CLUT <br> entries 0-15 and the polarity of COR and BLANK during black clamp <br> phase (See also Section 2.12.1. on page 66): <br> COR =1 <br> BLANK = 1 |

The CLUT has a maximum width of 64 entries. The RGB values of the CLUT entries from 0-15 are hardwired and can not be changed by software. The transparency for the hardwired CLUT values are set by a global attribute inside the global display word (GDW; see also Section 2.13.5. on page 75). This global setting can be overruled inside of boxes (see also Section 2.13.7.4. on page 86)

The RGB values of the CLUT entries from 16 to 63 are free programmable. The RGB values of the CLUT are organized in the TVTpro XRAM in a incremental serial order. CLUT locations inside XRAM which are not used for OSD can be used for any other storage purposes.

The CLUT is divided in 8 subCLUTs with 8 entries for 1-bit DRCS and ROM characters. For 2-bit DRCS characters the CLUT is divided in 8 subCLUTs with 4 entries. For 4-bit DRCS characters the CLUT is divided in 4 subCLUTs with 16 different entries.

The subCLUTs can be selected for each character position individual. For this three bits CLUT2, CLUT1 and CLUTO are reserved inside the character display word (CDW; see also Section 2.13.4. on page 70).

Table 2-67: Selection of used subCLUTX inside CDW for each individual character position

| CLUT2 | CLUT1 | CLUT0 | Meaning for ROM Character and <br> 1-bit/2-bit DRCS Characters | Meaning for 4-bit DRCS <br> Characters |
| :--- | :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | subCLUT0 is selected | subCLUT0 is selected |
| 0 | 0 | 1 | subCLUT1 is selected | subCLUT1 is selected |
| 0 | 1 | 0 | subCLUT2 is selected | subCLUT2 is selected |
| 0 | 1 | 1 | subCLUT3 is selected | subCLUT3 is selected |
| 1 | 0 | 0 | subCLUT4 is selected | subCLUT0 is selected |
| 1 | 0 | 1 | subCLUT5 is selected | subCLUT1 is selected |
| 1 | 1 | 0 | subCLUT6 is selected | subCLUT2 is selected |
| 1 | 1 | 1 | subCLUT7 is selected | subCLUT3 is selected |
| See also Section 2.13.4. on page $70-C h a r a c t e r ~ D i s p l a y ~ W o r d ~(C D W) ~$ |  |  |  |  |

CLUT entries from 0-15 are hardwired and can not be changed by the user.

Each of the 48 RAM programmable CLUT locations have a width of 2 Byte. These 2 Bytes are used to define a $3 \times 4$-bit RGB value plus the behavior of the BLANK and COR output pins. The following format is used.

Fig. 2-13: RGB/Transparency Memory Format of CLUT

Fig. 2-13 shows the RBG/Transparency memory format of CLUT:
Bit $3 \ldots 0$. 0 4-bit representation of Blue value
Bit $7 \ldots 4$. 4-bit representation of Green value
Bit 11 ... 8: 4-bit representation of Red value
Bit 12 Directly fed to BLANK pin
Bit 13 Directly fed to COR pin
Bit 14 Reserved
Bit 15 Reserved

Table 2-68: Organization of CLUT

### 2.13.7.5.1. CLUT Access for ROM Characters/1-bit DRCS Characters

For each pixel of a character a 1-bit background/foreground information is available. 1 out of 8 sub CLUTs can be selected by character display word (CDW; see also Section 2.13.4.). 1 out of 8 color vectors can be selected as a foreground and background color vector by the character display word (CDW; see also Section 2.13.4. on page 70). Please notice Table 2-68 on page 90.

### 2.13.7.5.2. CLUT Access for 2-Bit DRCS Characters

2-bit DRCS characters are stored in the RAM. Within a 2-bit DRCS character a 2-bit color vector information is available for each pixel. By this 2-bit information 1 out of 4 color vectors is selected from a subCLUT.

1 out of 8 subCLUTs is selected by character display word (CDW; see also Section 2.13.4. on page 70). Please notice Table 2-68 on page 90.

### 2.13.7.5.3. CLUT Access for 4-bit DRCS Characters

4-bit DRCS characters are stored in the RAM. Within a 4-bit DRCS character a 4-bit color vector information is available for each pixel. By this 1 out of 16 color vectors is selected from a subCLUT.

One out of 4 subCLUTs are selected by character display word (CDW; see also Section 2.13.4. on page 70).
Please notice Table 2-68 on page 90.

### 2.13.7.6. Character Resolution

The character matrix of DRCS characters can be adjusted in vertical direction from 9 lines up to 16 lines. In horizontal direction the character matrix is fixed to 12 pixels.

Table 2-69: Character resolution

| CHADRC2 | CHADRC1 | CHADRC0 | Description |
| :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | 9 lines |
| 0 | 0 | 1 | 10 lines |
| 0 | 1 | 0 | 11 lines |
| 0 | 1 | 1 | 12 lines |
| 1 | 0 | 0 | 13 lines |
| 1 | 0 | 1 | 14 lines |
| 1 | 1 | 0 | 15 lines |
| 1 | 1 | 1 | 16 lines |
| See also Section 2.13.5. on page $75-G l o b a l ~ D i s p l a y ~$ <br> Word (GDW) |  |  |  |

The character matrix of the ROM characters can also be adjusted in vertical direction from 9 lines up to 16 lines. In horizontal direction the ROM character matrix is fixed to 12 pixels.

Table 2-70: Character matrix settings

| CHAROM <br> $\mathbf{2}$ | CHAROM <br> $\mathbf{1}$ | CHAROM <br> $\mathbf{0}$ | Description |
| :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | 9 lines |
| 0 | 0 | 1 | 10 lines |
| 0 | 1 | 0 | 11 lines |
| 0 | 1 | 1 | 12 lines |
| 1 | 0 | 0 | 13 lines |
| 1 | 0 | 1 | 14 lines |
| 1 | 1 | 0 | 15 lines |
| 1 | 1 | 1 | 16 lines |
| See also Section 2.13.5. on page $75-G l o b a l ~ D i s p l a y ~$ <br> Word (GDW) |  |  |  |

The parameter CHAROM is used to characterize the organization of ROM characters. The parameter CHADRC is used to characterize the organization of DRCS characters and the vertical count of lines for a character row on output side. If the count of lines of ROM characters is smaller than the count of DRCS characters the lines of ROM characters are filled up with background colored pixels.

### 2.13.7.7. Shadowing

If shadowing is enabled the ROM characters and 1-bit DRCS characters of the characters are displayed by west shadow or east shadow. The color vector of the shadow is defined by software. The shadow color vector has a width of 6 bit.

The shadow feature is enabled by the bit SHEN.

Table 2-71: Shadow settings

| SHEN | Description |
| :--- | :--- |
| 0 | Shadow disabled. |
| 1 | Shadow for ROM characters and 1-bit <br> DRCS characters. |
| See also Section 2.13.5. on page 75-Global Display <br> Word (GDW) |  |

There are two options for shadowing, as shown in Fig. 2-72.

Table 2-72: Shadow options

| SHEAWE | Description |
| :--- | :--- |
| 0 | East shadowing. |
| 1 | West shadowing. |
| See also Section 2.13.5. on page 75 / Global Dis- <br> play Word (GDW) |  |

Example for a "A" displayed in shadow mode:
Within one character matrix shadowing is only processed for the pixels which are belonging to that character matrix. Pixels of one character matrix can not generate a shadow inside a neighbored character matrix.

Fig. 2-14: Processing of Shadowing

CLUT entries from 0-63 can be used as a shadow color vector as shown in Table 2-73.

Table 2-73: Shadow color vector settings

| SHCOL5 | SHCOL4 | SHCOL3 | SHCOL2 | SHCOL1 | SHCOLO | Description |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 0 | 0 | 0 | Defines a color vector for shadowing <br> See also Section 2.13.7.5. on page 88 |
| 0 | 0 | 0 | 0 | 0 | 1 |  |
| $\ldots$ |  |  |  |  |  |  |
| 1 | 1 | 1 | 1 | 1 | 0 |  |
| 1 | 1 | 1 | 1 | 1 | 1 |  |
| See also Section 2.13.5. on page 75-Global Display Word (GDW) |  |  |  |  |  |  |

### 2.13.7.8. Progressive Scan

This feature is useful for TV-devices in which a frame consists of 1 field with 625 lines instead of 2 fields with 312.5 lines each.

For this TV-fields on RGB-output lines are be repeated twice by enabling the progressive scan feature. This repetition of lines in vertical direction is only processed for lines inside the character display area.

Table 2-74: Progressive scan settings

| Progress | Description |
| :--- | :--- |
| 0 | Progressive scan support is disabled. |
| 1 | Progressive scan support is enabled. |
| See also Section 2.13.5. on page 75-Global Display <br> Word (GDW) |  |

Fig. 2-15: Allocation of Pixels Inside the Character Matrix

### 2.13.8. DRCS Characters

DRCS characters are available in the XRAM. There are three different DRCS color resolution formats available:

- 1-bit per pixel DRCS characters
- 2-bit per pixel DRCS characters
- 4-bit per pixel DRCS characters

In which way this 1-bit, 2-bit or 4-bit color vector information is used to access the CLUT, see Section 2.13.7.5. on page 88.

### 2.13.8.1. Memory Organization of DRCS Characters

The following examples are proceeded on the assumption that a height of 11 character lines is selected. The memory organization behaves the same for any other count of lines.

Each character starts at a new Byte address. This causes, that for odd heights nibbles may be left free.

Table 2-75: 1-Bit DRCS characters

| Char | Address | Bit7 | Bit6 | Bit5 | Bit4 | Bit3 | Bit2 | Bit1 | Bit0 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\begin{aligned} & \text { DRC1POINT }_{\mathrm{H}} \\ & +00_{\mathrm{H}} \end{aligned}$ | CHAR 1 | CHAR 1 | CHAR 1 | CHAR 1 | CHAR 1 | CHAR 1 | CHAR 1 | CHAR 1 |
|  |  | LINE 0 | LINE 0 | LINE 0 | LINE 0 | LINE 0 | LINE 0 | LINE 0 | LINE 0 |

### 2.13.9. Memory Organization

The memory organization concept of the OSD is based on a flexible pointer concept. All display memory registers reside in the internal XRAM only.

There are 4 Bytes of SFR registers which are pointing to two pointer arrays inside the XRAM as shown in Table 2-78

Fig. 2-16: Memory Organization of On Screen Display

Table 2-78: Pointers to start address of on-screen display registers inside XRAM

| SFR Address | Name | Function |
| :--- | :--- | :--- |
| $X X_{H}$ | POINTARRAY0 | Pointer to pointer array 0 |
| $X X_{H}+02_{H}$ | POINTARRAY1 | Pointer to pointer array 1 |

These 2 SFR pointers are used to point to $2 \times 3$ other pointers. These 6 pointers are pointing to the start address of the following memory areas:

- Start address of character display area memory
- Start address of CLUT
- Start address of 1-bit DRCS characters matrixes
- Start address of 2-bit DRCS characters matrixes
- Start address of 4-bit DRCS characters matrixes
- Start address of global display word / cursor matrix

User has to take care for a pointer definition so that memory areas do not overlap each other on the one hand and that the definition is optimized in a way, so that no memory is wasted on the other hand. The length of the global display word is fixed to 10 Byte and the length of the CLUT is fixed to $2 \times 48$ Byte. The length of all the other areas depend on the OSD requirements (see also Section 2.13.9.1. to Section 2.13.9.4. on page 102).

Each of the six pointers to the memory areas is stored in an array of pointers. Each pointer in this array has got a width of 16 bits and uses 2 Bytes inside the RAM.

Table 2-79: Memory pointers

| Pointer Array | Start address in Array | Name | Function |
| :---: | :---: | :---: | :---: |
| POINTFIELDO | $\begin{aligned} & 0_{\mathrm{H}} \text { (LByte) } \\ & 1_{\mathrm{H}} \text { (HByte) } \end{aligned}$ | DISPOINTh | Pointer to display memory |
|  | $\begin{aligned} & 2_{\mathrm{H}} \text { (LByte) } \\ & 3_{\mathrm{H}} \text { (HByte) } \end{aligned}$ | CLUTPOINT | Pointer to CLUT |
|  | $\begin{aligned} & 4_{\mathrm{H}} \text { (LByte) } \\ & 5_{\mathrm{H}} \text { (HByte) } \end{aligned}$ | GDWCURPOINTh | Pointer to GDW and cursor matrix |
| POINTFIELD1 | $\begin{aligned} & 0_{\mathrm{H}} \text { (LByte) } \\ & 1_{\mathrm{H}} \text { (HByte) } \end{aligned}$ | DRC1POINTh | Pointer 1-bit DRCS matrices |
|  | $\begin{aligned} & 2_{\mathrm{H}} \text { (LByte) } \\ & 3_{\mathrm{H}} \text { (HByte) } \end{aligned}$ | DRC2POINTh | Pointer 2-bit DRCS matrices |
|  | $\begin{aligned} & 4_{\mathrm{H}} \text { (LByte) } \\ & 5_{\mathrm{H}} \text { (HByte) } \end{aligned}$ | DRC4POINTh | Pointer 4-bit DRCS matrices |

### 2.13.9.1. Character Display Area

The character display area consists of 3 Bytes for each character position of the character display area. These three Bytes are used to store the character display word as it is described in Section 2.13.4. on page 70.

The array is sorted in a incremental serial order coming from the top left character throughout the bottom right character of the character display area. For further information see Section 2.13.2. on page 69.

The length of this display memory area depends on the parameter settings of DISALH0 ... DISALH4.

### 2.13.9.2. CLUT Area

The CLUT area consist of $48 \times 2$ Byte CLUT contents. The CLUT contents are stored in a serial incremental order.

For further information see Section 2.13.7.5. on page 88.

The length of the CLUT is fixed to 96 Bytes.

### 2.13.9.3. Global Display Word/Cursor

The area of the global display word is fixed to 10 Byte. All the global display relevant informations are stored inside global display word (GDW; see also Section 2.13.5. on page 75). The cursor matrix for cursor display is stored after the global display word.See also Section 2.13.2. on page 69.

The length of the memory area of global display word is fixed to 10 Byte. The length of the memory area of cursor matrix depends on the settings of CHADRC2 ... CHADRC0.

### 2.13.9.4. 1-bit/2-bit/4-bit DRCS Character

In this area the pixel information of the dynamically reconfigurable characters is stored. For further information on the memory format refer to Section 2.13.8. on page 96 .

The length of these areas depends on the settings of DRCSB1_3... DRCSB1_0 and the settings of DRCSB2_3 ... DRCSB2_0.

### 2.13.9.5. Overview on the SFR Registers

Other than the settings in the XRAM, SFR registers are used for OSD control.

Table 2-80: SFR registers used for OSD control

| SFR <br> Address | Name | Bit Programmable | Width | Purpose |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{F}_{\mathrm{H}}$ | EN_Ld_Cur | Yes | 1 bit | Used to avoid the download of the parameter settings of the GDW from the RAM to the local display generator register bank. See also Section : <br> 0 : Download disabled. <br> 1: Download enabled. <br> Initial value: 0 |
| $\mathrm{F}_{\mathrm{H}}$ | EN_DGOut | Yes | 1 bit | Used to disable/enable the output of the display generator. <br> If display generator is disabled the RGB outputs of the IC are set to black and the outputs BLANK and COR are set to. <br> COR = ENABLECOR <br> BLANK = ENABLEBLA <br> If display generator is enabled the display information RGB, COR and BLANK is generated according to the parameter settings in the XRAM. <br> 0 : Display generator is disabled. <br> 1: Display generator is enabled. <br> Initial value: 0 |
| $\mathrm{F}_{\mathrm{H}}$ | Dis_Cor | No | 1 bit | Defines the level of the COR output if display generator is disabled. <br> Initial value: 0 |
| $\mathrm{F}_{\mathrm{H}}$ | Dis_Blank | No | 1 bit | Defines the level of the BLANK output if display generator is disabled. <br> Initial value: 1 |
| $\mathrm{F}_{3} \mathrm{H}$ | POINTARRAY 1_1 | No | 6 bit | Defines a pointer to a pointer array. See also Section 2.13.9. on page 100 Initial value: 0 |
| $\mathrm{F}_{4} \mathrm{H}$ | POINTARRAY 1_0 | No | 8 bit | Defines a pointer to a pointer array. See also Section 2.13.9. on page 100 Initial value: 0 |
| $\mathrm{F}_{5} \mathrm{H}$ | POINTARRAY 0_1 | No | 6 bit | Defines a pointer to a pointer array. See also Section 2.13.9. on page 100 Initial value: 0 |
| $\mathrm{F}_{6} \mathrm{H}$ | POINTARRAY 0_0 | No | 8 bit | Defines a pointer to a pointer array. See also Section 2.13.9. on page 100 Initial value: 0 |

Fig. 2-18: ROM Character Matrices

Fig. 2-19: ROM Character Matrices

Fig. 2-20: ROM Character Matrices

Fig. 2-21: ROM Character Matrices

### 2.14. D/A Converter

TVTpro uses a $3 \times 2$-bit voltage $\mathrm{D} / \mathrm{A}$ converter to generate analog RGB output signals with a nominal amplitude of 0.7 V (also available: $0.5 \mathrm{~V}, 1.0 \mathrm{~V}$ and 1.2 V ) peak-to-peak.

### 2.14.1. Related Registers

Table 2-81: Related registers

| Register Name | Bit Name |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| ${ }^{1)}$ Addresses in bold are controller fix addresses. <br> 2) All the empty bits in "grey" are reserved <br> 3) Reserved. <br> ${ }^{4)}$ These registers are for internal use of the device. Do not write in these locations. <br> As a general rule: Software should only write to the bits which it wants to change. All other bits implemented or not should be masked in order to avoid problems with future versions. |  |  |  |  |  |  |  |  |  |

### 3.4. SFR Register Description

Note: For compatibility reasons every undefined bit in a writeable register should be set to '0'. Undefined bits in a readable register should be treated as "don't care"!

Table 3-4: SFR register description

| Name | Sub | Dir | Reset | Range | Function |
| :---: | :---: | :---: | :---: | :---: | :---: |
| PORT |  |  |  |  |  |

| MICRO |  |  |  |  |  |
| SP | h81 | RW | h07 |  | Stack Pointer |
| SP_[7:0] | h81[7:0] | RW | 7 | $0 . .255$ | Stack Pointer |
| DPL | h82 | RW | h00 |  | Data Pointer Low |
| DPL[7:0] | h82[7:0] | RW | 0 | $0 . .255$ | Data Pointer low byte |
| DPH | h83 | RW | h00 |  | Data Pointer High |
| DPH[7:0] | h83[7:0] | RW | 0 | $0 . .255$ | Data Pointer high byte |
| DPSEL | h84 | RW | h00 |  | Data Pointer Select |
| DPSEL[2:0] | h84[2:0] | RW | 0 | $0 . .7$ | Data Pointer Select selects one of eight data pointer |
| PCON | h87 | RW | h00 |  | Power Control |
| SMOD | h87[7] | RW | 0 | $0 . .1$ | UART Baud Rate <br> 0: Normal baud rate. <br> 1: Double baud rate. |
| PDS | h87[6] | RW | 0 | $0 . .1$ | Power Down Start Bit <br> 0: Power Down Mode not started. <br> 1: Power Down Mode started. <br> The instruction that sets this bit is the last instruction before entering power down mode. Additionally, this bit is protected by a delay cycle. Power down mode is entered, if and only if bit PDE was set by the previous instruction. Once set, this bit is cleared by hardware and always reads out a 0 . <br> DAC, PLL and Oscillator are switched off during Power Down. <br> The CADC is completely switched off (no wake up possible). |

Table 3-4: SFR register description, continued

| Name | Sub | Dir | Reset | Range | Function |
| :---: | :---: | :---: | :---: | :---: | :---: |
| IDLS | h87[5] | RW | 0 | $0 . .1$ | Idle Start Bit <br> 0: Idle Mode not started. <br> 1: Idle Mode started. <br> The instruction that sets this bit is the last instruction before entering idle mode. Additionally, this bit is protected by a delay cycle. Idle mode is entered, if and only if bit IDLE was set by the previous instruction. Once set, this bit is cleared by hardware and always reads out a 0 . |
| SD | h87[4] | RW | 0 | $0 . .1$ | Slow-Down Bit <br> 0 : Slow-down mode is disabled. <br> 1: Slow-down mode is enabled. <br> This bit is set to indicate the external clock generating circuitry to slow down the frequency. This bit is not protected by a delay cycle. |
| GF1 | h87[3] | RW | 0 | $0 . .1$ | Power Control |
| GFO | h87[2] | RW | 0 | $0 . .1$ | General purpose flag bits For user. |
| PDE | h87[1] | RW | 0 | $0 . .1$ | Power-Down Mode Enable Bit <br> When set, a delay cycle is started. The following instruction can then set the device into power down mode. Once set, this bit is cleared by hardware and always reads out a 0 . |
| IDLE | h87[0] | RW | 0 | $0 . .1$ | Idle Start Bit <br> 0: Idle Mode not started. <br> 1: Idle Mode started. <br> The instruction that sets this bit is the last instruction before entering idle mode. Additionally, this bit is protected by a delay cycle. Idle mode is entered, if and only if bit IDLE was set by the previous instruction. Once set, this bit is cleared by hardware and always reads out a 0 . The CADC is switched off but the CADC-Wake-Up-Unit is active. |
| TCON | h88 | RW | h00 |  | Timer/Counter Control |
| TF1 | h88[7] | RW | 0 | $0 . .1$ | Timer 1 overflow flag. Set by hardware on timer/counter overflow. Cleared by hardware when processor vectors to interrupt routine. |
| TR1 | h88[6] | RW | 0 | $0 . .1$ | Timer 1 run control bit. Set/cleared by software to turn timer/counter on/off. |
| TF0 | h88[5] | RW | 0 | $0 . .1$ | Timer 0 overflow flag. Set by hardware on timer/counter overflow. Cleared by hardware when processor vectors to interrupt routine. |
| TR0 | h88[4] | RW | 0 | $0 . .1$ | Timer 0 run control bit. Set/cleared by software to turn timer/counter on/off. |
| IE1 | h88[3] | RW | 0 | $0 . .1$ | Interrupt 1 edge flag. Set by hardware when external interrupt edge detected. Cleared when interrupt processed. |
| IT1 | h88[2] | RW | 0 | $0 . .1$ | Interrupt 1 type control bit. Set/cleared by software to specify falling edge/low level triggered external interrupts. IT1 = 1 selects transitionactivated external interrupts. |
| IE0 | h88[1] | RW | 0 | $0 . .1$ | Interrupt 0 edge flag. Set by hardware when external interrupt edge detected. Cleared when interrupt processed. |
| ITO | h88[0] | RW | 0 | $0 . .1$ | Interrupt 0 type control bit. <br> Set/cleared by software to specify falling edge/low level triggered external interrupts. ITO $=1$ selects transition-activated external interrupts. |
| TMOD | h89 | RW | h00 |  | Timer/Counter Mode Control |
| GATE1 | h89[7] | RW | 0 | $0 . .1$ | Timer/Ctr Mode |
| C_NT1 | h89[6] | RW | 0 | $0 . .1$ | Timer/Ctr Mode |
| M1[1:0] | h89[5:4] | RW | 0 | $0 . .3$ | Timer/Ctr Mode |
| GATE0 | h89[3] | RW | 0 | $0 . .1$ | Gating control when set. Timer/counter ëxí is enabled only while ëINTxí pin is high and ëTRxí control pin is set. When cleared, timer ëxí is enabled, whenever ëTRxí control bit is set. |

| MSIZ | hFF | RW | h0F |  | Scratch Pad Register |
| MSIZ[7:0] | hFF[7:0] | RW | 15 | 0.. 255 | Scratch Pad Register |
| UART |  |  |  |  |  |
| SCON | h98 | RW | h00 |  | Serial Control |
| SM0 | h98[7] | RW | 0 | $0 . .1$ | Serial Control |
| SM1 | h98[6] | RW | 0 | $0 . .1$ | Serial Control |
| SM2 | h98[5] | RW | 0 | $0 . .1$ | Enables the multiprocessor communication feature in modes 2 and 3. In mode 2 or 3 , if SM2 is set to 1 then RI will not be activated if the received 9th data bit (RB8) is 0 . In mode 1 , if $S M 2=1$ then RI will not be activated if a valid stop bit was not received. In mode 0, SM2 should be 0 . |
| REN | h98[4] | RW | 0 | $0 . .1$ | Enables serial reception. Set by software to enable reception. Cleared by software to disable reception. |
| TB8 | h98[3] | RW | 0 | $0 . .1$ | Is the 9th data bit that will be transmitted in modes 2 and 3 . Set or cleared by software as desired. |
| RB8 | h98[2] | RW | 0 | $0 . .1$ | In modes 2 and 3, is the 9th data bit that was received. In mode 1, if $\mathrm{SM} 2=0$, RB8 is the stop bit that was received. In mode 0, RB8 is not used. |
| TI | h98[1] | RW | 0 | $0 . .1$ | Is the transmit interrupt flag. Set by hardware at the end of the 8th bit time in mode 0 , or at the beginning of the stop bit in the other modes, in any serial transmission. Must be cleared by software. |
| RI | h98[0] | RW | 0 | $0 . .1$ | Is the receive interrupt flag. Set by hardware at the end of the 8th bit time in mode 0 , or halfway through stop bit time in the other modes, in any serial reception. Must be cleared by software. |
| SBUF | h99 | RW | h00 |  |  |
| D[7:0] | h99[7:0] | RW | 0 | 0.. 255 | Serial Data Buffer |

Table 3-4: SFR register description, continued

| Name | Sub | Dir | Reset | Range | Function |
| :---: | :---: | :---: | :---: | :---: | :---: |
| COR_BL | hE1[4] | RW |  |  | 3-Level Contrast Reduction Output <br> By means of COR_BL the user is able to switch the COR signal to a three level signal providing BLANK and contrast reduction information on pin BLANK/COR. <br> 0 : Two level signal for contrast reduction. <br> 1: Three level signal; <br> Three level signal Level0: BLANK off; COR off. <br> Level1: BLANK off; COR on. <br> Level2: BLANK on; COR off. <br> Note: See Section 4.10.3. on page 165 for the detailed specification of these levels. |
| VSU[3:0] | hE1[3:0] | RW | 0 | $0 . .15$ | Vertical Set Up Time <br> The vertical sync signal is internally sampled with the next edge of the horizontal sync edge. The phase relation between V and H differs from application to application. To guarantee (vertical) jitter free processing of external sync signals, the vertical sync impulse can be delayed before it is internally processed. The following formula shows how to delay the external V-sync before it is internally latched and processed. tV_delay $=3.84$ us * VSU |
| SCRO | hE2 | RW | h00 |  | DSync Control 0 |
| RGB_D[1:0] | hE2[7:6] | RW | 0 | $0 . .3$ | RGB/COR Delay Circuitry <br> In some applications of our customers the blanking is fed through other devices before it is used as a signal to control the multiplexing of video/RGB-mix. These other devices may create a delay of the blank signal. If no special effort is taken, this delay would create a vertical band at the beginning and the end of the active blanking zone. <br> To compensate this, the generated RGB and the COR signals can be delayed by TVT in reference to the generated blank signal. This delay is always a multiple of the pixel-frequency from zero delay up to 3 times pixel delay: <br> 00: Zero delay of RGB/COR-output in reference to BLANK-output. <br> 01: One pixel delay of RGB/COR-output in reference to BLANKoutput. <br> 10: Two pixel delay of RGB/COR-output in reference to BLANK-output. <br> 11: Three pixel delay of RGB/COR-output in reference to BLANKoutput. |
| HP | hE2[5] | RW | 0 | $0 . .1$ | H-Pin Polarity <br> This bit defines the polarity of the H pin (master and slave mode). <br> 0: Normal polarity (active high). <br> 1: Negative polarity. |
| VP | hE2[4] | RW | 0 | $0 . .1$ | V-Pin Polarity <br> This bit defines the polarity of the V pin (master and slave mode). <br> 0 : Normal polarity (active high). <br> 1: Negative polarity. |
| INT | hE2[3] | RW | 0 | $0 . .1$ | Interlace / Non-interlace <br> TVT can either generate an interlaced or a non-interlaced timing (master mode only). Interlaced timing can only be created if VLR is an odd number. <br> 0 : Interlaced timing is generated. <br> 1: Non-interlaced timing is generated. |

| SDH[7:0] | hE6[7:0] | RW | 72 | 0.. 255 | Horizontal Sync Delay (master and slave mode) <br> This register defines the delay (in pixels) from the horizontal sync to the first pixel character display area on the screen. |
| HCR1 | hE7 | RW | h0A |  | DSync H Clamp End |
| EHCR[7:0] | hE7[7:0] | RW | 10 | $0 . .255$ | End of Horizontal Clamp Phase (master and slave mode) <br> This register defines the end of the horizontal clamp phase from the positive edge of the horizontal sync impulse (at normal polarity). The end of clamp phase can be calculated by the following formula: <br> tH_clmp_e $=480$ ns * EHCR <br> If EHCR is smaller than BHCR the clamp phase will appear during Hsync. |

Table 3-4: SFR register description, continued

| Name | Sub | Dir | Reset | Range | Function |
| :---: | :---: | :---: | :---: | :---: | :---: |
| HCRO | hE9 | RW | h00 |  | DSync H Clamp Begin |
| BHCR[7:0] | hE9[7:0] | RW | 0 | $0 . .255$ | Beginning of Horizontal Clamp Phase (master and slave mode) <br> This register defines the delay of the horizontal clamp phase from the positive edge of the horizontal sync impulse (normal polarity is assumed). The beginning of clamp phase can be calculated by the following formula: <br> tH_clmp_b $=480$ ns * BHCR <br> If EHCR is smaller than BHCR the clamp phase will appear during Hsync. |
| BVCR | hEA | RW | h00 |  | DSync V Clamp Begin 1 |
| BVCR[9:8] | hEA[1:0] | RW | 0 | $0 . .3$ | Beginning of Vertical Clamp Phase (master and slave mode) <br> This register defines the beginning of the vertical clamp phase from the positive edge of the vertical sync impulse (at normal polarity) in count of lines. <br> If EVCR is smaller than BVCR than the clamp phase will appear during Vsync. |
| BVCRO | hEB | RW | h00 |  | DSync V Clamp Begin 0 |
| BVCR[7:0] | hEB[7:0] | RW | 0 | $0 . .255$ | Beginning of Vertical Clamp Phase (master and slave mode) <br> This register defines the beginning of the vertical clamp phase from the positive edge of the vertical sync impulse (at normal polarity) in count of lines. <br> If EVCR is smaller than BVCR than the clamp phase will appear during Vsync. |
| EVCR1 | hEC | RW | h00 |  | DSync V Clamp End 1 |
| EVCR[9:8] | $\mathrm{hEC}[1: 0]$ | RW | 0 | $0 . .3$ | End of Vertical Clamp Phase (master and slave mode) <br> This register defines the end of the vertical clamp phase from the positive edge of the vertical sync impulse (at normal polarity) in count of lines. <br> If EVCR is set to a value smaller than BVCR than the vertical blanking phase will last over the vertical blanking interval. <br> If EVCR is smaller than BVCR than the clamp phase will appear during Vsync. |
| EVCRO | hED | RW | h04 |  | DSync V Clamp End 0 |
| EVCR[7:0] | hED[7:0] | RW | 4 | $0 . .255$ | End of Vertical Clamp Phase (master and slave mode) <br> This register defines the end of the vertical clamp phase from the positive edge of the vertical sync impulse (at normal polarity) in count of lines. <br> If EVCR is set to a value smaller than BVCR than the vertical blanking phase will last over the vertical blanking interval. <br> If EVCR is smaller than BVCR than the clamp phase will appear during Vsync. |
| VLR1 | hEE | RW | h02 |  | DSync Vertical Line 1 |
| Odd_Ev | hEE[6] | RW | 0 | $0 . .1$ | ODD/EVEN detection (slave mode only) <br> Used as a interface from the hardware odd/even field detection to software. <br> Set to 1 for odd fields and to 0 for even fields. |

Table 3-4: SFR register description, continued

| Name | Sub | Dir | Reset | Range | Function |
| :---: | :---: | :---: | :---: | :---: | :---: |
| VSU2[3:0] | hEE[5:2] | RW | 0 | $0 . .15$ | Vertical Set Up Time 2 (slave mode only) <br> To realize the odd/even detection of a field next to VSU a second vertical setup time VSU2 is defined by the VSU2 register bits. This horizontal delay is used to recognize the VSYNC to another time than it is recognized at VSU. The field detection is realized by detecting if in between these two latching-points the VSync is rising or stable: $\text { tV_delay2 = } 3.84 \text { us * VSU2 }$ <br> If VSYNC became active for both VSU and VSU2, an odd field is detected. If VSYNC became active only for VSU an even field is detected: <br> Generated field signal bei utilization of VSU and VSU2 <br> field <br> with inverted VSU and VSU2: |
| VL[9:8] | hEE[1:0] | RW | 2 | $0 . .3$ | DSync Vetical line 1 |
| VLRO | hEF | RW | h71 |  | DSync Vertical Line 0 |
| VL[7:0] | hEF[7:0] | RW | 113 | $0 . .255$ | Amount of Vertical Lines in a Frame (master mode only) <br> TVT generates in sync master mode vertical sync impulses. If for example a normal PAL timing should be generated, set this register to " 625 d " and set the interlace bit to " 0 ". The hardware will generate a vertical impulse periodically after 312.5 lines. If a non-interlace picture with 312 lines should be generated, set this register to " 312 " and set the interlace bit to " 1 ". The hardware will generate a vertical impulse every 312 lines. A progressive timing can be generated by setting VLR to " 625 " and interlace to "0". |
| HPR1 | hF1 | RW | h08 |  | DSync Horizontal Period 1 |
| HPR[11:8] | hF1[3:0] | RW | 8 | $0 . .15$ | Horizontal Period Factor (master mode only) <br> This register allows to adjust the period of the horizontal sync signal. The horizontal period is independent from the pixel frequency and can be adjusted with the following resolution: <br> tH-period $=$ HP $\times 30 n s$ |
| HPRO | hF2 | RW | h55 |  | DSync Horizontal Period 0 |
| HPR[7:0] | hF2[7:0] | RW | 85 | 0.. 255 | Horizontal Period Factor (master mode only) <br> This register allows to adjust the period of the horizontal sync signal. The horizontal period is independent from the pixel frequency and can be adjusted with the following resolution: <br> tH-period $=$ HP x $30 n s$ |

Weight approximately 6.72 g
4.5. Outline Dimensions for PMQFP100-1 Package

Fig. 4-5:
PMQFP100-1: Plastic Metric Quad Flat Package, 100 leads, $14 \times 20 \times 2.7 \mathrm{~mm}^{3}$
Ordering code: QB
Weight approximately 1.7 g

### 4.6. Pin Connections and Short Descriptions

$N C=$ not connected, leave vacant
$\mathrm{LV}=$ if not used, leave vacant

| Pin No. |  |  |  | Pin Name | Type | Connection (If not used) | Short Description |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\begin{aligned} & \text { PMQFP } \\ & 100-1 \end{aligned}$ | PMQFP 64-1 | $\begin{aligned} & \text { PSDIP } \\ & 52-1 \\ & 52-2 \end{aligned}$ | PLCC 84-1 |  |  |  |  |
| 1 | - | - | 9 | D1 | I/O |  | Data bus for external memory or data RAM |
| 2 | - | - | 10 | D4 | I/O |  | Data bus for external memory or data RAM |
| 3 | - | - | 11 | D2 | I/O |  | Data bus for external memory or data RAM |
| 4 | - | - | 12 | D3 | I/O |  | Data bus for external memory or data RAM |
| 5 | - | - | 13 | $\overline{\text { XROM }}$ | I/O |  | This pin must be pulled low to access external ROM |
| 6 | 3 | 9 | 14 | VDD 2.5 | PS |  | Supply voltage ( 2.5 V ) |
| 7 | 4 | 10 | 15 | VSS2.5 | PS |  | Ground (0 V) |
| 8 | 5 | 11 | 16 | VDD 3.3 | PS |  | Input/Output (3.3 V) |
| 9 | 57 | 1 | 17 | P0.0 | PS |  | Port 0 is ab-bit open drain |
| 10 | 58 | 2 | 18 | P0. 1 | I/O |  | pins that have " 1 " written to |
| 11 | 59 | 3 | 19 | P0.2 | I/O |  | them float. In this stage, they can be used as high |
| 12 | 60 | 4 | 20 | P0.3 | I/O |  | impedance inputs (e.g. for software driven $I^{2} \mathrm{C}$ Bus |
| 13 | 61 | 5 | 21 | P0.4 | I/O |  | support) |
| 14 | 62 | 6 | 22 | P0.5 | I/O |  |  |
| 15 | 64 | 7 | 23 | P0.6 | I/O |  |  |
| 16 | 2 | 8 | 24 | P0.7 | I/O |  |  |
| 17 | - | - | - | ENE | I |  | Enable Emulation. Only if this pin is set to zero externally, STOP and OCF are operational. ENE has an internal pull-up resistor which switches auotomatically to non-emulation mode if ENE is not connected. |
| 18 | - | - | - | $\overline{\text { STOP }}$ | I |  | Emulation control line. Driving a low level during the input phase freezes the real time relevant internal peripherals such as timers and interrupt controller. |

| Pin No. |  |  |  | Pin Name | Type | Connection (If not used) | Short Description |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\begin{aligned} & \text { PMQFP } \\ & \text { 100-1 } \end{aligned}$ | $\begin{aligned} & \text { PMQFP } \\ & 64-1 \end{aligned}$ | $\begin{aligned} & \text { PSDIP } \\ & 52-1 \\ & 52-2 \end{aligned}$ | $\begin{aligned} & \text { PLCC } \\ & 84-1 \end{aligned}$ |  |  |  |  |
| 19 | - | - | - | $\overline{\text { OCF }}$ | I |  | Opcode Fetch. Emulation control line. A high level driven by the controller during output phase indicates the beginning of a new instruction. |
| 20 | - | - | - | $\overline{\text { EXTIF }}$ | I/O |  | This pin must be pulled low to enable extended memory interface. |
| 21 | 8 | 12 | 25 | CVBS | I/O |  | CVBS input for the acquisition circuit |
| 22 | 9 | 13 | 26 | VDDA 2.5 | PS |  | Supply voltage for analog components. |
| 23 | 10 | 14 | 27 | VSSA | PS |  | Ground for analog components |
| 24 | 12 | 15 | 28 | P2.0 | I/O |  | Port 2 is a 4-bit port without |
| 25 | 13 | 16 | 29 | P2.1 | I/O |  | pull-up resistors. |
| 26 | 14 | 17 | 30 | P2.2 | I/O |  | Port 2 has an alternate function. |
| 27 | 15 | 18 | 31 | P2.3 | I/O |  | See Section on page 155. |
| 28 | - | - | - | - | - | NC | Not connected |
| 29 | 16 | 19 | 32 | HS/SSC | I/O |  | In slave mode horizontal sync input or sandcastle input for display synchronization. <br> In master mode HS or VCS output |
| 30 | 17 | 20 | 33 | VS | I/O |  | Vertical sync input/ouput for display synchronization. $\qquad$ <br> It also can be used as digital input P4.7. <br> See Section on page 155. $\qquad$ <br> Furthermore, this pin can be selected as an ODD/EVEN indicator alternatively to P3.0. <br> See Section on page 155. |

| 31 | 18 | 21 | 34 | P3.0 | I/O |  | Port 3 is an 8-bit bidirectional I/O port with internal pull-up resistors. <br> Port 3 pins that have " 1 " written to them are pulled high by the internal pull-up resistros.In that state the pins can be used as inputs. $\qquad$ <br> To use the alternated functions of Port 3, the corresponding output latch must be programmed to a "1" for that function to operate. See Section on page 155. |
| 32 | 19 | 22 | 35 | P3.1 | I/O |  |  |
| 33 | 20 | 23 | 36 | P3.2 | I/ O |  |  |
| 34 | 21 | 24 | 37 | P3.3 | $1 / 0$ |  |  |
| 35 | 22 | 25 | 38 | P3.4 | $1 / 0$ |  |  |
| 36 | 23 | 26 | 39 | P3.5 | I/ O |  |  |
| 37 | 26 | 27 | 40 | P3.6 | I/ 0 |  |  |
| 38 | 27 | 28 | 41 | P3.7 | I/ O |  |  |
| 39 | 28 | 29 | 42 | VSS | PS |  | Ground ( 0 V ) |
| 40 | 29 | 30 | 43 | VDD 3.3 | PS |  | Input/Output (3.3 V) |
| 41 | 47 | 45 | 44 | P1.0 | I/ O |  | Port 1 is a 8 -bit bidirectional multifunction I/O port with internal pull-up resistors. <br> Port 1 pins that have " 1 " written to them are pulled high by the internal pull-up resistors and in that state can be used as inputs. $\qquad$ <br> Port 1 pins have a alternated function. <br> See Section on page 155. |
| 42 | 49 | 46 | 45 | P1.1 | $1 / 0$ |  |  |
| 43 | 51 | 47 | 46 | P1.2 | $1 / \mathrm{O}$ |  |  |
| 44 | 52 | 48 | 47 | P1.3 | $1 / \mathrm{O}$ |  |  |
| 45 | 53 | 49 | 48 | P1.4 | I/O |  |  |
| 46 | 54 | 50 | 49 | P1.5 | I/O |  |  |
| 47 | 55 | 51 | 50 | P1.6 | I/O |  |  |
| 48 | 30 | 31 | 51 | P4.2 | I/O |  | Port 4 is a bidirectional I/O port with internal pull-up resistors. <br> Port 4 pins that have 1 written to them are pulled high by the internal pull-up resistors. In that state, the pins can be used as inputs. $\qquad$ <br> Port 4 pins have a alternated function. <br> See Section on page 155. |
| 49 | 31 | 32 | 52 | P4.3 | I/O |  |  |
| 50 | 32 | 33 | 53 | $\overline{\mathrm{RST}}$ | I/O |  | A low level on this pin resets the device. An internal pullup resistor permits poweron reset using only one external capacitor connected to $\mathrm{V}_{\mathrm{SS}}$. |
| 51 |  |  |  |  |  | NC | Not connected. |

| Pin No. |  |  |  | Pin Name | Type | Connection (If not used) | Short Description |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\begin{aligned} & \text { PMQFP } \\ & \text { 100-1 } \end{aligned}$ | $\begin{aligned} & \text { PMQFP } \\ & 64-1 \end{aligned}$ | $\begin{aligned} & \text { PSDIP } \\ & 52-1 \\ & 52-2 \end{aligned}$ | $\begin{aligned} & \text { PLCC } \\ & 84-1 \end{aligned}$ |  |  |  |  |
| 52 | 34 | 34 | 54 | XTAL2 | 1 |  | Input of the inverting oscillator amplifier. |
| 53 | 35 | 35 | 55 | XTAL1 | 0 |  | Output of the inverting oscillator amplifier |
| 54 |  |  |  |  |  | NC | Not connected. |
| 55 | 36 | 14 | 56 | VSSA | PS |  | Ground for analog components |
| 56 | 37 | 13 | 57 | VDDA 2.5 | PS |  | Supply voltage for analog components. |
| 57 | 38 | 38 | 58 | R | 0 |  | Red |
| 58 | 39 | 39 | 59 | G | 0 |  | Green |
| 59 | 40 | 40 | 60 | B | 0 |  | Blue |
| 60 | 42 | 41 | 61 | BLANK/COR | 0 |  | Blanking and contrast reduction. |
| 61 |  |  |  |  |  | NC | Not connected. |
| 62 | 56 | 52 | 62 | P1.7 | I/O |  | Port 1 is a 8 -bit bidirectional multifunction I/O port with internal pull-up resistors. <br> Port 1 pins that have " 1 " written to them are pulled high by the internal pull-up resistors and in that state can be used as inputs. $\qquad$ <br> Port 1.7 has an alternated function. <br> See Section on page 155. |
| 63 |  |  |  |  |  | NC | Not connected. |
| 64 |  |  |  | $\overline{W R}$ | 0 |  | Control output. Indicates a write access to the internal XRAM. $\qquad$ <br> It can be used as a write strobe for writing data into an external data RAM by a MOVX instruction. $\qquad$ <br> This signal is also available as P4.3 <br> See Section on page 155. |

| Pin No. |  |  |  | Pin Name | Type | Connection (If not used) | Short Description |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\begin{aligned} & \text { PMQFP } \\ & \text { 100-1 } \end{aligned}$ | $\begin{aligned} & \text { PMQFP } \\ & 64-1 \end{aligned}$ | $\begin{aligned} & \text { PSDIP } \\ & 52-1 \\ & 52-2 \end{aligned}$ | $\begin{aligned} & \text { PLCC } \\ & 84-1 \end{aligned}$ |  |  |  |  |
| 65 |  |  |  | $\overline{\mathrm{RD}}$ | 0 |  | Control output. Indicates a read access to the internal XRAM. $\qquad$ <br> It can be used for latching data from the data bus into an external data RAM by a MOVX instruction. $\qquad$ <br> This signal is also available as P4.2 <br> See Section on page 155. |
| 66 |  |  |  |  |  | NC | Not connected. |
| 67 |  |  | 63 | A19 | I/O |  | After power-on Port P4.0, |

| 74 | 45 | 43 | 69 | VSS | PS |  | Ground (0 V) |
| 75 | 46 | 44 | 70 | VDD 3.3 | PS |  | Input/Output (3.3 V) |
| 76 |  |  | 71 | A14 | O |  | Address bus for external |
| 77 |  |  | 72 | A12 | 0 |  |  |
| 78 |  |  | 73 | A13 | 0 |  |  |
| 79 |  |  | 74 | A7 | 0 |  |  |
| 80 |  |  |  | FL_RST | 1 |  | All the pins prefix by FL_ are test pins that must be left open. |
| 81 |  |  | 75 | A8 | 0 |  | Address bus for external |
| 82 |  |  | 76 | A6 | 0 |  |  |
| 83 |  |  | 77 | A9 | 0 |  |  |
| 84 |  |  | 78 | A5 | 0 |  |  |
| 85 |  |  | 79 | A11 | $\bigcirc$ |  |  |
| 86 |  |  | 80 | A4 | 0 |  |  |

| Pin No. |  |  |  | Pin Name | Type | Connection (If not used) | Short Description |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\begin{aligned} & \text { PMQFP } \\ & \text { 100-1 } \end{aligned}$ | PMQFP 64-1 | $\begin{aligned} & \text { PSDIP } \\ & 52-1 \\ & 52-2 \end{aligned}$ | $\underset{84-1}{\text { PLCC }}$ |  |  |  |  |
| 87 |  |  |  | ALE | 0 |  | Address Latch Enable |
| 88 |  |  | 81 | $\overline{\text { PSEN }}$ | O |  | Program Store Enable. It is a control output signal, which is usually connected to OE input line of the external program memory to enable the data output. |
| 89 |  |  | 82 | A3 | 0 |  | Address bus for external |
| 90 |  |  | 83 | A10 | 0 |  | RAM. |
| 91 |  |  | 84 | VSS | PS |  | Ground (0 V) |
| 92 |  |  | 1 | VDD 3.3 | PS |  | Input/Output (3.3 V) |
| 93 |  |  | 2 | A2 | O |  | Address bus for external |
| 94 |  |  | 3 | A1 | 0 |  |  |
| 95 |  |  |  | FL_CE | I |  | All the pins prefix by FL_ are test pins that must be left open. |
| 96 |  |  | 4 | D7 | I/O |  | Data bus for external memory or data RAM. |
| 97 |  |  | 5 | AO | 0 |  | Address bus for external program memory or data RAM. |
| 98 |  |  | 6 | D6 | I/O |  | Data bus for external mem- |
| 99 |  |  | 7 | D0 | I/O |  | ory or data RAM. |
| 100 |  |  | 8 | D5 | I/O |  |  |

4.7. Port Alternate Functions

| Pin No. |  |  |  | Pin Name | Type | Connection (If not used) | Short Description |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\begin{aligned} & \text { PMQFP } \\ & \text { 100-1 } \end{aligned}$ | $\begin{aligned} & \text { PMQFP } \\ & 64-1 \end{aligned}$ | $\begin{aligned} & \text { PSDIP } \\ & 52-1 \\ & 52-2 \end{aligned}$ | $\begin{aligned} & \text { PLCC } \\ & 84-1 \end{aligned}$ |  |  |  |  |
| 24 | 12 | 15 | 28 | CADCCO(ADO) | 1 |  | Alternate function of P 2.0 : ADC. |
| 25 | 13 | 16 | 29 | CADCCO(AD1) | 1 |  | Alternate function of P2.1: <br> ADC. |
| 26 | 14 | 17 | 30 | CADCCO(AD2) | I |  | Alternate function of P2.2: <br> ADC. |
| 27 | 15 | 18 | 31 | CADCCO(AD3) | I |  | Alternate function of P2.3: <br> ADC. |
| 31 | 18 | 21 | 34 | CSCR0(O_E_P3_0) | I/O |  | Alternate function of P3.0: ODD/EVEN indicator |
| 32 | 19 | 22 | 35 | PORT INPUT MODE | I/O |  | Alternate function of P3.1: External extra interrupt 0 (INTXO)/UART(TXD) |
|  |  |  |  | PORT OUTPUT MODE | I/O |  | $\frac{\text { Alternate funtion of P3.1: }}{\text { TXD }}$ |
| 33 | 20 | 23 | 36 | PORT INPUT MODE | I/O |  | Alternate function of P3.2: Interrupt 0 input/timer 0 gate control input (INTO) |
| 34 | 21 | 24 | 37 | PORT INPUT MODE | I/O |  | Alternate function of P3.3: Interrupt 1 input/timer 1 gate control input (INT1) |
| 35 | 22 | 25 | 38 | PORT INPUT MODE | 1 |  | Alternate function of P3.4: <br> Counter 0 input (TO) |
| 36 | 23 | 26 | 39 | PORT INPUT MODE | I/O |  | Alternate function of P3.5: Counter 1 input (T1) or in master mode HS or VCS output |
| 37 | 27 | 28 | 41 | PORT INPUT MODE | 0 |  | Alternate function of P3.7: External extra interrupt 1 (INTX1)/UART(RXD) |
| 38 | 47 | 45 | 44 | PWME(E0) | I/O |  | Alternate function of P1.0: Output 8-bit pulse PWM channel 0 |
| 39 | 49 | 46 | 45 | PWME(E1) | I/O |  | Alternate function of P1.1: Output 8-bit pulse PWM channel 1 |
| 40 | 51 | 47 | 46 | PWME(E2) | I/O |  | Alternate function of P1.2: Output 8-bit pulse PWM channel 2 |

| Pin No. |  |  |  | Pin Name | Type | Connection (If not used) | Short Description |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\begin{aligned} & \text { PMQFP } \\ & \text { 100-1 } \end{aligned}$ | PMQFP 64-1 | $\begin{aligned} & \text { PSDIP } \\ & 52-1 \\ & 52-2 \end{aligned}$ | $\begin{aligned} & \text { PLCC } \\ & 84-1 \end{aligned}$ |  |  |  |  |
| 41 | 52 | 48 | 47 | PWME(E3) | I/O |  | Alternate function of P1.3: Output 8-bit pulse PWM channel 3 |
| 42 | 53 | 49 | 48 | PWME(E4 | I/O |  | Alternate function of P1.4: Output 8-bit pulse PWM channel 4 |
| 43 | 54 | 50 | 49 | PWME(E5) | I/O |  | Alternate function of P1.5: Output 8-bit pulse PWM channel 5 |
| 44 | 55 | 51 | 50 | PWME(E6) | I/O |  | Alternate function of P1.6: Output 14-bit pulse PWM channel 0 |
| 45 | 56 | 52 | 62 | PWME(E7) | I/O |  | Alternate function of P1.7: Output 14-bit pulse PWM channel 1 |
| 48 | 30 | 31 | 51 | CSCR1(ENARW) | I/O |  | Alternate function of P4.2: Read signal |
| 49 | 31 | 32 | 52 | CSCR1(ENARW) | I/O |  | Alternate function of P4.3: <br> Write signal |
| 62 | 56 | 52 | 62 | CSCRO(VS_OE, P1_7_ALT) | 0 |  | Alternate function of P1.7: <br> VS output |
|  |  |  |  | CSCRO(VS_OE, P1_7_ALT) | O |  | Alternate function of P1.7: OddEven output |
| 67 |  |  |  | CSCR1( $\overline{\mathrm{A} 19}$ _P4_1) |  |  | Alternate function of P4.4: Port pin |
| 68 |  |  | 64 | CSCR1( $\overline{\mathrm{A} 18}$ _P4_1) | I/O |  | Alternate function of P4.1: Port pin |
| 69 |  |  | 65 | CSCR1( $\overline{\mathrm{A} 17}$ _P4_0) | I/O |  | Alternate function of P4.0: Port pin |

### 4.8. Pin Descriptions

Pin numbers refer to the PMQFP100-1 package.
Pin 1, 2, 3, 4, D0, D1, D2, D3 - Data bus for external memory or data RAM.

Pin 5, $\overline{\text { XROM }}$ - This pin must be pulled low to access external ROM.

Pin 6, 73, VDD 2.5 - Supply voltage (2.5 V).
Pin 7, 39, 74, 91, VSS - Ground (0 V).
Pin 8, 40, 75, 92, VDD 3.3 - Input/Output (3.3 V).
Pin 9, 10, 11, 12, 13, 14, 15, 16, P0.0, P0.1, P0.2, P0.3, P0.4, P0.5, P0.6, P0.7 - Port 0 is a 8-bit open drain bidirectional I/O-port. Port 0 pins that have "1" written to them float; in this state they can be used as high impedance inputs (e.g. for software driven $I^{2} \mathrm{C}$ Bus support).

Pin 17, $\overline{\text { ENE }}$ - Enable Emulation. Only if this pin is set to zero externally, $\overline{\text { STOP }}$ and $\overline{\mathrm{OCF}}$ are operational. $\overline{E N E}$ has an internal pull-up resistor which switches automatically to non-emulation mode if ENE is not connected.

Pin 18, $\overline{\mathbf{S T O P}}$ - Stop. Emulation control line. Driving a low level during the input phase freezes the real time relevant internal peripherals such as timers and interupt controller.

Pin 19, $\overline{\mathbf{O C F}}$ - Opcode Fetch. Emulation control line. A high level driven by the controller during output phase indicates the beginning of a new instruction.

Pin 20, EXTIF - This pin must be pulled low to enable extended memory interface.

Pin 21, CVBS - CVBS input for the acquisition circuit.
Pin 22, 56, VDDA 2.5 - Supply voltage for analog components.

Pin 23, 55, VSSA - Ground for analog components.
Pin 24, , 25, 26, 27, P2.0, P2.1, P2.2, P2.3 - Port 2 is a 4-bit input port without puul-up resistors. Port 2 also works as analog input for the 4-channel-ADC. See Section on page 155.

Pin 28, NC - Pin not connected.
Pin 29, HS/SSC - In slave mode horizontal sync input or sandcastle input for display synchronisation. In master mode HS or VCS output.

Pin 30, VS/P4.7 - Vertical sync input/output for diaplay synchronisation. Can also be used as digital input P4.7 Furthermore this pin can be selected as an ODD/ EVEN indicator alternatively to P3.0. See Section on page 155.

Pin 31, 32, 33, 34, 35, 36,37 ,38, P3.0, P3.1, P3.2, P3.3, P3.4, P3.5, P3.6, P3.7 - Port 3 is an 8-bit bidirectional I/O-port with internal pull-up resistors. Port 3 pins that have " 1 " written to them are pulled high by the internal pull-up resistors and in that state can be used as inputs. To use the secondary functions of Port 3, the corresponding output latch must be programmed to a " 1 " for that function to operate.
The secondary functions are as follows:
P3.0: ODD/EVEN indicates output.
P3.1: External extra interrupt 0 ( $\overline{\text { INTXO }}) / \mathrm{UART}(\mathrm{TXD})$
P3.2: Interrupt 0 input/timer 0 gate control input (INTO)
P3.3: Interrupt 1 input/timer 1 gate control input (INT1)
P3.4: Counter 0 input (T0)
P3.5: Counter 1 input (T1) or in master mode HS or VCS output
P3.7: External extra interrupt 1 (INTX1)/UART(RXD)
Note: P3.6 mustnot be kept to "0" during reset, otherwise a testmode will be activated.
See Section on page 155.
Pin 41, 42, 43, 44, 45, 46, 47, 62, P1.0, P1.1, P1.2, P1.3, P1.4, P1.5, P1.6, P1.7 - Port 1 is a 8-bit bidirectional multifunction I/O-port with internal pull-up resistors. Port 1 pins that have " 1 " written to them are pulled high by the internal pull-up resistors and in that state can be used as inputs.
The secondary functions of Port 1 pins are:
Port bits P1.0-P1.5 contain the 6 output channels of the 8-bit pulse width modulation unit.
Port bits P1.6-P1.7 contain the two output channels of the 14-bit pulse width modulation unit.
See Section on page 155.
Pin 48, 49, P4.2, P4.3 - Port 4 is a bidirectional I/0-port with internal pull-up resistors. Port 4 pins that have an " 1 " written to them are pulled high by the internal pullup resistors and in that state can be used as inputs. The secondary functions are:
P4.2: $\overline{R D}$, Read line. This signal is the same as the outcoming signal of pin $\overline{\mathrm{RD}}$ available in some packages.
P4.3: $\overline{W R}$, write line. Thissignal is the same as the outcoming signal of pin WR, which is only available in some packages.
See Section on page 155.
Pin 50, $\overline{\text { RST }}$ - A low level on this pin resets the device. An internal pull-up resistor permits power-on reset using only one extrnal capacitor connected to VSS.

Pin 51, NC - Pin is not conected.
Pin 52, XTAL2 - Output of the inverting oscillator amplifier.

Pin 53, XTAL1 - Input of the inverting oscillator amplifier.

Pin 54, NC - Pin is not connected.
Pin $57,58,59$, R, G, B - Red, Green, Blue.
Pin 60, BLANK/COR - Blanking and contrast reduction.

Pin 61, NC - Pin is not connected.
Pin 63, NC - Pin is not connected.
Pin 64, $\overline{\mathbf{W R}}$ - Control output. Indicates a write access to the internal XRAM. Can be used as a write strobe for writing data into an external data RAM by a MOVX instruction. The signal is also available as P4.3.
See Section on page 155.
Pin 65, $\overline{\mathbf{R D}}$ - Control output. Indicates a read access to the internal XRAM. Can be used for latching data from the data bus into an external data RAM by a MOVX instruction. This signal is also available as P4.2 See Section on page 155

Pin 66, NC - Pin is not connected.
Pin 67, 68, 69, A16, A17, A18, A19, P4.0, P4.1, P4.4After power-on P4.0, P4.1, P4.4 work as additional address lines A17 ... A19. In port mode, these port lines act as bidirectional I/O-port with internal pul--up resistors. Port pins that have " 1 " written to them are pulled high by the internal pull-up resistors and in that stage they can be used as inputs.
See Section on page 155.
Pin 70, 71, 76, 77, 78, 79, 81, 82,83, 84, 85, 86, 89, 90, 93, 94, 97, A15, A14, A13, A7, A8, A9, A5, A11, A4, A3, A10, A2, A1, A0 - Address bus for external program memory od data RAM.

Pin 72, 80, 95, FL_PGM, FL_RST, FL_CE - All the pins prefix by $\mathrm{FL}_{-}$are test pins, which must be left open.

Pin 87, ALE - Address Latche Enable.
Pin 88, $\overline{\text { PSEN }}$ - Program Store Enable. $\overline{\text { PSEN }}$ is a control output signal which is usually connected to OE input line of the external program memory to enable the data output.

Pin 96, 98, 99, 100, D7, D6, D0, D5 - Data bus for external memory or data RAM.

### 4.10. Electrical Characteristics

### 4.10.1. Absolute Maximum Ratings

Stresses beyond those listed in the "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only. Functional operation of the device at these conditions is not implied. Exposure to absolute maximum ratings conditions for extended periods will affect device reliability.

This device contains circuitry to protect the inputs and outputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than absolute maximum-rated voltages to this high-impedance circuit.

All voltages listed are referenced to ground excepted where noted.
All GND pins must be connected to a low-resistive ground plane close to the IC.

| Symbol | Parameter | Pin Name | Limit Values |  | Unit |

### 4.10.2. Recommended Operating Conditions

Functional operation of the device beyond those indicated in the "Recomended Operating Conditions/Characteristics" is not implied and may result in unpredictable behavior, reduce reliability and lifetime of the device.

All voltages listed are referenced to ground except where noted.
All GND pins must be connected to a low-resistive ground plane close to the IC.

Do not insert the device into a live socket. Instead, apply power by switching on the external power supply.

## Intentionally Vacant

## 6. Data Sheet History

1. Data Sheet: "SDA 55xx TVText Pro", July 27, 2001, 6251-556-1DS. First release of the data sheet.
2. Data Sheet: "SDA 55xx TVText Pro", March 23, 2004, 6251-556-2DS. Second release of the data sheet.
Major changes:

- New revision, completely updated
- Outline Dimensions, new graphics
- Pin configuration, new graphics
- Electrical Characteristics updated

3. Data Sheet: "SDA 55xx TVText Pro", Sept. 10, 2004, 6251-556-3DS. Third release of the data sheet.
Major changes:

- New type SDA 5577 added to the SDA 55xx-family
- Absolute maximum Ratings: Ambient temperature limit value min: $-10^{\circ} \mathrm{C}$

#### Abstract

All information and data contained in this data sheet are without any commitment, are not to be considered as an offer for conclusion of a contract, nor shall they be construed as to create any liability. Any new issue of this data sheet invalidates previous issues. Product availability and delivery are exclusively subject to our respective order confirmation form; the same applies to orders based on development samples delivered. By this publication, Micronas GmbH does not assume responsibility for patent infringements or other rights of third parties which may result from its use. Further, Micronas GmbH reserves the right to revise this publication and to make changes to its content, at any time, without obligation to notify any person or entity of such revisions or changes. No part of this publication may be reproduced, photocopied, stored on a retrieval system, or transmitted without the express written consent of Micronas GmbH.

[^0]:    ORL PCON,\#00000010 ${ }_{B}$;Set bit PDE, bit PDS must not be set.

    ORL PCON, \#01000000 ${ }_{B}$;Set bit PDS, bit
    PDE must not be set.

[^1]:    Note: Before utilizing the timer for PWM channels PWM_Tmr bit must be reset.
    On reset the CISRO (PWtmr) bit is initialized to 0 , however if the counter overflows this bit might be set along with OV bit. However clearing OV bit does not clear the CISR0 (PWtmr) bit. Therefore the software must clear this bit before enabling the corresponding interrupt.
