

5CH Power Driver for CD-ROM, DVD-ROM

BD7903FS

BD7903FS is a 5-channel driver IC that integrates all drivers necessary for CD-ROM, and DVD-ROM systems into a single chip. Low noise, and low vibration can be achieved by applying the 180° PWM driving system for spindle motor drivers. Current lag phase occurred by the load of the inductance can be reduced by using the current feedback linear BTL system to driver the actuator.

●Applications

CD-ROM, DVD-ROM

●Features

- 1) 4channel BTL driver and 3phase motor driver.
 - ALL of the motor and actuator for CD-ROM, DVD-ROM etc.
- 2) These mode is able to be selected by the two control terminals.
 - ON/OFF of loading, and other 4channels, brake mode of spindle driver and standby mode.
- 3) Built-in triangular-wave generator.
- 4) Package SSOP-A54 has large power dissipation.
- 5) Built in thermal-shut-down circuit.

< Spindle driver >

- Efficient drive by current feedback PWM drive.
- Built in current limit, hall bias, short brake, FG 3-phase mixed signal output and reverse protection circuit.
- Low ON-Resistor. (RON=0.85Ω)

< Sled motor driver, Loading driver >

- Voltage feedback Linear BTL drive system.

< Actuator driver >

- Current feedback Linear BTL drive system.
- Current phase lag influenced load inductance is little, because this type is current feedback.

●Circuit operations

1. Driver control terminal 1 and 2 (pin49 and pin51)

All the drivers and spindle-drive braking mode can be switched on/off by inputting combinations of H-level signal (higher than 2V) and L-level signal (lower than 0.5V) to these terminals.

CTL1 (Pin22)	CTL2 (Pin23)	Spindle	Slide	Focus	Tracking	Loading	
L	L	×	×	×	×	×	1)
H	L	×	×	×	×	○	2)
-	H	○	○	○	○	×	○ ... ON × ... OFF

CTL1 (Pin22)	CTL2 (Pin23)	SPIN < V _c	SPIN > V _c	
L	H	Forward-rotation mode	Reverse-rotation braking mode	3)
H	H	Forward-rotation mode	Short-circuit braking mode	4)

1) Standby mode

The IC is brought into standby state, and its power dissipation can be limited. The outputs of all the channels are turned high-impedance.

2) Drivers muting

All the output channels except the loading are muted and their outputs are turned high-impedance.

3) Reverse-rotation braking mode (spindle)

A reverse-rotation torque is applied when SPIN > V_c.

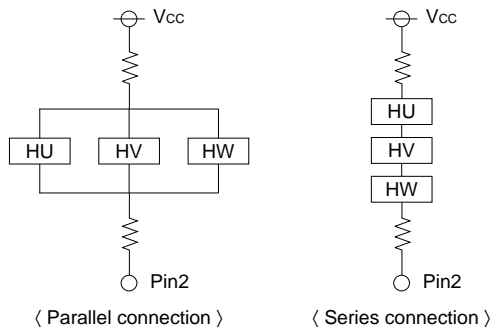

Reverse-rotation is detected with SPIN input and Hall input. If the spindle detects reverse rotation when SPIN > V_c, all the outputs are shorted out to GND.

4) Short-circuit braking mode (spindle)

All the spindle driver outputs are shorted out to GND when SPIN > V_c.

2. Hall inputs (pin 4 to 9) and Hall bias (pin 2) (Spindle)

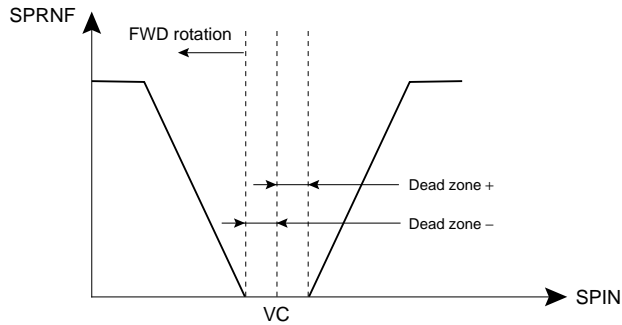

Hall elements can be connected either in series or in parallel. Set the Hall input voltage to 1.0 to 4.0V.

Optical disc ICs

3. Torque command (pin 20) / output current detection terminals (pin 19)

The relation between the torque command input SPIN and the output current detection terminals input SPRNF is expressed as shown below.

The input-output gain (g_m) and the output-limit current (ILIM) depend on the resistance of RNF (output current detection resistor). Please refer to the following expression.

The gain to drive the spindle motor can be decreased by connecting a resistor in series to each input terminal.

● Gain expression (typ.)

	Spindle
Input-output gain	$0.5/RNF$ (Arms/V)
Output-limit current	$0.6/RNF$ (A/V)
Gain with the added resistor	$29.7k/\{RNF \times (Rin + 60k)\}$ (Arms/V)

Rin : added series resistor

4. PWM oscillation frequency

The PWM oscillation for driving the spindle is free running. The oscillating frequency is 100kHz (typ.).

5. Muting functions

a) V_C -drop muting

When the voltage at V_C terminal (pin 27) drops to a value lower than 0.7V (typ.), the outputs of all the channels are turned high-impedance. Set the V_C terminal voltage to larger than 1.0V.

b) V_{CC} -drop muting

When the voltages at DV_{CC} terminal (pin 54) or V_{CC} terminal (pin 50) drop to lower than 4.0V (typ.), the outputs of all the channels are turned high-impedance. When the voltages rise to more than 4.25V (Typ.), the IC start operating again.

6. Thermal-shutdown

A thermal-shutdown circuit (over-temperature protection circuit) is built in to prevent the IC from thermal breakdown. Use the IC under the thermal loss allowed to the package. In case the IC is left running over the allowable loss, the junction temperature rises, and the thermal-shutdown circuit works at the junction temperature of 175°C (typ.) (the outputs of all the channels are turned off). When the junction temperature drops to 150°C (typ.), the IC start operating again.

●Operation notes

(1) Wiring for SPRNF

Considering the wiring resistance, connect each detecting resistor as close as possible to the current detection terminals for the spindle drive SPRNF (pin 19) of the IC.

Optical disc ICs

(2) Filtering capacitor

It is recommended to connect 0.1μF filtering capacitor to CFIL terminals. This capacitor filters PWM output carrier frequency. Dispersion of the cut off frequency due to circuit board wiring layout is taken into consideration.

If it is difficult to filter at the recommended value due to circuit board wiring led round, the capacity can be increased. In this case, note that the output transmission delay time may be longer.

(3) Bypass capacitor

Please connect a bypass capacitor (0.1μF) across the supply voltage lines close to the IC pins and please connect large capacity and small ESR capacitor (10μF~) close to the power supply voltage lines.

(4) Supply fault, ground fault, and short-circuit between output terminals

Do not short-circuit between any output pin and supply pin (supply fault) or ground (ground fault), or between any output pins (load short-circuit). When mounting the IC on the circuit board, be extremely cautious about the orientation of the IC. If the orientation is mistaken, the IC may break down, and produce smoke in some cases.
