Typographic Conventions

This document uses the typographic conventions shown below.

Visual Cue	Meaning
Bold Type with Initial Capital Letters	Command names, dialog box titles, checkbox options, and dialog box options are shown in bold, initial capital letters. Example: **Save As** dialog box.
bold type	External timing parameters, directory names, project names, disk drive names, filenames, filename extensions, and software utility names are shown in bold type. Examples: **f$_{MAX}$**, **\qdesigns** directory, **d:** drive, **chiptrip.gdf** file.
Italic Type with Initial Capital Letters	Document titles are shown in italic type with initial capital letters. Example: *AN 75: High-Speed Board Design.*

Visual Cue	Meaning
Italic type	Internal timing parameters and variables are shown in italic type. Examples: t_{PIA}, n + 1. Variable names are enclosed in angle brackets (< >) and shown in italic type. Example: *<file name>*, *<project name>***.pof** file.
Initial Capital Letters	Keyboard keys and menu names are shown with initial capital letters. Examples: Delete key, the Options menu.
"Subheading Title"	References to sections within a document and titles of on-line help topics are shown in quotation marks. Example: "Typographic Conventions."
`Courier type`	Signal and port names are shown in lowercase Courier type. Examples: `data1`, `tdi`, `input`. Active-low signals are denoted by suffix `n`, e.g., `resetn`. Anything that must be typed exactly as it appears is shown in Courier type. For example: `c:\qdesigns\tutorial\chiptrip.gdf`. Also, sections of an actual file, such as a Report File, references to parts of files (e.g., the AHDL keyword `SUBDESIGN`), as well as logic function names (e.g., `TRI`) are shown in Courier.
1., 2., 3., and a., b., c., etc.	Numbered steps are used in a list of items when the sequence of the items is important, such as the steps listed in a procedure.
■ ● ∙	Bullets are used in a list of items when the sequence of the items is not important.
✓	The checkmark indicates a procedure that consists of one step only.
☞	The hand points to information that requires special attention.
⚠ CAUTION	The caution indicates required information that needs special consideration and understanding and should be read prior to starting or continuing with the procedure or process.
⚠	The warning indicates information that should be read prior to starting or continuing the procedure or processes.
↵	The angled arrow indicates you should press the Enter key.
👣	The feet direct you to more information on a particular topic.

This section provides a complete overview of all features relating to the Stratix® III device family, which is the most architecturally advanced, high performance, low power FPGA in the market place. This section includes the following chapters:

- Chapter 1, Cyclone III Device Family Overview

- Chapter 2, Logic Elements and Logic Array Blocks in Cyclone III Devices

- Chapter 3, MultiTrack Interconnect in Cyclone III Devices

- Chapter 4, Memory Blocks in Cyclone III Devices

- Chapter 5, Embedded Multipliers in Cyclone III Devices

- Chapter 6, Clock Networks and PLLs in Cyclone III Devices

Revision History

Refer to each chapter for its own specific revision history. For information on when each chapter was updated, refer to the Chapter Revision Dates section, which appears in the full handbook.

CIII51001-1.0

Cyclone III: Lowest System-Cost FPGAs

The Cyclone® III FPGA family offered by Altera® is a cost-optimized, memory-rich FPGA family. Cyclone III FPGAs are built on TSMC's 65-nm low-power (LP) process technology with additional silicon optimizations and software features to minimize power consumption. With this third generation in the Cyclone series, Altera broadens the number of high volume, cost-sensitive applications that can benefit from FPGAs.

Features

Cyclone III devices are designed to offer low-power consumption and increased system integration at reduced cost.

Reduced Cost

Cyclone III devices deliver the lowest device and system costs based on the following facts:

- Staggered I/O ring to lower die area
- Wide range of low cost packages
- Support for low-cost serial flash and commodity parallel flash devices for configuration

Lowest-Power 65-nm FPGA

Cyclone III devices are the lowest-power 65-nm FPGAs designed via TSMC's 65-nm low power process and Altera's power aware design flow. Cyclone III devices support hot-socketing operation, hence, unused I/O banks can be powered down when the devices to which they are connected are turned off. Cyclone III device low power operation:

- Extends battery life for portable and handheld applications
- Enables operation in thermally challenged environments
- Eliminates or reduces cooling system costs

Increased System Integration

Cyclone III devices provide increased system integration by offering the following features:

- Density is up to 119,088 logic elements (LEs) and memory is up to 3.8 Mbits. See Table 1–1 on page 1–3.
- High memory to logic ratio for embedded DSP applications

Altera Corporation-Preliminary
March 2007

■ Highest multiplier-to- logic ratio in the industry at every density; 260 MHz multiplier performance

■ High I/O count, low and mid range density devices for user I/O constrained applications

■ Up to four phase-locked loops (PLLs) provide robust clock management and synthesis for device clocks, external system clocks, and I/O interfaces
  ● Up to five outputs per PLL
  ● Cascadable to save I/Os, ease PCB routing, and reduce the number of external reference clocks needed
  ● Dynamically reconfigurable to change phase shift, frequency multiplication/division, and input frequency in-system without reconfiguring the device

■ Support for high-speed external memory interfaces including DDR, DDR2, SDR SDRAM, and QDRII SRAM at up to 400 Mbps
  ● Auto-calibrating physical layer (PHY) feature accelerates timing closure process and eliminates variations over process, voltage and temperature (PVT) for DDR, DDR2, SDRAM, and QDRII SRAM interfaces

■ Up to 534 user I/O pins arranged in 8 I/O banks that support a wide range of industry I/O standards
  ● Up to 875 Mbps receive and 840 Mbps transmit LVDS communications
  ● LVDS, RSDS, mini-LVDS and PPDS transmission without the use of external resistors
  ● Supported I/O standards include LVTTL, LVCMOS, SSTL, HSTL, PCI, PCI-X, LVPECL, LVDS, mini-LVDS, RSDS, and PPDS; PCI Express and Serial Rapid I/O are supported using external PHY devices

■ Multi-value on-chip termination (OCT) support with calibration feature to eliminate variations over PVT

■ Adjustable I/O slew rates to improve signal integrity

■ Support for low-cost Altera serial flash and commodity parallel flash configuration devices from Intel and Spansion

■ Remote system upgrade feature without requiring an external controller

■ Dedicated Cyclic Redundancy Code (CRC) checker circuitry to detect single event upset (SEU) conditions

■ Nios® II embedded processors for Cyclone III devices offer low cost and custom-fit embedded processing solutions

■ Broad portfolio of pre-built and verified intellectual property cores from Altera and Altera Megafunction Partners Program (AMPP^SM) partners

Table 1–1 displays Cyclone III device family features.

Table 1–1. Cyclone III FPGA Device Family Features								
Feature	**EP3C5**	**EP3C10**	**EP3C16**	**EP3C25**	**EP3C40**	**EP3C55**	**EP3C80**	**EP3C120**

Global Clock Networks	10	10	20	20	20	20	20	20

All Cyclone III devices support vertical migration within the same package. Vertical migration means that you can migrate to devices whose dedicated pins, configuration pins, and power pins are the same for a given package across device densities. This allows designers to optimize density and cost as the design evolves.

Table 1–2 lists the Cyclone III device package options and user I/O pin counts. The highest I/O count in the family is delivered by the EP3C40.

Table 1–2. Cyclone III FPGA Package Options and I/O Pin Counts Note (1), (2), (3)

Device	144-pin Plastic Enhanced Quad Flat Pack (EQFP) (5)	240-pin Plastic Quad Flat Pack (PQFP)	256-pin FineLine Ball-Grid Array (FBGA)	256-pin Ultra FineLine Ball-Grid Array (UBGA)(6)	324-pin FineLine Ball-Grid Array (FBGA)	484-pin FineLine Ball-Grid Array (FBGA)	484-pin Ultra FineLine Ball-Grid Array (UBGA)(6)	780-pin FineLine Ball-Grid Array (FBGA)
EP3C5	94	—	182	182	—	—	—	—
EP3C10	94	—	182	182	—	—	—	—

EP3C55	—	—	—	—	—	327	327	377
EP3C80	—	—	—	—	—	295	295	429
EP3C120	—	—	—	—	—	283	—	531

Note to Table 1–2:

(1) For more information on Device Packaging Specifications, refer to the support section of the Altera website. (**http://www.altera.com/support/devices/packaging/specifications/pkg-pin/spe-index.html**).

(2) The numbers are the maximum I/O counts (including clock input pins) supported by the device-package combination and can be affected by the configuration scheme selected for the device.

(3) All the packages available in lead-free and leaded options.

(4) The EP3C40 device in the F780 package supports restricted vertical migration. Maximum user I/O is restricted to 510 I/Os if you enable migration to the EP3C120 and are using voltage referenced I/O standards. If you are not using voltage referenced I/O standards the maximum number of I/Os can be increased.

(5) The E144 package has an exposed pad at the bottom of the package. This exposed pad is a ground pad that must be connected to the ground plane on your PCB. This exposed pad is used for electrical connectivity and not for thermal purposes.

(6) All the UBGA packages will be supported starting in Quartus II v7.1 SP1 except for the UBGA packages of EP3C16 which will be supported starting in Quartus II v7.2

Table 1–3 lists the Cyclone III FPGA package sizes.

Table 1–3. Cyclone III FPGA Package Sizes

Dimensions	144-pin EQFP	240-pin PQFP	256-pin FBGA	256-pin UBGA	324-pin FBGA	484-pin FBGA	484-pin UBGA	780-pin FBGA

Cyclone III Device Architecture

Cyclone III FPGAs include a customer-defined feature set optimized for cost-sensitive applications and offer a wide range of density, memory, embedded multiplier, I/O, and packaging options. Cyclone III FPGAs support numerous external memory interfaces and I/O protocols common in high volume applications.

Figure 1–1 shows a floor plan view of the Cyclone III device architecture.

Figure 1–1. Cyclone III Device Architecture Overview Note (1)
Note to Figure 1–1:
(1)   EP3C5 and EP3C10 have only 2 PLLs

LEs and LABs

The logic array block (LAB) consists of 16 logic elements (LEs) and a LAB-wide control block. An LE is the smallest unit of logic in the Cyclone III device architecture. Each LE has four inputs, a 4-input Look-Up-Table (LUT), a register, and output logic. The 4-input LUT is a function generator that can implement any function of four variables.

For more information, refer to the *Logic Elements (LE) and Logic Array Blocks (LAB)* chapter in the *Cyclone III Device Handbook.*

MultiTrack Interconnect

In the Cyclone III device architecture, interconnections between LEs, LABs, M9K memory blocks, embedded multipliers, and device I/O pins are provided by the MultiTrack™ interconnect structure which is a fabric of routing wires. The MultiTrack interconnect structure consists of performance-optimized routing lines of different speeds used for inter- and intra-design block connectivity. The Quartus® II software automatically optimizes designs by placing the critical path on the fastest interconnects.

For more information, refer to the *MultiTrack Interconnect* chapter in the *Cyclone III Device Handbook*.

Memory Blocks

Each Cyclone III FPGA M9K memory block provides up to 9 kbits of on-chip memory capable of operation at up to 260 MHz. The embedded memory structure consists of columns of M9K memory blocks that can be configured as RAM, first-in first-out (FIFO) buffers, or ROM. Cyclone III memory blocks are optimized for applications such as high throughput packet processing, high definition (HD) line buffers for video processing functions, and embedded processor program and data storage. The Quartus II software allows you to take advantage of M9K memory blocks by instantiating memory using a dedicated megafunction wizard, or by inferring memory directly from VHDL or Verilog source code.

Table 1–5. Cyclone III Memory Modes

Port Mode	Port Width Configuration
Single Port	x1, x2, x4, x8, x9, x16, x18, x32 and x36
Simple Dual Port	x1, x2, x4, x8, x9, x16, x18, x32 and x36
True Dual Port	x1, x2, x4, x8, x9, x16 and x18

For more information, refer to the *Memory Blocks* chapter in the *Cyclone III Device Handbook*.

Embedded Multipliers and Digital Signal Processing Support

Cyclone III devices offer up to 288 embedded multiplier blocks and support the following modes: one individual 18-bit x18-bit multiplier per block, or two individual 9-bit x 9-bit multipliers per block. The Quartus II software includes megafunctions that are used to control the mode of

operation of the embedded multiplier blocks based on user parameter settings. Multipliers can also be inferred directly from VHDL or Verilog source code.

In addition to embedded multipliers, Cyclone III FPGAs include a combination of on-chip resources and external interfaces that make them ideal to increase performance, reduce system cost, and lower the power consumption of digital signal processing (DSP) systems. Cyclone III FPGAs can be used alone or as DSP device co-processors to improve price-to-performance ratios of DSP systems.

Cyclone III FPGA DSP system design support includes the following features:

- DSP IP cores; which include:
    - Common DSP processing functions such as finite impulse response (FIR), fast Fourier transform (FFT), and numerically controlled oscillator (NCO) functions
    - Suite of common video and image processing functions
- Complete reference designs for end-market applications
- DSP Builder interface tool between The MathWorks Simulink® and MATLAB® design environment, and Quartus II software
- DSP development kits

For more information, refer to the *Embedded Multipliers* chapter in the *Cyclone III Device Handbook*.

I/O Features

All Cyclone III devices contain eight I/O banks. All I/O banks support the single-ended and differential I/O standards listed in Table 1–6.

Table 1–6. Cyclone III FPGA I/O Standards Support *Note (1)*	
Type	**I/O Standard**
Single-Ended I/O	● LVTTL ● LVCMOS ● SSTL ● HSTL ● PCI ● PCI-X
Differential I/O	● SSTL ● HSTL ● LVPECL ● LVDS ● mini-LVDS ● RSDS ● PPDS

Note to Table 1–6:

(1)   PCI Express and Serial Rapid I/O can be supported using an external PHY device.

The Cyclone III device I/O also supports programmable bus hold, programmable pull-up and pull-down resistors, programmable slew rate control to optimize signal integrity, and hot socketing. Cyclone III devices support calibrated on-chip series termination (OCT) or driver impedance matching (Rs) for single-ended I/O standards with one OCT calibration block per side.

For more information, refer to the *Device I/O Features* chapter in the *Cyclone III Device Handbook*.

Clock Networks and PLLs

Cyclone III FPGAs include up to 20 global clock networks. Global clock signals can be driven from dedicated clock pins, dual purpose clock pins, user logic, and phase-locked loops. Cyclone III FPGAs include up to four PLLs with five outputs per PLL to provide robust clock management and synthesis. PLLs can be used for device clock management, external system clock management, and I/O interfaces.

Cyclone III PLLs can be dynamically reconfigured to enable auto-calibration of external memory interfaces while the device is in operation. This feature also enables support of multiple input source

frequencies and corresponding multiplication, division, and phase shift requirements. PLLs in Cyclone III devices may be cascaded to generate up to 10 internal clocks and 2 external clocks on output pins from a single external clock source.

For PLL specifications and information, please refer to the *DC and Switching Characteristics* and *Clock Networks and PLLs* chapters in the *Cyclone III Device Handbook*.

High-Speed Differential Interfaces

Cyclone III FPGAs support high-speed differential interfaces, such as LVDS, mini-LVDS, RSDS, and PPDS. These high-speed I/O standards in Cyclone III FPGAs are ideal for low-cost applications by providing high data throughput using a relatively small number of I/O pins. All device I/O banks contain LVDS receivers that operate at up to 875 Mbps data rates. Dedicated differential output drivers on the left and right I/O banks can transmit at up to 840 Mbps data rates without the need for any external resistors to save board space and simplify PCB routing. Top and bottom I/O banks support differential transmit functionality with the addition of an external resistor network at up to 640 Mbps data rates.

For more information, refer to the *High-Speed Differential Interfaces* chapter in the *Cyclone III Device Handbook*.

Auto-Calibrating External Memory Interfaces

Cyclone III devices support common memory types including DDR, DDR2, SDR SDRAM, and QDRII SRAM. The DDR2 SDRAM memory interfaces support data rates of up to 400 Mbps. Memory interfaces are supported on all sides of the Cyclone III FPGA. The Cyclone III FPGA contains features such as on-chip termination, DDR output registers, and 8- to 36-bit programmable DQ group widths to enable rapid and robust implementation of different memory standards.

An auto-calibrating megafunction is available in the Quartus II software for DDR and QDR memory interface PHYs. The megafunction is optimized to take advantage of the Cyclone III I/O structure, simplify timing closure requirements, and take advantage of the Cyclone III PLL dynamic reconfiguration feature to calibrate over process, voltage and temperature changes.

For more information, refer to the *External Memory Interfaces* chapter in the *Cyclone III Device Handbook*.

Quartus II Software Support

Quartus II software is the number one design software for performance and productivity. It is the industry's only complete design solution for CPLDs, FPGAs, and structured ASICs. Quartus II software includes an integrated development environment to accelerate system-level design and seamless integration with leading third-party software tools and flows. Cyclone III FPGAs are supported by both the subscription and free Quartus II Web Edition software.

See the *Quartus II Handbook* for more information on the Quartus II software features.

Nios II – The World's Most Versatile Embedded Processor

Cyclone III devices support the Nios® II embedded processor which allows you to implement custom-fit embedded processing solutions. Cyclone III devices can also expand the peripheral set, memory, I/O, or performance of embedded processors. Single or multiple Nios II embedded processors can be designed into a Cyclone III device to provide additional co-processing power or even replace existing embedded processors in your system. Using Cyclone III and Nios II together allows for low-cost, high-performance embedded processing solutions which allow you to extend your product's life cycle and improve time to market over standard product solutions.

Configuration

Cyclone III devices use SRAM cells to store configuration data. Configuration data is downloaded to Cyclone III devices each time the device powers up. Low-cost configuration options include Altera EPCS family serial flash devices, as well as parallel flash configuration options using commodity Intel and Spansion devices. These options provide flexibility for general-purpose applications and the ability to meet

specific configuration and *wake up* time requirements of applications, such as the 100 ms requirement in many automotive applications. *Wake up* time can be adjusted by choosing a configuration option and selecting a fast or standard power-on-reset time.

For more information, refer to the *Configuring Cyclone III Devices* chapter in the *Cyclone III Device Handbook*.

Remote System Upgrades

Cyclone III devices offer remote system upgrade without an external controller. Remote system upgrade capability in Cyclone III devices allows deployment of system upgrades from a remote location. Soft logic (either the Nios II embedded processor or user logic) implemented in a Cyclone III device can download a new configuration image from a remote location, store it in configuration memory, and direct the dedicated remote system upgrade circuitry to initiate a reconfiguration cycle. The dedicated circuitry performs error detection during and after the configuration process, and can recover from an error condition by reverting back to a safe configuration image, and provides error status information. This feature supports serial and parallel flash configuration topologies.

For more information, refer to the *Remote System Upgrade* chapter in the *Cyclone III Device Handbook*.

Hot Socketing and Power-On-Reset

Cyclone III devices feature hot socketing, also known as hot plug-in or hot swap, and power sequencing support without the use of external devices. You can insert or remove a board populated with one or more Cyclone III devices during system operation without causing undesirable effects to the running system bus or the board that was inserted into the system.

The hot socketing feature allows you to use FPGAs on printed circuit boards (PCBs) that also contain a mixture of 3.3 V, 2.5 V, 1.8 V, 1.5 V, and 1.2 V devices. The Cyclone III devices hot socketing feature eliminates power-up sequence requirements for other devices on the board for proper FPGA operation.

For more information, refer to the *Hot Socketing and Power-On Reset* chapter in the *Cyclone III Device Handbook*.

SEU Mitigation

Cyclone III devices offer built-in error detection circuitry to detect data corruption due to soft errors in the configuration random-access memory (CRAM) cells. This feature allows all CRAM contents to be read and verified to match a configuration-computed CRC value. The Quartus II software activates the Cyclone III built-in 32-bit CRC checker.

For more information, refer to the *SEU Mitigation* chapter in the *Cyclone III Device Handbook*.

JTAG Boundary Scan Testing

Cyclone III devices support the JTAG IEEE Std. 1149.1 specification. The Boundary-Scan Test (BST) architecture offers the capability to test pin connections without using physical test probes and capture functional data while a device is operating normally. Boundary-scan cells in the Cyclone III device can force signals onto pins or capture data from pins or logic array signals. Forced test data is serially shifted into the boundary-scan cells. Captured data is serially shifted out and externally compared to expected results. In addition to BST, you can use the IEEE Std. 1149.1 controller for Cyclone III device in-circuit reconfiguration (ICR).

For more information, refer to *IEEE 1149.1 (JTAG) Boundary-Scan Testing* chapter in the *Cyclone III Device Handbook*.

Introduction

This chapter contains feature definitions for logic elements (LEs) and logic array blocks (LABs). It provides details on how an LE works, how LABs contain groups of LEs, and how LABs interface with the other blocks in Cyclone® III devices.

Overview

The logic array consists of LABs, with 16 LEs in each LAB. An LE is a small unit of logic providing efficient implementation of user logic functions. LABs are grouped into rows and columns across the device. Cyclone III devices range from 5,136 to 119,088 LEs.

Logic Elements

The smallest unit of logic in the Cyclone III architecture, the LE, is compact and provides advanced features with efficient logic utilization. Each LE features:

- A four-input look-up table (LUT), which can implement any function of four variables
- A programmable register
- A carry chain connection
- A register chain connection
- The ability to drive all types of interconnects: local, row, column, register chain, and direct link interconnects
- Support for register packing
- Support for register feedback

Figure 2–1 shows a Cyclone III LE.

Altera Corporation-Preliminary
March 2007

2–1

Figure 2–1. Cyclone III LE
LE Features

You can configure each LE's programmable register for D, T, JK, or SR operation. Each register has data, clock, clock enable, and clear inputs. Signals that use the global clock network, general-purpose I/O pins, or any internal logic can drive the register's clock and clear control signals. Either general-purpose I/O pins or internal logic can drive the clock enable. For combinational functions, the LUT output bypasses the register and drives directly to the LE outputs.

Each LE has three outputs that drive the local, row, and column routing resources. The LUT or register output can drive these three outputs independently. Two LE outputs drive column or row and direct link routing connections and one drives local interconnect resources. This allows the LUT to drive one output while the register drives another output. This feature, called register packing, improves device utilization because the device can use the register and the LUT for unrelated

functions. When using register packing, the LAB-wide synchronous load control signal is not available. Refer to the "LAB Control Signals" section for more information on the synchronous load control signal.

Another special packing mode allows the register output to feed back into the LUT of the same LE so that the register is packed with its own fan-out LUT, providing another mechanism for improved fitting. The LE can also drive out registered and unregistered versions of the LUT output.

In addition to the three general routing outputs, the LEs within a LAB have register chain outputs. Register chain outputs allow registers within the same LAB to cascade together. The register chain output allows the LUTs to be used for combinational functions and the registers to be used for an unrelated shift register implementation. These resources speed up connections between LABs while saving local interconnect resources. Figure 2–2 shows a register cascading among LEs in Cyclone III.

Figure 2–2. LE Register Cascade
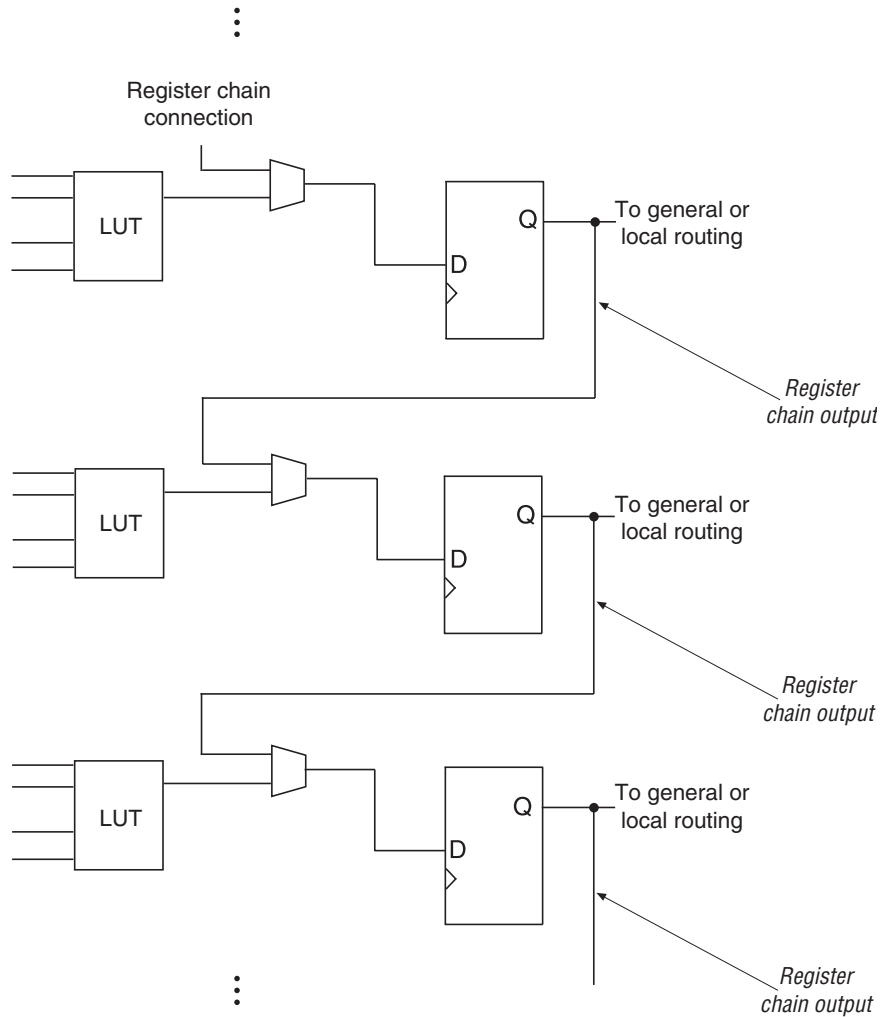

The LUT carry chain may connect to other LUTs from different LEs. The LE carry chain feature is achieved by connecting an LE carry-out to the next LE carry-in. LE carry chains can span more than 16 LEs by using the LAB carry-in and LAB carry-out. Figure 2–3 shows LE carry chains.

Figure 2–3. LE Carry Chains
LE Operating Modes

The Cyclone III LE operates in normal or arithmetic mode.

LE operating modes use LE resources differently. In each mode, there are six available inputs to the LE. These inputs include the four data inputs from the LAB local interconnect, the LE carry-in from the previous carry-chain LE, and the register chain connection. Each input is directed to different destinations to implement the desired logic function. LAB-wide signals provide clock, asynchronous clear, synchronous clear, synchronous load, and clock enable control for the register. These LAB-wide signals are available in all LE modes.

The Quartus® II software, in conjunction with parameterized functions such as the library of parameterized modules (LPM) functions, automatically chooses the appropriate mode for common functions such as counters, adders, subtractors, and arithmetic functions. If required, you can also create special-purpose functions that specify which LE operating mode to use for optimal performance.

Normal Mode

The normal mode is suitable for general logic applications and combinational functions. In normal mode, four data inputs from the LAB local interconnect are inputs to a four-input LUT (see Figure 2–4). The Quartus II Compiler automatically selects the carry-in (cin) or the data3 signal as one of the inputs to the LUT. LEs in normal mode support packed registers and register feedback.

Figure 2–4. LE in Normal Mode
Arithmetic Mode

The arithmetic mode is ideal for implementing adders, counters, accumulators, and comparators. An LE in arithmetic mode implements a 2-bit full adder and basic carry chain (Figure 2–5). LEs in arithmetic mode can drive out registered and unregistered versions of the LUT output. Register feedback and register packing are supported when LEs are used in arithmetic mode.

Figure 2–5. LE in Arithmetic Mode
The Quartus II Compiler automatically creates carry chain logic during design processing, or you can create it manually during design entry. Parameterized functions such as LPM functions automatically take advantage of carry chains for the appropriate functions.

The Quartus II Compiler creates carry chains longer than 16 LEs by automatically linking LABs in the same column. For enhanced fitting, a long carry chain runs vertically, which allows fast horizontal connections to M9K memory blocks or embedded multipliers through direct link interconnects. For example, if a design has a long carry chain in a LAB column next to a column of M9K memory blocks, any LE output can feed an adjacent M9K memory block through the direct link interconnect. Whereas if the carry chains ran horizontally, any LAB not next to the column of M9K memory blocks would use other row or column interconnects to drive a M9K memory block. A carry chain continues as far as a full column.

Logic Array Blocks

Topology

Each LAB consists of the following:

- 16 LEs
- LAB control signals
- LE carry chains
- Register chains
- Local interconnect

The local interconnect transfers signals between LEs in the same LAB. Register chain connections transfer the output of one LE register to the adjacent LE register within a LAB. The Quartus II Compiler places associated logic within a LAB or adjacent LABs, allowing the use of local, and register chain connections for performance and area efficiency. Figure 2–6 shows the Cyclone III LAB.

Figure 2–6. Cyclone III LAB Structure
LAB Interconnects

LAB local interconnect is driven by column and row interconnects and LE outputs within the same LAB. Neighboring LABs, PLLs, M9K RAM blocks, and embedded multipliers from the left and right can also drive the local interconnect of a LAB through the direct link connection. The direct link connection feature minimizes the use of row and column interconnects, providing higher performance and flexibility. Each LE can drive up to 48 LEs through fast local and direct link interconnects. Figure 2–7 shows the direct link connection.

Figure 2–7. Direct Link Connection

Direct link interconnect from right LAB, M9K memory block, embedded multiplier, PLL, or IOE output

Direct link interconnect to left

Direct link interconnect to right

Local Interconnect

LAB
LAB Control Signals

Each LAB contains dedicated logic for driving control signals to its LEs. The control signals include:

- Two clocks
- Two clock enables
- Two asynchronous clears
- One synchronous clear
- One synchronous load

You may use up to eight control signals at a time. Register packing and the synchronous load cannot be used simultaneously.

Each LAB can have up to four non-global control signals. You can use additional LAB control signals as long as they are global signals.

Synchronous clear and load signals are useful for implementing counters and other functions. The synchronous clear and synchronous load signals are LAB-wide signals that affect all registers in the LAB.

Each LAB can use two clocks and two clock enable signals. Each LAB's clock and clock enable signals are linked. For example, any LE in a particular LAB using the `labclk1` signal also uses `labclkena1`. If the LAB uses both the rising and falling edges of a clock, it also uses both LAB-wide clock signals. Deasserting the clock enable signal turns off the LAB-wide clock.

The LAB row clocks `[5..0]` and LAB local interconnect generate the LAB-wide control signals. The MultiTrack™ interconnect's inherent low skew allows clock and control signal distribution in addition to data distribution. Figure 2–8 shows the LAB control signal generation circuit.

Figure 2–8. LAB-Wide Control Signals
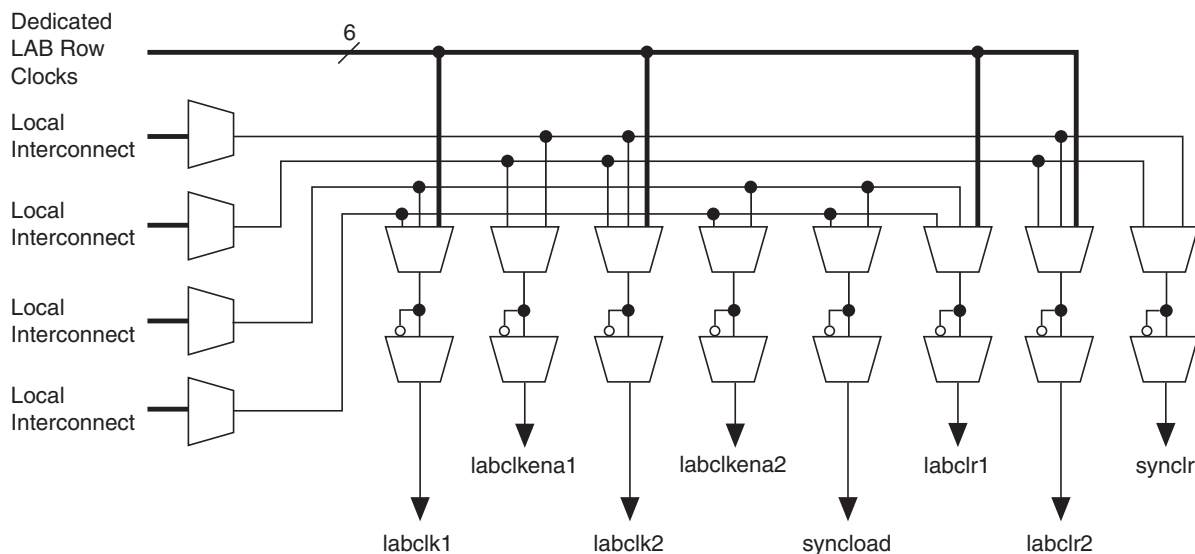

LAB-wide signals control the logic for the register's clear signal. The LE directly supports an asynchronous clear function. Each LAB supports up to two asynchronous clear signals (`labclr1` and `labclr2`).

A LAB-wide asynchronous load signal to control the logic for the register's preset signal is not available. The register preset is achieved by using a NOT gate push-back technique. Cyclone III devices can only support either a preset or asynchronous clear signal.

In addition to the clear port, Cyclone III devices provide a chip-wide reset pin (`DEV_CLRn`) that resets all registers in the device. An option set before compilation in the Quartus II software controls this pin. This chip-wide reset overrides all other control signals.

Conclusion

Cyclone III device LEs and LABs enable you to keep pace with increasing design complexity using a low-cost FPGA device family. The Quartus II software makes it easy to implement Cyclone III device designs in LEs and LABs, making the process invisible to you, thus freeing you from the complexity of LEs and LABs.

3. MultiTrack Interconnect in Cyclone III Devices

Introduction

This Cyclone® III handbook chapter, *MultiTrack Interconnect in Cyclone III Devices*, provides in-depth information about the routing architecture of Cyclone III devices. This document explains the connections between each functional block in Cyclone III devices.

MultiTrack Interconnect

In the Cyclone III device architecture, connections between LEs, M9K memory blocks, embedded multipliers, and device I/O pins are provided by the MultiTrack interconnect structure with DirectDrive™ technology. The MultiTrack interconnect consists of continuous, performance-optimized routing lines of different speeds used for inter- and intra-design block connectivity. The Quartus® II Compiler automatically places critical paths on faster interconnects to improve design performance.

DirectDrive technology is a deterministic routing technology that ensures identical routing resource usage for any function regardless of placement within the device. The MultiTrack interconnect and DirectDrive technology simplify the integration stage of block-based designing by eliminating the re-optimization cycles that typically follow design changes and additions.

The MultiTrack interconnect consists of row (direct link, R4, and R24) and column (register chain, C4, and C16) interconnects that span fixed distances. A routing structure with fixed-length resources for all devices allows predictable and repeatable performance when migrating through different device densities.

Row Interconnects

Row interconnects route signals to and from logic array blocks (LABs), phase-locked loops (PLLs), M9K memory blocks, and embedded multipliers within the same row. These row resources include:

- Direct link interconnects between LABs and adjacent blocks
- R4 interconnects traversing four blocks to the right or left
- R24 interconnects for high-speed access across the length of the device

The direct link interconnect allows blocks to drive into the local interconnect of its left and right neighbors. The direct link interconnect provides fast communication between adjacent blocks without using row interconnect resources.

The R4 interconnects span four LABs, three LABs, and one M9K memory block, or three LABs and one embedded multiplier to the right or left of a source LAB. These resources are used for fast row connections in a four-LAB region. Every LAB has its own set of R4 interconnects to drive either left or right. Figure 3–1 shows R4 interconnect connections from a LAB. The R4 interconnects can drive and be driven by LABs, M9K memory blocks, embedded multipliers, PLLs, and row input/output elements (IOEs). For LAB interfacing, a primary LAB or LAB neighbor (see Figure 3–1) can drive a given R4 interconnect. For R4 interconnects that drive to the right, the primary LAB and right neighbor can drive on to the interconnect. For R4 interconnects that drive to the left, the primary LAB and its left neighbor can drive on to the interconnect. R4 interconnects can drive other R4 interconnects to extend the range of LABs they can drive. Additionally, R4 interconnects can drive R24 interconnects, C4, and C16 interconnects for connections from one row to another.

Figure 3–1. R4 Interconnect Connections   Notes (1), (2), (3)
Notes to Figure 3–1:
(1)   The C4 interconnects can drive R4 interconnects.
(2)   This pattern is repeated for every LAB in the LAB row.
(3)   The R24 row interconnects span 24 LABs and provide the fastest resource for long row connections between non-adjacent LABs, M9K memory blocks, dedicated multipliers, and row IOEs. R24 row interconnects drive to other row or column interconnects at every fourth LAB. R24 row interconnects drive LAB local interconnects via R4 and C4 interconnects and do not drive directly to LAB local interconnects. R24 interconnects can drive R24, R4, C16, and C4 interconnects.

Column Interconnects

The column interconnect operates similar to the row interconnect. Each column of LABs is served by a dedicated column interconnect, which vertically routes signals to and from LABs, M9K memory blocks, embedded multipliers, and row and column I/O elements. These column resources include:

■   Register chain interconnects within a LAB
■   C4 interconnects traversing a distance of four blocks in an up or down direction
■   C16 interconnects for high-speed vertical routing through the device

Cyclone III devices include an enhanced interconnect structure within LABs to route logic element (LE) outputs to LE input connections faster by using register chain connections. The register chain connection allows the register output of one LE to connect directly to the register input of the next LE in the LAB for fast shift registers. The Quartus® II compiler automatically takes advantage of these resources to improve utilization and performance. Figure 3–2 shows the register chain interconnects.

Figure 3–2. Register Chain Interconnects
The C4 interconnects span four blocks up or down from a source LAB, M9K block, or embedded multiplier. Every LAB, M9K block, or embedded multiplier has its own set of C4 interconnects to drive either up or down. Figure 3–3 shows the C4 interconnect connections from a LAB in a column. The C4 interconnects can drive and be driven by all types of architecture blocks, including M9K memory blocks, embedded multiplier blocks, and column and row I/O elements. The C4 interconnect can be driven by the two neighboring LABs or blocks (see Figure 3–3). The C4 interconnects can drive both blocks to extend their range and drive blocks to the left or right for column-to-column connections.

Figure 3–3. C4 Interconnect Connections *Notes (1)*, *(2)*
Notes to Figure 3–3:
(1) Each C4 interconnect can drive either up or down four rows.
(2) The C16 column interconnects span a length of 16 LABs and provide the fastest resource for long column connections between LABs, M9K memory blocks, embedded multipliers, and I/O elements. The C16 column interconnects drive to other row and column interconnects at every fourth LAB. The C16 column interconnects drive LAB local interconnects via C4 and R4 interconnects and do not drive LAB local interconnects directly. The C16 interconnects can drive R24, R4, C16, and C4 interconnects.

Device Routing

All embedded blocks communicate with the logic array similar to LAB-to-LAB interfaces. Each block (for example, M9K memory, embedded multiplier, or PLL) connects to row and column interconnects and has local interconnect regions driven by row and column interconnects. These blocks also have direct link interconnects for fast connections to and from a neighboring LAB.

Table 3–1 shows the Cyclone III device routing scheme.

Table 3–1. Cyclone III Device Routing Scheme

Source	Destination

LAB Local Interconnects

The LAB local interconnect can drive LEs within the same LAB. The LAB local interconnect is driven by column and row interconnects and LE outputs within the same LAB. Neighboring blocks from the left and right can also drive an LAB's local interconnect through the direct link connection. The direct link connection feature minimizes the use of row and column interconnects, providing higher performance and flexibility. Each LE can drive 48 LEs through fast local and direct link interconnects. Figure 3–4 shows the direct link connection.

Figure 3–4. Direct Link Connection

Direct link interconnect to right

LAB

Local Interconnect
See the *Logic Elements and Logic Array Blocks in Cyclone III Devices* chapter in volume 1 of the *Cyclone III Device Handbook* for more information about Cyclone III LABs and LEs.

M9K Routing Interface

The R4, C4, and direct link interconnects from adjacent LABs or blocks drive the M9K block local interconnect. The M9K blocks can communicate with LABs or blocks on either the left or right side through these row resources, or with LAB columns on either left or right with the column resources. Up to 16 direct link input connections to the M9K block are possible from the left adjacent LAB and another 16 possible from the right adjacent LAB. The M9K block outputs can also connect to left and right LABs through each 18 direct link interconnects. Figure 3–5 shows the M9K block to logic array interface.

Figure 3–5. M9K RAM Block LAB Row Interface
See the *Embedded Memory Blocks in Cyclone III Devices Chapter* in volume 1 of the *Cyclone III Device Handbook* for more information about Cyclone III embedded memory blocks.

Embedded Multiplier Routing Interface

The R4, C4, and direct link interconnects from adjacent LABs drive the embedded multiplier row interface interconnect. The embedded multipliers can communicate with LABs on either the left or right side through these row resources or with LAB columns on either the right or left with the column resources. Up to 16 direct link input connections to the embedded multiplier are possible from the left adjacent LABs and another 16 possible from the right adjacent LAB. Embedded multiplier outputs can also connect to left and right LABs through 18 direct link interconnects each. Figure 3–6 shows the embedded multiplier to logic array interface.

Figure 3–6. Embedded Multiplier LAB Row Interface
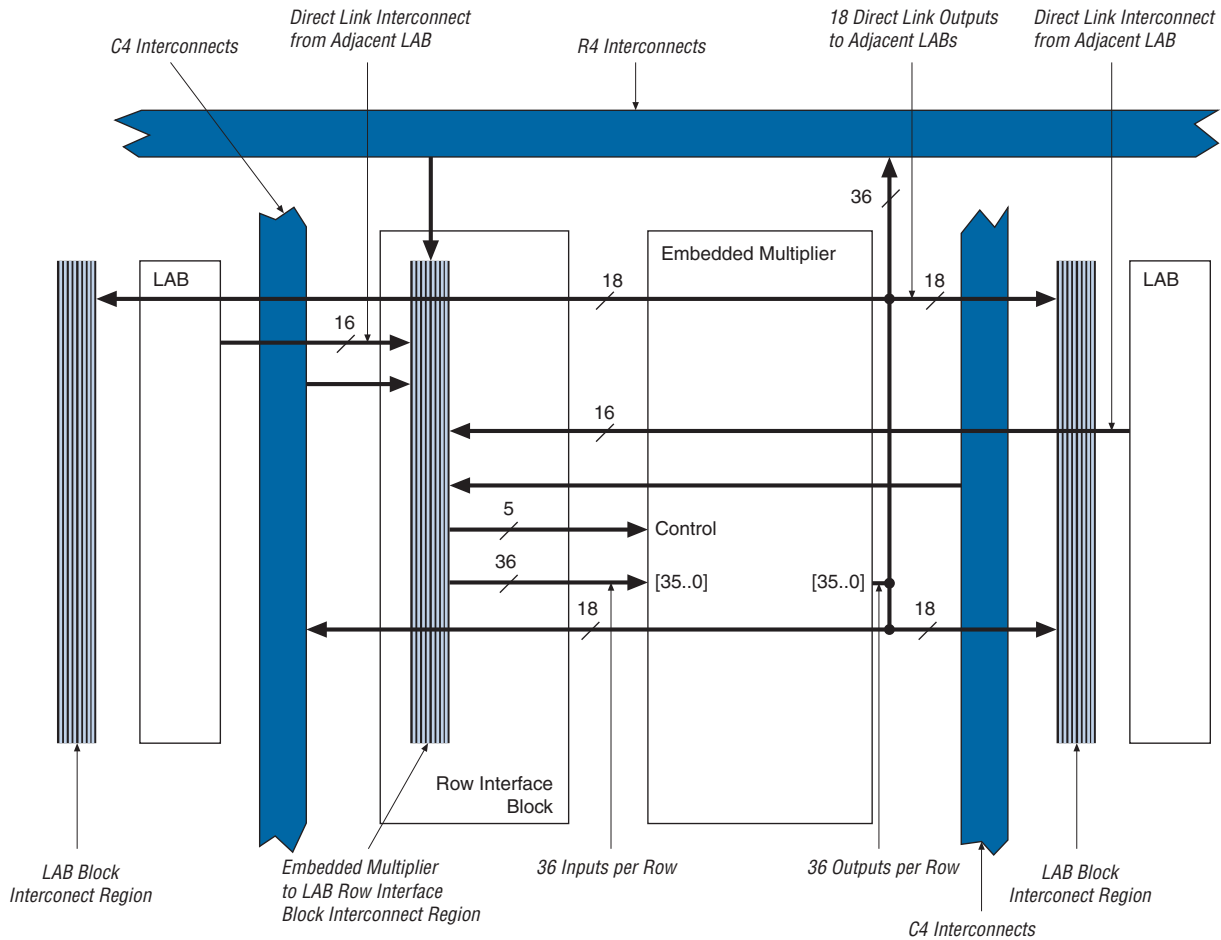

There are five dynamic control input signals that feed the embedded multiplier:

- `signa`
- `signb`
- `clk`
- `clkena`
- `aclr`

The `signa` and `signb` signal can be registered to match the data signal input path. The `clk`, `clkena`, and `aclr` signals feed all registers within a single embedded multiplier.

See the *Embedded Multipliers in Cyclone III Devices Chapter* in volume 1 of the *Cyclone III Device Handbook* for more information about Cyclone III embedded multipliers.

Conclusion

The Cyclone III device provides fast and optimal performance interconnections between LEs, M9K memory blocks, embedded multipliers, and device I/O pins. The Quartus II software provides the most suitable routing interconnects for your design to deliver optimum performance.

CIII51005-1.0

Introduction

Cyclone® III devices feature embedded memory structures to address the on-chip memory needs of Altera® Cyclone III device designs. The embedded memory structure consists of columns of M9K memory blocks that you can configure to provide various memory functions, such as RAM, shift registers, ROM, and first-in first-out (FIFO) buffers. M9K memory blocks provide up to 3.98 Mbit of RAM at a maximum of 260 MHz for synchronous operation (see Table 4–2 for total RAM bits-per-density).

Overview

The M9K blocks support the following features:

- Up to 3.98 Mbit of RAM available without reducing available logic
- 8,192 memory bits per block (9,216 bits per block including parity)
- Independent read-enable and write-enable signals for each port
- Packed mode in which the M9K memory block is split into two 4.5 K single-port RAMs
- Variable port configurations
- Single-port and simple dual-port modes support for all port widths
- True dual-port (one read and one write, two reads, or two writes) operation
- Byte enables for data input masking during writes
- Two clock-enable control signals for each port (port A and port B)
- Initialization file to pre-load content of memory in RAM and ROM modes
- Up to 260 MHz for synchronous only operation

Table 4–1 summarizes the features supported by the M9K memory.

Table 4–1. Summary of M9K Memory Features (Part 1 of 2)	
Feature	**M9K Blocks**
Maximum performance	260 MHz

EP3C80	305	2,810,880
EP3C120	432	3.981,312

Control Signals

Figure 4–1 shows how the register clocks, clears, and control signals are implemented in the Cyclone III memory block.

The clock-enable control signal controls clock entering for the entire memory block, not just the input and output registers. This signal disables the clock so that the memory block does not see any clock edges and will not perform any operations.

The read-enable (rden) and write-enable (wren) control signals control the read and write operations for each port of the memory blocks. You can disable read-enable or write-enable signals independently to save power whenever the operation is not required.

Figure 4–1. M9K Control Signal Selection
Parity Bit Support

Parity checking for error detection is possible by using the parity bit along with internal logic resources. Cyclone III M9K memory blocks support a parity bit for each storage byte. You can use this bit optionally as a parity bit or as an additional data bit. No parity function is actually performed on this bit.

Byte Enable Support

Cyclone III M9K memory blocks support byte enables that mask the input data so that only specific bytes of data are written. The unwritten bytes retain the previous written value. The write enable (`wren`) signals, along with the byte enable (`byteena`) signals, control the RAM block's write operations. The default value for the byte-enable signals is high

(enabled), in which case writing is controlled only by the write-enable signals. There is no clear port to the byte-enable registers. M9K blocks support byte enables when the write port has a data width of ×16, ×18, ×32, or ×36 bits.

Byte enables operate in one-hot manner, with the least significant bit (LSB) of the byteena signal corresponding to the least significant byte of the data bus. For example, if using a RAM block in ×18 mode, with byteena = 01, data[8..0] is enabled and data[17..9] is disabled. Similarly, if byteena = 11, both data[8..0] and data[17..9] are enabled. Byte enables are active high. Table 4–3 summarizes the byte selection.

Table 4–3. Byte Enable for Cyclone III M9K Blocks (1)				
byteena[3..0]	**Affected Bytes**			
	datain×16	**datain×18**	**datain×32**	**datain×36**
[0] = 1	[7..0]	[8..0]	[7..0]	[8..0]
[1] = 1	[15..8]	[17..9]	[15..8]	[17..9]
[2] = 1	-	-	[23..16]	[26..18]
[3] = 1	-	-	[31..24]	[35..27]

Note to Table 4–3:
(1)   Any combination of byte enables is possible.

Figure 4–2 shows how the `wren` and `byteena` signals control the operations of the RAM.

Figure 4–2. Cyclone III Byte Enable Functional Waveform (1)
Note to Figure 4–2:
(1)   For this functional waveform, "New Data" mode is selected.

When a byte-enable bit is de-asserted during a write cycle, the old data in the memory appears in the corresponding data-byte output. When a byte-enable bit is asserted during a write cycle, the corresponding data-byte output depends on the setting chosen in the Quartus® II software. It can be either the newly written data or the old data at that location.

Packed Mode Support

Cyclone III M9K memory blocks support packed mode. You can implement two single-port memory blocks in a single block under the following conditions:

■   Each of the two independent block sizes is less than or equal to half of the M9K block size. The maximum data width for each independent block is 18-bits wide.
■   Each of the single-port memory blocks is configured in single-clock mode.

See "Single-Port Mode" on page 4–10 and "Single-Clock Mode" on page 4–25 for more information.

Address Clock Enable Support

All Cyclone III memory blocks support address clock enable, which holds the previous address value for as long as the signal is enabled and `addressstall` is active high (`addressstall = '1'`). When you configure the memory blocks in dual-port mode, each port has its own independent address clock enable.

Figure 4–3 shows an address clock enable block diagram. The address register output feeds back to its input via a multiplexer. The multiplexer output is selected by the address clock enable (`addressstall`) signal.

Figure 4–3. Cyclone III Address Clock Enable Block Diagram
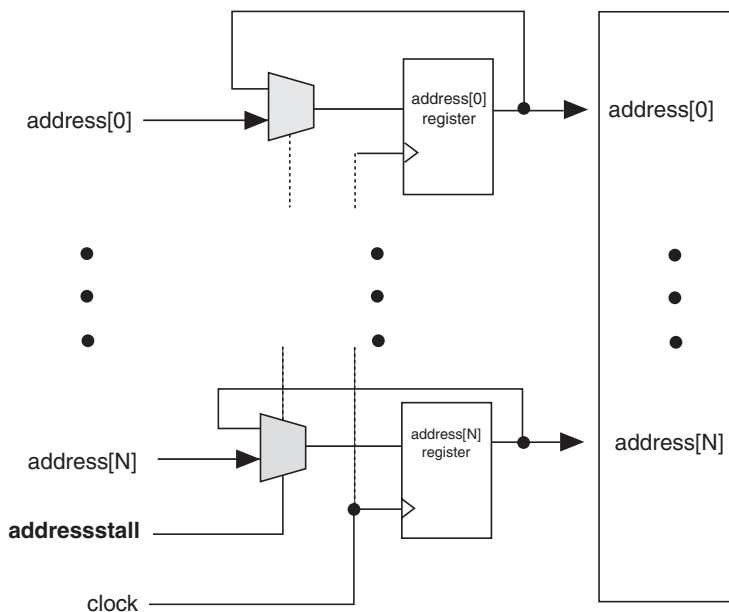

The address clock enable is typically used for cache memory applications to improve efficiency during a cache-miss. The default value for the address clock enable signals is low (disabled). Figures 4–4 and 4–5 show the address clock enable waveforms during read and write cycles, respectively.

Figure 4–4. Cyclone III Address Clock Enable During Read Cycle Waveform

contents at a1	XX	01	02	03			
contents at a2	XX						
contents at a3	XX						
contents at a4	XX					04	
contents at a5	XX					05	
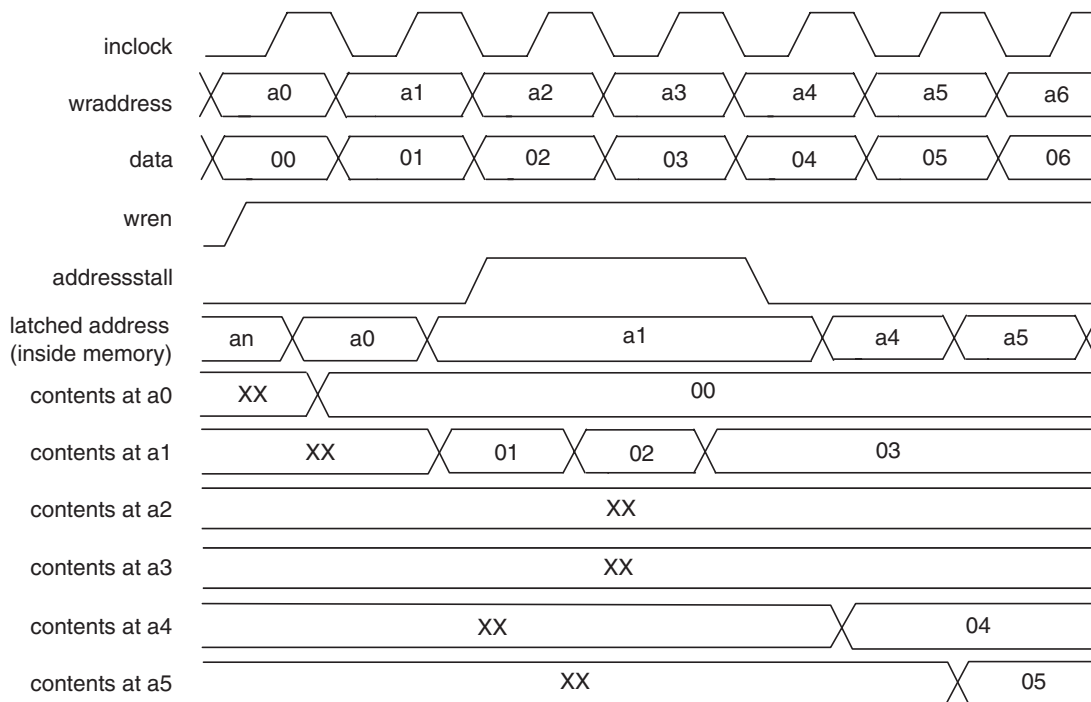

Mixed Width Support

M9K memory blocks support mixed data widths. When using simple dual-port, true dual-port, or FIFO modes, mixed width support allows you to read and write different data widths to a memory block. See "Memory Modes" on page 4–10 for details on the different widths supported per memory mode.

Asynchronous Clear

Cyclone III devices support asynchronous clears for read address registers, output registers and output latches only. Input registers other than read address registers are not supported. When applied to output registers, the asynchronous clear signal clears the output registers. You can see the effects immediately. If your RAM does not use the output registers, you can still clear the RAM outputs via the output latch asynchronous clear.

☞ Asserting asynchronous clear to the read address register duringa read operation could corrupt the memory content.

Figure 4–6 shows the functional waveform for this feature.

Figure 4–6. Output Latch Asynchronous Clear Waveform
☞ You can selectively enable asynchronous clears per logical memory via the Quartus II RAM MegaWizard®.

👣 See the *RAM Megafunction User Guide* for more details.

There are three ways to reset registers in the M9K blocks: power up the device, use the `aclr` signal for output register only, or assert the device-wide reset signal using the `DEV_CLRn` option.

Memory Modes

The Cyclone III M9K memory blocks allow you to implement fully synchronous SRAM memory in multiple modes of operation. Cyclone III M9K memory does not support asynchronous (unregistered) memory inputs.

The M9K memory blocks support the following modes:

■ Single-port
■ Simple dual-port
■ True dual-port
■ Shift-register
■ ROM
■ FIFO

☞ Violating the setup or hold time on the memory block input registers could corrupt memory contents. This applies to both read and write operations.

Single-Port Mode

Single-port mode supports non-simultaneous read and write operations from a single address. Figure 4–7 shows the single-port memory configuration for Cyclone III memory blocks.

Figure 4–7. Single-Port Memory (1), (2)
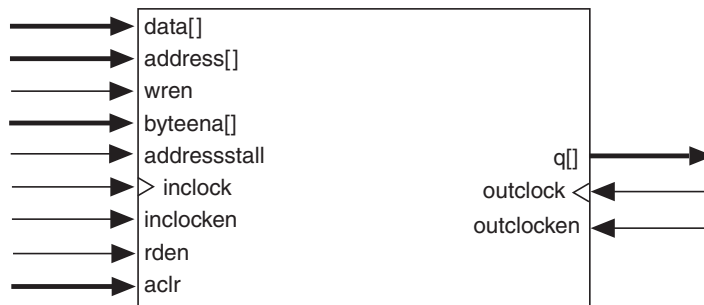

Notes to Figure 4–7:
(1)   You can implement two single-port memory blocks in a single M9K block.
(2)   See "Packed Mode Support" for more details.

During a write operation, behavior of the RAM outputs is configurable. If you activate read enable during a write operation, RAM outputs will show either the new data being written or the old data at that address. If you perform a write operation with read enable deactivated, the RAM outputs retain the values they held during the most recent active read enable. To choose the desired behavior, set the **Read-During-Write** option

to either "New Data" or "Old Data" in the RAM MegaWizard in the Quartus II software. See "Read-During-Write Operations" on page 4–28 for more information about read-during-write mode.

The port width configurations for M9K blocks in single-port mode are as follows:

- 8192 × 1
- 4096 × 2
- 2048 × 4
- 1024 × 8
- 1024 × 9
- 512 × 16
- 512 × 18
- 256 × 32
- 256 × 36

Figure 4–8 shows timing waveforms for read and write operations in single-port mode with unregistered outputs. Registering the RAM's outputs would simply delay the q output by one clock cycle.

Figure 4–8. Cyclone III Single-Port Mode Timing Waveforms
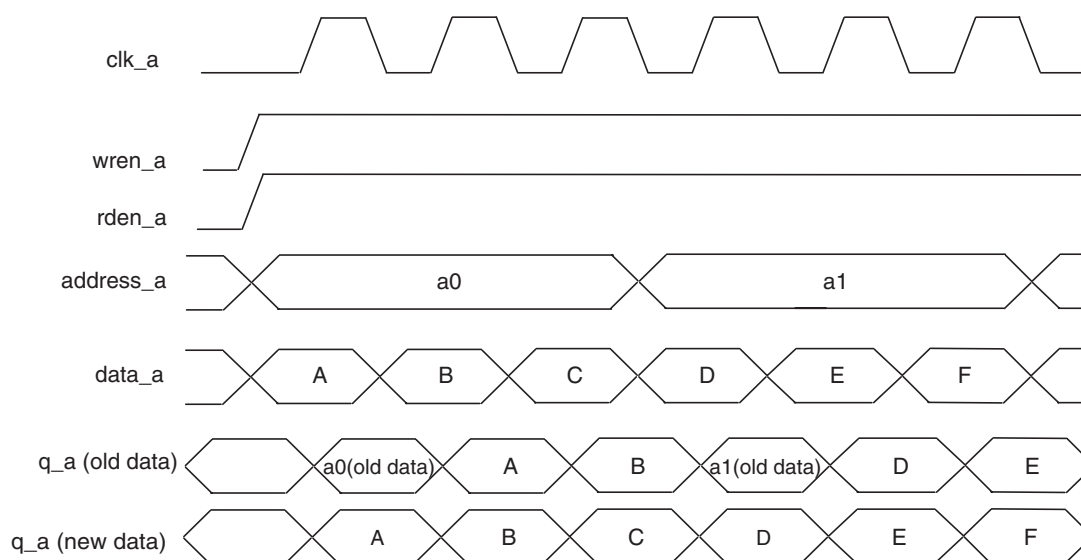

Simple Dual-Port Mode

Simple dual-port mode supports simultaneous read and write operation to different locations. Figure 4–9 shows the simple dual-port memory configuration.

Figure 4–9. Cyclone III Simple Dual-Port Memory (1)
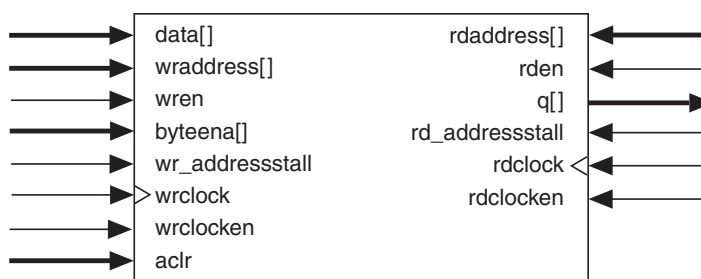

Note to Figure 4–9:
(1)   Simple dual-port RAM supports input/output clock mode in addition to the read/write clock mode shown.

Cyclone III memory blocks support mixed-width configurations, allowing different read and write port widths. Table 4–4 shows mixed-width configurations.

Table 4–4. Cyclone III M9K Block Mixed-Width Configurations (Simple Dual-Port Mode)

Read Port	Write Port								
	8192 × 1	4096 × 2	2048 × 4	1024 × 8	512 × 16	256 × 32	1024 × 9	512 × 18	256 × 36
8192 × 1	✓	✓	✓	✓	✓	✓			
4096 × 2	✓	✓	✓	✓	✓	✓			
2048 × 4	✓	✓	✓	✓	✓	✓			
1024 × 8	✓	✓	✓	✓	✓	✓			
512 × 16	✓	✓	✓	✓	✓	✓			
256 × 32	✓	✓	✓	✓	✓	✓			
1024 × 9							✓	✓	✓
512 × 18							✓	✓	✓
256 × 36							✓	✓	✓

In simple dual-port mode, M9K memory blocks support separate write-enable and read-enable signals. You can save power by keeping the read-enable signal low (inactive) when not reading. Read-during-write operations to the same address can either output "Don't Care" data at that location or output "Old Data". To choose the desired behavior, set the **Read-During-Write** option to either "Don't Care" or "Old Data" in the RAM MegaWizard in the Quartus II software. See "Read-During-Write Operations" on page 4–28 for more details about this behavior.

Figure 4–10 shows timing waveforms for read and write operations in simple dual-port mode with unregistered outputs. Registering the RAM's outputs would simply delay the q output by one clock cycle.

Figure 4–10. Cyclone III Simple Dual-Port Timing Waveforms
True Dual-Port Mode

True dual-port mode supports any combination of two-port operations: two reads, two writes, or one read and one write, at two different clock frequencies. Figure 4–11 shows Cyclone III true dual-port memory configuration.

Figure 4–11. Cyclone III True Dual-Port Memory (1)
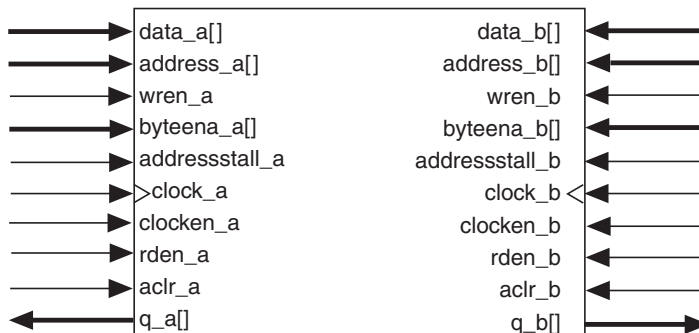

Note to Figure 4–11:
(1)   True dual-port memory supports input/output clock mode in addition to the
       independent clock mode shown.

☞   The widest bit configuration of the M9K blocks in true dual-port
        mode is 512 × 16-bit (18-bit with parity).

Table 4–5 lists the possible M9K block mixed-port width configurations.

Table 4–5. Cyclone III M9K Block Mixed-Width Configurations (True Dual-Port Mode)

Read Port	Write Port						
	8192 × 1	4096 × 2	2048 × 4	1024 × 8	512 × 16	1024 × 9	512 × 18
8192 × 1	✓	✓	✓	✓	✓		
4096 × 2	✓	✓	✓	✓	✓		
2048 × 4	✓	✓	✓	✓	✓		
1024 × 8	✓	✓	✓	✓	✓		
512 × 16	✓	✓	✓	✓	✓		
1024 × 9						✓	✓
512 × 18						✓	✓

In true dual-port mode, M9K memory blocks support separate
write-enable and read-enable signals. You can save power by keeping the
read-enable signal low (inactive) when not reading. Read-during-write
operations to the same address can either output "New Data" at that
location or "Old Data". To choose the desired behavior, set the
Read-During-Write option to either "New Data" or "Old Data" in the
RAM MegaWizard in the Quartus II software. See "Read-During-Write
Operations" on page 4–28 for more details on this behavior.

In true dual-port mode, you can access any memory location at any time from either port A or port B. When accessing the same memory location from both ports, you must avoid possible write conflicts. A write conflict happens when you attempt to write to the same address location from both ports at the same time. This will result in unknown data being stored to that address location. There is no conflict resolution circuitry built into the Cyclone III M9K memory blocks. You must handle address conflicts external to the RAM block.

Figure 4–12 shows true dual-port timing waveforms for the write operation at port A and read operation at port B. Registering the RAM's outputs would simply delay the q outputs by one clock cycle.

Figure 4–12. Cyclone III True Dual-Port Timing Waveforms
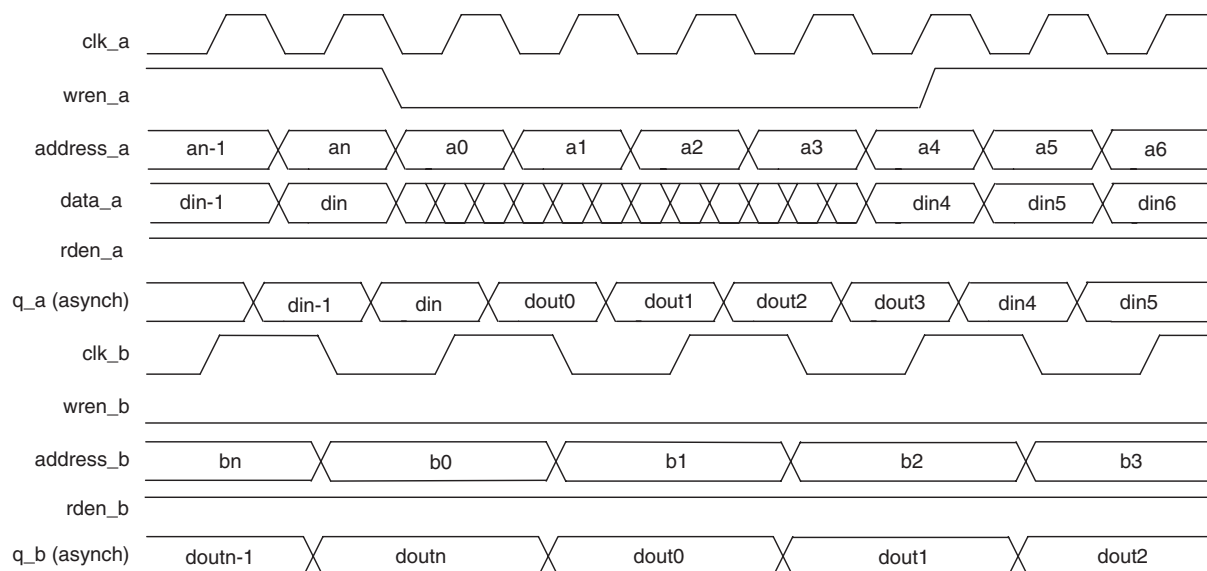

Shift Register Mode

Cyclone III memory blocks can implement shift registers for digital signal processing (DSP) applications, such as finite impulse response (FIR) filters, pseudo-random number generators, multi-channel filtering, and auto-correlation and cross-correlation functions. These and other DSP applications require local data storage, traditionally implemented with standard flip-flops that quickly exhaust many logic cells for large shift registers. A more efficient alternative is to use embedded memory as a shift register block, which saves logic cell and routing resources.

The size of a ($w \times m \times n$) shift register is determined by the input data width (w), the length of the taps (m), and the number of taps (n), and must be less than or equal to the maximum number of memory bits, which is

9,216 bits. In addition, the size of (w x n) must be less than or equal to the maximum width of the block, which is 36 bits. If a larger shift register is required, you can cascade the memory blocks.

Figure 4–13 shows the Cyclone III memory block in the shift register mode.

Figure 4–13. Cyclone III Shift Register Mode Configuration
ROM Mode

Cyclone III memory blocks support ROM mode. A memory initialization file (**.mif**) initializes the ROM contents of these blocks. The address lines of the ROM are registered. The outputs can be registered or unregistered. The ROM read operation is identical to the read operation in the single-port RAM configuration.

FIFO Buffer Mode

Cyclone III memory blocks support single clock or dual clock FIFO buffer. Dual clock FIFO buffers are useful when transferring data from one clock domain to another clock domain. Cyclone III memory blocks do not support simultaneous read and write from an empty FIFO buffer.

Refer to the *Single- and Dual-Clock FIFO Megafunctions User Guide* for more information on FIFO buffers. You will find this at the Altera web site at **http://www.altera.com/literature/ug/ug_fifo.pdf**.

Clocking Modes

Cyclone III M9K memory blocks support the following clocking modes:

- Independent
- Input/output
- Read/write
- Single-clock

☞ Violating the setup or hold time on the memory block input registers could corrupt the memory contents. This applies to both read and write operations.

☞ Asynchronous clears are available on read address registers, output registers and output latches only.

Table 4–6 shows the clocking mode versus memory mode support matrix.

Table 4–6. Cyclone III Memory Clock Modes

Clocking Mode	True Dual-Port Mode	Simple Dual-Port Mode	Single-Port Mode	ROM Mode	FIFO Mode
Independent	✓			✓	
Input/output	✓	✓	✓	✓	
Read/write		✓			✓
Single-clock	✓	✓	✓	✓	✓

Independent Clock Mode

Cyclone III M9K memory blocks can implement independent clock mode for true dual-port memories. In this mode, a separate clock is available for each port (port A and port B). `Clock A` controls all registers on the port A side, while `clock B` controls all registers on the port B side. Each port also supports independent clock enables for port A and B registers.

Figure 4–14 shows a memory block in independent clock mode.

Figure 4–14. Cyclone III Memory Block in Independent Clock Mode
Input/Output Clock Mode

Cyclone III M9K memory blocks can implement input/output clock mode for FIFO, single-port, true, and simple dual-port memories. In this mode, an input clock controls all input registers to the memory block including data, address, byte enables, write enables and also read-enable registers. An output clock controls the data-output registers. Each memory block port also supports independent clock enables for input and output registers.

Figures 4–15, 4–16, and 4–17 show the memory block in input/output clock mode for true dual-port, simple dual-port, and single-port modes, respectively.

Figure 4–15. Cyclone III Input/Output Clock Mode in True Dual-Port Mode
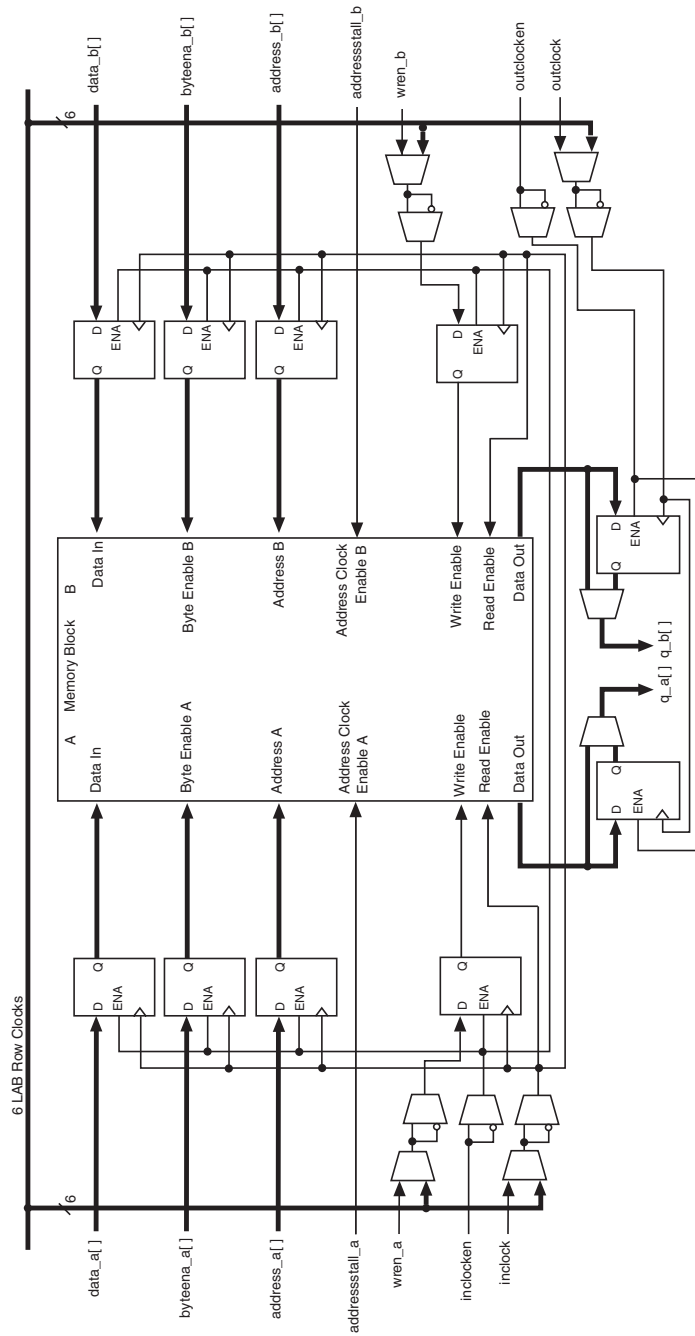

Figure 4–16. Cyclone III Input/Output Clock Mode in Simple Dual-Port Mode
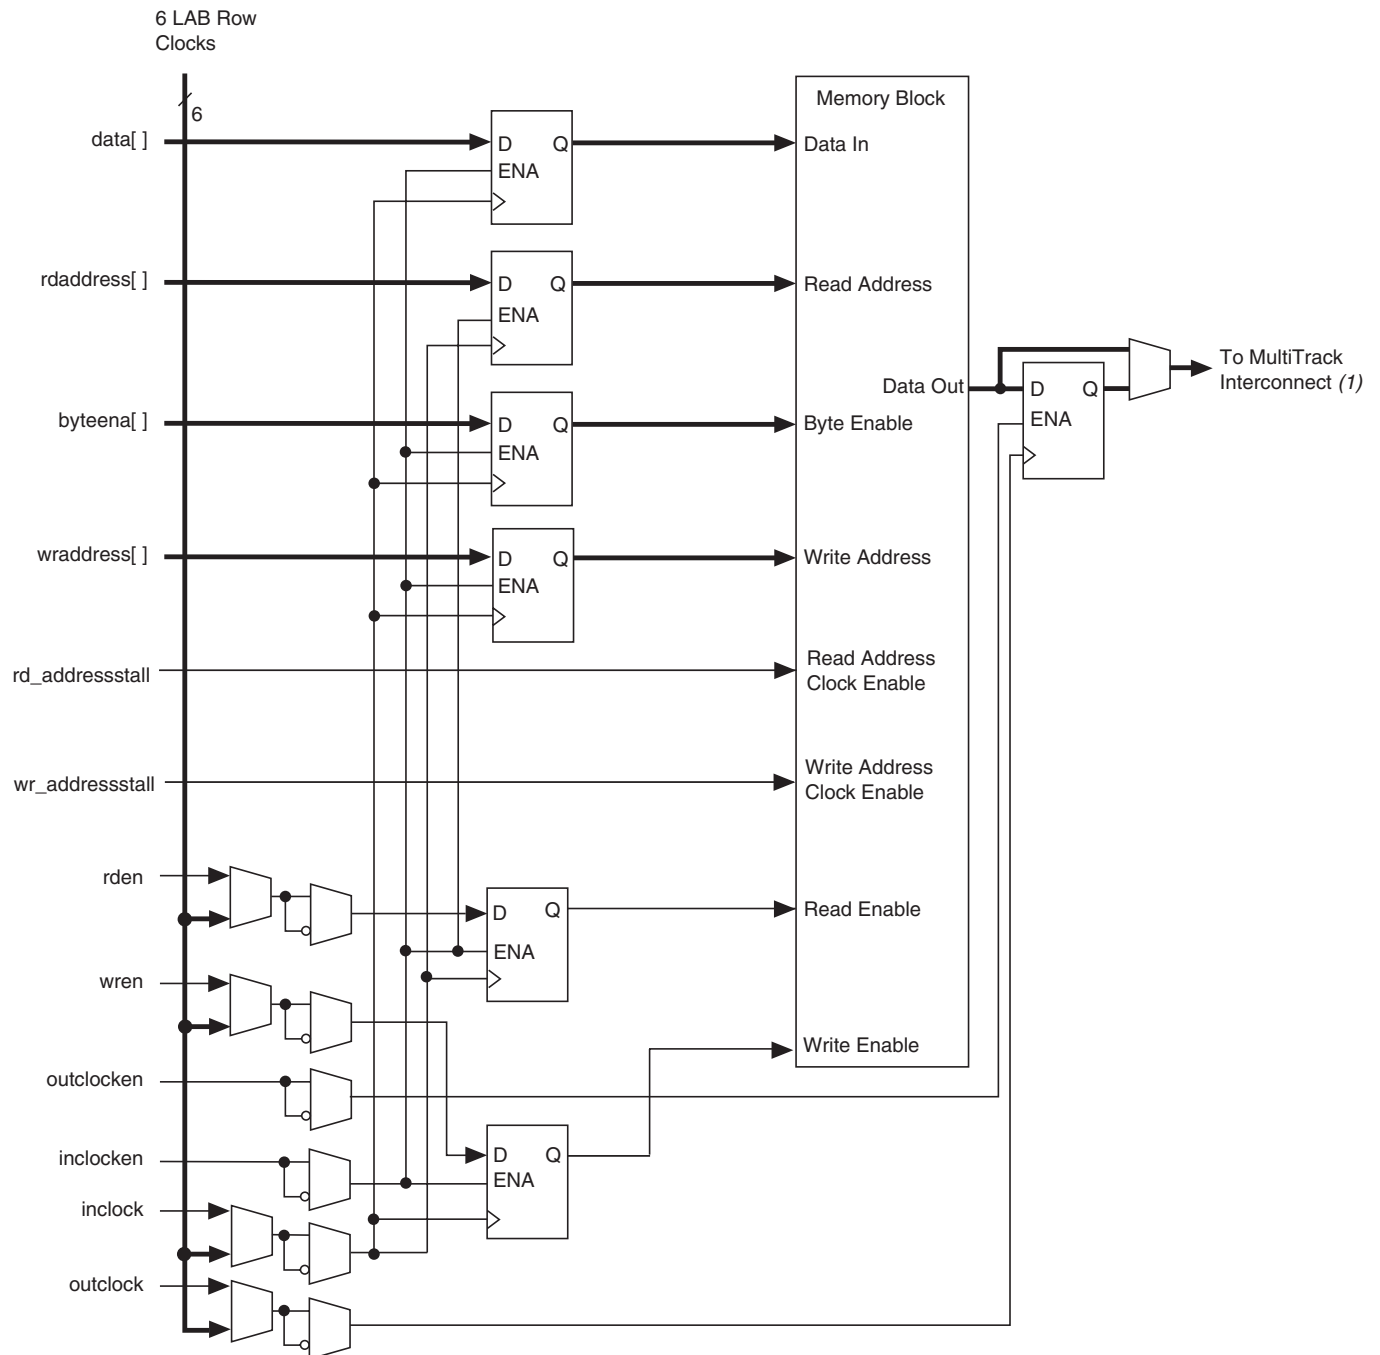

Note to Figure 4–16:

(1)   See the *Cyclone III Device Family Data Sheet* in the *Cyclone III Device Handbook, Volume 1*, for more information on the MultiTrack interconnect.

Figure 4–17. Cyclone III Input/Output Clock Mode in Single-Port Mode
Note to Figure 4–17:

(1)	See the *Cyclone III Device Family Data Sheet* in the *Cyclone III Device Handbook, Volume 1,* for more information on the MultiTrack interconnect.

Read/Write Clock Mode

Cyclone III M9K memory blocks can implement read/write clock mode for FIFO and simple dual-port memories. In this mode, a write clock controls the data inputs, write address, and write-enable registers. Similarly, a read clock controls the data outputs, read address, and read-enable registers. The memory blocks support independent clock enables for both the read and write clocks. Figure 4–18 shows memory block in read/write clock mode.

Figure 4–18. Cyclone III Read/Write Clock Mode
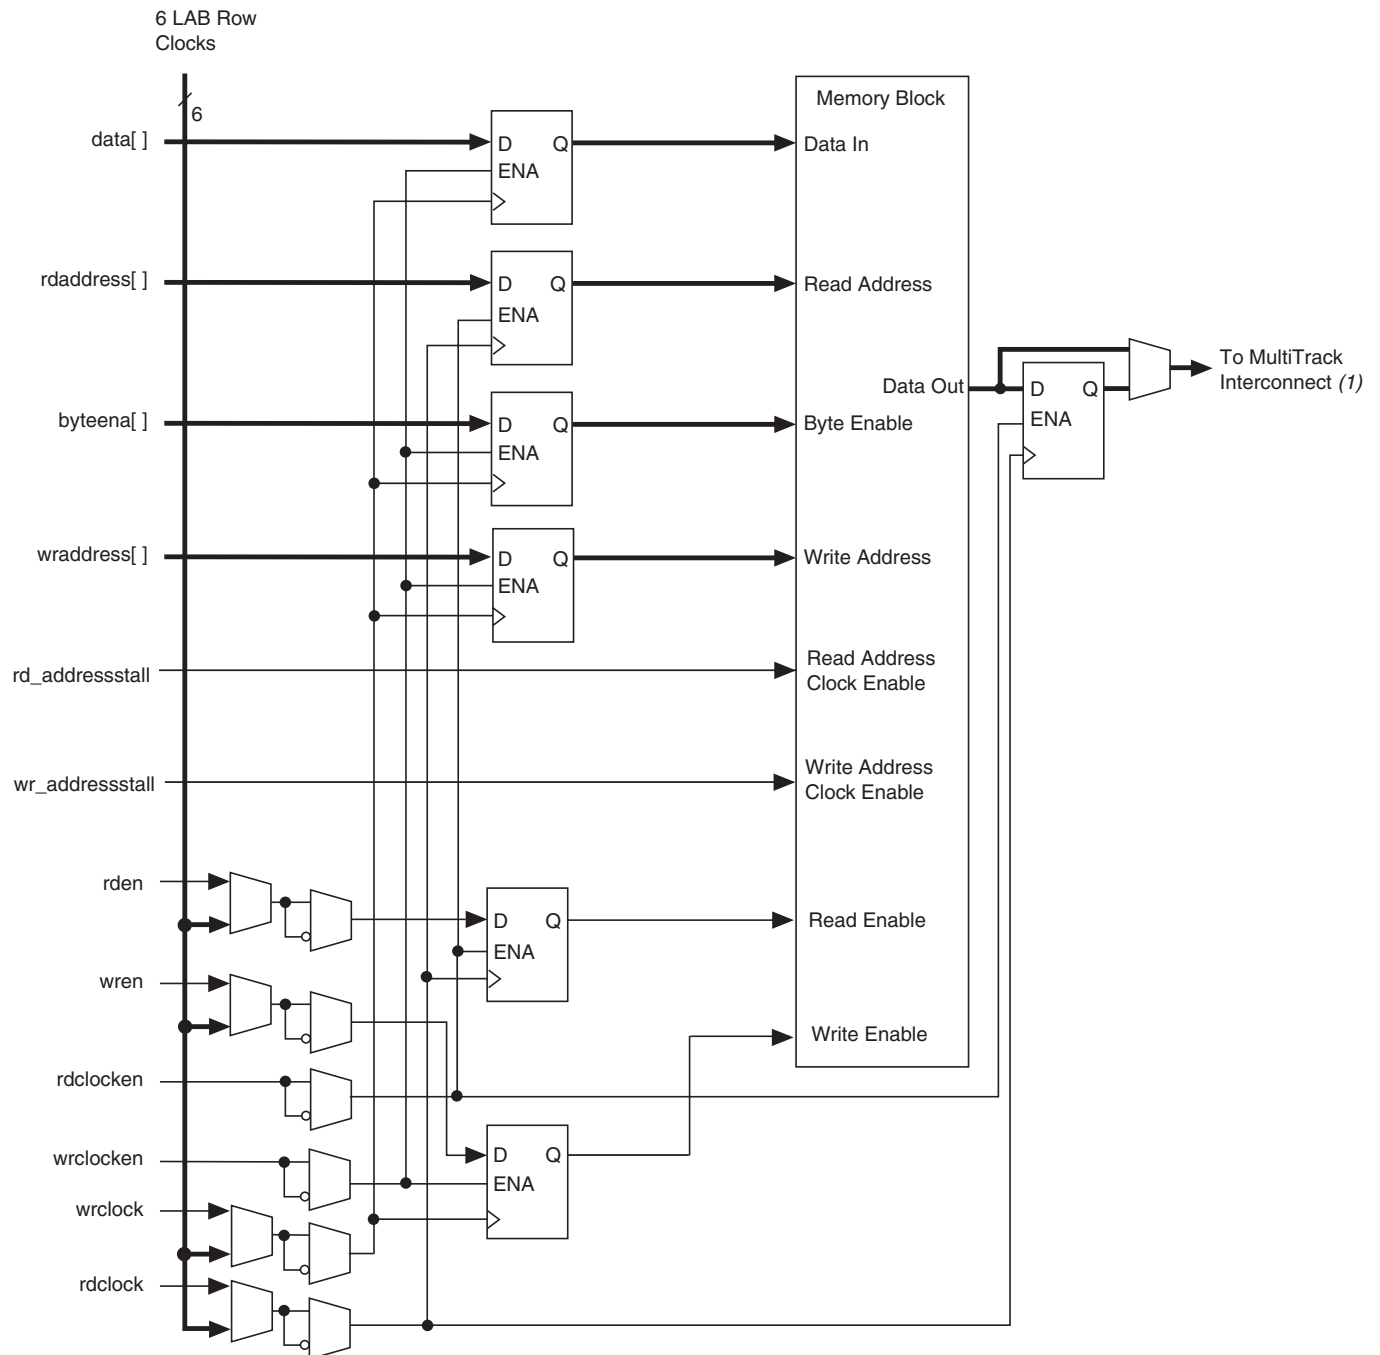

Note to Figure 4–18:

(1)   See the *Cyclone III Device Family Data Sheet* in the *Cyclone III Device Handbook, Volume 1,* for more information on the MultiTrack interconnect.

Single-Clock Mode

Cyclone III M9K memory blocks can implement single-clock mode for FIFO, ROM, true dual-port, simple dual-port, and single-port memories. In this mode, you can control all registers of the memory block with a single clock together with clock enable.

Figures 4–19, 4–20, and 4–21 show the memory block in single-clock mode for true dual-port, simple dual-port, and single-port modes, respectively.

Figure 4–19. Cyclone III Single-Clock Mode in True Dual-Port Mode (1)
Note to Figure 4–19:
(1)   See the *Cyclone III Device Family Data Sheet* in the *Cyclone III Device Handbook, Volume 1,* for more information on the MultiTrack interconnect.

Design Considerations

Read-During-Write Operations

"Same-Port Read-During-Write Mode" on page 4–29 and "Mixed-Port Read-During-Write Mode" on page 4–30 describe the functionality of the various RAM configurations when reading from an address during a write operation at that same address. There are two read-during-write data flows: same-port and mixed-port.

Figure 4–22 shows the difference between these flows.

Figure 4–22. Cyclone III Read-During-Write Data Flow
Same-Port Read-During-Write Mode

This mode applies to a single-port RAM or the same port of a true dual-port RAM. In the same port read-during-write mode, there are two output choices: "New Data" mode (or flow-through) and "Old Data" mode. In the "New Data" mode, new data is available on the rising edge of the same clock cycle on which it was written. In "Old Data" mode, the RAM outputs reflect the old data at that address before the write operation proceeds.

When using New Data mode together with byte enable (`byteena`), you can control the output of the RAM. When byte enable is high, the data written into the memory passes to the output (flow-through). When byte enable is low, the masked-off data is not written into the memory and the old data in the memory appears on the outputs. Therefore, the output can be a combination of new and old data determined by byte enable.

Figures 4–23 and 4–24 show sample functional waveforms of same port read-during-write behavior with both "New Data" and "Old Data" modes, respectively.

Figure 4–23. Same Port Read-During Write: New Data Mode
Figure 4–24. Same Port Read-During-Write: Old Data Mode
Mixed-Port Read-During-Write Mode

This mode applies to a RAM in simple or true dual-port mode, which has one port reading and the other port writing to the same address location with the same clock.

In this mode, you also have two output choices: "Old Data" or "Don't Care". In "Old Data" mode, a read-during-write operation to different ports causes the RAM outputs to reflect the old data at that address location. In "Don't Care" mode, the same operation results in a "Don't Care" or unknown value on the RAM outputs.

Refer to the *RAM Megafunction User Guide* for more details on how to implement the desired behavior.

Figure 4–25 shows a sample functional waveform of mixed port read-during-write behavior for the "Old Data" mode. In "Don't Care" mode, the old data shown in the figure is simply replaced with "Don't Care".

Figure 4–25. Mixed Port Read-During-Write: Old Data Mode
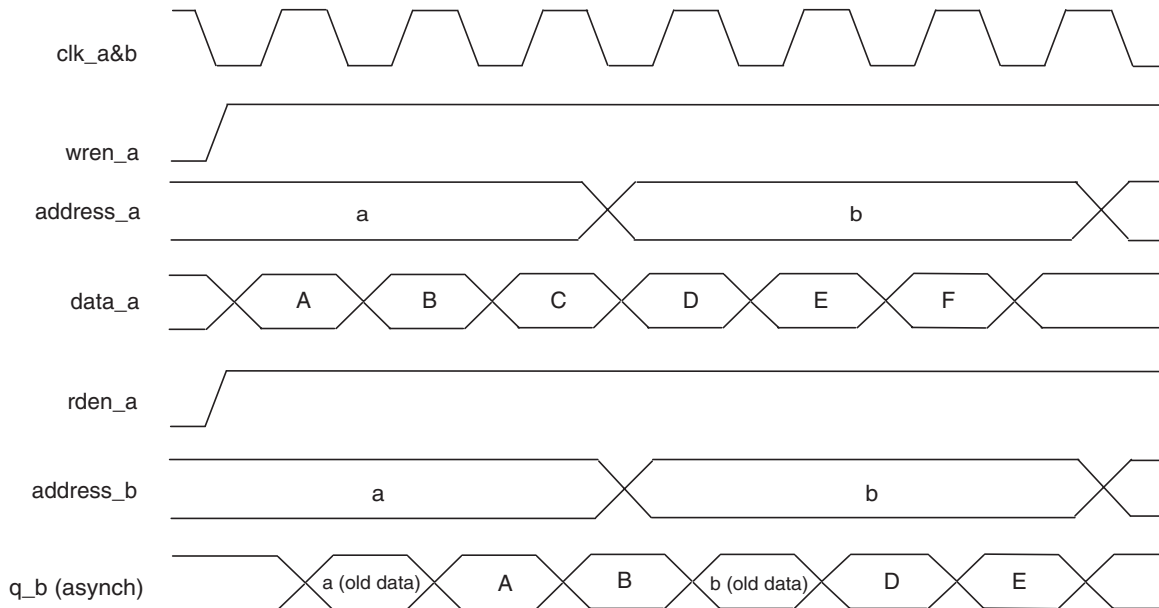

Cyclone III M9K memory blocks do not support mixed-port read-during-write when two different clocks are used in a dual-port RAM. The output value is unknown during a dual-clock mixed-port read-during-write operation.

Conflict Resolution

When using the memory blocks in true dual-port mode, it is possible to attempt two write operations to the same memory location (address). Since there is no conflict resolution circuitry built into the memory blocks, this results in unknown data being written to that location. Therefore, you need to implement conflict-resolution logic external to the memory block.

Power-Up Conditions and Memory Initialization

The Cyclone III memory block outputs power up to zero (cleared) regardless of whether the output registers are used or bypassed. All memory blocks support initialization via a memory initialization file (**.mif**) file. You can create **.mif**s in the Quartus II software and specify their use via the RAM MegaWizard when instantiating memory in your design. Even if memory is pre-initialized (via a **.mif** file, for example), it still powers up with its outputs cleared. Only the subsequent read after power up outputs the pre-initialized values.

For more information on MIF files, refer to the *RAM Megafunction User Guide* as well as the *Quartus II Handbook*. You will find these documents at the Altera web site at **http://www.altera.com/literature/ug/ug_ram.pdf** and **http://www.altera.com/literature/lit-qts.jsp**, respectively.

Power Management

Cyclone III memory block clock enables allow you to control clocking of each memory block to reduce AC power consumption. Use the read-enable signal to ensure that read operations only occur when necessary. If your design does not require read-during-write, reduce power consumption by de-asserting the read-enable signal during write operations, or any period when there are no memory operations.

The Quartus II software automatically powers down any unused memory blocks in order to save static power.

Conclusion

The Cyclone III M9K embedded memory structure provides flexible memory architecture with high memory bandwidth. It addresses the needs of different memory applications in Cyclone III device designs with features such as different memory modes, byte enables, parity bit storage, address clock enables, mixed clock mode, and mixed-port width support. All these configurations are possible via the Quartus II MegaWizard.

Document Revision History

Table 4–7. Document Revision History		
Date and Document Version	**Changes Made**	**Summary of Changes**
March 2007 v1.0	Initial Release	

Introduction

Cyclone® III devices offer up to 244 embedded multiplier blocks and support the following modes: one individual 18 bit × 18 bit multiplier per block, or two individual 9 bit × 9 bit multipliers per block.

In addition to embedded multipliers, Cyclone III FPGAs include a combination of on-chip resources and external interfaces that helps increase performance, reduce system cost, and lower the power consumption of digital signal processing (DSP) systems. You can use Cyclone III FPGAs alone or as DSP device co processors to improve price-to-performance ratios of DSP systems. Particular focus has been placed on optimizing Cyclone III FPGAs for applications benefiting from an abundance of parallel processing resources including video and image processing, IF modems used in wireless communications systems, and multi-channel communications and video systems. Cyclone III FPGA DSP system design support includes:

■ Up to 244 18 × 18 multipliers
■ Up to 2,811 Kbit of on-chip embedded M9K memory blocks
■ High-speed interfaces to external memory such as DDR and DDR2 SDRAM
■ DSP Intellectual Property (IP) cores that include:
   ● Common DSP processing functions like finite impulse response (FIR), fast Fourier transform (FFT), and numerically controlled oscillator (NCO) functions
   ● Video and image processing suite
■ Complete reference designs for end market applications
■ DSP Builder interface between the Mathworks Simulink and MATLAB design environment and the Altera® Quartus® II software
■ DSP optimized development kits

This chapter focuses on the Cyclone III embedded multiplier blocks. Quartus II software makes it easy to take advantage of embedded multipliers by instantiating multipliers using dedicated megafunction wizard interfaces or by inferring multipliers directly in VHDL or Verilog code.

For more information about Quartus II software support of Cyclone III embedded multipliers, refer to "Software Support" on page 5–10.

Embedded Multiplier Block Overview

Each Cyclone III device has one to four columns of embedded multipliers that implement multiplication functions. Figure 5–1 shows one of the embedded multiplier columns with the surrounding logic array blocks (LABs). You can configure each embedded multiplier as one 18 x 18 multiplier or two 9 x 9 multipliers. For multiplication greater than 18 x 18, Quartus II software cascades multiple embedded multiplier blocks together. There is no restriction on the data width of the multiplier, but the greater the data width, the slower the multiplication process.

Figure 5–1. Embedded Multipliers Arranged in Columns with Adjacent LABs
The number of embedded multipliers per column and the number of columns available increases with device density. Table 5–1 shows the number of embedded multipliers in each Cyclone III device and the multiplier modes that you can implement.

Table 5–1. Number of Embedded Multipliers in Cyclone III Devices

Device	Embedded Multipliers	9 x 9 Multipliers *(1)*	18 x 18 Multipliers *(1)*
EP3C5	23	46	23
EP3C10	23	46	23
EP3C16	56	112	56
EP3C25	66	132	66
EP3C40	126	252	126
EP3C55	156	312	156
EP3C80	244	488	244

Note to Table 5–1:

(1) These columns show the number of 9 x 9 or 18 x 18 multipliers for each device. The total number of multipliers for each device is not the sum of all the multipliers.

In addition to the embedded multipliers, you can also implement soft multipliers using Cyclone III M9K memory blocks. You can use M9K blocks as look-up tables (LUTs) that contain partial results from the multiplication of input data with coefficients that implements variable depth/width high-performance soft multipliers for low-cost, high-volume DSP applications. The availability of soft multipliers increases the number of multipliers available within the device. Table 5–2 shows the total number of multipliers available in Cyclone III devices using embedded multipliers and soft multipliers.

Table 5–2. Number of Multipliers in Cyclone III Devices   (Part 1 of 2)

Device	Embedded Multipliers (18 × 18)	Soft Multipliers (16 × 16) *(1)*	Total Multipliers *(2)*
EP3C5	23	--	23
EP3C10	23	46	69
EP3C16	56	56	112
EP3C25	66	66	132
EP3C40	126	126	252

Table 5–2. Number of Multipliers in Cyclone III Devices (Part 2 of 2)			
Device	Embedded Multipliers (18 × 18)	Soft Multipliers (16 × 16) *(1)*	Total Multipliers *(2)*
EP3C55	156	260	416
EP3C80	244	305	549

Notes to Table 5–2:
(1) Soft multipliers are implemented in sum of multiplication mode. The M9K memory blocks are configured with 18-bit data widths to support 16-bit coefficients. The sum of the coefficients requires 18-bits of resolution to account for overflow.
(2) The total number of multipliers may vary according to the multiplier mode you use.

Refer to the *Cyclone III Memory Blocks* chapter in volume 1 of the *Cyclone III Device Handbook* for more information on Cyclone III M9K memory blocks.

Refer to *AN 306: Techniques for Implementing Multipliers in FPGA Devices* for more information about soft multipliers.

Architecture

Each embedded multiplier consists of the following elements:

■   Multiplier stage
■   Input and output registers
■   Input and output interfaces

Figure 5–2 shows the multiplier block architecture.

Figure 5–2. Multiplier Block Architecture
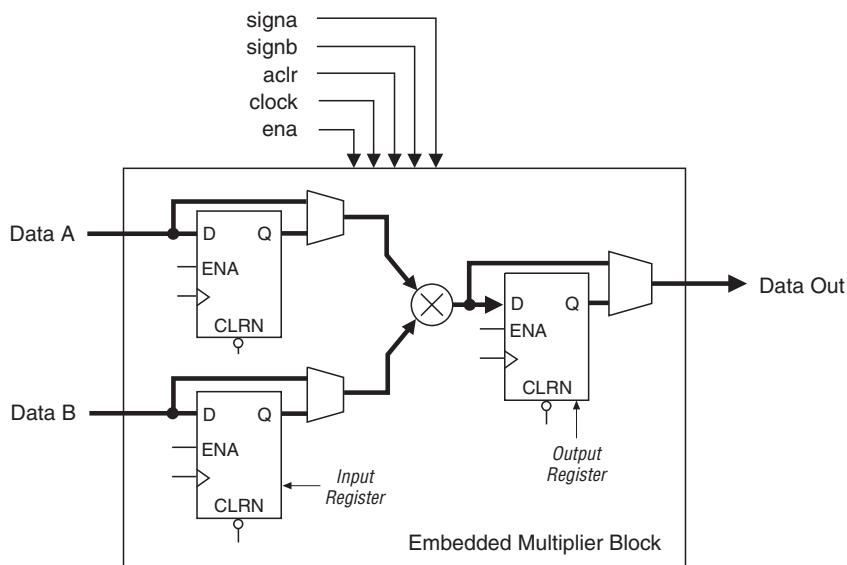

Input Registers

You can send each multiplier input signal into an input register or directly into the multiplier in 9- or 18-bit sections, depending on the operational mode of the multiplier. You can send each multiplier input signal through a register independently of each other (for example, you can send the multiplier's data A signal through a register and send the data B signal directly to the multiplier). The following control signals are available to each input register within the embedded multiplier:

- clock
- clock enable
- asynchronous clear

All input and output registers within a single embedded multiplier are fed by the same clock, clock enable, and asynchronous clear signals.

Multiplier Stage

The multiplier stage of an embedded multiplier block supports 9 x 9 or 18 x 18 multipliers as well as other multipliers in between these configurations. Depending on the data width or operational mode of the multiplier, a single embedded multiplier can perform one or two multiplications in parallel.

Refer to "Operational Modes" on page 5–7 for multiplier details.

Each multiplier operand can be a unique signed or unsigned number. Two signals, signa and signb, control an input of a multiplier and determine if the value is signed or unsigned. If the signa signal is high, the data A operand is a signed number. If the signa signal is low, the data A operand is an unsigned number. Table 5–3 shows the sign of the multiplication result for the various operand sign representations. The result of the multiplication is signed if any one of the operands is a signed value.

Table 5–3. Multiplier Sign Representation				
Data A		**Data B**		**Result**
signa Value	**Logic Level**	**signb Value**	**Logic Level**	
Unsigned	Low	Unsigned	Low	Unsigned
Unsigned	Low	Signed	High	Signed
Signed	High	Unsigned	Low	Signed
Signed	High	Signed	High	Signed

Each embedded multiplier block has only one signa and one signb signal to control the sign representation of the input data to the block. If the embedded multiplier block has two 9 × 9 multipliers, the data A input of both multipliers share the same signa signal, and the data B input of both multipliers share the same signb signal. You can change the signa and signb signals dynamically to modify the sign representation of the input operands at run time. You can send the signa and signb signals through a dedicated input register. The multiplier offers full precision, regardless of the sign representation.

☞ When the signa and signb signals are unused, the Quartus II software sets the multiplier to perform unsigned multiplication by default.

Output Registers

You can choose to register the embedded multiplier output using the output registers in 18- or 36-bit sections, depending on the operational mode of the multiplier. The following control signals are available to each output register within the embedded multiplier:

■ clock
■ clock enable
■ asynchronous clear

All input and output registers within a single embedded multiplier are fed by the same clock, clock enable, and asynchronous clear signals.

Refer to the *MultiTrack Interconnect in Cyclone III Devices* chapter in volume 1 of the *Cyclone III Device Handbook* for more information on embedded multiplier routing and interface.

Operational Modes

You can use an embedded multiplier block in one of two operational modes, depending on the application needs:

■ One 18-bit multiplier
■ Up to two 9-bit independent multipliers

The Quartus II software includes megafunctions used to control the operational modes of the multipliers. After you have made the appropriate parameter settings using the megafunction's MegaWizard® Plug-In Manager, the Quartus II software automatically configures the embedded multiplier.

You can also use the Cyclone III embedded multipliers to implement multiplier adder and multiplier accumulator functions where the multiplier portion of the function is implemented using embedded multipliers and the adder or accumulator function is implemented in logic elements (LEs).

For more information about Quartus II support for Cyclone III embedded multipliers, refer to "Software Support" on page 5–10.

18-Bit Multipliers

You can configure each embedded multiplier to support a single 18 x 18 multiplier for input widths of 10 to 18 bits. Figure 5–3 shows the embedded multiplier configured to support an 18-bit multiplier.

Figure 5–3. 18-Bit Multiplier Mode
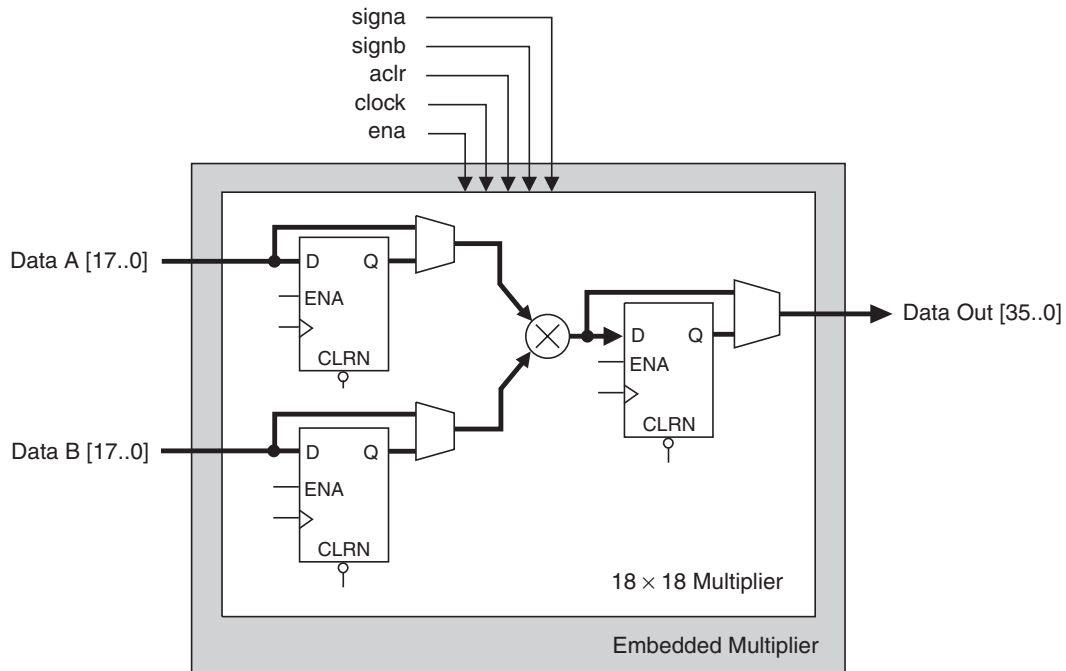

All 18-bit multiplier inputs and results can be sent independently through registers. The multiplier inputs can accept signed integers, unsigned integers, or a combination of both. Additionally, you can change the signa and signb signals dynamically and send these signals through dedicated input registers.

9-Bit Multipliers

You can configure each embedded multiplier to support two 9 x 9 independent multipliers for input widths of up to 9 bits. Figure 5–4 shows the embedded multiplier configured to support two 9-bit multipliers.

Figure 5–4. 9-Bit Multiplier Mode
All 9-bit multiplier inputs and results can be sent independently through registers. The multiplier inputs can accept signed integers, unsigned integers, or a combination of both. Two 9 × 9 multipliers in the same embedded multiplier block share the same `signa` and `signb` signal. Therefore, all of the `data A` inputs feeding the same embedded multiplier must have the same sign representation. Similarly, all of the `data B` inputs feeding the same embedded multiplier must have the same sign representation.

Software Support

Altera provides two methods for implementing multipliers in your design using embedded multiplier resources: instantiation and inference. Both methods use the following four Quartus II megafunctions:

- `lpm_mult`
- `altmult_add`
- `altmult_accum`
- `altfp_mult`

In the first method, you can use the `lpm_mult`, `altmult_add`, and `altfp_mult` megafunctions to implement multipliers. Additionally, you can use the `altmult_add` megafunction as multiplier-adders where embedded multipliers are used as multiply function and LEs configured as adders.

The `altfp_mult` megafunction is a floating point multiplier. It implements the embedded multiplier for floating point numbers multiplication.

The `altmult_accum` megafunction implements multiply accumulate functions where the embedded multiplier implements the multiplier and the accumulator function is implemented in LEs.

Refer to the Quartus II On-Line Help for instructions on using the megafunctions and the MegaWizard Plug-In Manager.

In the second method, you can infer the megafunctions by creating an HDL design and synthesizing it using Quartus II Native Synthesis, or a third-party synthesis tool such as Cadence or Synplify, which recognizes and infers the appropriate multiplier megafunction. With both options, the Quartus II software maps the multiplier functionality to the embedded multipliers during compilation.

For information on our complete DSP Design and Intellectual Property offerings, refer to the Altera web site (**www.altera.com)**.

Refer to the *Synthesis* section in volume 1 of the *Quartus II Handbook* for more information.

Conclusion

Cyclone III embedded multipliers are optimized to support multiplier-intensive DSP applications such as FIR filters, FFT functions, and encoders. You can configure these embedded multipliers to implement multipliers of various bit widths up to 18-bits to suit a particular application, resulting in efficient resource utilization and improved performance and data throughput. The Quartus II software, together with the Synplify software, provide a complete and easy-to-use flow for implementing multiplier functions using embedded multipliers.

6. Clock Networks and PLLs in Cyclone III Devices

Introduction

Cyclone® III devices provide a large number of global clock resources in combination with the clock synthesis precision provided by phase-locked loops (PLLs). This provides a complete clock-management solution. Cyclone III devices provide up to 20 dedicated global clock networks (GCLK). Clock networks that are not being used in the design are automatically turned off in the Quartus® II software to reduce overall power consumption. Cyclone III devices include up to four PLLs per device and up to five outputs per PLL. The additional global clock networks and additional PLL outputs compared to Cyclone II devices enables more efficient use of PLL resources. You can independently program every output, creating a unique, customizable clock frequency with no fixed relation to any other input or output clock. Inherent jitter filtration and fine granularity control over multiply, divide ratios, and dynamic phase shift reconfiguration provide the high performance precision required in today's high-speed applications.

Cyclone III device PLLs are feature rich, supporting advanced capabilities such as clock switchover, dynamic phase shifting, and PLL reconfiguration. Dynamic phase reconfiguration allows implementation of high performance, easy to implement, and self calibrating external memory interfaces. Dynamic phase reconfiguration allows support for advanced display applications where the PLL input frequency may not be known ahead of time or may change. Cyclone III PLLs also support spread-spectrum tracking to support clock sources that lower EMI. The Altera® Quartus II software enables the PLL features without requiring any external devices. The following sections describe the Cyclone III clock networks and PLLs in detail.

Clock Networks

Cyclone III devices provide up to 16 dedicated clock pins (`CLK[15..0]`) that can drive the global clock networks. The smaller Cyclone III devices (EP3C5 and EP3C10) support four dedicated clock pins on the left and right sides of the device, capable of driving a total of ten global clock networks. The larger devices (EP3C16 devices and larger) support four dedicated clock pins on each side of the device. These clock pins can drive 20 global clock networks.

Table 6–1 shows the number of global clocks available across the Cyclone III family members.

Table 6–1. Number of Global Clocks Available in Cyclone III Devices	
Device	**Number of Global Clocks**
EP3C5	10
EP3C10	10
EP3C16	20
EP3C25	20
EP3C40	20
EP3C55	20
EP3C80	20

Global Clock Network

Global clocks drive throughout the entire device, feeding all device quadrants. All resources within the device (I/O elements, logic array blocks (LABs), dedicated multiplier blocks, and M9K memory blocks) can use the global clock networks as clock sources. You can use these clock network resources for control signals, such as clock enables and clears fed by an external pin. Internal logic can also drive the global clock networks for internally generated global clocks and asynchronous clears, clock enables, or other control signals with high fan-out.

Table 6–2 shows the connectivity of the clock sources to the global networks.

Table 6–2. Global Clock Network Connections (Part 1 of 3)

Global Clock Network Clock Sources	Global Clock Networks																			
	All Cyclone III Devices										EP3C16 through EP3C80 Devices Only									
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19

Note to Table 6–2:

(1) EP3C5 and EP3C10 have only PLLs 1 and 2.
(2) This pin only applies to EP3C5 and EP3C10 devices.
(3) These pins only apply to EP3C16 devices and larger. Only one of the two CDPCLK pins can feed the clock control block. The other pin can be used as a regular I/O pin.

If you do not use the dedicated clock pins to feed the global clock networks, you can use them as general-purpose input pins to feed the logic array. However, when using them as general-purpose input pins, they do not have support for an I/O register and must use LE-based registers in place of an I/O register.

Clock Control Block

The clock control block drives global clock networks. Clock control blocks are located on each side of the device, close to the dedicated clock input pins. Global clock networks are optimized for minimum clock skew and delay.

Table 6–3 lists the sources that can feed the clock control block, which in turn feeds the global clock networks.

Table 6–3. Clock Control Block Inputs	
Input	**Description**
Dedicated clock inputs	Dedicated clock input pins can drive clocks or global signals, such as synchronous and asynchronous clears, presets, or clock enables onto given global clock networks.
Dual-purpose clock (DPCLK and CDPCLK) I/O inputs	DPCLK and CDPCLK I/O pins are bidirectional dual function pins that can be used for high fan-out control signals, such as protocol signals, TRDY and IRDY signals for PCI, or DQS for DDR, via the global clock network. Clock control blocks which have inputs driven by internal logic will not be able to drive PLL inputs.
PLL outputs	The PLL counter outputs can drive the global clock network.
Internal logic	You can drive the global clock network through the logic array routing to enable internal logic (Logic Elements) to drive a high fan-out, low skew signal path. Clock control blocks which have inputs driven by internal logic will not be able to drive PLL inputs.

In Cyclone III devices, the dedicated clock input pins, PLL counter outputs, dual-purpose clock I/O inputs, and internal logic can all feed the clock control block for each global clock network. The output from the clock control block in turn feeds the corresponding global clock network. This global clock can drive the PLL input if the clock control block inputs are outputs of another PLL or dedicated clock input pins. The clock control blocks are at the device periphery and there are a maximum of 20 clock control blocks available per Cyclone III device.

The control block has two functions:

■ Dynamic global clock network clock source selection
■ Global clock network power-down (dynamic enable and disable)

Figure 6–1 shows the clock control block.

Figure 6–1. Clock Control Block *Notes (1), (2), (3), (4)*
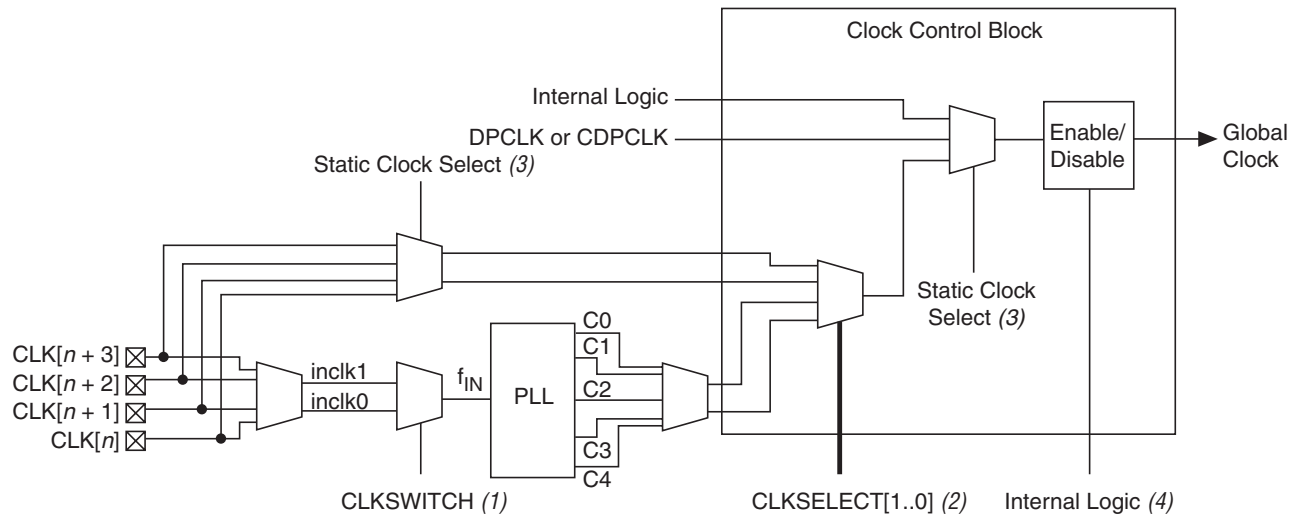

Notes to Figure 6–1:
(1) The `clkswitch` signal can either be set through the configuration file or dynamically set when using the manual PLL switchover feature. The output of the multiplexer is the input clock (f_{IN}) for the PLL.
(2) The `clkselect[1..0]` signals are fed by internal logic and can be used to dynamically select the clock source for the global clock network when the device is in user mode.
(3) The static clock select signals are set in the configuration file. Therefore, dynamic control when the device is in user mode is not feasible.
(4) You can use internal logic to enable or disable the global clock network in user mode.

Each PLL generates five clock outputs through the `c[4..0]` counters. Two of these clocks can drive the global clock network through a clock control block as shown in Figure 6–1.

Global Clock Network Clock Source Generation

There are a total of ten clock control blocks in the smaller Cyclone III devices (EP3C5 and EP3C10), and a total of 20 clock control blocks in the larger Cyclone III devices (EP3C16 devices and larger). Figure 6–2 and Figure 6–3 show the Cyclone III PLL, clock inputs and the clock control block location for different device densities.

Figure 6–2. EP3C16 and Larger PLL, CLK[], DPCLK[] and Clock Control Block Locations Note (1)
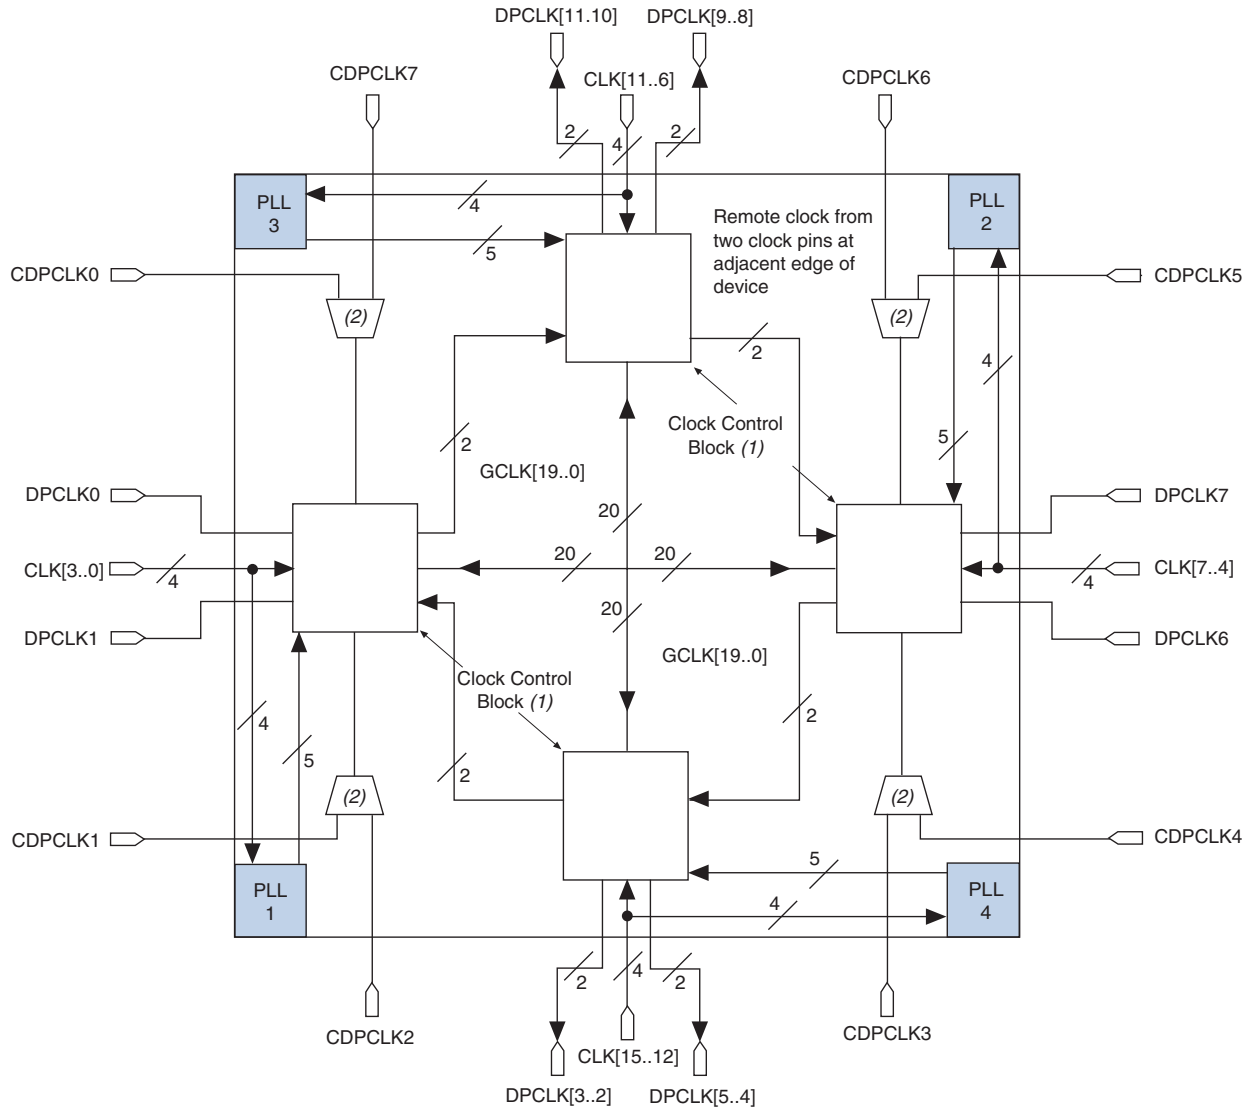

Notes to Figure 6–2:
(1) There are five clock control blocks on each side.
(2) Only one of the corner CDPCLK pins in each corner can feed the clock control block at a time. The other CDPCLK pins can be used as general-purpose I/O pins.

Figure 6–3. Cyclone III Clock Control Blocks Placement
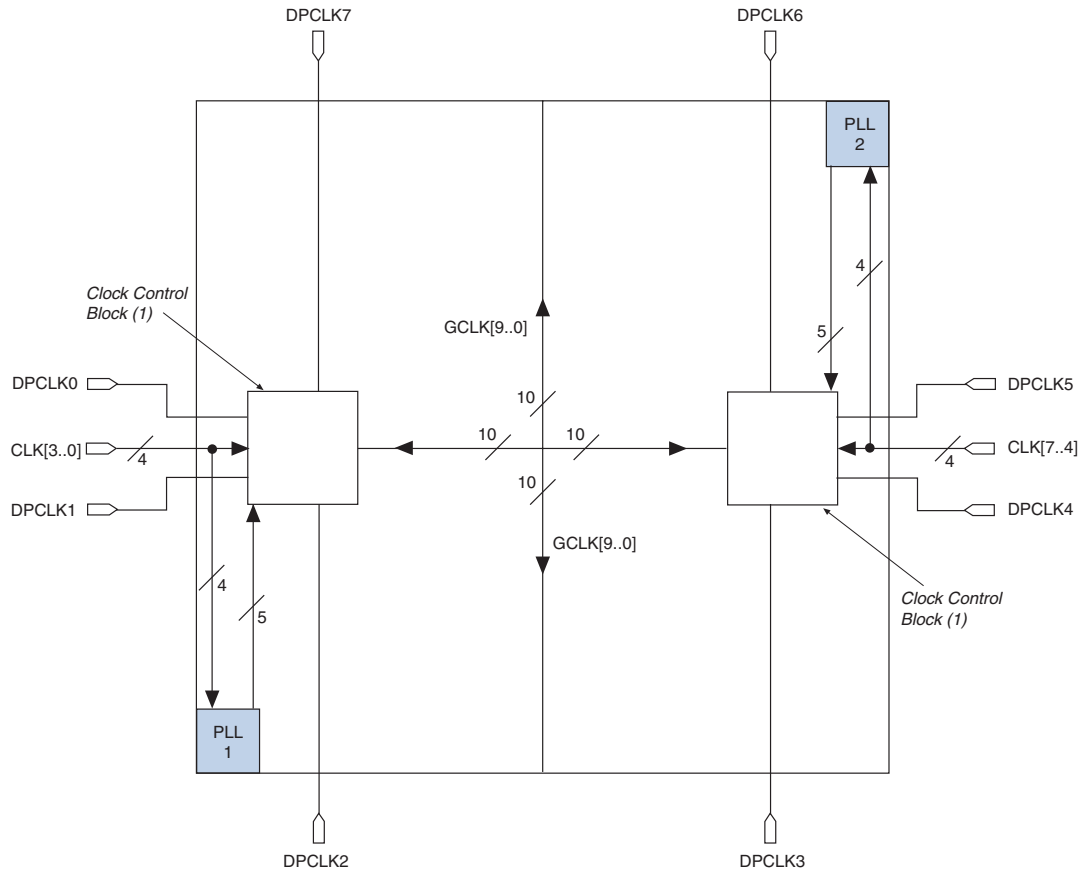

Note to Figure 6–3:
(1)   There are five clock control blocks on each side.

The inputs to the five clock control blocks on each side must be chosen from among the following clock sources:

■ Four clock input pins

■ Five PLL counter outputs

■ Two DPCLK pins and two CDPCLK pins from both the left and right sides and four DPCLK pins and two CDPCLK pins from both the top and bottom

■ Five signals from internal logic

From the clock sources listed above, only two clock input pins, two PLL clock outputs, one DPCLK or CDPCLK pin, and one source from internal logic can drive into any given clock control block, as shown in Figure 6–1. Out of these five inputs to any clock control block, the two clock input pins and two PLL outputs can be dynamically selected to feed a global clock network. The clock control block supports static selection of the signal from internal logic.

Figure 6–4 shows the simplified version of the five clock control blocks on each side of the Cyclone III device periphery. The Cyclone III devices support up to 20 of these clock control blocks and this allows for up to a maximum of 20 global clocks in Cyclone III devices.

Figure 6–4. Clock Control Blocks on Each Side of the Cyclone III Device *Note (1)*
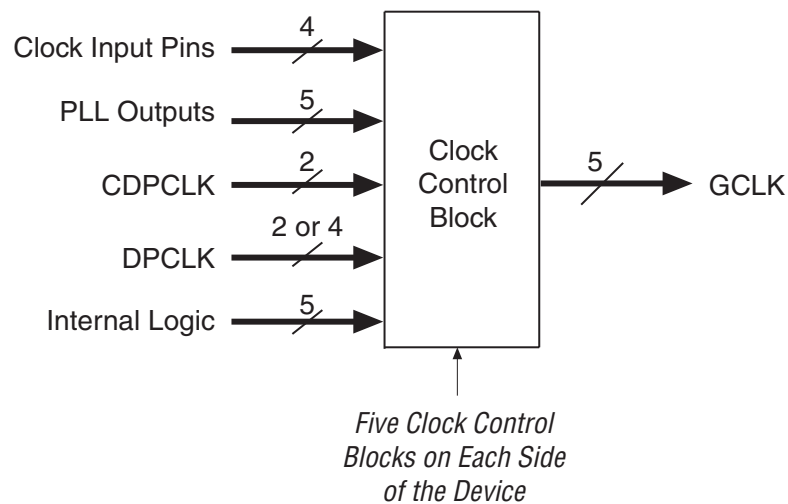

Note to Figure 6–4:

(1)   The left and right sides of the device have two DPCLK pins, and the top and bottom of the device have four DPCLK pins.

Global Clock Network Power Down

You can disable the Cyclone III global clock network (power down) by both static and dynamic approaches. In the static approach, configuration bits are set in the configuration file generated by the Quartus II software, which automatically disables unused global clock networks. The dynamic clock enable or disable feature allows internal logic to control clock enable or disable of the global clock networks in the Cyclone III device.

When a clock network is disabled, all the logic fed by the clock network is in an off-state, thereby reducing the overall power consumption of the device. This function is independent of the PLL and is applied directly on the clock network, as shown in Figure 6–1 on page 6–7. The input clock sources and the `clkena` signals for the global clock network multiplexers can be set through the Quartus II software using the `altclkctrl` megafunction.

Refer to the `altclkctrl` *Megafunction User Guide* for more information.

Clkena Signals

In Cyclone III, devices support `clkena` signals at the clock network level. Figure 6–5 shows how to implement `clkena`. This allows you to gate off the clock even when a PLL is used. Upon re-enabling the output clock, the PLL does not need a resynchronization or re-lock period because the circuit gates off the clock at the clock network level. In addition, the PLL can remain locked independent of the `clkena` signals since the loop-related counters are not affected.

Figure 6–5. Clkena Implementation
Figure 6–6 shows the waveform example for a clock output enable. The `clkena` signal is sampled on the falling edge of the clock (`clkin`).

This feature is useful for applications that require a low power or sleep mode.

Figure 6–6. Clkena Implementation - Output Enable
The `clkena` signal can also disable clock outputs if the system is not tolerant to frequency overshoot during PLL resynchronization.

Altera recommends using the `clkena` signals when switching the clock source to the PLLs or the global clock network. The recommended sequence is:

1. Disable the primary output clock by de-asserting the `clkena` signal.

2. Switch to the secondary clock using the dynamic select signals of the clock control block.

3. Allow some clock cycles of the secondary clock to pass before re-asserting the `clkena` signal. The exact number of clock cycles you need to wait before enabling the secondary clock is design dependent. You can build custom logic to ensure glitch-free transition when switching between different clock sources.

PLLs in Cyclone III Devices

Cyclone III devices offer up to four PLLs that provide robust clock management and synthesis for device clock management, external system clock management, and high-speed I/O interfaces. Table 6–4 shows the PLLs available for each Cyclone III device.

Table 6–4. Cyclone III Device Availability				
Device	**PLL1**	**PLL 2**	**PLL 3**	**PLL 4**
EP3C5	✓	✓		
EP3C10	✓	✓		
EP3C16	✓	✓	✓	✓
EP3C25	✓	✓	✓	✓
EP3C40	✓	✓	✓	✓
EP3C55	✓	✓	✓	✓
EP3C80	✓	✓	✓	✓

All Cyclone III PLLs have the same core analog structure. Table 6–5 shows the features available in Cyclone III PLLs.

Table 6–5. Cyclone III PLL Hardware Features (Part 1 of 2)	
Hardware Features	**Availability**
C (output counters)	5
M, N, C counter sizes	1 to 512 *(1)*
Dedicated clock outputs	1 single-ended or 1 differential
Clock input pins	4 single-ended or 2 differential pins
Spread-spectrum input clock tracking	Yes *(2)*
PLL Cascading	Through GCLK
Compensation modes	Source-Synchronous Mode, No Compensation Mode, Normal Mode, and Zero Delay Buffer Mode
Phase shift resolution	Down to 96-ps increments *(3)*
Programmable duty cycle	Yes
Output counter cascading	Yes
Input clock Switchover	Yes
User mode reconfiguration	Yes

Table 6–5. Cyclone III PLL Hardware Features (Part 2 of 2)	
Hardware Features	**Availability**
Loss of lock detection	Yes

Notes to Table 6–5:

(1)   C counters range from 1 through 512 if the output clock uses a 50% duty cycle. For any output clocks using a non-50% duty cycle, the post-scale counters range from 1 through 256.

(2)   Provided input clock jitter is within input jitter tolerance specifications.

(3)   The smallest phase shift is determined by the VCO period divided by eight. For degree increments, the Cyclone III device can shift all output frequencies in increments of at least 45 degrees. Smaller degree increments are possible depending on the frequency and divide parameters.

Figure 6–7 shows the location of PLLs in Cyclone III devices.

Figure 6–7. Cyclone III PLL Locations Note (1)
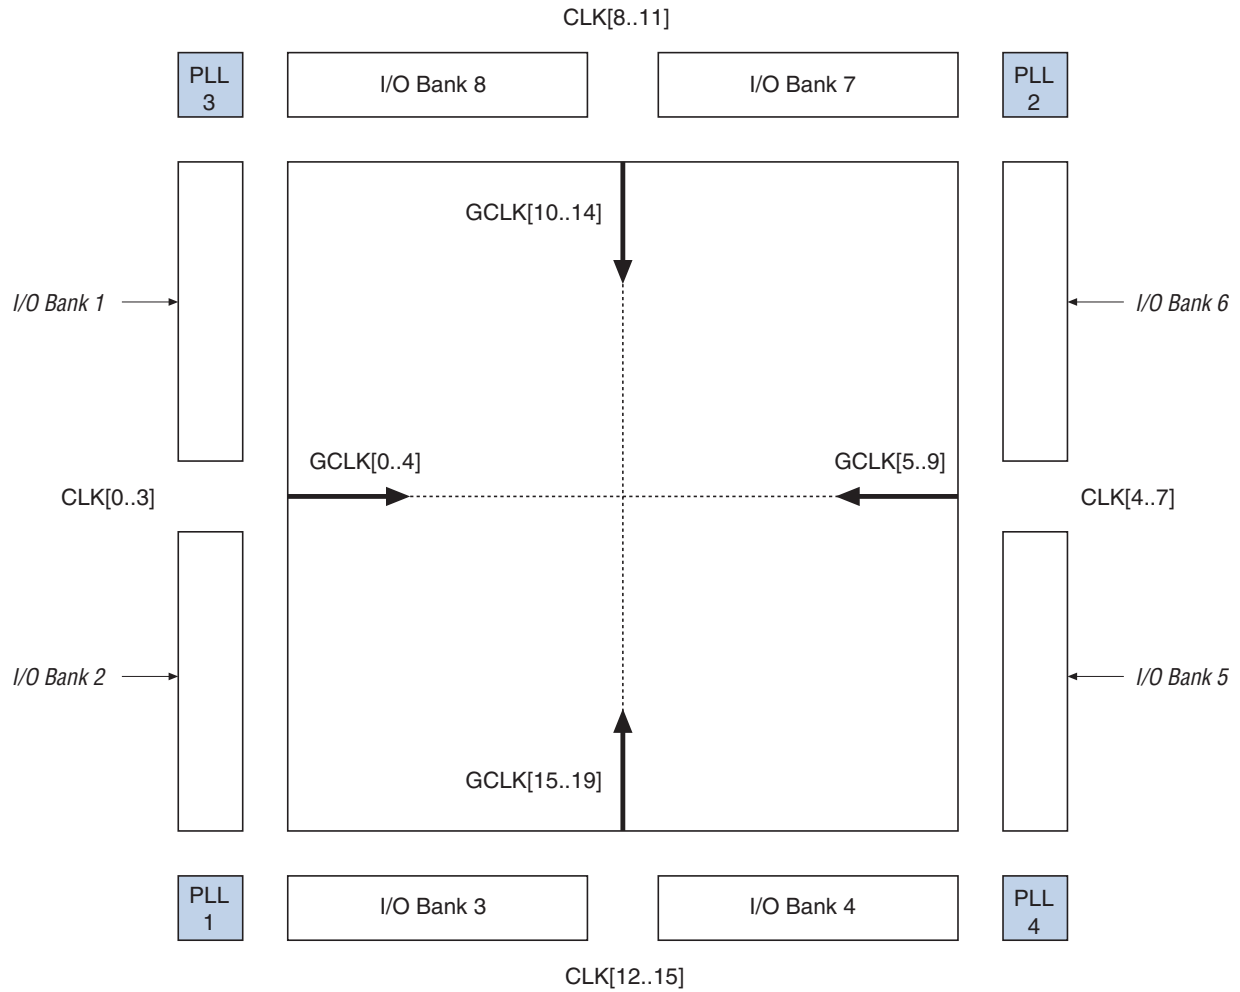

Note to Figure 6–7:

(1)   This figure shows the PLL and clock inputs in the EP3C16 through EP3C120 devices. The EP3C5 and EP3C10 devices have only eight global clock input pins (`CLK[0..3]` and `CLK[4..7]`) and PLLs 1 and 2.

Cyclone III PLL

Cyclone III PLL Hardware Overview

Cyclone III devices contain up to four PLLs with advanced clock management features. The main goal of a PLL is to synchronize the phase and frequency of an internal or external clock to an input reference clock. There are a number of components that comprise a PLL to achieve this phase alignment.

Cyclone III PLLs align the rising edge of the input reference clock to a feedback clock using the phase-frequency detector (PFD). The duty-cycle specifications determine the falling edges. The PFD produces an *up* or *down* signal that determines whether the voltage-controlled oscillator (VCO) needs to operate at a higher or lower frequency. The output of the PFD feeds the charge pump and loop filter, which produces a control voltage for setting the VCO frequency. If the PFD produces an *up* signal, then the VCO frequency increases. A *down* signal decreases the VCO frequency. The PFD generates these *up* and *down* signals to a charge pump. If the charge pump receives an *up* signal, it drives current into the loop filter. Conversely, if it receives a *down* signal, it draws current from the loop filter.

The loop filter converts these *up* and *down* signals to a voltage used to bias the VCO. The loop filter also removes glitches from the charge pump and prevents voltage over-shoot, which filters the jitter on the VCO. The voltage from the loop filter determines how fast the VCO operates. A divide counter (m) is inserted in the feedback loop to increase the VCO frequency above the input reference clock. VCO frequency (f_{VCO}) is equal to (m) times the input reference clock (f_{REF}). The input reference clock (f_{REF}) to the PFD is equal to the input clock (f_{IN}) divided by the pre-scale counter. Therefore, the feedback clock (f_{FB}) applied to one input of the PFD is locked to the f_{REF} that is applied to the other input of the PFD.

The VCO output from the PLLs can feed five post-scale counters (C[4..0]). These post-scale counters allow the PLL to produce a number of harmonically related frequencies.

Figure 6–8 shows a simplified block diagram of the major components of the Cyclone III PLL.

Figure 6–8. Cyclone III PLL Notes (1), (2)
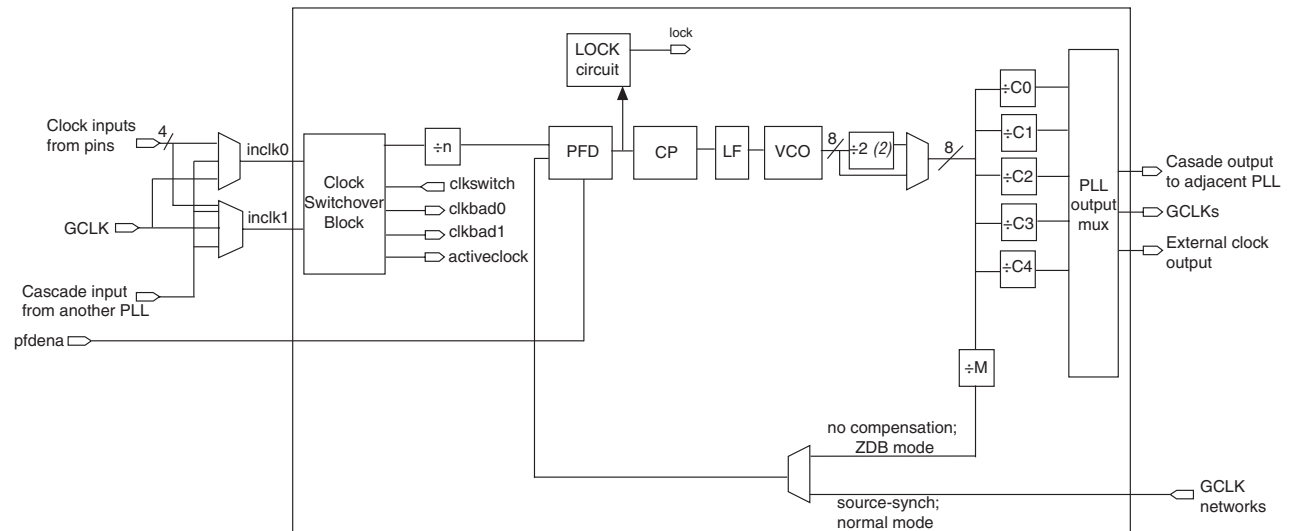

Notes to Figure 6–8:
(1)   Each clock source can come from any of the four clock pins located on the same side of the device as the PLL.
(2)   This is the VCO post-scale counter, K.

External Clock Outputs

Cyclone III PLLs each support one single-ended clock output (or one differential pair). Only the c0 output counter can feed the dedicated external clock outputs, as shown in Figure 6–9.

Figure 6–9. External Clock Outputs for PLLs Notes (1), (2)
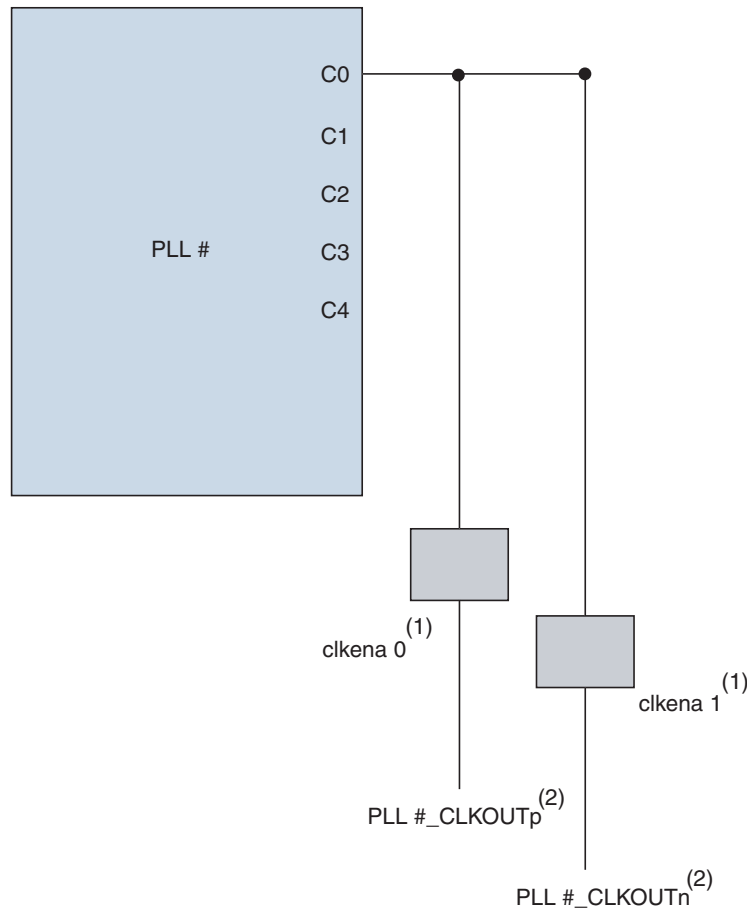

Notes to Figure 6–9:
(1) These external clock enable signals are available only when using the `altclkctrl` megafunction.
(2) `PLL#_CLKOUTp` and `PLL#_CLKOUTn` pins are dual-purpose I/O pins that can be used as one single-ended or one differential clock output.

Each pin of a differential output pair is 180° out of phase. The Quartus II software places the NOT gate in the design into the I/O element to implement 180° phase with respect to the other pin in the pair. The clock output pin pairs support the same I/O standards as standard output pins (in the top and bottom banks) as well as LVDS, LVPECL, differential HSTL, and differential SSTL.

Refer to the *Cyclone III Device I/O Features* chapter of the *Cyclone III Device Handbook, Volume 1*, to determine which I/O standards are supported by the PLL clock input and output pins.

Cyclone III PLLs can also drive out to any regular I/O pin through the global clock network. You can also use the external clock output pins for general purpose I/O pins if you do not need external PLL clocking.

Cyclone III PLL Software Overview

The `altpll` megafunction in Quartus II software enables the Cyclone III PLLs. Figure 6–10 shows the Cyclone III PLL ports as named in the `altpll` megafunction of the Quartus II software.

Figure 6–10. Cyclone III PLL Ports Notes (1), (2)
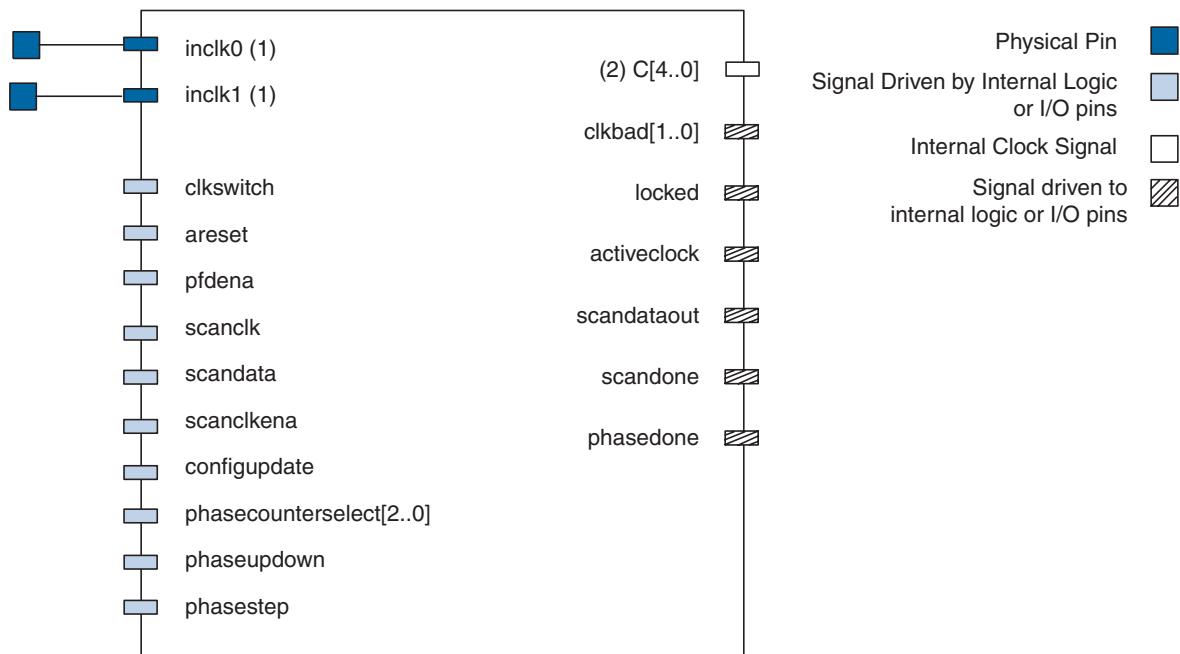

Notes to Figure 6–10:
(1) You can feed `inclk0` or `inclk1` clock input from any one of the four clock pins located on the same side of the device as the PLL. This input port can also be fed by an output from another PLL, a pin-driven dedicated global clock, or through a clock control block if the clock control block is fed by an output from another PLL or a pin-driven dedicated global clock. An internally generated global signal cannot drive the PLL.
(2) You can drive to global clock network (`C[4..0]`) or dedicated external clock output pins (only C0).

Table 6–6 and Table 6–7 describe all the basic PLL ports. Please refer to "PLL Reconfiguration" on page 6–37 for additional information on real-time PLL reconfiguration ports and dynamic phase shifting.

Table 6–6. PLL Input Signals			
Port	**Description**	**Source**	**Destination**
inclk0	Clock input to the PLL.	Dedicated input clock pin or another PLL	Clock switchover circuit
inclk1	Clock input to the PLL.	Dedicated input clock pin or another PLL	Clock switchover circuit
clkswitch	Switchover signal used to initiate external clock switchover control. Active high.	Logic array	PLL switchover circuit
areset	Signal used to reset the PLL, which resynchronizes all the counter outputs. Active high.	Logic array	General PLL control signal
pfdena	Enables the outputs from the phase frequency detector. Active high.	Logic array	PFD

Table 6–7. PLL Output Signals			
Port	**Description**	**Source**	**Destination**
c[4..0]	PLL output counters driving global or external clocks.	PLL counter	Internal or external clock (only c0)
clkbad[1..0]	Signals indicating which reference clock is no longer toggling. clkbad1 indicates inclk1 status, clkbad0 indicates inclk0 status. 1 = good; 0 = bad	PLL switch-over circuit	Logic array
locked	Lock output from lock detect circuit. Active high.	PLL lock detect	Logic array
activeclock	Signal to indicate which clock (0=inclk0 or 1=inclk1) is driving the PLL. If this signal is low, inclk0 drives the PLL. If this signal is high, inclk1 drives the PLL.	PLL clock multiplexer	Logic array

Clock Feedback Modes

Cyclone III PLLs support up to four different clock feedback modes. Each mode allows clock multiplication and division, phase shifting, and programmable duty cycle.

☞ The input/output delays are fully compensated by the PLL only when using the dedicated clock input pins associated with a given PLL as the clock sources. For example, when using PLL1 in normal mode, the clock delays from the input pin to PLL and PLL clock output-to-destination register are fully compensated provided the clock input pin is one of the following four pins: CLK0, CLK1, CLK2, or CLK3. When driving the PLL using the GCLK network, the input/output delays may not be fully compensated in the Quartus II software.

Source-Synchronous Mode

If data and clock arrive at the same time at the input pins, the phase relationship between them remains the same at the clock and data ports of any I/O element input register. Figure 6–11 shows an example waveform of the clock and data in this mode. You should use this mode for source-synchronous data transfers. Data and clock signals at the I/O element experience similar buffer delays as long as the same I/O standard is used.

Figure 6–11. Phase Relationship Between Clock and Data in Source-Synchronous Mode
The source-synchronous mode compensates for delay of the clock network used plus any difference in the delay between these two paths:

■ Data pin to I/O element register input
■ Clock input pin to the PLL PFD input

☞ Set the input pin to the register delay chain within the I/O element to zero in the Quartus II software for all data pins clocked by a source-synchronous mode PLL. Also, all data pins must use the PLL COMPENSATED logic option in the Quartus II software.

No Compensation Mode

In the no compensation mode, the PLL does not compensate for any clock networks. This provides better jitter performance because the clock feedback into the PFD does not pass through as much circuitry. Both the PLL internal and external clock outputs are phase shifted with respect to the PLL clock input. Figure 6–12 shows a waveform example of the phase relationship of the PLL clock in this mode.

Figure 6–12. Phase Relationship between PLL Clocks in No Compensation Mode Notes (1), (2)
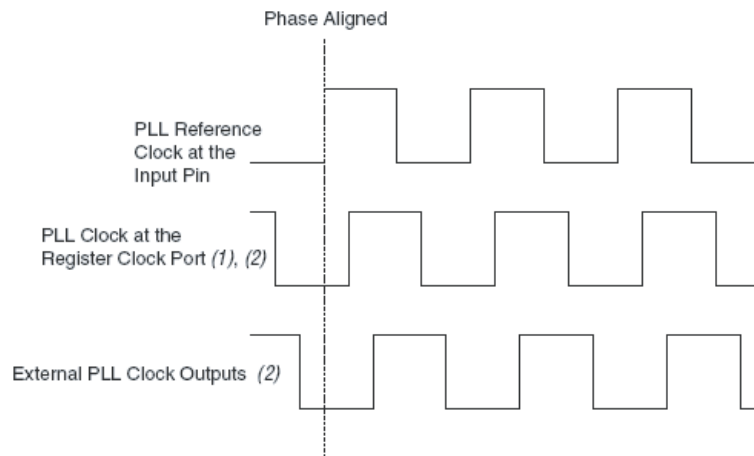

Notes to Figure 6–12:
(1)   Internal clocks fed by the PLL are phase-aligned to each other.
(2)   The PLL clock outputs can lead or lag the PLL input clocks.

Normal Mode

An internal clock in normal mode is phase-aligned to the input clock pin. The external clock output pin has a phase delay relative to the clock input pin if connected in this mode. The Quartus II software timing analyzer reports any phase difference between the two. In normal mode, the PLL fully compensates the delay introduced by the GCLK network. Figure 6–13 shows a waveform example of the PLL clocks' phase relationship in this mode.

Figure 6–13. Phase Relationship Between PLL Clocks in Normal Mode Note (1)
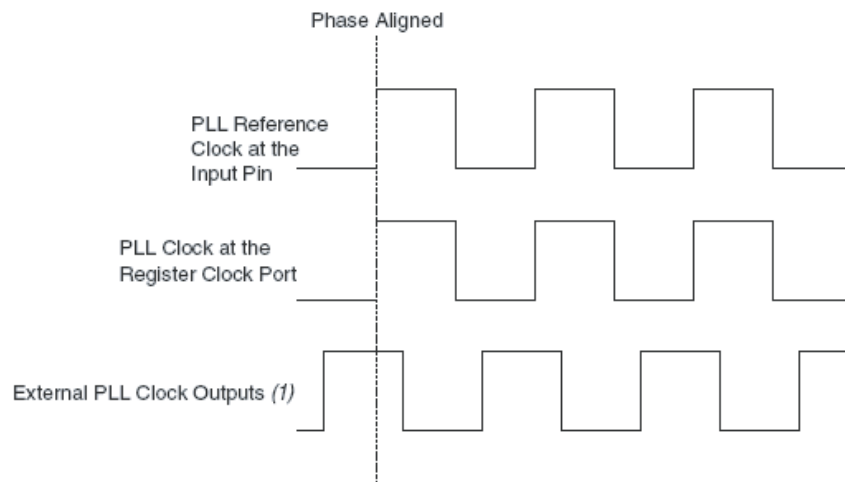

Note to Figure 6–13:
(1) The external clock output can lead or lag the PLL internal clock signals.

Zero Delay Buffer (ZDB) Mode

In the zero delay buffer mode, the external clock output pin is phase-aligned with the clock input pin for zero delay through the device. When using this mode, you must use the same I/O standard on the input clock and output clocks in order to guarantee clock alignment at the input and output pins.

Figure 6–14 shows an example waveform of the PLL clocks' phase relationship in ZDB mode.

Figure 6–14. Phase Relationship Between PLL Clocks in Zero Delay Buffer Mode
Hardware Features

Cyclone III PLLs support a number of features for general-purpose clock management. This section discusses clock multiplication and division implementation, phase-shifting implementations and programmable duty cycles.

Clock Multiplication and Division

Each Cyclone III PLL provides clock synthesis for PLL output ports using $m/(n*\text{post-scale counter})$ scaling factors. The input clock is divided by a pre-scale factor, n, and is then multiplied by the m feedback factor. The control loop drives the VCO to match f_{in} (m/n). Each output port has a unique post-scale counter that divides down the high-frequency VCO. For multiple PLL outputs with different frequencies, the VCO value is the least common multiple of the output frequencies that meets its frequency specifications. For example, if output frequencies required from one PLL are 33 and 66 MHz, then the Quartus II software sets the VCO to 660 MHz (the least common multiple of 33 and 66 MHz within the VCO range). Then, the post-scale counters scale down the VCO frequency for each output port.

There is one pre-scale counter, n, and one multiply counter, m, per PLL, with a range of 1 to 512 for both m and n. The n counter does not use duty cycle control since the purpose of this counter is only to calculate frequency division. There are five generic post-scale counters per PLL

that can feed GCLKs, or external clock outputs. These post-scale counters range from 1 to 512 with a 50% duty cycle setting. The post-scale counters range from 1 to 256 with any non-50% duty cycle setting. The sum of the high/low count values chosen for a design selects the divide value for a given counter.

The Quartus II software automatically chooses the appropriate scaling factors according to the input frequency, multiplication, and division values entered into the `altpll` megafunction.

Post-scale Counter Cascading

The Cyclone III PLLs supports post-scale counter cascading to create counters larger than 512. This is implemented by feeding the output of one C counter into the input of the next C counter as shown in Figure 6–15.

Figure 6–15. Counter Cascading
When cascading counters to implement a larger division of the high-frequency VCO clock, the cascaded counters behave as one counter with the product of the individual counter settings. For example, if C0 = 4 and C1 = 2, then the cascaded value is C0 × C1 = 8.

☞ Post-scale counter cascading is automatically set by the Quartus II software in the configuration file. It cannot be done using PLL reconfiguration.

Programmable Duty Cycle

The programmable duty cycle allows PLLs to generate clock outputs with a variable duty cycle. This feature is supported on the PLL post-scale counters. You can achieve the duty cycle setting by a low and high time count setting for the post-scale counters. The Quartus II software uses the frequency input and the required multiply or divide rate to determine the duty cycle choices. The post-scale counter value determines the precision of the duty cycle. The precision is defined by 50% divided by the post-scale counter value. For example, if the C0 counter is 10, then steps of 5% are possible for duty cycle choices between 5 to 90%.

Combining the programmable duty cycle with programmable phase shift allows the generation of precise non-overlapping clocks.

PLL Control Signals

You can use the following three signals to observe and/or control the PLL operation and resynchronization.

pfdena

Use the `pfdena` signal to maintain the last locked frequency so that your system has time to store its current settings before shutting down. The `pfdena` signal controls the PFD output with a programmable gate. If you disable the PFD, the VCO operates at its last set value of control voltage and frequency with some long-term drift to a lower frequency. The PLL continues running even though it goes out of lock or the input clock is disabled. You can use your own control signal or the control signals available from the clock switchover circuit (activeclock, `clkbad[0]`, or `clkbad[1]`) to control `pfdena`.

areset

The `areset` signal is the reset or resynchronization input for each PLL. The device input pins or internal logic can drive these input signals. When driven high, the PLL counters reset, clearing the PLL output and placing the PLL out of lock. The VCO is then set back to its nominal setting. When driven low again, the PLL resynchronizes to its input as it re-locks.

You must assert the `areset` signal every time the PLL loses lock to guarantee the correct phase relationship between the PLL input clock and output clocks. You must include the `areset` signal in designs if one of the following conditions is true:

■ PLL reconfiguration or clock switchover enabled in the design
■ Phase relationships between the PLL input clock and output clocks need to be maintained after a loss of lock condition

☞ If the input clock to the PLL is toggling or unstable upon power up, assert the `areset` signal after the input clock is stable and within specifications.

locked

The `locked` output indicates that the PLL has locked onto the reference clock and the PLL clock outputs are operating at the desired phase and frequency set in the Quartus II Megawizard. Without any additional circuitry, the lock signal toggles as the PLL begins the locking process. The lock detection block provides a signal to core-logic that gives an indication if the feedback clock has locked onto the reference clock both in phase and frequency.

☞ Altera recommends that you use the `areset` and `locked` signals in your designs to control and observe the status of your PLL.

Clock Switchover

The clock switchover feature allows the PLL to switch between two reference input clocks. Use this feature for clock redundancy or for a dual clock domain application such as in a system that turns on the redundant clock if the previous clock stops running. The design can perform clock switchover automatically, when the clock is no longer toggling, or based on a user control signal, `clkswitch`.

Automatic Clock Switchover

Cyclone III device PLLs support a fully configurable clock switchover capability. Figure 6–16 shows the block diagram of the switchover circuit built into the PLL. When the current reference clock is not present, the clock sense block automatically switches to the backup clock for PLL reference. The clock switchover circuit also sends out three status signals—`clkbad[0]`, `clkbad[1]`, and `activeclock`—from the PLL to implement a custom switchover circuit. You can select a clock source at the backup clock by connecting it to the `inclk1` port of the PLL in your design.

Figure 6–16. Automatic Clock Switchover Circuit Block Diagram
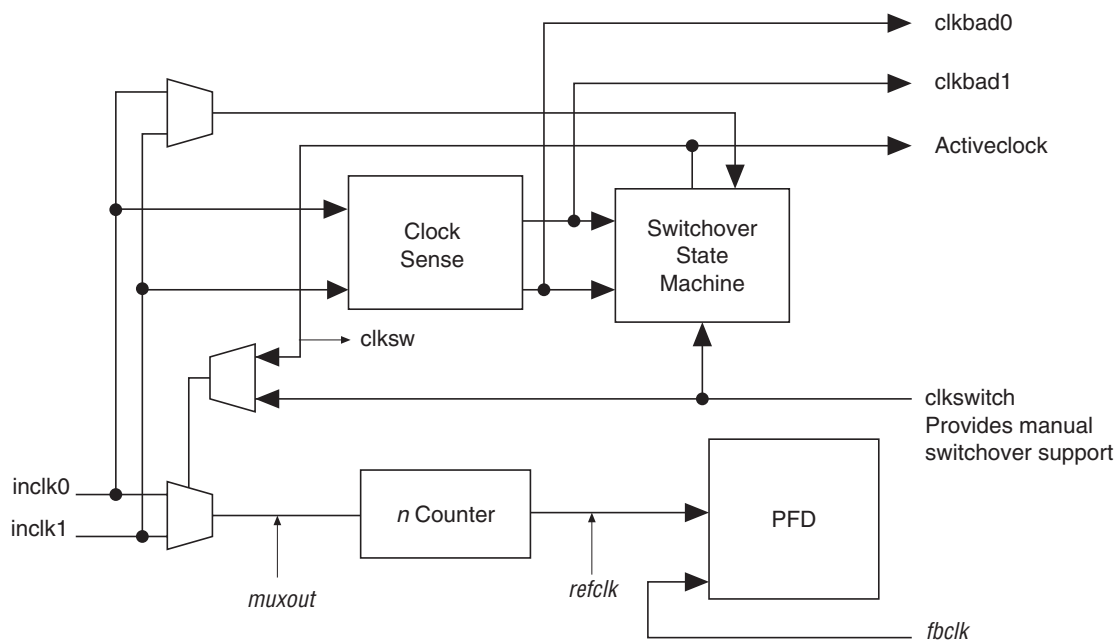

There are two possible ways to use the clock switchover feature.

■ Use the switchover circuitry for switching from `inclk0` to `inclk1` running at the same frequency. For example, in applications that require a redundant clock with the same frequency as the reference clock, the switchover state machine generates a signal that controls the multiplexer select input shown in Figure 6–16. In this case, `inclk1` becomes the reference clock for the PLL. This automatic switchover can switch back and forth between `inclk0` and `inclk1` clocks any number of times, when one of the two clocks fails and the other clock is available.

- Use the `clkswitch` input for user- or system-controlled switch conditions. This is possible for same-frequency switchover or to switch between inputs of different frequencies. For example, if `inclk0` is 66 MHz and `inclk1` is 200 MHz, you must control the switchover because the automatic clock-sense circuitry cannot monitor primary and secondary clock frequencies with a frequency difference of more than 20%. This feature is useful when clock sources can originate from multiple cards on the backplane, requiring a system-controlled switchover between frequencies of operation. You should choose the secondary clock frequency so the VCO operates within the recommended frequency range. You should also set the m, n, and c counters accordingly to keep the VCO operating frequency in the recommended range.

Figure 6–17 shows a waveform example of the switchover feature when using the automatic loss of clock detection. Here, the `inclk0` signal remains low. After the `inclk0` signal remains low for approximately two clock cycles, the clock sense circuitry drives the `clkbad[0]` signal high. Also, because the reference clock signal is not toggling, the switchover state machine controls the multiplexer through the `clksw` signal to switch to `inclk1`.

Figure 6–17. Automatic Switchover Upon Clock Loss Detection Note (1)
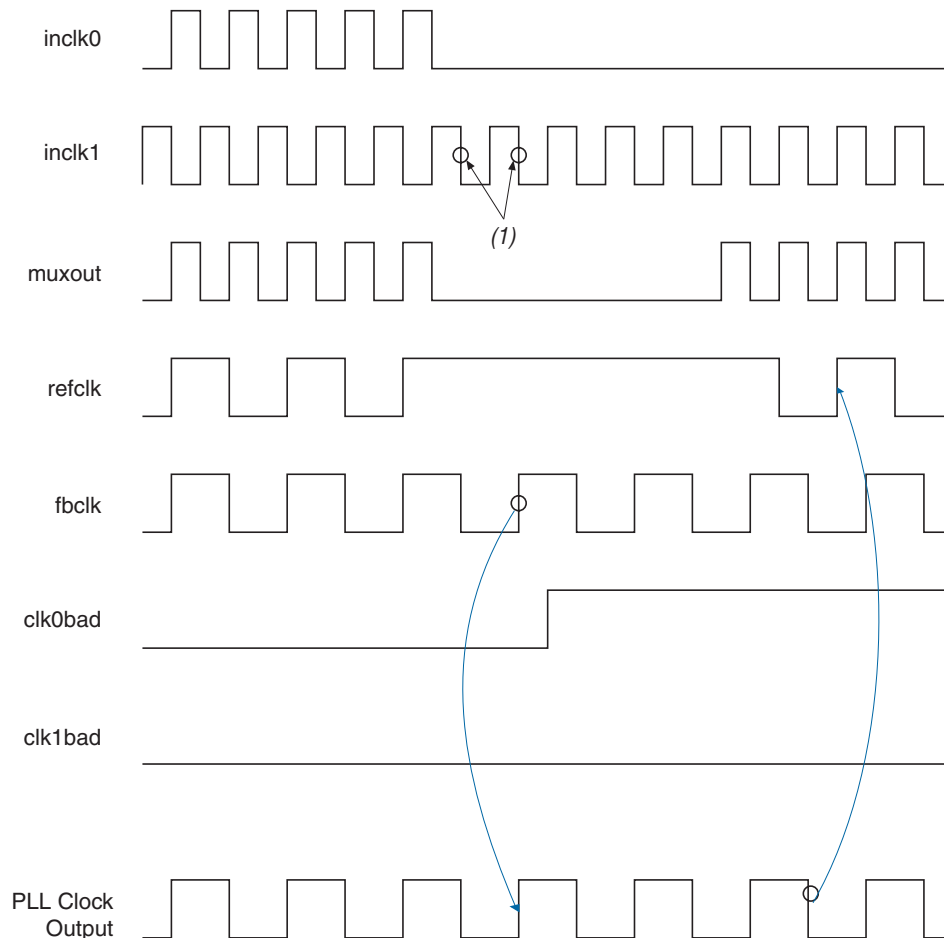

Note to Figure 6–17:
(1)   Switchover is enabled on the falling edge of INCLK0 or INCLK1, depending on which clock is available. In this figure, the switchover is enabled on the falling edge of INCLK1.

Manual Override

When using automatic switchover, you can switch input clocks by using the manual override feature with the clkswitch input.

Figure 6–18 shows an example of a waveform illustrating the switchover feature when controlled by clkswitch. In this case, both clock sources are functional and inclk0 is selected as the reference clock. The clkswitch goes high, which starts the switchover sequence. On the falling edge of inclk0, the counter's reference clock, muxout, is gated off to prevent any clock glitching. On the falling edge of inclk1, the reference clock multiplexer switches from inclk0 to inclk1 as the PLL reference. This is also when the activeclock signal changes to indicate which clock is currently feeding the PLL.

In this mode, the `activeclock` signal mirrors the `clkswitch` signal. As both blocks are still functional during the manual switch, neither `clkbad` signals go high. Since the switchover circuit is edge-sensitive, the falling edge of the `clkswitch` signal does not cause the circuit to switch back from `inclk1` to `inclk0`. When the `clkswitch` signal goes high again, the process repeats. The `clkswitch` signal and automatic switch only work if the clock being switched to is available. If the clock is not available, the state machine waits until the clock is available.

Figure 6–18. Clock Switchover Using the Clkswitch Control
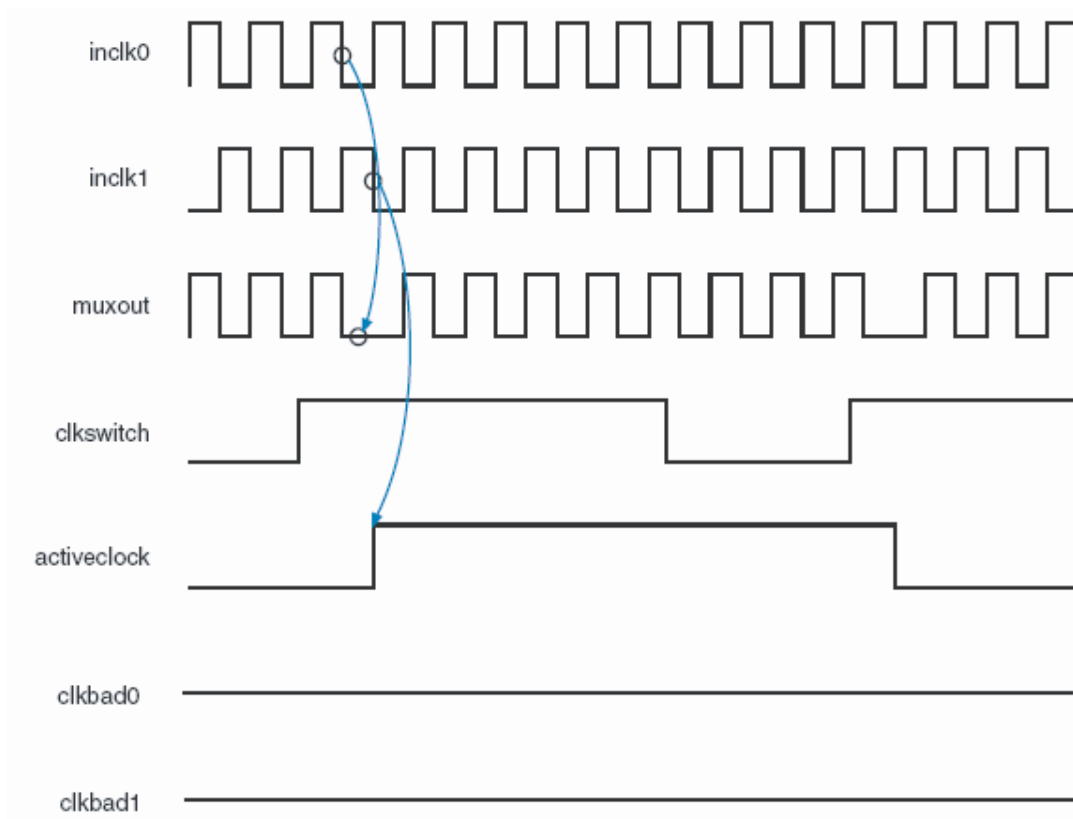

Manual Clock Switchover

Cyclone III PLLs support manual switchover, where the `clkswitch` signal controls whether `inclk0` or `inclk1` is the input clock to the PLL. The characteristics of the manual switchover is similar to the manual override feature in an automatic clock switchover, where the switchover circuit is edge-sensitive. When the `clkswitch` signal goes high, the switchover sequence starts. The falling edge of the `clkswitch` signal does not cause the circuit to switch back to the previous input clock.

For more information on PLL software support in the Quartus II software, see the *altpll Megafunction User Guide*.

Guidelines

Use the following guidelines to design with clock switchover in PLLs.

- Clock loss detection and automatic clock switchover requires that the `inclk0` and `inclk1` frequencies be within 2X of each other. Failing to meet this requirement causes the `clkbad[0]` and `clkbad[1]` signals to function improperly.
- When using manual clock switchover, the difference between `inclk0` and `inclk1` can be more than 2X. However, differences in frequency, phase, or both of the two clock sources will likely cause the PLL to lose lock. Resetting the PLL ensures that the correct phase relationships are maintained between input and output clocks.
- Applications that require a clock switchover feature and a small frequency drift should use a low-bandwidth PLL. The low-bandwidth PLL reacts slower than a high-bandwidth PLL to reference input clock changes. When the switchover happens, a low-bandwidth PLL propagates the stopping of the clock to the output slower than a high-bandwidth PLL. A low-bandwidth PLL filters out jitter on the reference clock. However, be aware that the low-bandwidth PLL also increases lock time.
- After a switchover occurs, there may be a finite resynchronization period for the PLL to lock onto a new clock. The exact amount of time it takes for the PLL to re-lock is dependent on the PLL configuration.
- If the phase relationship between the input clock to the PLL and output clock from the PLL is important in your design, assert `areset` for 10 ns after performing a clock switchover. Wait for the locked signal (or gated lock) to go high before re-enabling the output clocks from the PLL.
- Figure 6–19 shows how the VCO frequency gradually decreases when the primary clock is lost and then increases as the VCO locks on to the secondary clock. After the VCO locks on to the secondary clock, some overshoot can occur (an over-frequency condition) in the VCO frequency.

Figure 6–19. VCO Switchover Operating Frequency
■ Disable the system during switchover if it is not tolerant to frequency variations during the PLL resynchronization period. You can use the `clkbad[0]` and `clkbad[1]` status signals to turn off the PFD (`pfdena` = 0) so the VCO maintains its last frequency. You can also use the switch over state machine to switch over to the secondary clock. Upon enabling the PFD, output clock enable signals (`clkena`) can disable clock outputs during the switchover and resynchronization period. Once the lock indication is stable, the system can re-enable the output clock(s)

Phase-Shift Implementation

Phase shift is used to implement a robust solution for clock delays in Cyclone III devices. Phase shift is implemented by using a combination of the VCO phase output and the counter starting time. The VCO phase output and counter starting time is the most accurate method of inserting delays, since it is purely based on counter settings, which are independent of process, voltage, and temperature.

You can phase shift the output clocks from the Cyclone III PLLs in either:

■ Fine resolution using VCO phase taps
■ Coarse resolution using counter starting time

Fine resolution phase shifts are implemented by allowing any of the output counters (`C[4..0]`) or the *m* counter to use any of the eight phases of the VCO as the reference clock. This allows you to adjust the delay time with a fine resolution. The minimum delay time that you can insert using this method is defined by:

$$\Phi_{fine} = 1/8 \ T_{VCO} = 1/8f_{vco} = N/8Mf_{ref}$$

where f_{REF} is input reference clock frequency.

For example, if f_{REF} is 100 MHz, n = 1, and m = 8, then f_{VCO} = 800 MHz and Φ_{fine} = 156.25 ps. The PLL operating frequency defines this phase shift, a value which depends on the reference clock frequency and the counter settings.

Coarse resolution phase shifts are implemented by delaying the start of the counters for a predetermined number of counter clocks. You can express coarse phase shift as:

Φ_{coarse} = C-1/f_{vco} = (C-1)N/Mf_{ref}

Where C is the count value set for the counter delay time (this is the initial setting in the PLL usage section of the compilation report in the Quartus II software). If the initial value is 1, C – 1 = 0° phase shift.

Figure 6–20 shows an example of phase shift insertion using the fine resolution through VCO phase taps method. The eight phases from the VCO are shown and labeled for reference. For this example, CLK0 is based on the 0° phase from the VCO and has the C value for the counter set to one. The CLK1 signal is divided by four, two VCO clocks for high time and two VCO clocks for low time. CLK1 is based on the 135° phase tap from the VCO and has the C value for the counter set to one. The CLK1 signal is also divided by 4. In this case, the two clocks are offset by 3 Φ_{fine}. CLK2 is based on the 0° phase from the VCO but has the C value for the counter set to three. This creates a delay of 2 Φ_{coarse} (two complete VCO periods).

Figure 6–20. Delay Insertion Using VCO Phase Output and Counter Delay Time
You can use the coarse and fine phase shifts to implement clock delays in Cyclone III devices.

Cyclone III devices support dynamic phase shifting of VCO phase taps only. The phase shift is configurable for any number of times, and each phase shift takes about one SCANCLK cycle, allowing you to implement large phase shifts quickly.

PLL Cascading

Two PLLs may be cascaded to each other through the clock network. If the design cascades PLLs, the source (upstream) PLL should have a high-bandwidth setting, while the destination (downstream) PLL should have a low-bandwidth setting. Figure 6–21 shows usage of GCLK while cascading PLLs.

Figure 6–21. PLL Cascading Using GCLK Note (1)
Note to Figure 6–21:
(1) For the EP3C5 and EP3C10 devices, there are only two PLLs (PLL1 and PLL2), ten clock control blocks and ten GCLKs.

PLL Reconfiguration

PLLs use several divide counters and different VCO phase taps to perform frequency synthesis and phase shifts. In Cyclone III PLLs, you can reconfigure both the counter settings and phase shift the PLL output clock in real time. You can also change the charge pump and loop filter components, which dynamically affects the PLL bandwidth. You can use these PLL components to update the output clock frequency, PLL bandwidth, and phase-shift in real time, without reconfiguring the entire FPGA.

The ability to reconfigure the PLL in real time is useful in applications that might operate at multiple frequencies. It is also useful in prototyping environments, allowing you to sweep PLL output frequencies and adjust the output clock phase dynamically. For instance, a system generating test patterns is required to generate and transmit patterns at 75 or 150 MHz, depending on the requirements of the device under test. Reconfiguring the PLL components in real time allows you to switch between two such output frequencies within a few microseconds. You can also use this feature to adjust clock-to-out (tco) delays in real time by changing the PLL output clock phase shift. This approach eliminates the need to regenerate a configuration file with the new PLL settings.

PLL Reconfiguration Hardware Implementation

The following PLL components are configurable in real time.

- Pre-scale counter (n)
- Feedback counter (m)
- Post-scale output counters (`c0-c4`)
- Dynamically adjust the charge pump current (I_{cp}), loop filter components (R, C) to facilitate on the fly reconfiguration of the PLL bandwidth.

Figure 6–22 shows how to dynamically adjust PLL counter settings, by shifting their new settings into a serial shift register chain or scan chain. Serial data shifts to the scan chain via the `scandataport` and shift registers are clocked by `scanclk`. The maximum `scanclk` frequency is 100 MHz. After shifting the last bit of data, asserting the `configupdate` signal for at least one `scanclk` clock cycle synchronously updates the PLL configuration bits with the data in the scan registers.

Figure 6–22. PLL Reconfiguration Scan Chain
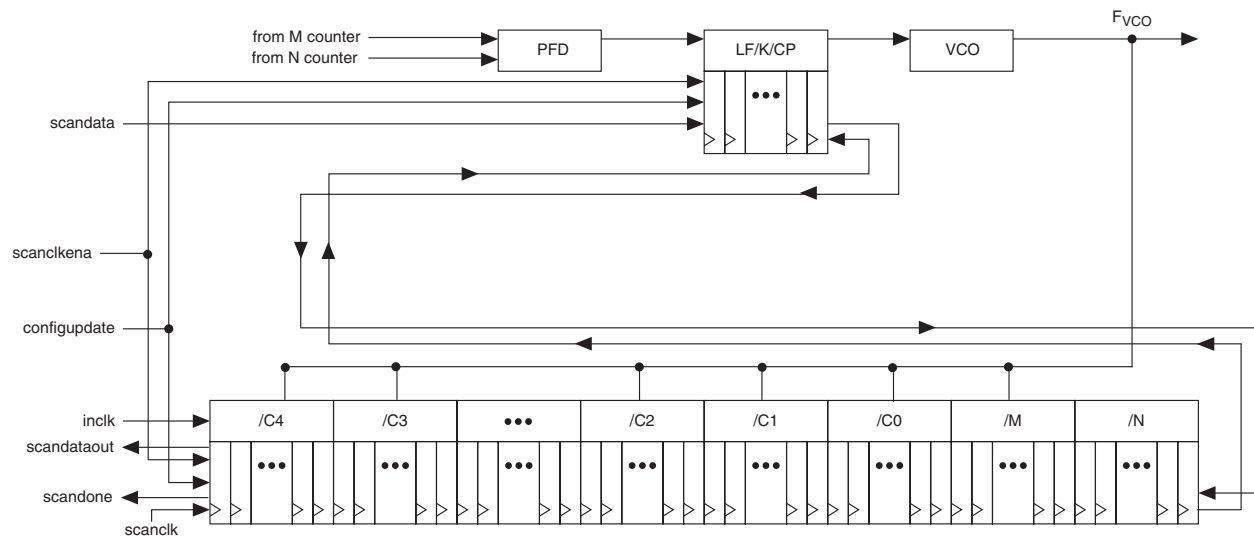

☞ The counter settings are updated synchronously to the clock frequency of the individual counters. Therefore, not all counters update simultaneously.

Table 6–8 shows how the programmable logic device (PLD) logic array or I/O pins drive these signals.

Table 6–8. Real-Time PLL Reconfiguration Ports			
PLL Port Name	**Description**	**Source**	**Destination**
scandata	Serial input data stream to scan chain.	Logic array or I/O pins	PLL reconfiguration circuit
scanclk	Serial clock input signal. This clock can be free running.	Logic array or I/O pins	PLL reconfiguration circuit
configupdate	Updates data in the scan chain to the PLL. Active high.	Logic array or I/O pins	PLL reconfiguration circuit
scanclkena	Enables scanclk and allows the scandata to be loaded in the scan chain. Active high.	Logic array or I/O pins	PLL reconfiguration circuit
scandone	A high pulse indicates the PLL has finished reconfiguration.	PLL reconfig. circuit	Logic array or I/O pins
scandataout	Shifts out contents of the scan chain.	PLL reconfig. circuit	Logic array or I/O pins

The procedure to reconfigure the PLL counters is shown below:

1. The `scanclkena` signal is asserted at least one `scanclk` cycle prior to shifting in the first bit of `scandata` (Dn).
2. Serial data (`scandata`) is shifted into the scan chain on the 2nd rising edge of `scanclk`.
3. After all 144 bits have been scanned into the scan chain, the `scanclkena` signal is de-asserted to prevent inadvertent shifting of bits in the scan chain.
4. The `configupdate` signal is asserted for one `scanclk` cycle to update the PLL counters with the contents of the scan chain.
5. The `scandone` signal goes high indicating that the PLL is being reconfigured. A falling edge indicates that the PLL counters have been updated with new settings.
6. Reset the PLL using the `areset` signal if you make any changes to the M, N counters or the Icp, R, C settings. You do not need to reset the PLL when reconfiguring just the post-scale counters.
7. Steps 1 through 5 can be repeated to reconfigure the PLL any number of times.

Figure 6–23 shows a functional simulation of the PLL reconfiguration feature.

Figure 6–23. PLL Reconfiguration Scan Chain
☞   When reconfiguring the counter clock frequency, the corresponding counter phase shift settings cannot be reconfigured using the same interface. You can reconfigure phase shifts in real time using the dynamic phase shift reconfiguration interface. If you reconfigure the counter frequency, but wish to keep the same non-zero phase shift setting (for example, 90 degrees) on the clock output, then you will need to reconfigure the phase shift after reconfiguring the counter clock frequency.

Post-Scale Counters (c0 to c4)

The multiply or divide values and duty cycle of post-scale counters can be configured in real time. Each counter has an 8-bit high time setting and an 8-bit low time setting. The duty cycle is the ratio of output high or low time to the total cycle time, which is the sum of the two. Additionally, these counters have two control bits, rbypass, for bypassing the counter, and rselodd, to select the output clock duty cycle.

When the rbypass bit is set to 1, it bypasses the counter, resulting in a divide by 1. When this bit is set to 0, the PLL computes the effective division of the VCO output frequency based on the high and low time counters. For example, if the post-scale divide factor is 10, the high and low count values could be set to 5 and 5 respectively, to achieve a 50-50% duty cycle. The PLL implements this duty cycle by transitioning the output clock from high to low on the rising edge of the VCO output clock. However, a 4 and a 6 setting for the high and low count values, respectively, would produce an output clock with 40-60% duty cycle.

The rselodd bit indicates an odd divide factor for the VCO output frequency along with a 50% duty cycle. For example, if the post-scale divide factor is 3, the high and low time count values is 2 and 1 respectively to achieve this division. This implies a 67%-33% duty cycle. If you need a 50%-50% duty cycle, you must set the rselodd control bit to 1 to achieve this duty cycle despite an odd division factor. The PLL implements this duty cycle by transitioning the output clock from high to low on a falling edge of the VCO output clock. When you set rselodd = 1, you subtract 0.5 cycles from the high time and you add 0.5 cycles to the low time. For example:

- High time count = 2 cycles
- Low time count = 1 cycle
- rselodd = 1 effectively equals:
  - High time count = 1.5 cycles
  - Low time count = 1.5 cycles
  - Duty cycle = (1.5/3) % high time count and (1.5/3) % low time count

Scan Chain Description

Cyclone III PLLs have a 144-bit scan chain. Table 6–9 shows the number of bits for each component of the PLL.

Table 6–9. Cyclone III PLL Reprogramming Bits			
Block Name	**Number of Bits**		
	Counter	**Other**	**Total**
C4 *(1)*	16	2 *(2)*	18
C3	16	2 *(2)*	18
C2	16	2 *(2)*	18
C1	16	2 *(2)*	18
C0	16	2 *(2)*	18
M	16	2 *(2)*	18
N	16	2 *(2)*	18
Charge Pump	9	0	9
Loop Filter *(3)*	9	0	9
Total number of bits			144

Notes to Table 6–9:
(1) LSB bit for C4 low-count value is the first bit shifted into the scan chain.
(2) These two control bits include `rbypass`, for bypassing the counter, and `rselodd`, to select the output clock duty cycle.
(3) MSB bit for loop filter is the last bit shifted into the scan chain.

Figure 6–24 shows the scan chain order of PLL components.

Figure 6–24. PLL Component Scan Chain Order
Figure 6–25 shows the scan chain bit order sequence for one PLL post-scale counters in Cyclone III PLLs.

Figure 6–25. Scan Chain Bit Order
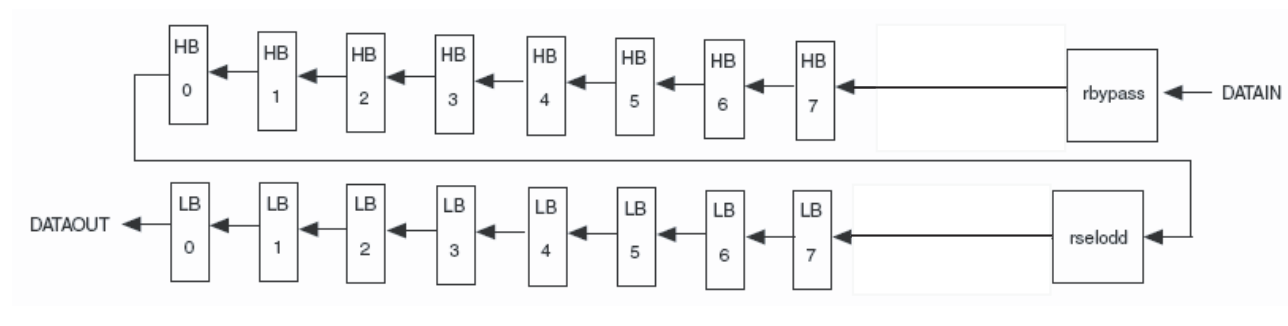

Charge Pump and Loop Filter

You can reconfigure the charge pump and loop filter settings to update the PLL bandwidth in real time. Table 6–10, Table 6–11, and Table 6–12 show the possible settings for charge pump (Icp) and loop filter resistor (R) and capacitor (C) values for the Cyclone III PLLs.

Table 6–10. Charge Pump Bit Control

Bypassing PLL Counter

Bypassing a PLL counter results in a multiply (m counter) or a divide (n, $C0$ to $C4$ counters) factor of one.

Table 6–13 shows the settings for bypassing the counters in Cyclone III PLLs.

Table 6–13. PLL Counter Settings

PLL Scan Chain Bits [0..8] Settings									Description
LSB								MSB	
X	X	X	X	X	X	X	X	1 *(1)*	PLL counter bypassed
X	X	X	X	X	X	X	X	0 *(1)*	PLL counter not bypassed

Note to Table 6–13:
(1)   Bypass bit.

To bypass any of the PLL counters, set the bypass bit to 1. This ignores the values on the other bits.

Dynamic Phase Shifting

The dynamic phase shifting feature allows the output phase of individual PLL outputs to be dynamically adjusted relative to each other and the reference clock without the need to send serial data through the scan chain of the corresponding PLL. This simplifies the interface and allows you to quickly adjust clock-to-out (tco) delays by changing output clock phase shift in real time. This is achieved by incrementing or decrementing the VCO phase-tap selection to a given C counter or to the M counter. The phase is shifted by 1/8 the VCO frequency at a time. The output clocks are active during this phase reconfiguration process.

Table 6–14 shows the control signals that are used for dynamic phase shifting.

Table 6–14. Dynamic Phase Shifting Control Signals

Signal Name	Description	Source	Destination
PHASECOUNTER SELECT[2:0]	Counter Select. Three bits decoded to select either the M or one of the C counters for phase adjustment. One address maps to select all C counters. This signal is registered in the PLL on the rising edge of SCANCLK.	Logic array or I/O pins	PLL reconfiguration circuit
PHASEUPDOWN	Selects dynamic phase shift direction; 1= UP; 0 = DOWN. Signal is registered in the PLL on the rising edge of SCANCLK.	Logic array or I/O pins	PLL reconfiguration circuit
PHASESTEP	Logic high enables dynamic phase shifting	Logic array or I/O pins	PLL reconfiguration circuit
SCANCLK	Free running clock from core used in combination with PHASESTEP to enable/disable dynamic phase shifting. Shared with SCANCLK for dynamic reconfiguration.	GCLK or I/O pins	PLL reconfiguration circuit
PHASEDONE	When asserted, it indicates to core-logic that the phase adjustment is complete and PLL is ready to act on a possible second adjustment pulse. Asserts based on internal PLL timing. De-asserts on rising edge of SCANCLK.	PLL reconfiguration circuit	Logic array or I/O pins

Table 6–15 shows the PLL counter selection based on the corresponding PHASECOUNTERSELECT setting:

Table 6–15. Phase Counter Select Mapping

PHASECOUNTERSELECT [2]	[1]	[0]	Selects
0	0	0	All Output Counters
0	0	1	M Counter
0	1	0	C0 Counter
0	1	1	C1 Counter
1	0	0	C2 Counter
1	0	1	C3 Counter
1	1	0	C4 Counter

Use the following procedure to perform one dynamic phase shift step:

1. Set `phaseupdown` and `phasecounterselect` as required.
2. Assert `phasestep`. Each `phasestep` pulse enables one phase shift. The `phasestep` pulses must be at least one `scanclk` cycle apart.
3. Wait for `phasedone` to go low.
4. De-assert `phasestep`.
5. Wait for `phasedone` to go high.
6. Repeat steps 1 through 5 as many times as required to get multiple phase shifts.

All signals are synchronous to `scanclk`, so they will be latched on the `scanclk` edges and must meet tsu/th requirements with respect to the `scanclk` edges.

Figure 6–26. PLL Dynamic Phase Shift
Dynamic phase shifting can be repeated indefinitely. All signals are synchronous to `scanclk`, so they must meet tsu/th requirements with respect to `scanclk` edges.

The `phasestep` signal is latched on the negative edge of `scanclk`. In Figure 6–26, this is shown by the second `scanclk` falling edge. `Phasestep` must stay high for at least two `scanclk` cycles. On the second `scanclk` rising edge after phasestep is latched (indicated by the fourth rising edge), the values of `phaseupdown` and `phasecounterselect` are latched and the PLL starts dynamic phase shifting for the specified counter(s) and in the indicated direction. On the fourth `scanclk` rising edge, `phasedone` goes high to low and remains

low until the PLL finishes dynamic phase shifting. You can perform another dynamic phase shift after the `phasedone` signal goes from low to high.

Depending on the VCO and `scanclk` frequencies, `phasedone` low time may be greater than or less than one `scanclk` cycle. The maximum time for reconfiguring phase shift dynamically is to be determined (TBD) based on device characterization.

After `phasedone` goes from low to high, you can perform another dynamic phase shift. Phasestep pulses must be at least one `scanclk` cycle apart.

For details on the **altpll_reconfig megawizard Plug-In Manager**, refer to the *altpll_reconfig Megafunction Users Guide*.

Spread-Spectrum Clocking

Cyclone III devices can accept a spread-spectrum input with typical modulation frequencies. However, the device cannot automatically detect that the input is a spread-spectrum signal. Instead, the input signal looks like deterministic jitter at the input of the PLL. Cyclone III PLLs can track a spread spectrum input clock as long as it is within the input jitter tolerance specifications. Cyclone III devices cannot internally generate spread spectrum signals.

PLL Specifications

Refer to the Cyclone III Device datasheet in the *DC and Switching Characteristics* chapter in Volume 1 of the *Cyclone III Device Handbook* for information on PLL timing specifications.

Board Layout

The PLL circuits in Cyclone III devices contain analog components embedded in a digital device. These analog components have separate power and ground pins to minimize noise generated by the digital components.

VCCA and GNDA

Each Cyclone III PLL uses separate VCC and ground pin pairs for their analog circuitry. The analog circuit power and ground pin for each PLL is called `VCCA`<*PLL number*> and `GNDA`. Connect the `VCCA` power pin to a 2.5-V power supply, even if you do not use the PLL. Run a thick trace from the power supply to each `VCCA` pin. The traces should be at least 20 mils thick.

VCCD and GND

The digital power and ground pins are labeled `VCCD_PLL<PLL` *number>* and `GND`. The `VCCD` pin supplies the power for the digital circuitry in the PLL. Connect these `VCCD` pins to the quietest digital supply on the board. In most systems, this is the digital 1.2-V supply supplied to the device's `VCCINT` pins. Connect the `VCCD` pins to a power supply even if you do not use the PLL. You can connect the `GND` pins directly to the same ground plane as the device's digital ground.

You should filter each `VCCA` and `VCCD` pin with a decoupling circuit shown in Figure 6–27. Place a ferrite bead that exhibits high impedance at frequencies of 50 MHz or higher and a 10µF tantalum parallel capacitor where the power enters the board. Decouple each `VCCA` pin with a 0.1µF, 0.001µF, 1µF, 47µF and 470µF parallel combination of ceramic capacitors located as close as possible to the Cyclone III device. You can connect the `GNDA` pins directly to the same ground plane as the device's digital ground.

Figure 6–27. PLL Power Schematic for Cyclone III PLLs Note (1)
Note to Figure 6–27:
(1)   Applies to PLL 1 through 4.

Conclusion

Cyclone III device PLLs provide you with complete control of device clocks and system timing. The ability to reconfigure the PLL counter clock frequency and phase shift in real time can be especially useful in prototyping environments, allowing you to sweep PLL output frequencies and adjust the output clock phase shift dynamically. These PLLs are capable of offering flexible system-level clock management that

was previously only available in discrete PLL devices. Cyclone III PLLs meet and exceed the features offered by these high-end discrete devices, reducing the need for other timing devices in the system.

Section II. I/O and External Memory Interfaces

This section provides information on Cyclone® III Device I/O features and high-speed differential and external memory interfaces.

This section includes the following chapters:

- Chapter 7, Cyclone III Device I/O Features

- Chapter 8, High-Speed Differential Interfaces in Cyclone III Devices

- Chapter 9, External Memory Interfaces in Cyclone III Devices

Revision History

Refer to each chapter for its own specific revision history. For information on when each chapter was updated, refer to the Chapter Revision Dates section, which appears in the complete handbook.

Introduction

Two key factors affecting board design today drove the design of Cyclone III devices I/O capabilities. The first is the diversification of I/O standards in many low-cost applications. The second is a significant increase in the required I/O performance. Our objective was to create a device that made accommodating these design needs easy and flexible.

Cyclone III I/O flexibility has been increased from previous generation low-cost FPGAs by allowing all I/O standards to be selected on all I/O banks. Improvements to on-chip termination (OCT) support and by adding dedicated differential buffers, eliminate the need for external resistors in many applications, such as display system interfaces. The Altera® Quartus® II software completes the solution with powerful pin planning features that allow you to plan and optimize I/O system designs even before the design files are available.

Overview

Each Cyclone III device I/O pin is fed by an I/O element (IOE) located at the ends of logic array block (LAB) rows and columns around the periphery of the Cyclone III device. The I/O pins support various single-ended and differential I/O standards. Each IOE contains a bidirectional I/O buffer and five registers for registering input, output, and output-enable signals. Cyclone III I/O supports a wide range of features:

- Single-ended non-voltage-referenced and voltage-referenced I/O standards
- Differential I/O standards
- Output current strength control
- Programmable slew rate control
- Open-drain outputs
- Bus-hold circuitry
- PCI-clamp diode
- Programmable pull-up resistors in user mode
- Programmable input and output delays
- Programmable low-voltage differential signaling (LVDS) pre-emphasis
- On-chip termination with and without calibration

Altera Corporation-Preliminary
March 2007

7–1

Cyclone III I/O Element

Cyclone III device IOEs contain a bidirectional I/O buffer and five registers for complete embedded bidirectional single-data rate transfer. Figure 7–1 shows the Cyclone III IOE structure. The IOE contains one input register, two output registers, and two output-enable registers. The two output registers and two output-enable registers are utilized for double-data rate (DDR) applications. You can use the input registers for fast setup times and the output registers for fast clock-to-output times. Additionally, you can use the output-enable (OE) registers for fast clock-to-output enable timing. You can use IOEs for input, output, or bidirectional data paths.

Figure 7–1. Cyclone III IOE Structure
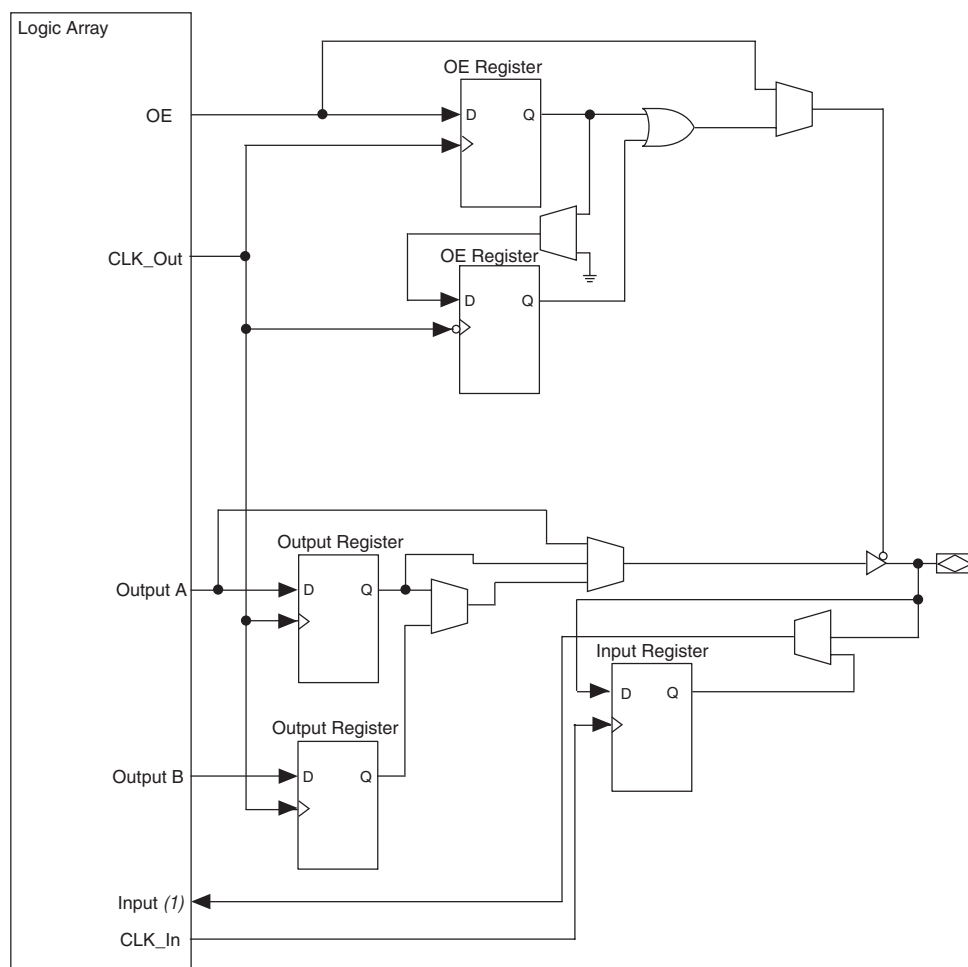

Note to Figure 7–1:
(1)   There are two paths available for combinational or registered inputs to the logic array. Each path contains a unique programmable delay chain.

The IOEs are located in I/O blocks around the periphery of the Cyclone III device. There are up to four IOEs per row I/O block and up to five IOEs per column I/O block (column I/O blocks span two columns), depending on logic element (LE)-rich or I/O-rich devices.

The row I/O blocks drive row, column, or direct link interconnects. The column I/O blocks drive column interconnects. Figure 7–2 shows how a row I/O block connects to the logic array. Figures 7–3 and 7–4 show how a column I/O block connects to the logic array.

For more information on Cyclone III routing architecture, please refer to the *MultiTrack Interconnect in Cyclone III Devices* chapter in the *Cyclone III Device Handbook*.

Figure 7–2. Row I/O Block Connection to the Interconnect
Notes to Figure 7–2
(1)   The 32 data and control signals are used to support up to four IOEs on each row I/O block.
(2)   Each of the four IOEs in the row I/O block can have two `io_datain` (combinational or registered) inputs.

Figure 7–3. Column I/O Block Connection to the Interconnect for LE-Rich Devices (EP3C5, EP3C10, EP3C25, EP3C55, EP3C80, and EP3C120)
Notes to Figure 7–3:
(1)   The 32 data and control signals are used to support up to four IOEs per two column I/O blocks.
(2)   Each of the four IOEs in the column I/O block can have two `io_datain` (combinational or registered) inputs.

Figure 7–4. Column I/O Block Connection to the Interconnect for I/O-Rich Devices (EP3C16 and EP3C40)
Notes to Figure 7–4:
(1)   The 40 data and control signals are used to support up to five IOEs per two column I/O block.
(2)   Each of the five IOEs in the column I/O block can have two `io_datain` (combinational or registered) inputs.

The pin's `datain` signals can drive the logic array. The logic array drives the control and data signals, providing a flexible routing resource. The row or column IOE clocks (`io_clk[5..0]`) provide a dedicated routing resource for low-skew, high-speed clocks. The global clock network generates the IOE clocks that feed the row or column I/O regions.

Each IOE contains its own control signal selection for the following control signals: `oe`, `ce_in`, `ce_out`, `aclr/preset`, `sclr/preset`, `clk_in`, and `clk_out`. Figure 7–5 illustrates the control signal selection.

Figure 7–5. Control Signal Selection Per IOE
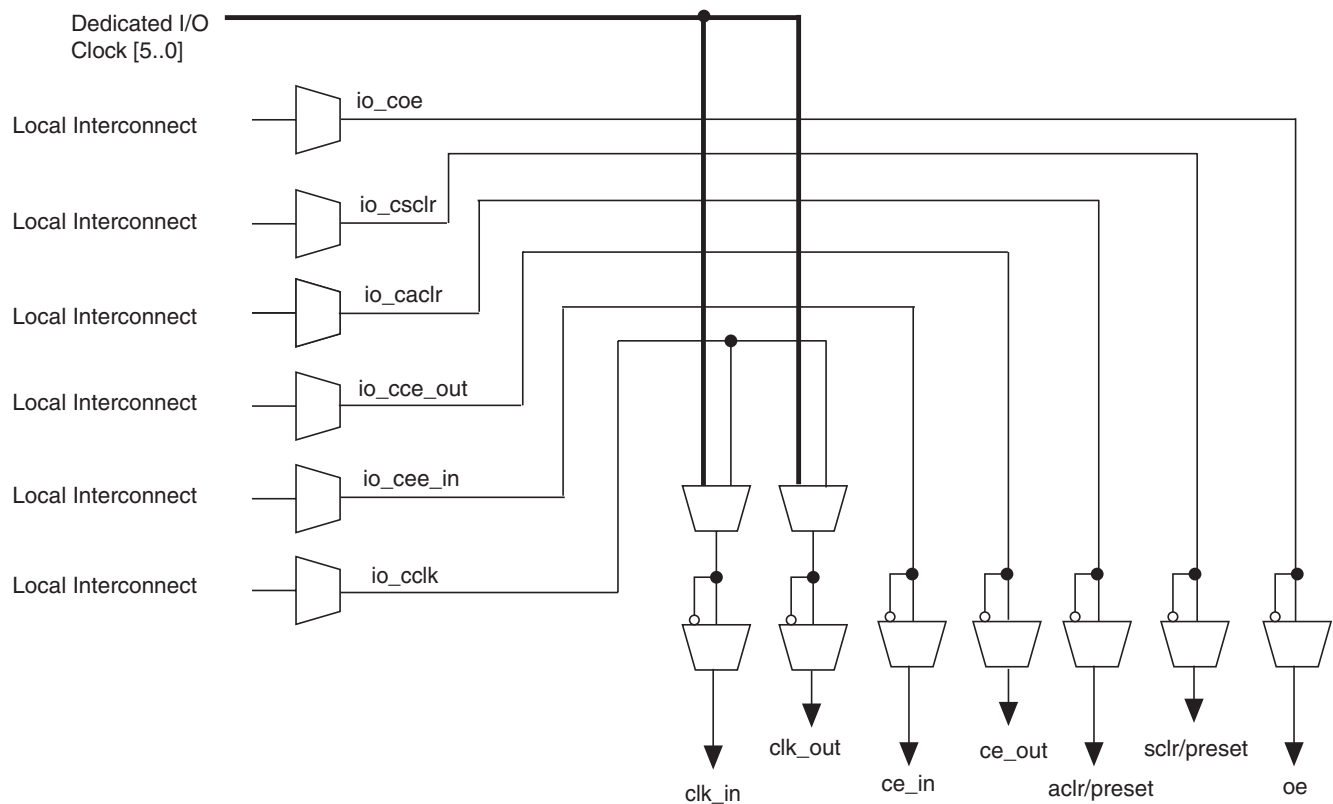

In bidirectional operation, you can use the input register for input data requiring fast setup times. The input register can have its own clock input and clock enable separate from the OE and output registers. You can use the output register for data requiring fast clock-to-output performance. The OE register is available for fast clock-to-output enable timing. The OE and output register share the same clock source and the same clock-enable source from the local interconnect in the associated LAB, dedicated I/O clocks, or column and row interconnects. All registers share `sclr` and `aclr`, but each register can individually disable `sclr` and `aclr`. Figure 7–6 shows the IOE in bidirectional configuration.

Figure 7–6. Cyclone III IOE in Bidirectional I/O Configuration
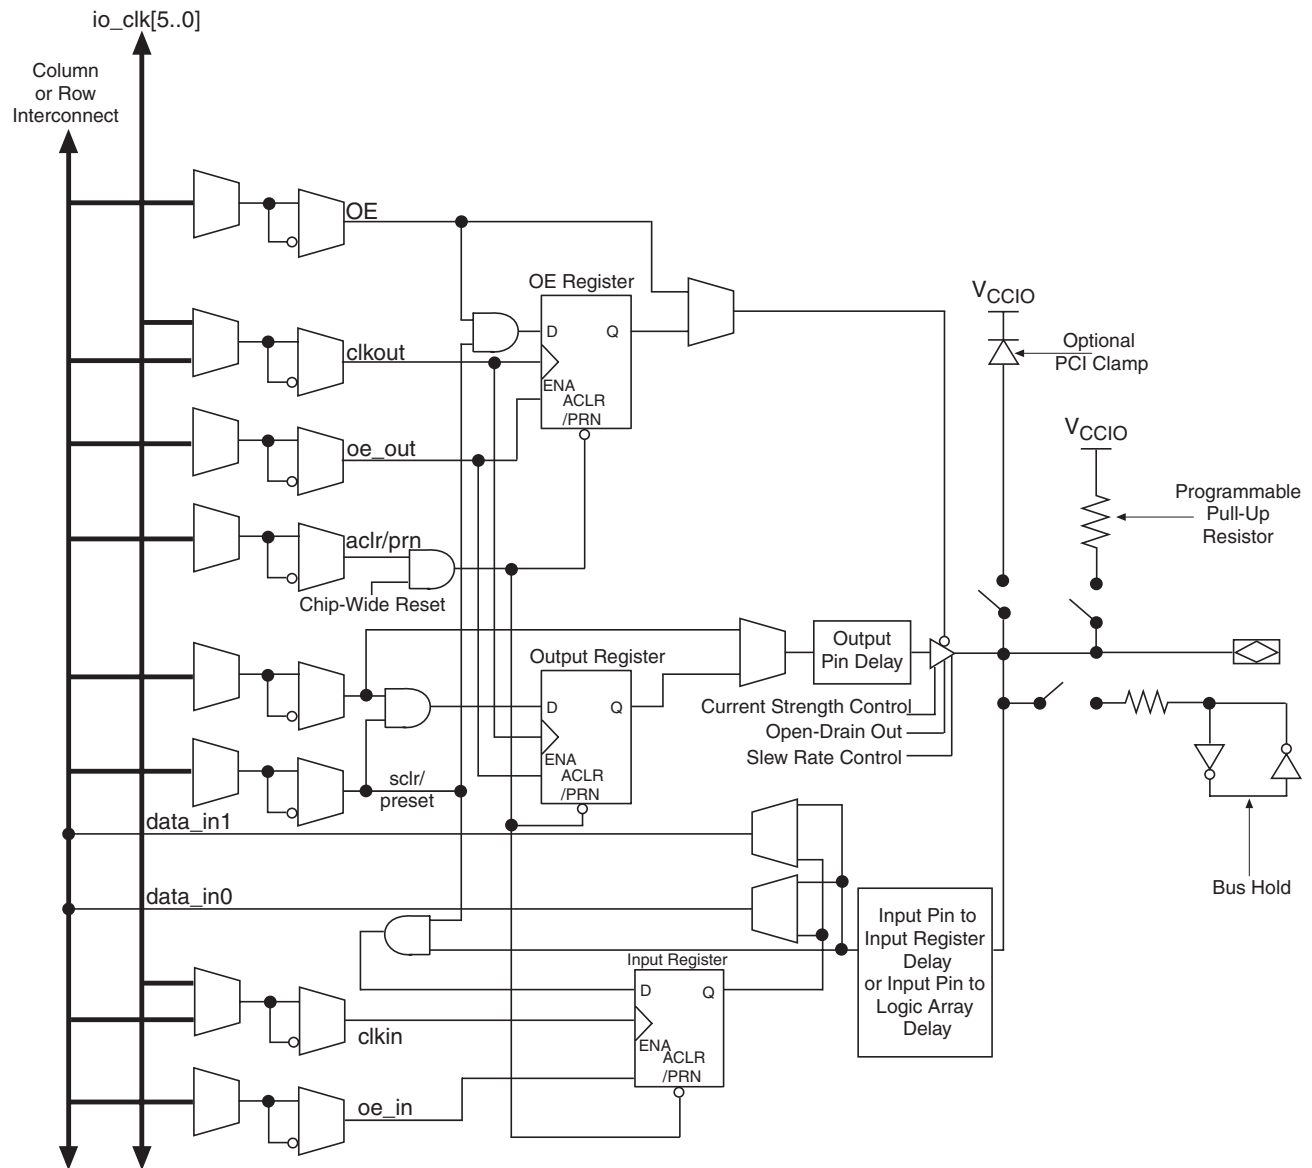

I/O Element Features

Programmable Current Strength

The output buffer for each Cyclone III device I/O pin has a programmable current strength control for certain I/O standards. The LVTTL, LVCMOS, SSTL-2 Class I and II, SSTL-18 Class I and II, HSTL-18 Class I and II, HSTL-15 Class I and II, and HSTL-12 Class I and II standards have several levels of current strength that you can control.

Refer to the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook* for more information about how to set the current strength feature.

Table 7–1 shows the possible settings for the I/O standards with current strength control. These programmable current-strength settings are a valuable tool in helping decrease the effects of simultaneously switching outputs (SSO) in conjunction with reducing system noise. The supported settings ensure that the device driver meets the specifications for I_{OH} and I_{OL} of the corresponding I/O standard.

☞ When you use programmable current strength, on-chip series termination is not available.

Note to Table 7–1:
(1) The default setting in the Quartus II software is 50 ΩOCT with calibration for all non-voltage reference and HSTL/SSTL class I I/O standards. The default setting is 25 ΩOCT without calibration for HSTL/SSTL class II I/O standards.
(2) The default current setting in the Quartus II software is highlighted in italic bold for 3.3-V LVTTL and 3.3-V LVCMOS I/O standard.

Cyclone III devices can interface to 3.3 V systems using 3.3 V and 3.0 V I/O standards by following a few simple guidelines. For more information, refer to *AN 447: Interfacing Cyclone III Devices with 3.3/3.0/2.5-V LVTTL/LVCMOS I/O Systems.*

Slew Rate Control

The output buffer for each Cyclone III device I/O pin provides optional programmable output slew-rate, with three settings for each supported I/O standard: slow, medium, and fast. The default slew rate is the fastest setting. A faster slew rate provides high-speed transitions for high-performance systems. However, these fast transitions may introduce noise transients into the system. A slower slew rate reduces system noise, but adds a nominal delay to rising and falling edges. Since each I/O pin has an individual slew-rate control, you can specify the slew rate on a pin-by-pin basis. The slew-rate control affects both the rising and falling edges. Slew rate control is available for single-ended I/O standards with current strength 8 mA or higher. 3.3-V LVTTL and 3.3-V LVCMOS I/O standards do not support slew rate control.

Refer to the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook* for more information about how to set the slew rate feature.

Open-Drain Output

Cyclone III devices provide an optional open-drain (equivalent to an open-collector) output for each I/O pin. This open-drain output enables the device to provide system-level control signals (for example, interrupt and write-enable signals) that can be asserted by multiple devices in your system.

Refer to the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook* for more information about how to set the open-drain output feature.

Bus Hold

Each Cyclone III device user I/O pin provides an optional bus-hold feature. The bus-hold circuitry holds the signal on an I/O pin at its last-driven state. Since the bus-hold feature holds the last-driven state of the pin until the next input signal is present, an external pull-up or pull-down resistor is not necessary to hold a signal level when the bus is tri-stated.

The bus-hold circuitry also pulls undriven pins away from the input threshold voltage where noise can cause unintended high-frequency switching. You can select this feature individually for each I/O pin. The bus-hold output drives no higher than V_{CCIO} to prevent overdriving signals.

☞ If you enable the bus-hold feature, the device cannot use the programmable pull-up option. Disable the bus-hold feature when the I/O pin is configured for differential signals. Bus-hold circuitry is not available on the dedicated clock pins.

The bus-hold circuitry is only active after configuration. When going into user mode, the bus-hold circuit captures the value on the pin present at the end of configuration.

Refer to the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook* for more information about how to set the bus hold feature.

Refer to the *DC and Switching Characteristics* chapter in volume 2 of the *Cyclone III Device Handbook*, for the specific sustaining current for each V_{CCIO} voltage level driven through the resistor and for the overdrive current used to identify the next driven input level.

Programmable Pull-Up Resistor

Each Cyclone III device I/O pin provides an optional programmable pull-up resistor while in user mode. If you enable this feature for an I/O pin, the pull-up resistor holds the output to the V_{CCIO} level of the output pin's bank.

☞ If you enable the programmable pull-up, the device cannot use the bus-hold feature. The programmable pull-up resistors are not supported on the dedicated configuration, Joint Test Action Group (JTAG), and dedicated clock pins.

📖 Refer to the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook* for more information about how to set the programable pull-up resistor.

Programmable Delay

The Cyclone III device IOE includes programmable delays to ensure zero hold times, minimize setup times, or increase clock-to-output times.

A path in which a pin directly drives a register may require a programmable delay to ensure zero hold time, whereas a path in which a pin drives a register through combinational logic may not require the delay. Programmable delays minimize setup time. The Quartus II Compiler can program these delays to automatically minimize setup time while providing a zero hold time. Programmable delays can increase the register-to-pin delays for output registers. Table 7–2 shows the programmable delays for Cyclone III devices.

Table 7–2. Cyclone III Programmable Delay Chain	
Programmable Delays	**Quartus II Logic Option**
Input pin to logic array delay	Input delay from pin to internal cells
Input pin to input register delay	Input delay from pin to input register
Output pin delay	Delay from output register to output pin

There are two paths in the IOE for an input to reach the logic array. Each of the two paths can have a different delay. This allows you to adjust delays from the pin to the internal LE registers that reside in two different areas of the device. You set the two combinational input delays by using the **Input delay from pin to internal cells** logic option in the Quartus II software for each path. If the pin uses the input register, one of delays is disregarded and the delay is set by using the **Input delay from pin to input register** logic option in the Quartus II software.

The IOE registers in each I/O block share the same source for the preset or clear features. You can program preset or clear for each individual IOE, but you cannot use both features simultaneously. You can also program the registers to power-up high or low after configuration is complete. If programmed to power-up low, an asynchronous clear can control the registers. If programmed to power-up high, an asynchronous preset can

control the registers. This feature prevents the inadvertent activation of another device's active-low input upon power up. If one register in an IOE uses a preset or clear signal, then all registers in the IOE must use that same signal if they require preset or clear. Additionally, a synchronous reset signal is available for the IOE registers.

Refer to the *Area and Timing Optimization* chapter in volume 2 of the *Quartus II Handbook* for more information about how to set the input and output pin delay.

PCI-Clamp Diode

Cyclone III devices provide an optional PCI-clamp diode enabled input and output for each I/O pin. The PCI-clamp diode is available for 3.3-V LVTTL, 3.3-V LVCMOS, 3.0-V LVTTL, 3.0-V LVCMOS, PCI, and PCI-X I/O standards. If the input I/O standard is 3.3-V LVTTL, 3.3-V LVCMOS, 3.0-V LVTTL, 3.3-V LVCMOS, PCI, or PCI-X, the PCI clamp diod is enabled by default in Quartus II.

Refer to the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook* for more information about how to set the PCI-Clamp diode feature.

For more information about Cyclone III PCI-clamp diode support, refer to *AN 447: Interfacing Cyclone III Devices with 3.3/3.0/2.5-V LVTTL/LVCMOS I/O Systems.*

LVDS Transmitter Programmable Pre-Emphasis

The Cyclone III dedicated LVDS transmitter supports programmable pre-emphasis. Programmable pre-emphasis is used to compensate the frequency-dependent attenuation of the transmission line. It increases the amplitude of the high-frequency components of the output signal, which cancels out much of the high-frequency loss of the transmission line.

Programmable pre-emphasis supports on and off settings. The amount of pre-emphasis needed depends on the amplification of the high-frequency components along the transmission line. You need to adjust the setting to suit your designs, as pre-emphasis decreases the amplitude of the low-frequency component of the output signal as well.

For more information about Cyclone III high-speed differential interface support, refer to *High-Speed Differential Interfaces* in the *Cyclone III Devices* chapter of the *Cyclone III Device Handbook*.

On-Chip Termination Support

Cyclone III devices feature on-chip termination (OCT) to provide I/O impedance matching and termination capabilities. On-chip termination helps to prevent reflections and maintain signal integrity while minimizing the need for external resistors in high pin-count ball grid array (BGA) packages. Cyclone III devices provide I/O driver on-chip impedance matching and on-chip series termination for single-ended outputs and bidirectional pins.

☞ When using on-chip series termination, programmable current strength is not available.

There are two ways to implement on-chip termination in Cyclone III devices:

■ OCT with calibration
■ OCT without calibration

On-Chip Termination With Calibration

Cyclone III devices support on-chip series termination with calibration in all banks. The on-chip series termination calibration circuit compares the total impedance of the I/O buffer to the external 25 Ω ±1% or 50 Ω ±1% resistors connected to the R_{UP} and R_{DN} pins, and dynamically adjusts the I/O buffer impedance until they match (as shown in Figure 7–7). The RS shown in Figure 7–7 is the intrinsic impedance of the transistors that make up the I/O buffer.

Figure 7–7. Cyclone III On-Chip Series Termination With Calibration
On-chip termination with calibration is achieved using the OCT calibration block circuitry. There is one OCT calibration block in bank 2, 4, 5, and 7. Each calibration block supports each side of the I/O banks. Since there are two I/O banks sharing the same calibration block, both banks must have the same V_{CCIO} if both banks enable OCT calibration. If two related banks have different V_{CCIOs}, only the bank where the calibration block resides can enable the OCT calibration. Figure 7–8 shows the top level view of the OCT calibration blocks placement.

Figure 7–8. Cyclone III OCT Block Placement
Each calibration block comes with a pair of R_{UP} and R_{DN} pins. When you use OCT with calibration, these two pins need to be connected with external resistors of 25 Ω ±1% or 50 Ω ±1%. The external resistors are compared with the internal resistance using comparators. The resultant outputs of the comparators are used by the OCT calibration block to dynamically adjust the buffer impendance. When OCT calibration is not used, R_{UP} and R_{DN} pins can be used as regular I/Os.

Table 7–3 lists the I/O standards that support impedance matching and series termination.

Table 7–3. Selectable I/O Drivers for On-Chip Termination without Calibration

HSTL-15 Class II	25	25	Ω
HSTL-12 Class I	50	50	Ω
HSTL-12 Class II	—	25	Ω

On-Chip Termination Without Calibration

Cyclone III devices support driver impedance matching to the impedance of the transmission line, typically 25 or 50 Ω. When used with the output drivers, on-chip termination sets the output driver impedance to 25 or 50 Ω. Cyclone III devices also support I/O driver series termination (R_S=

50 Ω) for SSTL-2 and SSTL-18. Figure shows the single-ended I/O standards for on-chip termination without calibration. The R_S shown is the intrinsic transistor impedance.

Figure 7–9. Cyclone III On-Chip Series Termination Without Calibration
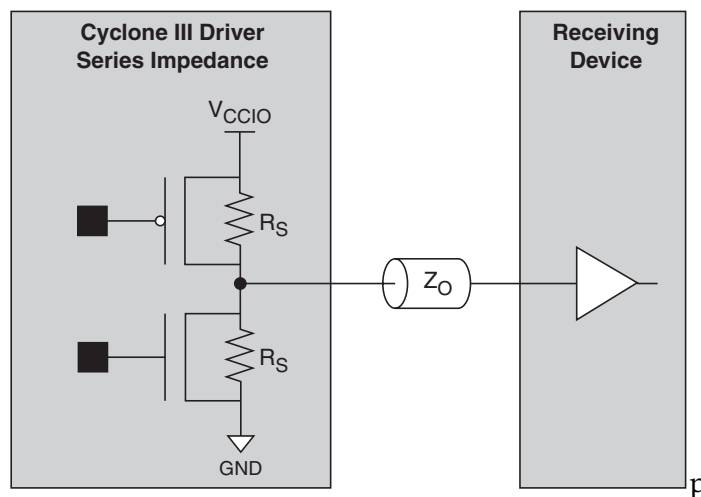

All I/O banks and I/O pins support impedance matching and series termination. Dedicated configuration pins and JTAG pins do not support impedance matching or series termination. Table 7–4 lists the I/O standards that support impedance matching the series termination.

Table 7–4. Selectable I/O Drivers for On-Chip Termination without Calibration   (Part 1 of 2)

I/O Standard	On Chip Series Termination without Calibration Setting

HSTL-15 Class II	25	25	Ω
HSTL-12 Class I	50	50	Ω
HSTL-12 Class II	-	25	Ω

On-chip series termination is supported on any I/O bank. V_{CCIO} and V_{REF} must be compatible for all I/O pins to enable on-chip series termination in a given I/O bank. I/O standards that support different R_S values can reside in the same I/O bank as long as their V_{CCIO} and V_{REF} are not conflicting.

Impedance matching is implemented using the capabilities of the output driver and is subject to a certain degree of variation, depending on the process, voltage, and temperature.

Refer to the *DC and Switching Characteristics* chapter in volume 2 of the *Cyclone III Device Handbook,* for more information about tolerance specification.

I/O Standards

Cyclone III devices support multiple single-ended and differential I/O standards. Apart from 3.3, 3.0, 2.5, 1.8, and 1.5 V support, Cyclone III devices also support 1.2 V I/O standards. Table 7–5 summarizes the I/O standards supported by Cyclone III devices and which I/O pins support them.

Table 7–5. Cyclone III Supported I/O Standards and Constraints   (Part 1 of 3)

I/O Standard	Type	Standard Support	V_CCIO Level		Top and Bottom I/O Pins			Side I/O Pins	
			Input	Output	CLK, DQS	PLL_OUT	User I/O Pins	CLK, DQS	User I/O Pins

Table 7–5. Cyclone III Supported I/O Standards and Constraints (Part 3 of 3)									
I/O Standard	**Type**	**Standard Support**	**V$_{CCIO}$ Level**		**Top and Bottom I/O Pins**			**Side I/O Pins**	
			Input	**Output**	**CLK, DQS**	**PLL_OUT**	**User I/O Pins**	**CLK, DQS**	**User I/O Pins**
LVPECL *(4)*	Differential	—	2.5 V	—	✓			✓	

Notes to Table 7–5:
(1) The PCI-clamp diode needs to be enabled for 3.3-V/3.0-V LVTTL/LVCMOS.
(2) Differential HSTL and SSTL outputs use two single-ended outputs with the second output programmed as inverted. Differential HSTL and SSTL inputs treat differential inputs as two single-ended HSTL and SSTL inputs and only decode one of them. Differential HSTL and SSTL only supported on `CLK` pins.
(3) PPDS, mini-LVDS, and RSDS are only supported on output pins.
(4) LVPECL is only supported on clock inputs.

Termination Scheme for I/O Standards

This section describes the recommended termination schemes for voltage-referenced and differential I/O standards.

The following I/O standards do not specify a recommended termination scheme per the JEDEC standard:

- 3.3-V LVTTL
- 3.0-V LVTTL and LVCMOS
- 2.5-V LVTTL and LVCMOS
- 1.8-V LVTTL and LVCMOS
- 1.5-V LVCMOS
- 1.2-V LVCMOS
- 3.0-V PCI and PCI-X

Voltage-Referenced I/O Standard Termination

Voltage-referenced I/O standards require both an input reference voltage (V$_{REF}$) and a termination voltage (V$_{TT}$). The reference voltage of the receiving device tracks the termination voltage of the transmitting device, as shown in Figures 7–10 and 7–11.

Figure 7–10. Cyclone III HSTL I/O Standard Termination
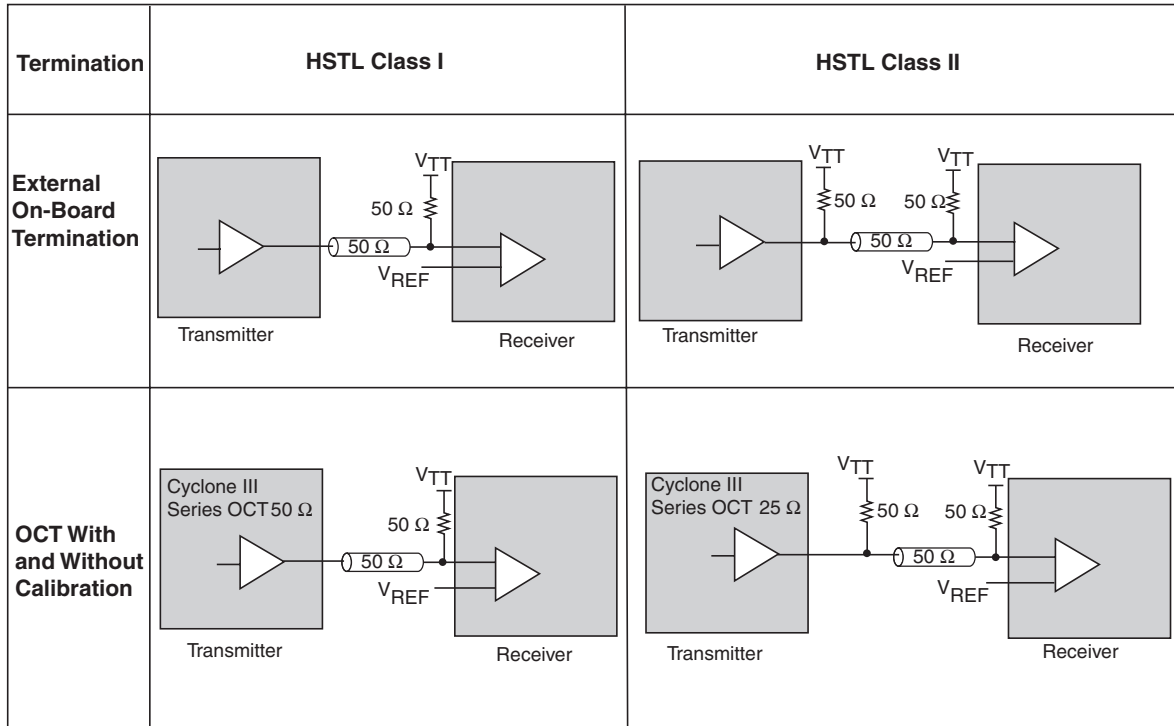

Figure 7–11. Cyclone III SSTL I/O Standard Termination
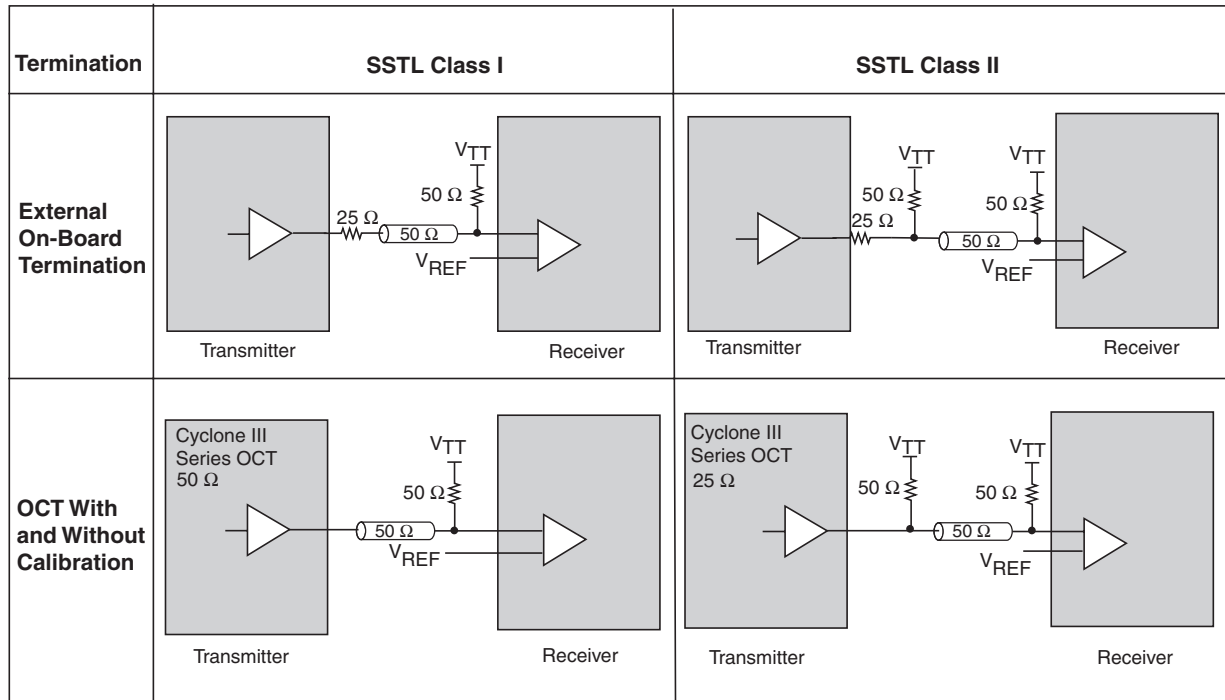

Differential I/O Standard Termination

Differential I/O standards typically require a termination resistor between the two signals at the receiver. The termination resistor must match the differential load impedance of the bus (refer to Figures 7–12 and 7–13).

Cyclone III devices support differential SSTL-2 and SSTL-18, differential HSTL-18, HSTL-15, and HSTL-12, PPDS, LVDS, RSDS, mini-LVDS, and differential LVPECL.

Figure 7–12. Cyclone III Differential HSTL I/O Standard Termination
Figure 7–13. Cyclone III Differential SSTL I/O Standard Termination
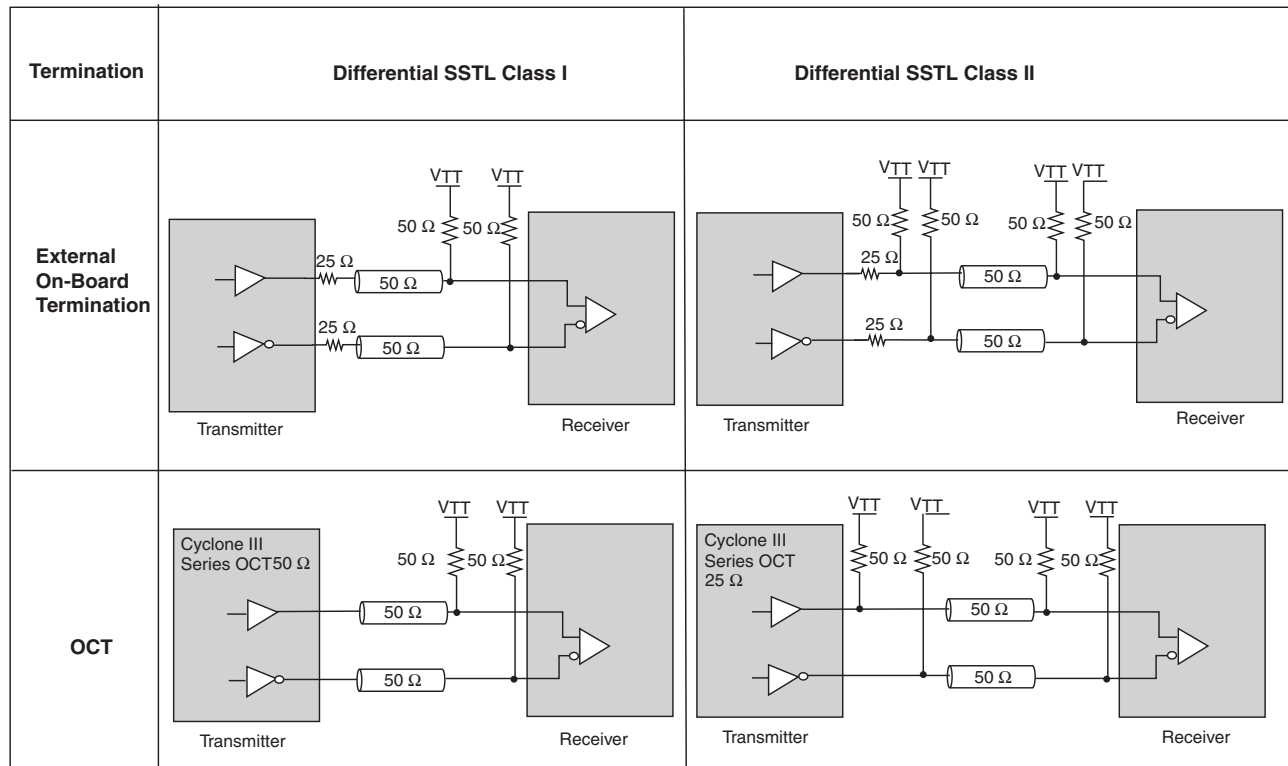

For information on Cyclone III differential PPDS, LVDS, mini LVDS, and RSDS I/O standard termination, refer to the *High-Speed Differential Interfaces in Cyclone III Devices* chapter of the *Cyclone III Device Handbook*.

I/O Banks

The I/O pins on Cyclone III devices are grouped together into I/O banks, and each bank has a separate power bus. All Cyclone III devices have eight I/O banks, as shown in Figure 7–14. Each device I/O pin is associated with one I/O bank. All single-ended and differential I/O standards are supported in all banks except HSTL-12 class II, which is only supported in column I/O banks.

Figure 7–14. Cyclone III Device I/O Banks (1)

All I/O Banks Support:

3.3-V LVTTL/LVCMOS
3.0-V LVTTL/LVCMOS
2.5-V LVTTL/LVCMOS
1.8-V LVTTL/LVCMOS
1.5-V LVCMOS
1.2-V LVCMOS

Differential SSTL-18 *(5)*
Differential HSTL-18 *(5)*
Differential HSTL-15 *(5)*
Differential HSTL-12 *(6)*

I/O Bank 8   I/O Bank 7   I/O Bank 1   I/O Bank 2   I/O Bank 6   I/O Bank 5   I/O Bank 3   I/O Bank 4

Notes to Figure 7–14:
(1) This is a top view of the silicon die. This is a graphic representation only. Refer to the pin list and the Quartus II software for exact pin locations.
(2) Dedicated PPDS, LVDS, mini-LVDS, and RSDS I/O standards are supported in row I/O banks 1, 2, 5, and 6 only. External resistors are needed for column I/O banks.
(3) The LVPECL I/O standard is only supported on clock input pins. This I/O standard is not supported on output pins.
(4) The HSTL-12 Class II is supported in column I/O banks 3, 4, 7, and 8 only.
(5) The differential SSTL-18 and SSTL-2, differential HSTL-18, and HSTL-15 I/O standards are only supported on clock input pins and PLL output clock pins.
(6) The differential HSTL-12 I/O standards is only supported on clock input pins and PLL output clock pins. Differential HSTL-12 class II is only supported in column I/O banks 3, 4, 7 and 8 only.

Table 7–6 shows I/O standards supported when a pin is used as a regular I/O pin in the I/O banks of Cyclone III devices.

Table 7–6. Cyclone III I/O Standards Support (Part 1 of 2)

Table 7–6. Cyclone III I/O Standards Support (Part 2 of 2)								
I/O Standard	**I/O Banks**							
	1	**2**	**3**	**4**	**5**	**6**	**7**	**8**
Differential LVPECL	*(4)*	*(4)*	*(4)*	*(4)*	*(4)*	*(4)*	*(4)*	*(4)*

Notes to Table 7–6:

(1) These differential I/O standards are only supported for clock inputs and dedicated `PLL_OUT` outputs.
(2) Dedicated LVDS I/O standard is supported in row I/O banks only. LVDS I/O standard in column I/O banks require external resistors network.
(3) This I/O standard is supported for outputs only.
(4) This I/O standard is supported for clock inputs only.

Each Cyclone III I/O bank has a V_{REF} bus to accommodate voltage-referenced I/O standards. When using V_{REF} pins, you must properly connect each V_{REF} pin to the appropriate voltage level. In the event you do not use these pins as V_{REF} pins, you may use them as regular I/O pins. However, they will have slightly higher pin capacitance than regular user I/O pins when used with regular user I/O pins. Table 7–7 summarizes the number of V_{REF} pins in each I/O bank.

Table 7–7. Number of V_{REF} Pins Per I/O Banks (Part 1 of 2)

	FBGA	780	3	3	3	3	3	3	3	3

Each Cyclone III I/O bank has its own V_{CCIO} pins. Any single I/O bank can only support one V_{CCIO} setting from among 1.2, 1.5, 1.8, 2.5, 3.0, or 3.3 V. Although there can only be one V_{CCIO} voltage per I/O bank, Cyclone III devices permit additional input signaling capabilities.

Any number of supported single-ended or differential standards can be simultaneously supported in a single I/O bank, as long as they use compatible V_{CCIO} levels for input and output pins. For example, an I/O bank with a 2.5-V V_{CCIO} setting can support 2.5-V LVTTL inputs and outputs, 2.5-V LVDS-compatible inputs and outputs, and 3.0-V LVTTL and 3.3-V LVCMOS inputs only.

Voltage-referenced standards can be supported in an I/O bank using any number of single-ended or differential standards, as long as they use the same V_{REF} and a compatible V_{CCIO} value. For example, if you choose to implement both SSTL-2 and SSTL-18 in your Cyclone III device, I/O pins using these standards—because they require different V_{REF} values—must be in different banks from each other. However, the same I/O bank can support SSTL-2 and 2.5-V LVCMOS with the V_{CCIO} set to 2.5 V and the V_{REF} set to 1.25 V.

Table 7–8 shows the acceptable input and output levels with corresponding bank voltage.

Bank V$_{CCIO}$ (V)	Input Signal						Output Signal					
	1.2 V	1.5 V	1.8 V	2.5 V	3.0 V	3.3 V	1.2 V	1.5 V	1.8 V	2.5 V	3.0 V	3.3 V
1.2 V	✓						✓					
1.5 V		✓	✓ (1)					✓				
1.8 V		✓ (2)	✓						✓			
2.5 V				✓	✓ (3)	✓ (3)				✓		
3.0 V				✓ (2)	✓ (3)	✓ (3)					✓	
3.3 V				✓ (2)	✓ (3)	✓ (3)						✓

Table 7–8. Acceptable Input and Output Levels *(1)*, *(2)*, *(3)*

Notes to Table 7–8:

(1) These input values overdrive the input buffer, so the pin leakage current is slightly higher than the default value.
(2) Because the input level does not drive to the rail, the input buffer does not completely shut off. The I/O current is slightly higher than the default value.
(3) The PCI clamping diode must be enabled for input signals at 3.0 V or 3.3V.

For more information about Cyclone III I/O interface support, refer to *AN 447: Interfacing Cyclone III Devices with 3.3/3.0/2.5-V LVTTL/LVCMOS I/O Systems.*

High-Speed Differential Interfaces

Cyclone III devices can transmit and receive data through LVDS signals. For the LVDS transmitter and receiver, the Cyclone III device's input and output pins support serialization and de-serialization through internal logic.

The reduced swing differential signaling (RSDS) and mini-LVDS standards are derivatives of the LVDS standard. The RSDS and mini-LVDS I/O standards are similar in electrical characteristics to LVDS, but have a smaller voltage swing and therefore provide increased power benefits and reduced electromagnetic interference (EMI).

The point-to-point differential signalling (PPDS) standard is the next generation of RSDS standard introduced by National Semiconductor Corporation. Cyclone III devices meet the National Semiconductor Corporation PPDS Interface Specification and support the PPDS standard for outputs only. All the I/O banks of Cyclone III devices support the PPDS standard for output pins only.

You can use I/O pins and internal logic to implement the LVDS I/O receiver and transmitter in Cyclone III devices. Cyclone III devices do not contain dedicated serialization or de-serialization circuitry. Therefore, shift registers, internal PLLs, and IOEs are used to perform serial-to-parallel conversions on incoming data and parallel-to-serial conversion on outgoing data.

The LVDS standard does not require an input reference voltage, but it does require a 100-Ω termination resistor between the two signals at the input buffer. An external resistor network is required on the transmitter side for top and bottom I/O banks.

For more information about Cyclone III high-speed differential interface support, refer to the *High-Speed Differential Interfaces in Cyclone III Devices* chapter in volume 1 of the *Cyclone III Device Handbook.*

External Memory Interfacing

Cyclone III devices support I/O standards required to interface with a broad range of external memory interfaces such as DDR SDRAM, DDR2 SDRAM, and QDRII SRAM.

For more information about Cyclone III external memory interface support, refer to the *External Memory Interfaces in Cyclone III Devices* chapter in volume 1 of the *Cyclone III Device Handbook.*

Pad Placement and DC Guidelines

This section provides pad placement guidelines for the programmable I/O standards supported by Cyclone III devices and includes essential information for designing systems using the devices' selectable I/O capabilities. This section also discusses DC limitations and guidelines.

Quartus II software provides user-controlled restriction relaxation options for some placement constraints. When you relax a default restriction, the Quartus II fitter generates warnings.

For more information about how Quartus II software checks I/O restrictions, see the *I/O Management* chapter in the *Quartus II Handbook.*

Differential Pad Placement Guidelines

To maintain an acceptable noise level on the V_{CCIO} supply, there are restrictions on placement of single-ended I/O pads in relation to differential pads. Use the following guidelines for placing single-ended pads with respect to differential pads and for differential output pads placement in Cyclone III devices.

For the LVDS I/O standard:

■ Single-ended inputs can be no closer than four pads away from an LVDS I/O pad.
■ Single-ended outputs can be no closer than five pads away from an LVDS I/O pad.
■ A maximum of four 160-MHz LVDS output channels per V_{CCIO} and ground pair in column I/O banks.
■ A maximum of three 320-MHz LVDS output channels per V_{CCIO} and ground pair in column I/O banks.
■ A maximum of four 210-MHz LVDS output channels per V_{CCIO} and ground pair in row I/O banks.
■ A maximum of three 420-MHz LVDS output channels per V_{CCIO} and ground pair in row I/O banks.

☞ The Quartus II software only checks the first two cases.

For the RSDS and mini-LVDS I/O standards:

■ Single-ended inputs can be no closer than four pads away from an RSDS and mini-LVDS output pad.
■ Single-ended outputs can be no closer than five pads away from an RSDS and mini-LVDS output pad.
■ A maximum of three 85-MHz RSDS and mini-LVDS output channels per V_{CCIO} and ground pair in column I/O banks.
■ A maximum of three 180-MHz RSDS output channels per V_{CCIO} and ground pair in row I/O banks.
■ A maximum of three 220-MHz mini-LVDS output channels per V_{CCIO} and ground pair in row I/O banks.

☞ The Quartus II software only checks the first two cases.

For the PPDS I/O standard:

■ Single-ended inputs can be no closer than four pads away from an PPDS output pad.
■ Single-ended outputs can be no closer than five pads away from an PPDS output pad.
■ A maximum of three 85-MHz PPDS output channels per V_{CCIO} and ground pair in column I/O banks.
■ A maximum of three 220-MHz PPDS output channels per V_{CCIO} and ground pair in row I/O banks.

☞ The Quartus II software only checks the first two cases.

For the LVPECL I/O standard:

- Single-ended inputs can be no closer than four pads away from an LVPECL input pad.
- Single-ended outputs can be no closer than five pads away from an LVPECL input pad.

V_{REF} Pad Placement Guidelines

To maintain an acceptable noise level on the V_{CCIO} supply and to prevent output switching noise from shifting the V_{REF} rail, there are restrictions on the placement of single-ended voltage referenced I/Os with respect to V_{REF} pads and V_{CCIO} and ground pairs. Use the following guidelines for placing single-ended pads in Cyclone III devices.

☞ The Quartus II software automatically does all the calculations in this section.

Input Pads

Each V_{REF} pad supports up to 32 input pads for FineLine BGA devices. Each V_{REF} pad supports up to 21 input pads for quad flat pack (QFP) devices. This is irrespective of V_{CCIO} and ground pairs and is guaranteed by the Cyclone III architecture.

Output Pads

When no voltage referenced input or bidirectional pads exist in a bank, there is no limit to the number of output pads that can be implemented in that bank. When a voltage referenced input exists, each V_{CCIO} and ground pair supports nine outputs for Fineline BGA packages or five outputs for QFP packages. Any non-SSTL and non-HSTL output can be no closer than two pads away from a V_{REF} pad to maintain acceptable noise levels. Altera recommends that any SSTL or HSTL output, except for pintable defined DQ and DQS outputs (when used for DDR/DDR2/QDRII applications), to be no closer than two pads away from a V_{REF} pad to maintain acceptable noise levels. See "DDR/DDR2 and QDRII Pads" on page 7–37 for details about guidelines for DQ and DQS pad placement.

Bidirectional Pads

Bidirectional pads must satisfy input and output guidelines simultaneously. See "DDR/DDR2 and QDRII Pads" on page 7–37 for details about guidelines for DQ and DQS pad placement.

If the bidirectional pads are all controlled by the same output enable (OE) and there are no other outputs or voltage referenced inputs in the bank, there would be no case where a voltage referenced input is active at the same time as an output. Therefore, the output limitation does not apply. However, since the bidirectional pads are linked to the same OE, all the bidirectional pads act as inputs at the same time. Therefore, the input limitation of 32 input pads (per V_{REF} pad) for FineLine BGA packages and 21 input pads (per V_{REF} pad) for QFP packages applies.

If the bidirectional pads are all controlled by different OEs, and there are no other outputs or voltage referenced inputs in the bank, there may be a case where one group of bidirectional pads is acting as inputs while another group is acting as outputs. In such cases, apply the formulas shown in Table 7–9.

Table 7–9. Input-Only Bidirectional Pad Limitation Formulas

Package Type	Formula
FineLine BGA	(Total number of bidirectional pads) – (Total number of pads from the smallest group of pads controlled by an OE) ≤ 9 (per V_{CCIO} and ground pair)
QFP	(Total number of bidirectional pads) – (Total number of pads from the smallest group of pads controlled by an OE) ≤ 5 (per V_{CCIO} and ground pair)

When at least one additional voltage referenced input and no other outputs exist in the same V_{REF} bank, the bidirectional pad limitation applies in addition to the input and output limitations. See the following equations:

Total number of bidirectional pads + total number of input pads ≤ 32 for Fineline BGA packages

Total number of bidirectional pads + total number of input pads ≤ 21 for QFP packages

After applying the equation above, apply one of the equations in Table 7–10, depending on the package type.

Table 7–10. Bidirectional Pad Limitation Formulas (Where V_{REF} Inputs Exist)	
Package Type	**Formula**
FineLine BGA	(Total number of bidirectional pads) ≤ 9 (per VCCIO and ground pair)
QFP	(Total number of bidirectional pads) ≤ 5 (per VCCIO and ground pair)

When at least one additional output exists but no voltage referenced inputs exist, apply the appropriate formula from Table 7–11.

Table 7–11. Bidirectional Pad Limitation Formulas (Where V_{REF} Outputs Exist)	
Package Type	**Formula**
FineLine BGA	(Total number of bidirectional pads) + (Total number of additional output pads) – (Total number of pads from the smallest group of pads controlled by an OE) ≤ 9 (per V_{CCIO} and ground pair)
QFP	(Total number of bidirectional pads) + (Total number of additional output pads) – (Total number of pads from the smallest group of pads controlled by an OE) ≤ 5 (per V_{CCIO} and ground pair)

When additional voltage referenced inputs and other outputs exist in the same V_{REF} bank, the bidirectional pad limitation must again simultaneously adhere to the input and output limitations. As such, the following rules apply:

Total number of bidirectional pads + total number of input pads ≤ 32 for Fineline BGA packages

Total number of bidirectional pads + total number of input pads ≤ 21 for QFP packages

After applying the equation above, apply one of the equations in Table 7–12, depending on the package type.

Table 7–12. Bidirectional Pad Limitation Formulas (Multiple V_{REF} Inputs and Outputs)	
Package Type	**Formula**
FineLine BGA	(Total number of bidirectional pads) + (Total number of output pads) ≤9 (per V_{CCIO}/GND pair)
QFP	Total number of bidirectional pads + Total number of output pads ≤5 (per V_{CCIO}/GND pair)

Each I/O bank can only be set to a single V_{CCIO} voltage level and a single V_{REF} voltage level at a given time. Pins of different I/O standards can share the bank if they have compatible V_{CCIO} values and compatible V_{REF} voltage levels (refer to Table 7–7 for more details).

DDR/DDR2 and QDRII Pads

For dedicated DQ and DQS pads on a DDR interface, DQ pads must be on the same power bank as DQS pads. With the DDR and DDR2 memory interfaces, a V_{CCIO} and ground pair can have a maximum of five DQ pads. No other I/O can be placed within the same power bank where DQ pins are located, except DDR/DDR2 usage pins.

For a QDRII interface, D is the QDRII output and Q is the QDRII input. D pads and Q pads must be on the same power bank as CQ. With the QDR and QDRII memory interfaces, a V_{CCIO} and ground pair can have a maximum of five D and Q pads. No other I/O can be placed within the same power bank where D or Q pins located. Besides, the D, cms, and address pads can not be placed at the same V_{REF} bank where Q pads are located.

By default, the Quartus II software assigns D and Q pads as regular I/O pins. If you do not specify the function of a D or Q pad in the Quartus II software, the software sets them as regular I/O pins. If this occurs, Cyclone III QDR and QDRII performance is not guaranteed.

DC Guidelines

There is a current limit of 240 mA per twelve consecutive output top and bottom pins per power pair, as shown by the following equation:

pin+11

$\Sigma\ I_{PIN}$ < 240 mA per power pair
pin

There is a current limit of 240 mA per 14 consecutive output side pins (left and right) per power pair, as shown by the following equation:

pin+13
$\Sigma\ I_{PIN}$ < 240 mA per power pair
pin

☞ In all the cases listed above, the Quartus II software generates an error message for illegally placed pads. The I_{PIN} varies with programmable current strength and is the same as the current strength as set in the Quartus II software.

For more information about Cyclone III FPGAs power estimation, refer to *The Power Play III Early Power Estimator User Guide for Cyclone III FPGAs*.

Conclusion

Cyclone III device I/O capabilities enable you to keep pace with increasing design complexity utilizing a low-cost FPGA device family. Support for various I/O standard compatibility allow Cyclone III devices to fit into a wide variety of applications. Quartus II software makes it easy to use these I/O standards in Cyclone III device designs.

After design compilation, the software also provides clear, visual representations of pads and pins and the selected I/O standards. Taking advantage of the support of these I/O standards in Cyclone III devices allows you to lower your design costs without compromising design flexibility or complexity.

Date and Document Version	Changes Made	Summary of Changes
March 2007 v1.0	Initial Release	

CIII51008-1.0

Introduction

High-speed differential I/O standards have become popular in high-speed interfaces because of their significant advantages over single-ended I/O standards. In response to the current market need, Altera® Cyclone® III devices support various differential I/O standards, including low-voltage differential signaling (LVDS), reduced swing differential signaling (RSDS), mini-LVDS, and point-to-point differential signaling (PPDS).

LVDS is the technology of choice from high-speed backplane applications to high-end switch boxes. LVDS is a low-voltage differential signaling standard, providing higher noise immunity than single-ended I/O technologies. Its low-voltage swing allows for high-speed data transfers, low power consumption, and reduced electromagnetic interference (EMI). LVDS I/O signaling is a data interface standard defined in the TIA/EIA-644 and IEEE Std. 1596.3 specifications.

Cyclone III devices can receive LVDS signals at 875 megabits per second (Mbps) on all I/O banks. Cyclone III devices include dedicated differential output buffers to transmit LVDS signals at up to 840 Mbps on the left and right I/O banks, with no external resistors required. The top and bottom I/O banks can transmit data at up to 640 Mbps using a simple resistor network.

The RSDS and mini-LVDS standards are derivatives of the LVDS standard. Because the RSDS and mini-LVDS I/O standards have smaller voltage swing than does LVDS, they provide increased power benefits and reduced EMI. National Semiconductor Corporation and Texas Instruments introduced the RSDS and mini-LVDS specifications, respectively. Currently, many designers use these specifications for flat panel display links between the controller and the display column drivers. Cyclone III devices support the RSDS and mini-LVDS I/O standards at speeds up to 360 Mbps and 400 Mbps, respectively, at the dedicated transmitter located on the left and right I/O banks, with no external resistors required.

The PPDS standard is the next generation of the RSDS standard introduced by National Semiconductor Corporation. PPDS technology was introduced to address the requirements for liquid crystal display (LCD) television interfaces to improve display performance. PPDS applications include multi-function LCD monitor and high-performance

professional LCD monitor. Cyclone III devices support the PPDS I/O standards at speed up to 440 Mbps with no external resistors required at the dedicated transmitter located on the left and right I/O banks.

The differential interface data serializers and deserializers (SERDES) are constructed automatically in Cyclone III logic elements with Quartus® II software `altlvds` megafunction.

This chapter describes how to use Cyclone III I/O pins for differential signaling and contains the following topics:

■ Cyclone III high-speed I/O banks
■ Cyclone III high-speed I/O interface
■ High-speed I/O standards support
■ High-speed I/O timing in Cyclone III devices
■ Design guidelines
■ Software Overview

Cyclone III High-Speed I/O Banks

Cyclone III device I/Os are separated into eight I/O banks, as shown in Figure 8–1. Each bank has an independent power supply. Dedicated output drivers for LVDS, RSDS, mini-LVDS, and PPDS are on the left and right I/O banks. These I/O standards are also supported on the top and bottom I/O banks using external resistors. On the left and right I/O banks, some of the differential pin pairs (p and n pins) of the dedicated output drivers are not located on adjacent pins. In these cases, a power pin is located between the p and n pins.

Refer to the pin tables on the Altera web site at **www.altera.com** for more details on the location of the dedicated differential pins.

Table 8–1 shows the performance target for various differential I/O standards.

Figure 8–1. Cyclone III I/O Banks
Notes to Figure 8–1:
(1) The PCI-X I/O standard does not meet the IV curve requirement at the linear region.
(2) The RSDS, mini-LVDS, and PPDS I/O standards are only supported on output pins. These I/O standards are not supported on input pins.
(3) The LVPECL I/O standard is only supported on dedicated clock input pins. This I/O standard is not supported on output pins.
(4) The differential SSTL-2, SSTL-18, HSTL-18, HSTL-15, and HSTL-12 I/O standards are only supported on dedicated clock input pins and PLL output clock pins.

Table 8–1. Performance Targets for Various Differential I/O Standards

Differential I/O Standards	I/O Bank Location	Pintable Package Note (1)	External Resistor Network at Transmitter	Fmax (Mbps)	
				Transmitter (TX)	Receiver (RX)
LVDS	1,2,5,6	Adj.	Not required	840	875
	1,2,5,6	Sep.	Not required	640	875
	3,4,7,8	Res.	Three resistors	640	875
RSDS	1,2,5,6	Adj.	Not required	360	Not supported
	1,2,5,6	Sep.	Not required	(4)	
	3,4,7,8	Res.	Three resistors	(4)	
	3,4,7,8	Res.	Single resistor	(4)	
mini-LVDS	1,2,5,6	Adj.	Not required	400	Not supported
	1,2,5,6	Sep.	Not required	(4)	
	3,4,7,8	Res.	Three resistors	(4)	
PPDS	1,2,5,6	Adj.	Not required	440	Not supported
	1,2,5,6	Sep.	Not required	(4)	
	3,4,7,8	Res.	Three resistors	(4)	
LVPECL (2)	All	N/A	N/A	Not supported	875
Differential SSTL-2 (3)	All	N/A	N/A	200	200
Differential SSTL-18 (3)	1,2,5,6	N/A	N/A	200	200
	3,4,7,8	N/A	N/A	267	267
Differential HSTL-18 (3)	All	N/A	N/A	200	200
Differential HSTL-15 (3)	All	N/A	N/A	200	200
Differential HSTL-12 (3)	All	N/A	N/A	(4)	(4)

Notes to Table 8–1:

(1) "Adj." denotes the dedicated differential output drivers with p and n pins located adjacent to each other. "Sep." denotes the dedicated differential output drivers with p and n pins not located adjacent to each other. "Res." denotes the differential output drivers that require an external resistor network. Refer to the pin tables on the Altera web site (**www.altera.com**) for details on the location of these pins.

(2) The LVPECL I/O standard is only supported on dedicated clock input pins.

(3) The differential SSTL-2, SSTL-18, HSTL-18, HSTL-15, and HSTL-12 I/O standards are only supported on clock input pins and PLL output clock pins.

(4) The performance target is pending device characterization.

Cyclone III High-Speed I/O Interface

Cyclone III devices provide a multi-protocol interface that allows communication between a variety of I/O standards, including LVDS, RSDS, mini-LVDS, PPDS, LVPECL, differential HSTL, and differential SSTL. This feature makes the Cyclone III device family ideal for applications that require multiple I/O standards, such as protocol translation.

You can use I/O pins and internal logic to implement a high-speed I/O receiver and transmitter in Cyclone III devices. Cyclone III devices do not contain dedicated serialization or deserialization circuitry. Therefore, shift registers, internal phase-locked loops (PLLs), and I/O cells are used to perform serial-to-parallel conversions on incoming data and parallel-to-serial conversion on outgoing data.

Table 8–2 shows the numbers of Cyclone III device differential channels.

Table 8–2. Cyclone III Device Differential Channels (Part 1 of 2) *(1)*, *(2)*

High-Speed I/O Standards Support

This section provides information on the high-speed I/O standards that Cyclone III devices support.

LVDS I/O Standard Support in Cyclone III Devices

The LVDS I/O standard is a high-speed, low-voltage swing, low power, and general purpose I/O interface standard. The Cyclone III device meets the ANSI/TIA/EIA-644 standard with the following exceptions:

■ The maximum voltage output differential (VOD) is increased to 600 mV. The maximum VOD for ANSI specification is 450 mV.

■ The input voltage range can be reduced to the range of 1.0 V to 1.6 V, 0.5 V to 1.85 V or 0 V to 1.8 V based on different frequency ranges. The ANSI/TIA/EIA-644 specification supports an input voltage range of 0 V to 2.4 V.

👣 See the Cyclone III Device Datasheet: *DC and Switching Characteristics of Cyclone III Devices* chapter in volume 2 of the *Cyclone III Device Handbook* for the LVDS I/O standard electrical specifications.

All the Cyclone III device I/O banks support LVDS channels. The left and right I/O banks support dedicated LVDS transmitters. On the top and bottom I/O banks, the LVDS transmitters are supported using external resistors. The LVDS standard does not require an input reference voltage; however, it does require an external 100-Ω termination resistor between the two signals at the input buffer.

LVDS Transmitter

Cyclone III LVDS dedicated transmitters, which are located on the left and right I/O banks, support a data rate up to 840 Mbps, and the transmitters located on the top and bottom I/O banks support up to 640 Mbps (using external resistors).

For LVDS data rates in Cyclone III devices with different speed grades, refer to the Cyclone III Device Datasheet: *DC and Switching Characteristics* chapter in volume 2 of the *Cyclone III Device Handbook*.

Figure 8–2 shows a simple point-to-point LVDS application using a Cyclone III dedicated transmitter in which the source of the data is an LVDS transmitter. These LVDS signals are typically transmitted over a pair of printed circuit board (PCB) traces, but a combination of a PCB trace, connectors, and cable is a common application setup.

Figure 8–2. Typical LVDS Application
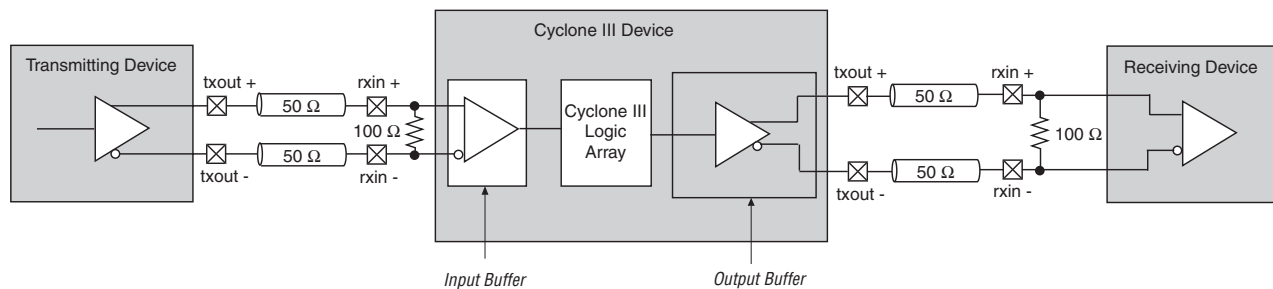

Figure 8–3 shows the LVDS I/O interface with dedicated output buffer on the left and right I/O banks. Figure 8–4 shows the LVDS I/O interface with external resistor network on the top and bottom I/O banks.

RSDS I/O Standard Support in Cyclone III Devices

The RSDS specification is used in chip-to-chip applications between the timing controller and the column drivers on the display panels. Cyclone III devices meet the National Semiconductor Corporation RSDS Interface Specification and support the RSDS output standard. All the Cyclone III device I/O banks support the RSDS output standard. The left and right I/O banks support dedicated RSDS transmitters which are able to run at up to 360 Mbps. On the top and bottom I/O banks, the RSDS transmitters are supported using external resistors. The performance target is pending device characterization. The RSDS standard does not require an input reference voltage; however, it does require a 100-Ω termination resistor between the two signals at the input buffer.

See the Cyclone III Device Datasheet: *DC and Switching Characteristics* chapter in volume 2 of the *Cyclone III Device Handbook* for the RSDS I/O standard electrical specifications.

Figure 8–7 shows the RSDS transmitter output signal waveforms.

Designing with RSDS

No external resistor network is required when using a dedicated RSDS output buffer. Figure 8–8 shows the RSDS I/O interface with a dedicated output buffer on the left and right I/O banks. For a non-dedicated output buffer on the top and bottom I/O banks, an external resistor network is required, as shown in Figure 8–9.

Figure 8–9. RSDS Interface with External Resistor Network on the Top and Bottom I/O Banks
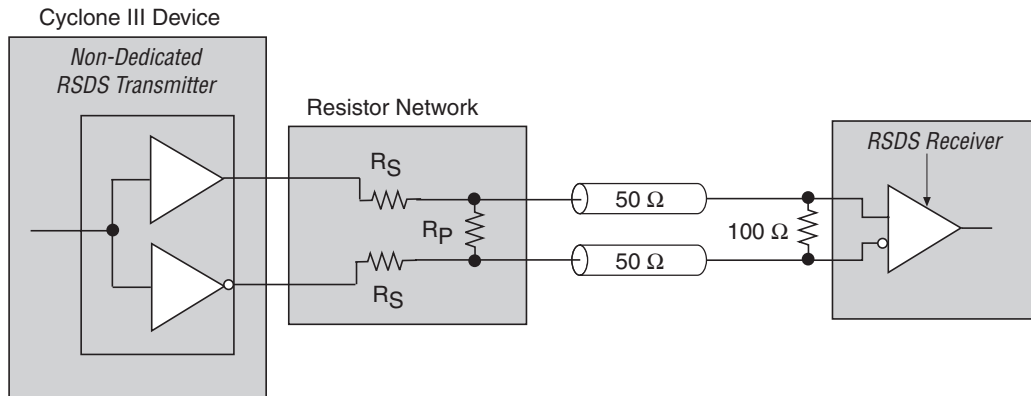

Note to Figure 8–9:
(1)   The R_S and R_P values are pending device characterization.

For more information on the RSDS I/O standard, refer to the RSDS specification from the National Semiconductor web site **(www.national.com)**.

A resistor network is required to attenuate the output voltage swing to meet RSDS specifications when using non-dedicated RSDS transmitters. You can modify the resistor network values to reduce power or improve the noise margin. The resistor values chosen should satisfy the following equation:

$$\frac{R_S \times \frac{R_P}{2}}{R_S + \frac{R_P}{2}} = 50\,\Omega$$

You should perform additional simulations using the IBIS models to validate that custom resistor values meet the RSDS requirements.

Instead of using three resistors in the resistor network, it is possible to use a single external resistor. The external single-resistor solution reduces the external resistor count while still achieving the required signaling level for RSDS. However, the performance of the single-resistor solution is lower than the performance with the resistor network. The performance target for a single-resistor solution is pending device characterization. To transmit the RSDS signal, an external resistor (Rp) is connected in parallel between the two adjacent I/O pins on the board, as shown in Figure 8–10.

Figure 8–10. RSDS Interface with Single Resistor Network on the Top and Bottom I/O Banks
Note to Figure 8–10:
(1)   The R_P value is pending device characterization.

mini-LVDS I/O Standard Support in Cyclone III Devices

The mini-LVDS specification defines its use in chip-to-chip applications between the timing controller and the column drivers on display panels. Cyclone III devices meet the Texas Instruments mini-LVDS Interface Specification and support the mini-LVDS output standard. All of the Cyclone III device I/O banks support the mini-LVDS output standard. The left and right I/O banks support dedicated mini-LVDS transmitters which are able to run at up to 400 Mbps. On the top and bottom I/O banks, the mini-LVDS transmitters are supported using external resistors. The performance target is pending device characterization. The mini-LVDS standard does not require an input reference voltage; however, it does require a 100-Ω termination resistor between the two signals at the input buffer.

See the Cyclone III Device Datasheet: *DC and Switching Characteristics of Cyclone III Devices* chapter in volume 2 of the *Cyclone III Device Handbook* for the mini-LVDS I/O standard electrical specifications.

Figure 8–11 shows the mini-LVDS transmitter output signal waveforms.

Figure 8–11. Transmitter Output Signal Level Waveforms for mini-LVDS
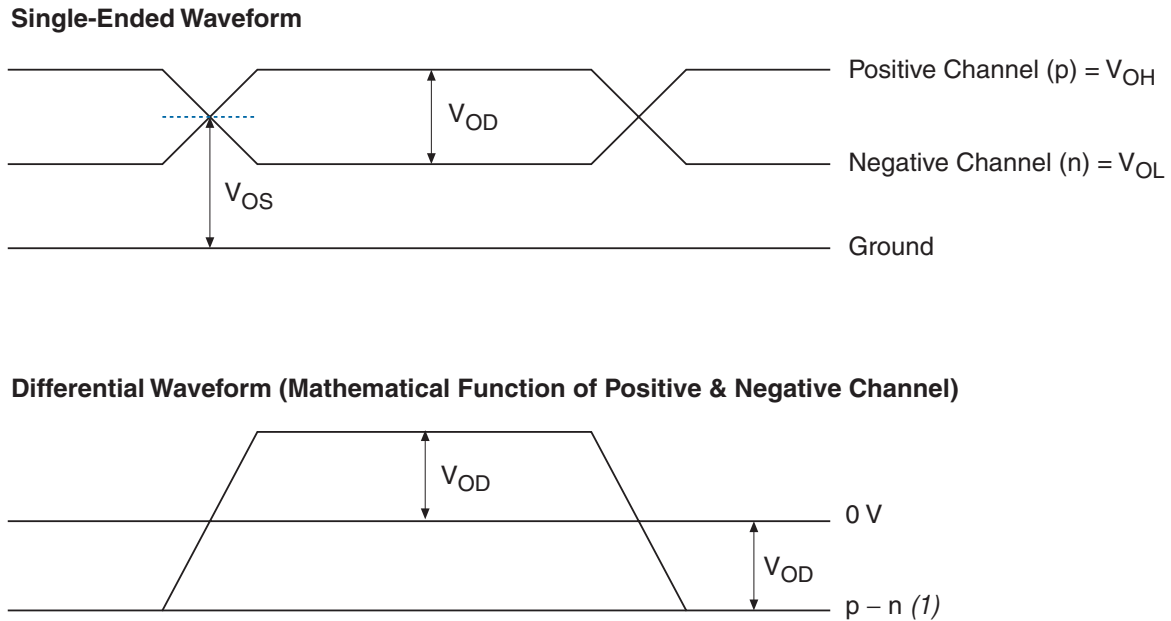

Note to Figure 8–11:
(1)   The p – n waveform is a function of the positive channel (p) and the negative channel (n).

Designing with mini-LVDS

Similar to RSDS, there is no external resistor network required when you use a dedicated mini-LVDS output buffer on the left and right I/O banks. Figure 8–12 shows the mini-LVDS I/O interface with a dedicated output buffer. For a non-dedicated output buffer on the top and bottom I/O banks, an external resistor network is required, as shown in Figure 8–13. The resistor values chosen should satisfy the equation shown in "Designing with RSDS" on page 8–10.

Figure 8–12. mini-LVDS Interface with Dedicated Output Buffer on the Left and Right I/O Banks
Figure 8–13. mini-LVDS Interface with External Resistor Network on the Top and Bottom I/O Banks
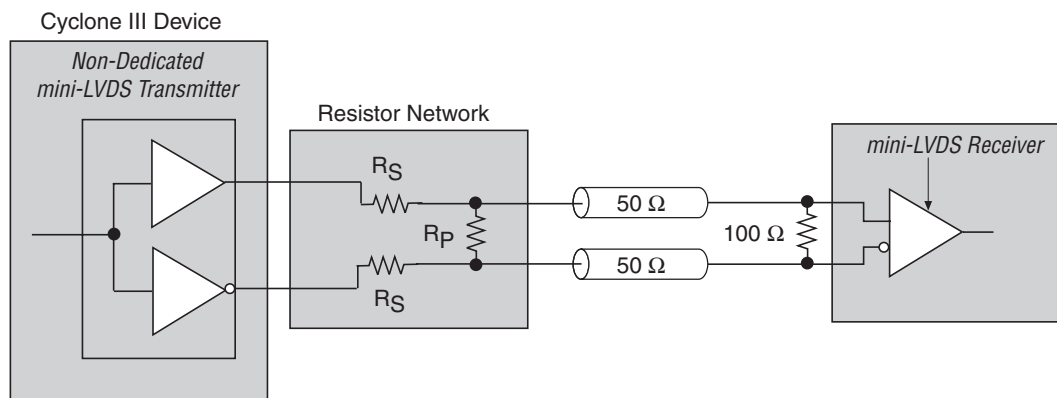

Note to Figure 8–13:
(1) The R_S and R_P values are pending device characterization.

PPDS I/O Standard Support in Cyclone III Devices

The PPDS specification is used in chip-to-chip applications between the timing controller and the column drivers on display panels such as LCD monitor panels and LCD televisions. Cyclone III devices meet the National Semiconductor Corporation PPDS Interface Specification and support the PPDS output standard. All the Cyclone III device I/O banks support the PPDS output standard. The left and right I/O banks support dedicated PPDS transmitters which run at up to 440 Mbps. On the top and bottom I/O banks, the PPDS transmitters are supported using external resistors. The performance target is pending device characterization. The PPDS standard does not require an input reference voltage; however, it does require a 100-Ω termination resistor between the two signals at the input buffer.

See the Cyclone III Device Datasheet: *DC and Switching Characteristics* chapter in volume 2 of the *Cyclone III Device Handbook* for the PPDS I/O standard electrical specification.

Figure 8–14 shows the PPDS transmitter output signal waveforms.

0 V

V_{OD}

p – n *(1)*
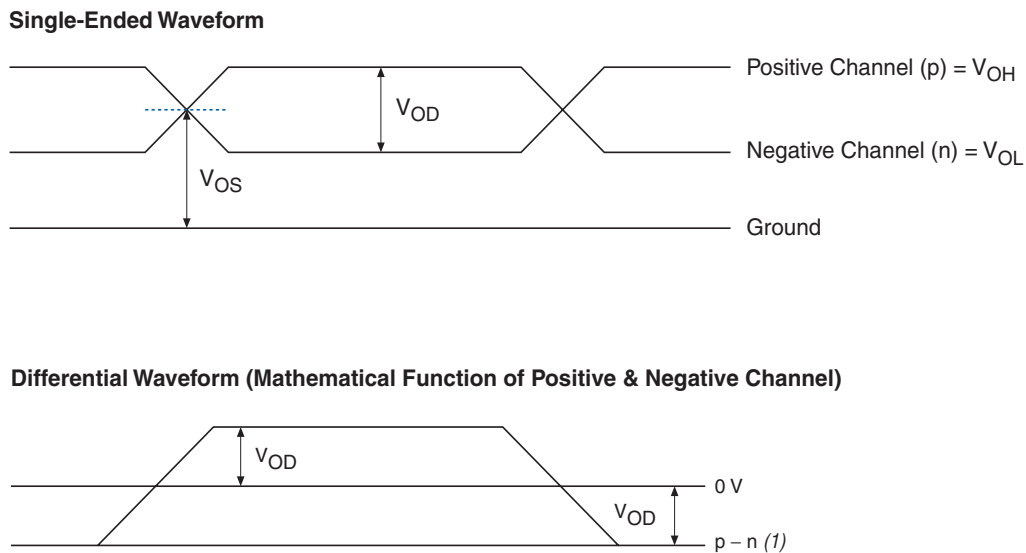

Note to Figure 8–14:
(1)   The p – n waveform is a function of the positive channel (p) and the negative channel (n).

Designing with PPDS

Similar to RSDS and mini-LVDS, no external resistor network is required when you use a dedicated PPDS output buffer. Figure 8–15 shows the PPDS I/O interface with a dedicated output buffer. For a non-dedicated output buffer, an external resistor network is required, as shown in Figure 8–16. The resistor values chosen should satisfy the equation shown in "Designing with RSDS" on page 8–10.

Figure 8–15. PPDS Interface with Dedicated Output Buffer on the Left and Right I/O Banks
Figure 8–16. PPDS Interface with External Resistor Network on the Top and Bottom I/O Banks
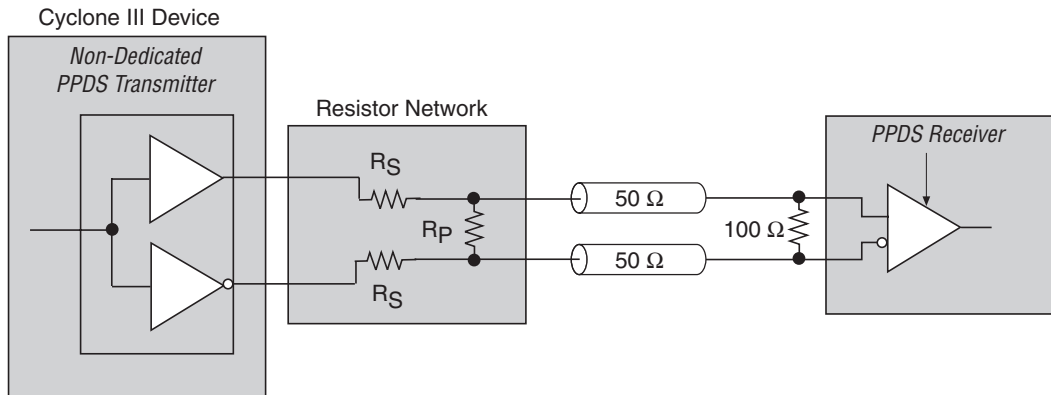

Note to Figure 8–16:

(1) The R_S and R_P values are pending device characterization.

LVPECL I/O Support in Cyclone III Devices

The LVPECL I/O standard is a differential interface standard that requires a 2.5-V V_{CCIO}. This standard is used in applications involving video graphics, telecommunications, data communications, and clock distribution. The high-speed, low-voltage swing LVPECL I/O standard uses a positive power supply. Cyclone III devices support the LVPECL input standard at the dedicated clock input pins only. The LVPECL standard does not require an input reference voltage; however, it does require an external 100-Ω termination resistor between the two signals at the input buffer.

☛ See the Cyclone III Device Datasheet: *DC and Switching Characteristics* chapter in Volume 2 of the *Cyclone III Device Handbook* for the LVPECL I/O standard electrical specification.

Figure 8–17. LVPECL I/O Interface
Differential SSTL I/O Standard Support in Cyclone III Devices

The differential SSTL I/O standard is a memory-bus standard used for applications such as high-speed double-data rate (DDR) SDRAM interfaces. The differential SSTL I/O standard AC and DC specifications are similar to SSTL single-ended specifications. The standard requires two differential inputs with an external reference voltage (V_{REF}) as well as an external termination voltage (V_{TT}) of 0.5 x V_{CCIO} to which termination resistors are connected. Cyclone III devices support differential SSTL-2 and SSTL-18 I/O standards. A 2.5-V output source voltage is required for differential SSTL-2, and a 1.8-V output source voltage is required for differential SSTL-18. The differential SSTL output standard is only supported at PLL#_CLKOUT pins using two single-ended SSTL output buffers (PLL#_CLKOUTp and PLL#_CLKOUTn) programmed to have opposite polarity.

☞   The differential SSTL input standard is supported at the global clock (GCLK) pins only, where it treats differential inputs as two single-ended SSTL and only decodes one of them.

👣   For SSTL signaling characteristics, see the *Cyclone III Device I/O Features* chapter and the Cyclone III Device Datasheet: *DC and Switching Characteristics of Cyclone III Devices* chapter in volumes 1 and 2, respectively, of the *Cyclone III Device Handbook*.

Figures 8–18 and 8–19 show the differential SSTL class I and II interfaces, respectively.

Figure 8–18. Differential SSTL Class I Interface
Figure 8–19. Differential SSTL Class II Interface
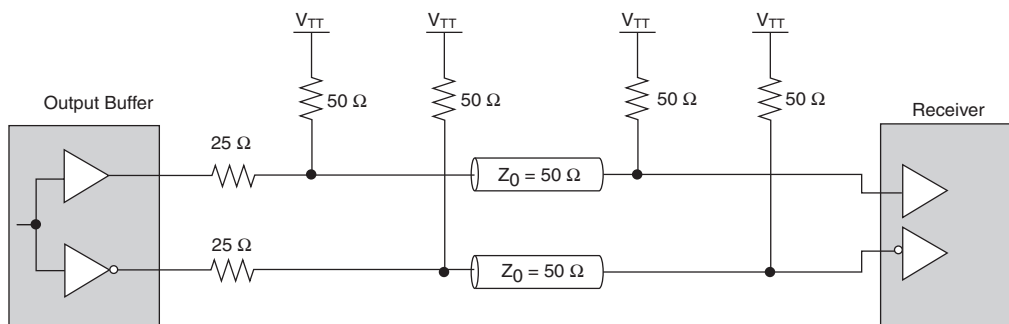

Differential HSTL I/O Standard Support in Cyclone III Devices

The differential HSTL I/O standard is used for the applications designed to operate in the 0 V to 1.2 V, 0 V to 1.5 V, or 0 V to 1.8 V HSTL logic switching range. Cyclone III devices support differential HSTL-18, HSTL-15, and HSTL-12 I/O standards. The differential HSTL AC and DC specifications are the same as the HSTL single-ended specifications. The differential HSTL input standard is available on the GCLK pins only, treating differential inputs as two single-ended HSTL and only decoding one of them. The differential HSTL output standard is only supported at the PLL#_CLKOUT pins using two single-ended HSTL output buffers (PLL#_CLKOUTp and PLL#_CLKOUTn), with the second output programmed as inverted. The standard requires two differential inputs with an external reference voltage (V_{REF}), as well as an external termination voltage (V_{TT}) of 0.5 x V_{CCIO} to which termination resistors are connected.

For HSTL signaling characteristics, refer to the *Cyclone III Device I/O Features* chapter and the Cyclone III Device Datasheet: *DC and Switching Characteristics* chapter in volumes 1 and 2, respectively, of the *Cyclone III Device Handbook*.

Figures 8–20 and 8–21 show differential HSTL class I and II interfaces, respectively.

Figure 8–20. Differential HSTL Class I Interface
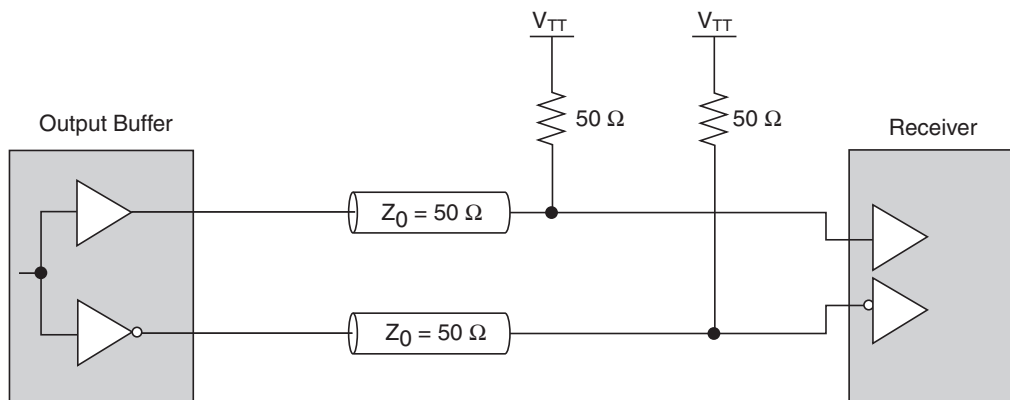

Figure 8–21. Differential HSTL Class II Interface
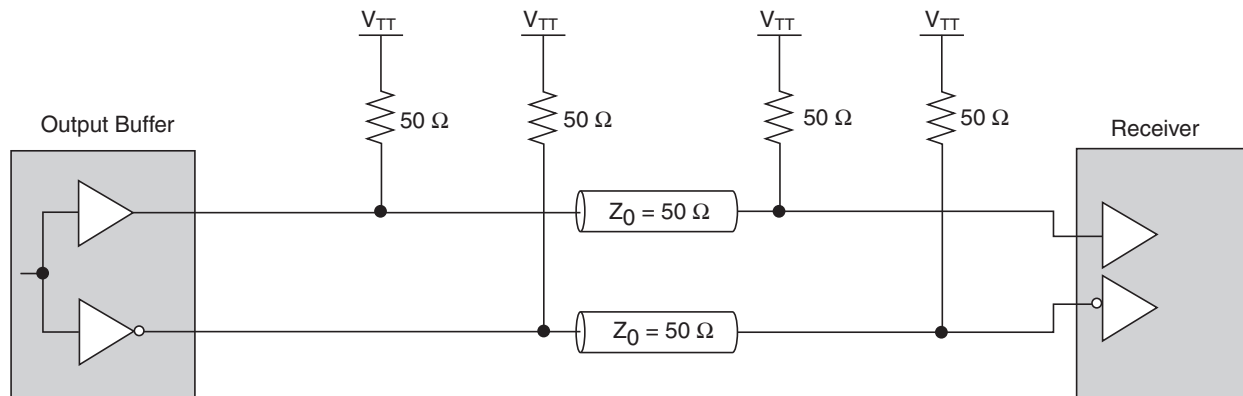

Feature of the Dedicated Output Buffer

Cyclone III dedicated differential transmitters offer programmable pre-emphasis to further improve the signal integrity in high frequency applications.

Programmable Pre-Emphasis

The programmable pre-emphasis boosts the high frequencies of the output signal, which may be attenuated in the transmission media. It is used to compensate the frequency-dependant attenuation of the transmission line to maximize the data eye opening at the far-end receiver. Without pre-emphasis, the output current is limited by the V_{OD} specification and the output impedance of the transmitter. At high frequency, the slew rate may not be fast enough to reach full V_{OD} before the next edge; this may lead to pattern dependent jitter. With pre-emphasis, the output current is boosted momentarily during switching to increase the output slew rate. The overshoot produced by this extra switching current is different from the overshoot caused by signal reflection. This overshoot happens only during switching and does not produce ringing. Figure 8–22 shows the differential output signal with pre-emphasis.

The pre-emphasis setting in Cyclone III devices is programmable — you can choose to turn it ON or OFF. You may need to enable the pre-emphasis if there is high attenuation in the transmission line.

Figure 8–22. The Output Signal with Pre-Emphasis
This section discusses the timing budget, waveforms, and specifications for source-synchronous signaling in Cyclone III devices. LVDS, RSDS, mini-LVDS, PPDS, and LVEPCL I/O standards enable high-speed data transmission. Timing for these high-speed signals is based on skew between the data and clock signals.

High-Speed I/O Timing in Cyclone III Devices

High-speed differential data transmission requires timing parameters provided by integrated circuit (IC) vendors and requires consideration of board skew, cable skew, and clock jitter. This section provides details on high-speed I/O standards timing parameters in Cyclone III devices.

Table 8–3 defines the parameters of the timing diagram shown in Figure 8–23. Figure 8–24 shows the Cyclone III high-speed I/O timing budget.

Table 8–3. High-Speed I/O Timing Definitions

Parameter	Symbol	Description
Transmitter channel-to-channel skew *(1)*	TCCS	The timing difference between the fastest and slowest output edges, including t_{CO} variation and clock skew. The clock is included in the TCCS measurement.
Sampling window	SW	The period of time during which the data must be valid in order for you to capture it correctly. The setup and hold times determine the ideal strobe position within the sampling window. $T_{SW}=T_{SU}+T_{hd}+PLL$ jitter.
Receiver input skew margin	RSKM	RSKM is defined by the total margin left after accounting for the sampling window and TCCS. The RSKM equation is: RSKM = (TUI – SW – TCCS) / 2.
Input jitter tolerance (peak-to-peak)		Allowed input jitter on the input clock to the PLL that is tolerable while maintaining PLL lock.
Output jitter (peak-to-peak)		Peak-to-peak output jitter from the PLL.

Note to Table 8–3:

(1) The TCCS specification applies to the entire bank of differential I/O as long as the SERDES logic is placed within the LAB adjacent to the output pins.

Figure 8–23. High-Speed I/O Timing Diagram
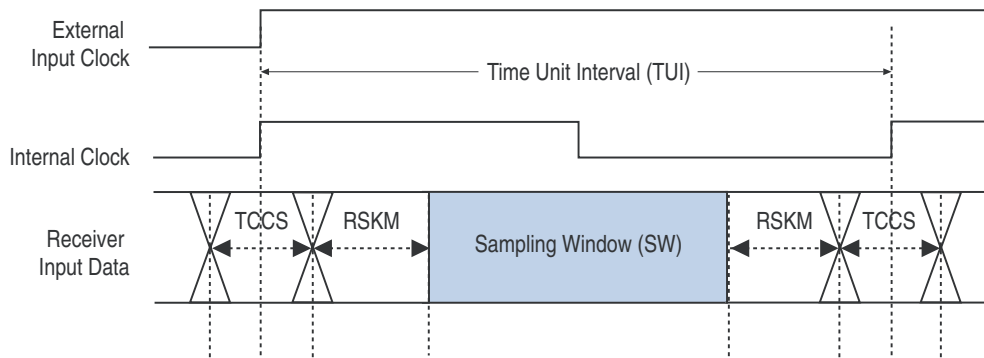

Figure 8–24. Cyclone III High-Speed I/O Timing Budget (1)
Note to Figure 8–24:
(1)   The equation for the high-speed I/O timing budget is: Period=0.5 x TCCS+RSKM+SW+RSKM+0.5 x TCCS.

See the Cyclone III Device Datasheet: *DC and Switching Characteristics* chapter in volume 2 of the *Cyclone III Device Handbook* for more details.

Design Guidelines

This section provides guidelines for designing with Cyclone III devices.

Differential Pad Placement Guidelines

To maintain an acceptable noise level on the V_{CCIO} supply, you must observe some restrictions on placement of single-ended I/O pins in relation to differential pads.

Refer to the guidelines in the *Cyclone III Device I/O Features* chapter in volume 1 of the *Cyclone III Device Handbook* for placing single-ended pads with respect to differential pads in Cyclone III devices.

Board Design Considerations

This section explains how to get the optimal performance from the Cyclone III I/O interface and ensure first-time success in implementing a functional design with optimal signal quality. You must consider the critical issues of controlled impedance of traces and connectors, differential routing, and termination techniques to get the best performance from the IC. Cyclone III devices generate signals that travel over the media at frequencies as high as 840 Mbps.

Use the following general guidelines for improved signal quality:

■ Base board designs on controlled differential impedance. Calculate and compare all parameters, such as trace width, trace thickness, and the distance between two differential traces.

■ Maintain equal distance between traces in differential I/O standard pairs as much as possible. Routing the pair of traces close to each other maximizes the common-mode rejection ratio (CMRR).

■ Longer traces have more inductance and capacitance. These traces should be as short as possible to limit signal integrity issues.

■ Place termination resistors as close to receiver input pins as possible.

■ Use surface mount components.

■ Avoid 90° corners.

■ Use high-performance connectors.

■ Design backplane and card traces so that trace impedance matches the impedance of the connector and/or termination.

■ Keep an equal number of vias for both signal traces.

■ Create equal trace lengths to avoid skew between signals. Unequal trace lengths result in misplaced crossing points and decrease system margins as the channel-to-channel skew (TCCS) value increases.

■ Limit vias because they cause discontinuities.

■ Use common bypass-capacitor values such as 0.001, 0.01, and 0.1 μF to decouple the high-speed PLL power and ground planes.

■ Keep switching transistor-to-transistor logic (TTL) signals away from differential signals to avoid possible noise coupling.

■ Do not route TTL clock signals to areas under or above the differential signals.

■ Analyze system-level signals.

For PCB layout guidelines, refer to *AN 224: High-Speed Board Layout Guidelines* and *AN 315: Guidelines for Designing High-Speed FPGA PCBs.*

Software Overview

Cyclone III device high-speed I/O system interfaces are created in core logic by a Quartus II software megafunction, because they do not have a dedicated circuit for the serializer and deserializer (SERDES). Cyclone III devices use the I/O registers and logic element (LE) registers to improve the timing performance and support the SERDES. Altera Quartus II software allows you to design your high-speed interfaces using its *altlvds* megafunction. This megafunction implements either a high-speed deserializer receiver or a high-speed serializer transmitter. There is a list of parameters in the megafunction you can set to customize your SERDES based on your design requirements. The megafunction is optimized to use the Cyclone III resources to create the high-speed I/O interfaces in the most effective manner.

Refer to the *altlvds Megafunction User Guide* for more details in designing your high-speed I/O systems interfaces using the Quartus II software.

Conclusion

Cyclone III dedicated differential buffers allow you to transmit data at high speeds. Their use reduces cost and complexity, and lowers board space requirements by eliminating the need for external resistors in many backplane and video display applications.

Document Revision History

Table 8–4 shows the revision history for this document.

Table 8–4. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2007 v1.0	Initial Release	

CIII51009-1.0

Introduction

In addition to an abundant supply of on-chip memory, Cyclone® III devices can easily interface to a broad range of external memory including DDR2 SDRAM, DDR SDRAM, and QDRII SRAM. External memory devices are an important system component of a wide range of image processing, storage, communications, and general embedded applications.

Cyclone III devices are supported with a comprehensive infrastructure to create robust external memory interfaces. Table 9–1 highlights the major benefits of Cyclone III external memory interfaces.

Table 9–1. Major Benefits of Cyclone III Memory Interfaces	
Benefit	**Cyclone III Solution Description**
Robust	Self-calibrating to adjust for process, voltage, and temperature changes
Easy to use	● Push button timing closure ● DDR2/DDR available on all sides to ease PCB layout constraints ● Half rate solution available to lower f_{MAX} requirements
Resource Efficient	Maximum of 5 global clocks for ×72 interface
Good Performance	● 200 MHz DDR2 SDRAM on fastest speed grade

The Cyclone III external memory interface infrastructure includes the components listed in Table 9–2.

Table 9–2. Cyclone III External Memory Interface Infrastructure	
Memory Interface Feature	**Description**
Auto-calibrating ALTMEMPHY megafunction	Manages the physical (PHY) interfaces between the FPGA device and the external memory devices. Comes as a megafunction and is available in the Quartus® II software version 7.0 and later.
Altera®, third party, or user-designed memory controller	Controls the PHY interface and the interface between the PHY and the user's application. The Altera controllers are included with Altera software subscriptions as part of the IP-BASE Suite.
Silicon enhancements	The phase-locked loop (PLL) reconfiguration feature adjusts the clock phase shifts in the system to calibrate changes in voltage and temperature. Two additional registers were added to Cyclone III input/output elements (IOEs) to enhance double-data rate I/O (DDIO) timing.
Quartus II TimeQuest timing analyzer	Uses industry standard synopsys design constraint (SDC) language to easily support source-synchronous timing analysis.

Altera recommends that you construct all DDR2/DDR SDRAM and QDRII SRAM external memory interfaces using the Altera ALTMEMPHY megafunction. You can implement the controller function using the Altera DDR2/DDR SDRAM or QDRII SRAM memory controllers, third party controllers, or a custom controller for unique application needs. Figure 9–1 shows an overview of a Cyclone III external memory interface.

Figure 9–1. Cyclone III External Memory Interface Overview
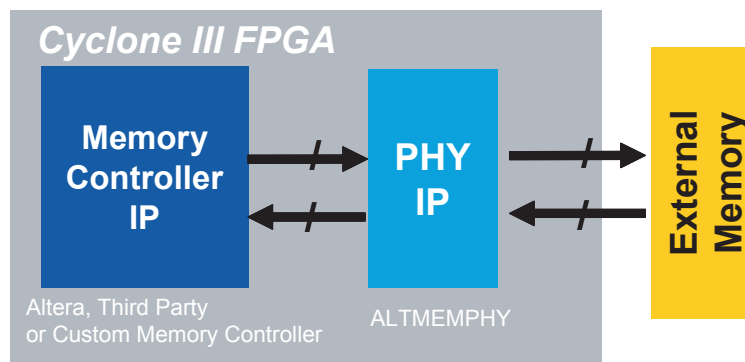

This chapter includes a description of the hardware interfaces for external memory interfaces available in the Cyclone III devices. For more information on implementing complete external memory interfaces, refer to the following documents found at the Altera web site at **www.altera.com**:

- *ALTMEMPHY Megafunction User Guide*
- *DDR and DDR2 SDRAM Controller Compiler User Guide*
- *AN 445: Interfacing DDR and DDR2 SDRAM with Cyclone III Devices*
- *AN 438: Constraining and Analyzing Timing for External Memory Interfaces*

Cyclone III Memory Support Overview

This section describes the interface between Cyclone III devices and external memory standards. Table 9–3 summarizes the maximum clock rate that Cyclone III devices can support with external memory interfaces.

Table 9–3. Cyclone III Maximum Clock Rate Support for External Memory Interfaces *Note (1)* **(Part 1 of 2)**

Memory Standard	I/O Standard	Commercial					
		-6 Speed Grade (MHz)		-7 Speed Grade (MHz)		-8 Speed Grade (MHz)	
		Top/Bottom I/O Banks	Left/Right I/O Banks	Top/Bottom I/O Banks	Left/Right I/O Banks	Top/Bottom I/O Banks	Left/Right I/O Banks
DDR2 SDRAM *(2)*	SSTL-18 class I	200	167	167	150	167	133
	SSTL-18 class II	133	125	125	*(3)*	*(3)*	*(3)*

Table 9–3. Cyclone III Maximum Clock Rate Support for External Memory Interfaces *Note (1)* *(Part 2 of 2)*							
Memory Standard	**I/O Standard**	**Commercial**					
		-6 Speed Grade (MHz)		**-7 Speed Grade (MHz)**		**-8 Speed Grade (MHz)**	
		Top/Bottom I/O Banks	**Left/Right I/O Banks**	**Top/Bottom I/O Banks**	**Left/Right I/O Banks**	**Top/Bottom I/O Banks**	**Left/Right I/O Banks**

	SSTL-2 class II	133	125	125	100	100	*(3)*
QDRII SRAM *(4)*	1.8-V HSTL class I	167	150	150	133	133	125
	1.8V HSTL class II	100	*(3)*	*(3)*	*(3)*	*(3)*	*(3)*

Notes to Table 9–3:
(1)   These numbers are preliminary until characterization is final.
(2)   The values apply for interfaces with both modules and components.
(3)   Support will be evaluated after characterization.
(4)   QDRII SRAM also supports the 1.5-V HSTL I/O standard. However, Altera recommends using the 1.8-V HSTL I/O standard for maximum performance because of the higher I/O drive strength.

Figure 9–2 shows the block diagram of a typical external memory interface data path in Cyclone III devices.

Figure 9–2. Cyclone III External Memory Data Path Note (1)
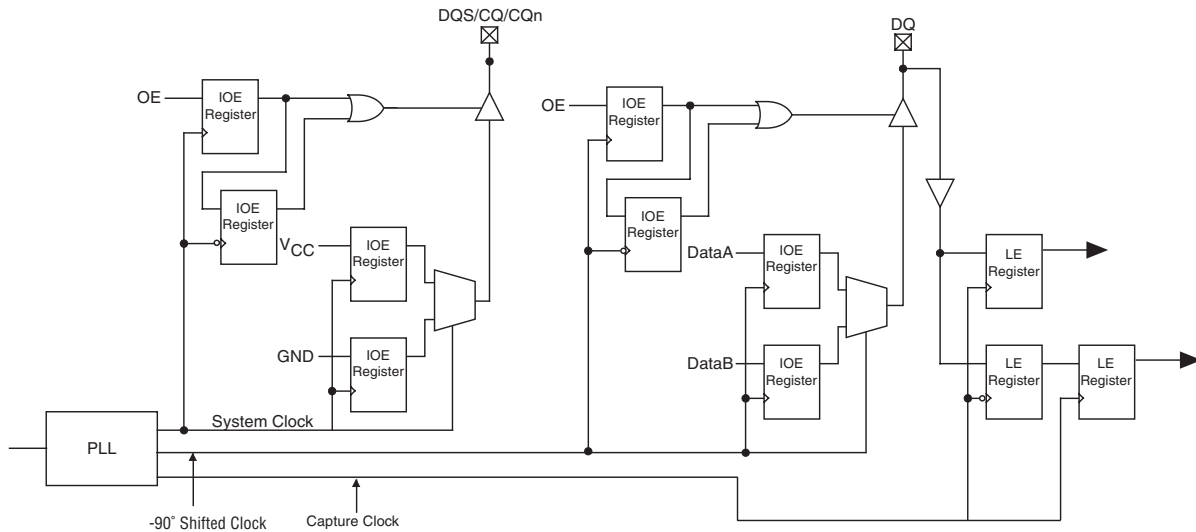

Note to Figure 9–2:
(1)   All clocks shown here are global clocks.

Cyclone III Memory Interfaces Pin Support

Cyclone III devices use data (DQ), data strobe (DQS), clock, command, and address pins to interface with external memory. Some memory interfaces use the data mask (DM) or byte write select (BWS#) pins to enable data masking. This section describes how Cyclone III supports all these different pins. Figure 9–3 illustrates the DQ and DQS pins.

Figure 9–3. Cyclone III DQ and DQS pins Note (1), (2), (3)

| DQ Pins | DQS Pin | DQ Pins | DM Pin |
Notes to Figure 9–3:

(1)   Each DQ group consists of a DQS pin, a DM pin and DQ pins.

(2)   DQ groups on the left and right sides of EP3C16, EP3C25, and EP3C40 (of the 240-pin PQFP package) do not support DM pin.

(3)   DQ groups on the bottom sides of EP3C10, EP3C16, and EP3C25 (of the 144-pin EQFP package) do not support DM pin.

Data and Data Clock/Strobe Pins

Cyclone III data pins for external memory interfaces are called D for write data, Q for read data, or DQ for shared read and write data pins. The read-data strobes or read clocks are called DQS pins. Cyclone III devices support both bidirectional data strobes and unidirectional read clocks. Depending on the external memory standard, the DQ and DQS are bidirectional signals (in DDR2 and DDR SDRAM) or unidirectional signals (in QDRII SRAM). Connect the bidirectional DQ data signals to the same Cyclone III DQ pins. For unidirectional D or Q signals, connect the read-data signals to a group of DQ pins and the write-data signals to a different group of DQ pins.

In Cyclone III devices, DQS is used only during write mode in DDR2 and DDR SDRAM interfaces. Cyclone III devices ignore DQS as the read-data strobe because the physical layer (PHY) internally generates the read capture clock for read mode. However, you must connect the DQS pin to the DQS signal in DDR2 and DDR SDRAM interfaces, or to the CQ signal in QDRII SRAM interfaces.

☞   Cyclone III does not support differential strobe pins, which is an optional feature in DDR2 SDRAM devices.

When you use the Altera Memory Controller MegaCores, the PHY is instantiated for you. For more information on the memory interface data path, refer to the ALTMEMPHY *Megafunction User Guide*.

☞ ALTMEMPHY is a self-calibrating megafunction, enhanced to simplify the implementation of the read-data path in different memory interfaces. The auto-calibration feature of ALTMEMPHY provides ease-of-use by optimizing clock phases and frequencies across process, voltage, and temperature (PVT) variations. You can save on the global clock resources in Cyclone III devices through the ALTMEMPHY megafunction because you do not need to route the DQS signals on the global clock buses (because DQS is ignored for read capture). Resynchronization issues do not arise because no transfer occurs from the memory domain clock (DQS) to the system domain for capturing data DQ.

All the I/O banks in Cyclone III devices support DQ and DQS signals with DQ-bus modes of ×8, ×9, ×16, ×18, ×32, and ×36. In ×8, ×16, and ×32 modes, one DQS pin drives up to 8, 16, or 32 DQ pins, respectively, within the group, to support DDR2 and DDR SDRAM interfaces.

In the ×9, ×18, and ×36 modes, a pair of DQS pins (CQ and CQ#) drives up to 9, 18, or 36 DQ pins, respectively, within the group, to support one, two, or four parity bits and the corresponding data bits. The ×9, ×18, and ×36 modes support the QDRII memory interface. CQ# is the inverted read-clock signal which is connected to the complementary data strobe (DQS#) pin. You can use any unused DQ pins as regular user I/O pins if they are not used as memory interface signals. Table 9–4 shows the number of DQS/DQ groups supported on each side of the Cyclone III device.

Notes to Table 9–4:
(1) These numbers are preliminary until characterization is final.
(2) This device package does not support ×32/×36 mode.
(3) For the top side of the device, the R_{UP}, R_{DN}, PLLCLKOUT3n and PLLCLKOUT3p are shared with the DQ/DM pins to gain ×8 DQ group. You cannot use these groups if you are using the R_{UP} and R_{DN} pins for on-chip termination (OCT) calibration or if you are using PLLCLKOUT3n and PLLCLKOUT3p.
(4) There is no DM pin support for these groups.
(5) The R_{UP} and R_{DN} are shared with the DQ pins. You cannot use these groups if you are using the R_{UP} and R_{DN} pins for OCT calibration.
(6) The ×8 DQ group can be formed in Bank 2.
(7) The ×8 DQ group can be formed in Bank 5.
(8) There is no DM and BWS# pins support for these groups.
(9) The R_{UP} is shared with the DQ pin to gain ×9 or ×18 DQ group. You cannot use these groups if you are using the R_{UP} and R_{DN} pins for OCT calibration.

The DQS pins are listed in the Cyclone III pin tables as DQSXY, where X indicates the DQS grouping number and Y indicates which side of the I/O bank the DQS pins belong. The Y can be T for pins on the top, B for pins on the bottom, L for pins on the left, or R for pins on the right side of the device. Similarly, the corresponding DQ pins are marked as DQXY, where the X denotes which DQ group the pins belong to and Y denotes the I/O bank location of the DQ pins. The Y can be T for pins on the top, B for pins on the bottom, L for pins on the left, or R for pins on the right side of the device. For example, DQS2T indicates a DQS pin belonging to group 2, located on the top side of the device. Similarly, the DQ pins belonging to that group is shown as DQ2T.

DQ pin numbering is based on ×8/×9 mode. There are up to 20 DQS/DQ groups in ×8 mode or up to 8 DQS/DQ groups in ×9 mode in the I/O banks, that can be utilized for the external memory interface. Figure 9–4 and Figure 9–5 show the location and numbering of the DQS/DQ/CQ# pins in the Cyclone III I/O banks.

Figure 9–4. DQS/CQ/CQ# Pins in Cyclone III I/O Banks Note (1)
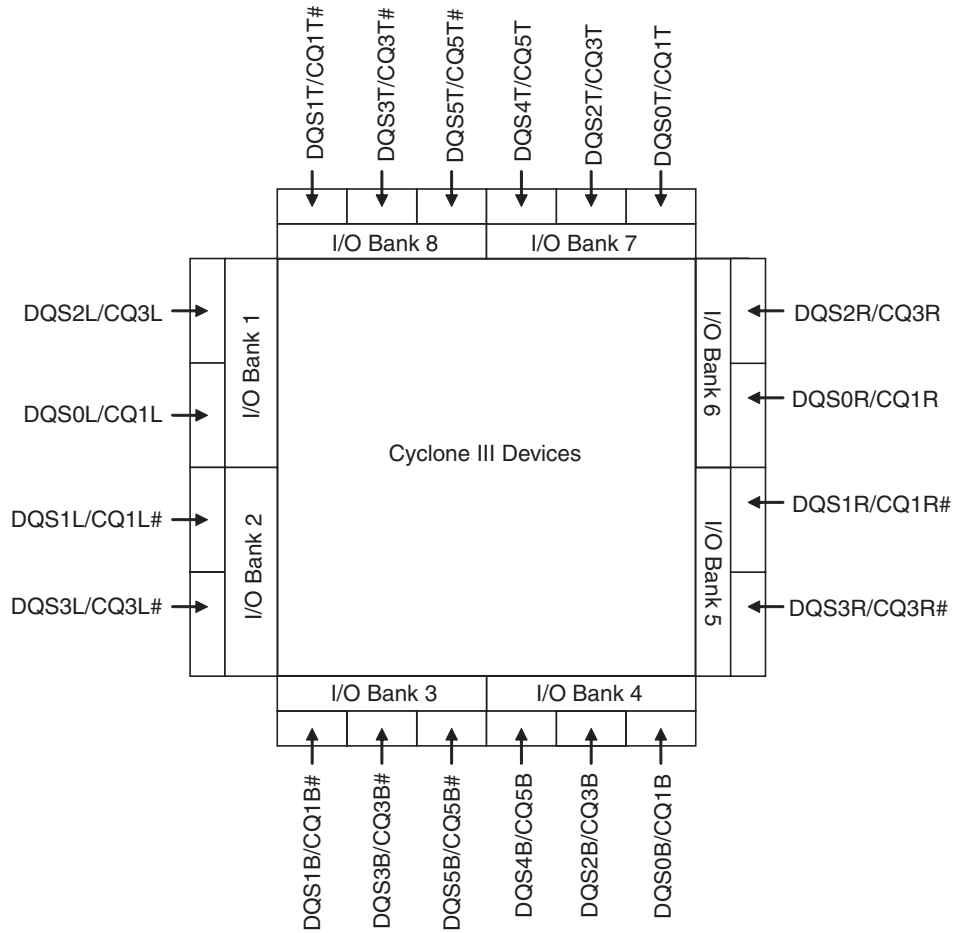

Note to Figure 9–4:
(1)   The DQS/CQ/CQ# pin locations in this diagram applies to all packages in the Cyclone III family except EP3C5, EP3C10, EP3C16 and EP3C25 devices in 144-pin EQFP package.

Figure 9–5. DQS/CQ/CQ# Pins in EP3C5, EP3C10, EP3C16, and EP3C25 Devices in the 144-Pin EQFP Package
In Cyclone III devices, the ×9 mode uses the same `DQ` and `DQS` pins as the ×8 mode, and one additional `DQ` pin that serves as a regular I/O pin in ×8 mode. The ×18 mode uses the same `DQ` and `DQS` pins as ×16 mode, with two additional `DQ` pins that serve as regular I/O pins in ×16 mode. Similarly, the ×36 mode uses the same `DQ` and `DQS` pins as ×32 mode, with four additional `DQ` pins that serve as regular I/O pins in ×32 mode. When not used as `DQ` or `DQS` pins, the memory interface pins are available as regular I/O pins.

Optional Parity, DM, and ECC Pins

Cyclone III devices support parity in the ×9, ×18, and ×36 modes. One parity bit is available per eight bits of data pins. You can use any of the `DQ` pins for parity in the Cyclone III devices because the parity pins are treated and configured like `DQ` pins.

The data mask (DM) pins are only required when writing to DDR2 and DDR SDRAM devices. QDRII SRAM devices use the BWS# signal to select the byte to be written into memory. A low signal on the DM or BWS# pin indicates the write is valid. Driving the DM or BWS# pin high causes the memory to mask the DQ signals. Each group of DQS and DQ signals has one DM pin. Similar to the DQ output signals, the DM signals are clocked by the –90° shifted clock.

In Cyclone III devices, the DM pins are preassigned in the device pinouts. The Quartus II fitter treats the DQ and DM pins in a DQS group equally for placement purposes. The preassigned DQ and DM pins are the preferred pins to use.

Some DDR2 SDRAM and DDR SDRAM devices support error correction coding (ECC), a method of detecting and automatically correcting errors in data transmission. In 72-bit DDR2 or DDR SDRAM, there are eight ECC pins and 64 data pins. Connect the DDR2 and DDR SDRAM ECC pins to a DQS/DQ group in Cyclone III devices. The memory controller needs additional logic to encode and decode the ECC data.

Address and Control/Command Pins

The address signals and the control or command signals are typically sent at a single data rate. You can use any of the user I/O pins on all I/O banks of Cyclone III devices to generate the address and control or command signals to the memory device.

☞ Cyclone III devices do not support QDRII SRAM in the burst length of two.

Memory Clock Pins

In DDR2 and DDR SDRAM memory interfaces, the memory clock signals (CK and CK#) are used to capture the address signals and the control or command signals. Similarly, QDRII SRAM devices use the write clocks (K and K#) to capture the address and command signals. The CK/CK# and K/K# signals are generated to mimic the write-data strobe using the DDIO registers in Cyclone III devices. You can use any regular adjacent I/O pins to generate the CK/CK# for DDR2 and DDR SDRAM interface or K/K# for QDRII SRAM.

Cyclone III Memory Interfaces Features

Cyclone III memory interfaces, including DDR input registers, DDR output registers, on-chip termination, and PLLs, are discussed below.

DDR Input Registers

The DDR input registers are implemented with three internal logic element (LE) registers for every DQ pin. These LE registers are located in the logic array block (LAB) adjacent to the DDR input pin. Figure 9–6 illustrates the Cyclone III DDR input registers.

Figure 9–6. Cyclone III DDR Input Registers
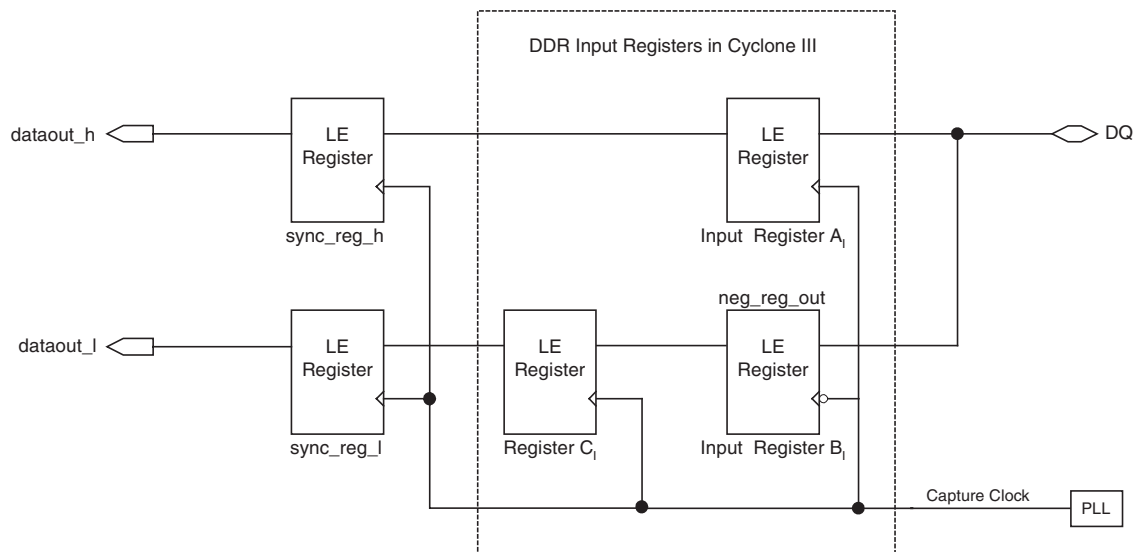

The DDR data is first fed to two registers, input register A_I and input register B_I.

- Input register A_I captures the DDR data present during the rising edge of the clock
- Input register B_I captures the DDR data present during the falling edge of the clock
- Register C_I aligns the data before it is synchronized with the system clock

The sync_reg_h and sync_reg_l registers accept the data from the DDR input registers, then transfer the data to a FIFO to synchronize the two data streams to the rising edge of the system clock. Since the read-capture clock is generated by the PLL, the read-data strobe signal (DQS or CQ) is not used during read in Cyclone III devices. Hence, postamble is not a concern in this case.

DDR Output Registers

A dedicated write DDIO block is implemented in the DDR output and output enable paths. Figure 9–7 shows how the Cyclone III dedicated write DDIO block is implemented in the IOE registers.

Figure 9–7. Cyclone III Dedicated Write DDIO
The two DDR output registers are located in the I/O element (IOE) block. Two serial data streams routed through `datain_l` and `datain_h`, are fed into two registers, `output register A`$_o$ and `output register B`$_o$, respectively, on the same clock edge. The output from `output register A`$_o$ is captured on the falling edge of the clock, while the output from `output register B`$_o$ is captured on the rising edge of the clock. The registered outputs are multiplexed by the common clock to drive the DDR output pin at twice the data rate.

The DDR output enable path has a similar structure to the DDR output path in the IOE block. The second output enable register provides the write preamble for the `DQS` strobe in DDR external memory interfaces. This active-low output enable register extends the high-impedance state of the pin by half a clock cycle to provide the external memory's `DQS` write preamble time specification. Figure 9–8 illustrates how the second output enable register extends the `DQS` high-impedance state by half a clock cycle during a write operation.

For more information on the Cyclone III IOE registers, refer to the *Cyclone III Device I/O Features* chapter in volume 1 of the *Cyclone III Device Handbook*.

Figure 9–8. Extending the OE Disable by Half a Clock Cycle for a Write Transaction Note (1)
Note to Figure 9–8:

(1)   The waveform reflects the software simulation result. The OE signal is an active low on the device. However, the Quartus II software implements the signal as an active high and automatically adds an inverter before the A_{OE} register D input.

On-Chip Termination (OCT)

Cyclone III supports calibrated on-chip series termination (OCT R_S) in both vertical and horizontal I/O banks. To use the calibrated OCT, you need to use the R_{UP} and R_{DN} pins for each OCT R_S control block (one for each side). You can use each OCT calibration block to calibrate one type of termination with the same V_{CCIO} for that given side.

For more information on the Cyclone III OCT calibration block, refer to the *Cyclone III Device I/O Features* chapter in volume 1 of the *Cyclone III Device Handbook*.

PLL

When interfacing with external memory, the PLL is used to generate the memory system clock, the write clock, the capture clock and the logic-core clock. The system clock generates the DQS write signals, commands, and addresses. The write-clock is shifted by –90° from the

system clock and generates the DQ signals during writes. You can use the PLL reconfiguration feature to calibrate the read-capture phase shift to balance the setup and hold margins.

☞ The PLL is instantiated within the ALTMEMPHY megafunction. All the outputs of the PLL are used when the ALTMEMPHY megafunction is instantiated to interface with external memories. For more information on usage of the PLL outputs by the ALTMEMPHY megafunction, refer to the *ALTMEMPHY Megafunction User Guide* found at the Altera web site at **www.altera.com**.

For more information on the Cyclone III PLL, refer to the *Clock Networks and PLLs in Cyclone III Devices* chapter in volume 1 of the *Cyclone III Device Handbook*.

Conclusion

Cyclone III devices support DDR2 SDRAM, DDR SDRAM, and QDRII SRAM external memory interfaces. The self-calibrating ALTMEMPHY megafunction simplifies the implementation of data paths for different memory interfaces and dynamically calibrates out the process, voltage, and temperature variations in Cyclone III devices and external memory devices without interrupting normal operation.

Cyclone III allows a transfer data rate between external memory interfaces of up to 200 MHz/400 Mbps for DDR2 SDRAM, 167 MHz/333 Mbps for DDR SDRAM, and 167 MHz/667 Mbps for QDRII SRAM devices. Cyclone III devices also offer dedicated write DDIO registers to improve the output duty cycle and provide a better write margin.

Refer to each chapter for its own specific revision history. For information on when each chapter was updated, refer to the Chapter Revision Dates section, which appears in the complete handbook.

CIII51010-1.0

Introduction

Cyclone® III devices use SRAM cells to store configuration data. Because SRAM memory is volatile, configuration data must be downloaded to Cyclone III devices each time the device powers up. Depending on device densities or package options, Cyclone III devices can be configured using one of five configuration schemes:

- Active serial (AS)
- Active parallel (AP)
- Passive serial (PS)
- Fast Passive parallel (FPP)
- Joint Test Action Group (JTAG)

AS and AP schemes use an external flash memory, such as a serial configuration device or a supported flash memory, respectively. PS, FPP, and JTAG schemes use either an external controller (for example, a MAX® II device or microprocessor), or a download cable. When used in a multi-device configuration scheme for PS and FPP, the external controller for the slave Cyclone III device(s) is a master Cyclone III device set in the AS and AP mode respectively. Refer to the "Configuration Features" on page 10–8 for more information.

In some applications, it may be necessary for a device to wake up very quickly in order to begin operation. Cyclone III devices offer the Fast-On feature for fast power-on reset (POR) time to support fast wake-up time applications such as in the automotive market. Cyclone III devices support a new configuration scheme such as the AP scheme which uses commodity parallel flash as configuration memory without the need for an external host which lowers system costs and offers fast configuration time. Additionally, Cyclone III devices can receive a compressed configuration bitstream and decompress the data in real-time, reducing storage requirements and configuration time. Furthermore, Cyclone III devices support remote system upgrade in the active configuration modes. Remote system upgrades help deliver feature enhancements and bug fixes without costly recalls, reduce time-to-market, and extend product life.

This chapter explains the Cyclone III device configuration features and describes how to configure Cyclone III devices using the supported configuration schemes. This chapter also includes configuration pin descriptions and the Cyclone III device configuration file formats. In this chapter, the generic term device(s) includes all Cyclone III devices.

Altera Corporation-Preliminary
March 2007

Configuration Devices

The Altera® serial configuration devices (EPCS64, EPCS16, and EPCS4) are used in the AS configuration scheme for Cyclone III devices. Serial configuration devices offer, a low cost, low pin count configuration solution.

For information about serial configuration devices, refer to the *Serial Configuration Devices (EPCS1, EPCS4, EPCS16 and EPCS64) Data Sheet* chapter in volume 2 of the *Configuration Handbook*.

Existing batches of EPCS4 manufactured on 0.15 μm process geometry supports AS configuration in Cyclone III devices. However, batches of EPCS4 manufactured on 0.18 μm process geometry does not support AS configuration in Cyclone III devices.

For information about product traceability and transition date to differentiate between supported and non-supported EPCS4 serial configuration devices, refer to the *PCN 0514 Manufacturing Changes on EPCS Family* process change notification on the Altera website at **www.altera.com**.

In the AP configuration scheme, the commodity parallel flash is used as configuration memory.

For information about the supported families for the commodity parallel flash, refer to Table 10–9 on page 10–32.

Configuration Schemes

A configuration scheme with different configuration voltage standards is selected by driving the Cyclone III device's MSEL pins either high or low as shown in Table 10–1. The MSEL pins are powered by the V_{CCINT} power supply of the bank they reside in. The `MSEL[3..0]` pins have 5-kΩ internal pull-down resistors that are always active. During power-on reset (POR) and during reconfiguration, the MSEL pins have to be at least LVTTL V_{IL} or V_{IH} levels to be considered a logic low or logic high, respectively.

☞ To avoid any problems with detecting an incorrect configuration scheme, hard-wire the MSEL pins to V_{CCIO} of the I/O bank they reside in and GND without any pull-up or pull-down resistors. Do not drive the MSEL pins with a microprocessor or another device.

Table 10–1. Cyclone III Configuration Schemes (Part 1 of 2)					
Configuration Scheme	**MSEL3** *(10)*	**MSEL2** *(10)*	**MSEL1**	**MSEL0**	**Configuration Voltage Standard** *(9)*

Notes to Table 10–1:

(1) These schemes support the remote system upgrade feature. Remote update mode is supported when using remote system upgrade feature. You can enable of disable the remote update mode with an option setting in the Quartus® II software. For more information on remote system upgrade feature, refer to the *Remote System Upgrade with Cyclone III Devices* chapter in the *Cyclone III Device Handbook*.

(2) Some of the smaller Cyclone III devices or package options do not support the AP configuration scheme. For more information, refer to Table 10–2.

(3) In the AP configuration scheme, the commodity parallel flash is used as configuration memory. For information on the supported families for the commodity parallel flash, refer to Table 10–9 on page 10–32.

(4) Some of the smaller Cyclone III devices or package options do not support the FPP configuration scheme. For more information, refer to Table 10–2.

(5) The EPCS16 and EPCS64 devices support up to a 40 MHz DCLK and are supported in Cyclone III devices. Existing batches of EPCS4 manufactured on 0.15 μm process geometry supports up to a 40 MHz DCLK and are supported in Cyclone III devices. However, batches of EPCS4 manufactured on 0.18 μm process geometry does not support AS configuration in Cyclone III devices. For information on product traceability and transition date to differentiate between supported and non-supported EPCS4 serial configuration devices, refer to *PCN 0514 Manufacturing Changes on EPCS Family* process change notification. For information on serial configuration devices, refer to the *Serial Configuration Devices (EPCS1, EPCS4, EPCS16 and EPCS64) Data Sheet* chapter in volume 2 of the *Configuration Handbook*.

(6) These schemes support data decompression.

(7) Do not leave the MSEL pins floating. Connect them to V_{CCIO} or GND. These pins support the non-JTAG configuration scheme used in production. If only JTAG configuration is used, you should connect the MSEL pins to GND.

(8) JTAG-based configuration takes precedence over other configuration schemes, which means MSEL pin settings are ignored.

(9) Configuration voltage standard applied to V_{CCIO}.

(10) Some of the smaller Cyclone III devices or package options do not support the AP configuration scheme and do not have the MSEL[3] pin. For information on the supported configuration schemes across device densities and package options, refer to Table 10–2.

(11) You must follow specific requirements when interfacing Cyclone III devices with 2.5V/3.0V/3.3V configuration voltage standards. For information on the requirements, refer to "Configuration and JTAG Pin I/O Requirements" on page 10–13.

In Cyclone III devices, the supported configuration schemes differ for different device densities and package options. Table 10–2 shows the supported configuration schemes across device densities and package options.

Table 10–2. Cyclone III Devices Supported Configuration Schemes Across Device Densities and Package Options *Note (1)*

Table 10–2. Cyclone III Devices Supported Configuration Schemes Across Device Densities and Package Options *Note (1)*								
Device	**Package Options** *(4)*							
	E144	**Q240**	**F256**	**F324**	**F484**	**F780**	**U256**	**U484**
EP3C120					AS, PS, FPP, AP, JTAG *(3)*	AS, PS, FPP, AP, JTAG *(3)*		

Notes to Table 10–2:

(1) AS is active serial, PS is passive serial, FPP is fast passive parallel, and AP is active parallel.

(2) These packages do not support AP configuration scheme and do not have the `MSEL[3]` pin.

(3) These packages support all the configuration schemes shown in Table 10–1 on page 10–3.

(4) For information about vertical package migration and package options for Cyclone III devices, refer to the *Cyclone III FPGA Device Family Overview* chapter and the *Package Information for Cyclone III Devices* chapter in the *Cyclone III Device Handbook*.

(5) EP3C40 package option F780 only partially supports vertical package migration to other F780 package options.

> For information about vertical package migration and package options for Cyclone III devices, refer to the *Cyclone III FPGA Device Family Overview* chapter and the *Package Information for Cyclone III Devices* chapter in the *Cyclone III Device Handbook.*

Cyclone III devices offer decompression, and remote system upgrade features. Cyclone III devices can receive a compressed configuration bitstream and decompress this data in real-time, reducing storage requirements and configuration time. Data decompression is supported in AS and PS configuration schemes. Data decompression is not supported in AP, FPP nor in JTAG-based configuration schemes. You can make real-time system upgrades from remote locations of your Cyclone III designs with the remote system upgrade feature. Remote update is supported in AS and AP configuration schemes.

Configuration File Format

Table 10–3 shows the approximate uncompressed configuration file sizes for Cyclone III devices. To calculate the amount of storage space required for multiple device configurations, add the file size of each device together.

Table 10–3. Cyclone III Uncompressed Raw Binary File Sizes *Notes (1), (2)*	
Device	**Data Size (Bits)**
EP3C5	3,500,000
EP3C10	3,500,000
EP3C16	4,500,000
EP3C25	6,500,000
EP3C40	10,500,000
EP3C55	16,000,000
EP3C80	21,000,000
EP3C120	30,500,000

Notes to Table 10–3:
(1) These values are preliminary.
(2) Raw Binary File (**.rbf**)

Use the data in Table 10–3 only to estimate the file size before design compilation. Different configuration file formats, such as a Hexidecimal (**.hex**) or Tabular Text File (**.ttf**) format, have different file sizes. However, for any specific version of the Quartus II software, any design targeted for the same device has the same uncompressed configuration file size. If you are using compression, the file size can vary after each compilation because the compression ratio is dependent on the design.

For more information about setting device configuration options or creating configuration files, refer to *Software Settings* chapter in the *Configuration Handbook*.

Configuration Features

Cyclone III devices offer configuration data decompression to reduce configuration file storage and remote system upgrade to allow for remotely updating your Cyclone III designs. Table 10–4 summarizes which configuration features you can use in each configuration scheme.

Table 10–4. Cyclone III Configuration Features

Configuration Scheme	Configuration Method	Decompression	Remote System Upgrade *(3)*
Active Serial Fast (AS Fast POR)	Serial Configuration Device	✓	✓
Active Serial Standard (AS Standard POR)	Serial Configuration Device	✓	✓
Intel Active Parallel x16 Fast (AP Fast POR)	Supported flash memory *(1)*		✓
Intel Active Parallel x16 (AP Standard POR)	Supported flash memory *(1)*		✓
Spansion Active Parallel x16 Fast (AP Fast POR)	Supported flash memory *(2)*		✓
Spansion Active Parallel x16 (AP Standard POR)	Supported flash memory *(2)*		✓
Passive Serial Fast (PS Fast POR)	MAX II device or a Microprocessor with flash memory	✓	
	Download cable	✓	
Passive Serial Standard (PS Standard POR)	MAX II device or a Microprocessor with flash memory	✓	
	Download cable	✓	
Fast Passive Parallel Fast (FPP Fast POR)	MAX II device or a Microprocessor with flash memory		
JTAG-based configuration	MAX II device or a Microprocessor with flash memory		
	Download cable		

Notes to Table 10–4:

(1) For information on the supported families for the Intel commodity parallel flash, refer to Table 10–9 on page 10–32.
(2) For information on the supported families for the Spansion commodity parallel flash, refer to Table 10–9 on page 10–32.
(3) Remote update mode is supported when using remote system upgrade feature. You can enable or disable the remote update mode with an option setting in the Quartus II software. For more information on remote system upgrade feature, refer to the *Remote System Upgrade with Cyclone III Devices* chapter in the *Cyclone III Device Handbook*.

Configuration Data Decompression

Cyclone III devices support configuration data decompression, which saves configuration memory space and time. This feature allows you to store compressed configuration data in configuration devices or other memory and transmit this compressed bitstream to Cyclone III devices. During configuration, Cyclone III devices decompress the bitstream in real time and programs its SRAM cells.

☞ Preliminary data indicates that compression typically reduces configuration bitstream size by 35 to 55%.

Cyclone III devices support decompression in the AS and PS configuration schemes. Decompression is not supported in the AP configuration scheme, FPP configuration scheme, or in JTAG-based configuration.

In PS mode, you should use the Cyclone III decompression feature because sending compressed configuration data reduces configuration time. You should use the Cyclone III decompression feature during AS configuration if you need to save configuration memory space in the serial configuration device.

When you enable compression, the Quartus II software generates configuration files with compressed configuration data. This compressed file reduces the storage requirements in the configuration device or flash memory and decreases the time needed to transmit the bitstream to the Cyclone III device. The time required by a Cyclone III device to decompress a configuration file is less than the time needed to transmit the configuration data to the device.

There two methods for enabling compression for Cyclone III bitstreams in the Quartus II software:

■ Before design compilation (in the **Compiler Settings** menu)
■ After design compilation (in the **Convert Programming Files** window).

To enable compression in the project's compiler settings, perform the following steps in the Quartus II software:

1. On the Assignment menu, click **Device**. The **Settings** dialog box appears.

2. Click **Device & Pin Options**. The **Device & Pin Options** dialog box appears.

3. Click the **Configuration** tab.

4. Turn on **Generate compressed bitstreams** (Figure 10–1).

5. Click **OK**.

6. In the **Setting** dialog box, click **OK**.

Figure 10–1. Enabling Compression for Cyclone III Bitstreams in Compiler Settings
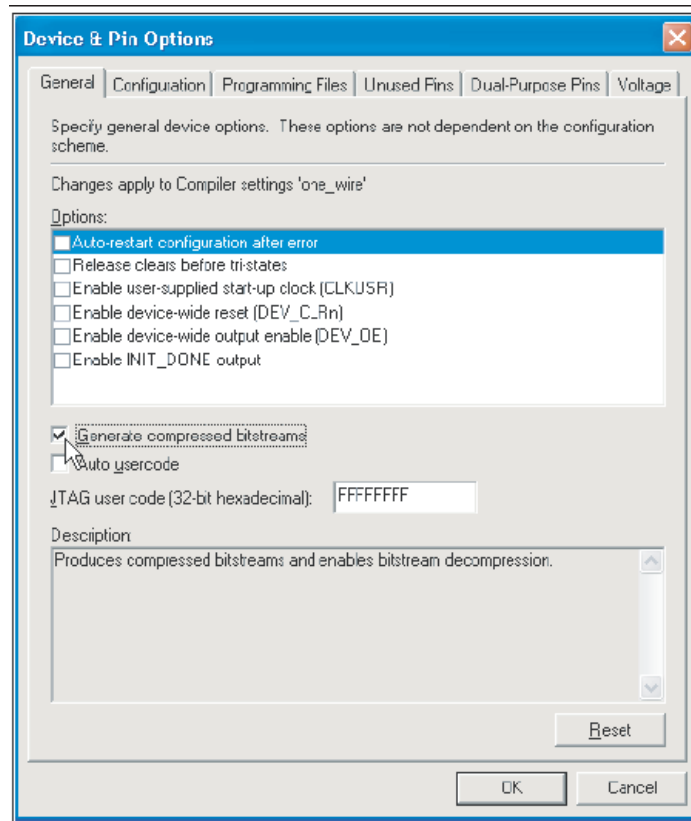

Compression can also be enabled when creating programming files from the **Convert Programming Files** dialog box.

1. Click **Convert Programming Files** (File menu).

2. Select the programming file type (POF, SRAM HEXOUT, RBF, or TTF).

3. For Programmer Object File (**.pof**) output files, select a configuration device.

4. In the **Input files to convert** box, select **SOF Data**.

5. Select **Add File** and add a Cyclone III device SRAM Object File(s).

6. Select the name of the file you added to the **SOF Data** area and click **Properties**.

7. Check the **Compression** check box.

When multiple Cyclone III devices are cascaded, you can selectively enable the compression feature for each device in the chain. Figure 10–2 depicts a chain of two Cyclone III devices. The first Cyclone III device has compression enabled and receives a compressed bitstream from the configuration device. The second Cyclone III device has the compression feature disabled and receives uncompressed data.

Figure 10–2. Compressed and Uncompressed Configuration Data in the Same Configuration File
You can generate programming files for this setup from the **Convert Programming Files** dialog box (File menu) in the Quartus II software.

Remote System Upgrade

Cyclone III devices support remote update mode when using the remote system upgrade feature. You can enable or disable remote update mode with an option setting in the Quartus II software. Remote system upgrades help deliver feature enhancements and bug fixes without costly recalls, reduce time-to-market, and extend product life.

Cyclone III devices support remote update in the AS and AP configuration schemes. You can implement remote update in conjunction with real-time decompression of configuration data if you need to save configuration memory space in the serial configuration device with AS configuration.

For more information about the remote system upgrade feature, refer to the *Remote System Upgrade with Cyclone III Devices* chapter in the *Cyclone III Device Handbook.*

Configuration Requirements

Power-On Reset Circuit

The POR circuit keeps the device in reset state until the power supply voltage levels have stabilized on power-up. Upon power-up, the device does not release nSTATUS until V_{CCINT}, V_{CCA}, and V_{CCIO} of banks 1, 6, 7, and 8 are above the device's POR trip point. On power up, V_{CCINT} and V_{CCA} are monitored for brown-out conditions.

☞ V_{CCA} is the analog power to the PLL.

In Cyclone III devices you can select between a fast POR time or a standard POR time depending on the MSEL pin settings. The fast POR time is 3 ms < T_{POR} < 9 ms for fast configuration time. The standard POR time is 50ms < T_{POR} < 200 ms which has a lower power ramp rate. In both cases, you can extend the POR time by using an external component to assert the nSTATUS pin low. Table 10–5 shows the supported POR times for each configuration scheme.

Table 10–5. Cyclone III Supported Power-On Reset Times Across Configuration Schemes (Part 1 of 2)

Configuration Scheme	Fast POR Time (3ms< T_{POR}<9ms)	Standard POR Time (50ms<T_{POR}<200ms)	Configuration Voltage Standard *(1)*
Passive Serial Standard (PS Standard POR)		✓	3.3/2.5 V
Active Serial Standard (AS Standard POR)		✓	3.3 V
Intel Active Parallel ×16 Fast (AP Fast POR)	✓		3.3 V
Intel Active Parallel × 16 Fast (AP Fast POR)	✓		1.8 V
Intel Active Parallel × 16 (AP Standard POR)		✓	3.3 V
Intel Active Parallel × 16 (AP Standard POR)		✓	1.8 V
Spansion Active Parallel × 16 Fast (AP Fast POR)	✓		1.8 V
Spansion Active Parallel × 16 (AP Standard POR)		✓	1.8 V
Intel Active Parallel × 16 (AP Slow POR)		✓	3.0/2.5 V
Passive Serial Fast (PS Fast POR)	✓		3.3/2.5 V
Active Serial Fast (AS Fast POR)	✓		3.3 V
Fast Passive Parallel Fast (FPP Fast POR)	✓		3.3/2.5 V

Table 10–5. Cyclone III Supported Power-On Reset Times Across Configuration Schemes (Part 2 of 2)			
Configuration Scheme	**Fast POR Time** $(3ms< T_{POR}<9ms)$	**Standard POR Time** $(50ms<T_{POR}<200ms)$	**Configuration Voltage Standard** *(1)*
Fast Passive Parallel Fast (FPP Fast POR)	✓		1.8/1.5 V
JTAG-based configuration	*(2)*	*(2)*	

Notes to Table 10–5:
(1) Configuration voltage standard applied to V_{CCIO}.
(2) JTAG-based configuration takes precedence over other configuration schemes, which means MSEL pin settings are ignored. However, the POR time is dependent on the MSEL pin settings.

In some applications, it may be necessary for a device to wake up very quickly in order to begin operation. The Cyclone III device family offers the fast POR time option to support fast wake-up time applications. The fast POR time option has stricter power up requirements compared to the standard POR time option. You can select either the fast POR option or the standard POR option using the MSEL pin settings.

☞ For more information on wake-up time, refer to the *Hot Socketing and Power-On Reset in Cyclone III Devices* chapter in the *Cyclone III Device Handbook*.

☞ The fast POR time feature in Cyclone III devices is similar to the Fast-On feature in Cyclone II devices designated with an "A" in the ordering code.

☞ The Cyclone III devices' fast wake-up time meets the requirement of common bus standards in automotive applications, such as Media Orientated Systems Transport (MOST) and Controller Area Network (CAN).

☞ For more information on power-on reset circuit, refer to the *Hot Socketing and Power-On Reset in Cyclone III Devices* chapter in the *Cyclone III Device Handbook*.

Configuration and JTAG Pin I/O Requirements

Cyclone III devices are manufactured using TSMC's 65-nm low-k dielectric process. Although Cyclone III devices use TSMC 2.5-V transistor technology in I/O buffers, the devices are compatible and able to interface with 2.5V/3.0V/3.3V configuration voltage standards. However, you must follow specific requirements when interfacing Cyclone III devices with 2.5V/3.0V/3.3V configuration voltage standards.

All I/O inputs must maintain a maximum AC voltage of 4.1 V. When using a serial configuration device in the AS configuration scheme, you must connect a 25-Ω series resistor at the near end of the serial configuration device for the `DATA[0]`. When cascading Cyclone III devices in multi-device configuration, you must connect repeater buffers between the Cyclone III master and slave device(s) for `DATA` and `DCLK`. The output resistance of the repeater buffers has to fit the maximum overshoot equation given by: $0.8Z_O \leq R_E \leq 1.8Z_O$

In this equation Z_O is the transmission line impedence and R_E is the equivalent resistance of the output buffer.

Active Serial Configuration (Serial Configuration Devices)

In the AS configuration scheme, Cyclone III devices are configured using a serial configuration device. These configuration devices are low-cost devices with non-volatile memory that feature a simple four-pin interface and a small form factor. These features make serial configuration devices an ideal low-cost configuration solution.

For more information on serial configuration devices, refer to the *Serial Configuration Devices (EPCS1, EPCS4, EPCS16 and EPCS64) Data Sheet* in the *Configuration Handbook*.

In Cyclone III devices, the active master clock frequency runs at a maximum of 40 MHz, and around a typical 30 MHz. Cyclone III devices only work with serial configuration devices that support up to 40 MHz. Existing batches of EPCS4 manufactured on 0.15 µm process geometry supports AS configuration in Cyclone III devices up to 40 MHz. However, batches of EPCS4 manufactured on 0.18 µm process geometry support only up to 20 MHz. EPCS16 and EPCS64 serial configuration devices are not affected.

For information about product traceability and transition date to differentiate between 0.15 µm process geometry and 0.18 µm process geometry EPCS4 serial configuration devices, refer to *PCN 0514 Manufacturing Changes on EPCS Family* process change notification on the Altera website at **www.altera.com**.

Serial configuration devices provide a serial interface to access configuration data. During device configuration, Cyclone III devices read configuration data via the serial interface, decompress data if necessary, and configure their SRAM cells. This scheme is referred to as the AS configuration scheme because the device controls the configuration interface. This scheme contrasts with the PS configuration scheme, where the external host controls the interface.

☞ The Cyclone III decompression, and remote system upgrade features are available when configuring your Cyclone III device using AS configuration scheme.

Table 10–6 shows the MSEL pin settings when using the AS configuration scheme with different configuration voltage standard.

Table 10–6. Cyclone III MSEL Pin Settings for AS Configuration Schemes					
Configuration Scheme	**MSEL3**	**MSEL2**	**MSEL1**	**MSEL0**	**Configuration Voltage Standard** *(3)*
Active Serial Standard (AS Standard POR) *(1)*, *(2)*	0	0	1	0	3.3 V *(4)*
Active Serial Fast (AS Fast POR) *(1)*, *(2)*	1	1	0	1	3.3 V *(4)*

Notes to Table 10–6:
(1) These schemes support the remote system upgrade feature. Remote update mode is supported when using remote system upgrade feature. You can enable or disable remote update mode with an option setting in the Quartus II software. For more information about the remote system upgrade feature, refer to the *Remote System Upgrade with Cyclone III Devices* chapter in the *Cyclone III Device Handbook*.
(2) These schemes support data decompression.
(3) Configuration voltage standard applied to V_{CCIO}.
(4) You must follow specific requirements when interfacing Cyclone III devices with 2.5V/3.0V/3.3V configuration voltage standards. For information on the requirements, refer to "Configuration and JTAG Pin I/O Requirements" on page 10–13.

Single Device AS Configuration

The four-pin interface of serial configuration devices consists of a serial clock input (DCLK), serial data output (DATA), AS data input (ASDI), and an active-low chip select (nCS). This four-pin interface connects to Cyclone III device pins, as shown in Figure 10–3.

Figure 10–3. Single Device AS Configuration
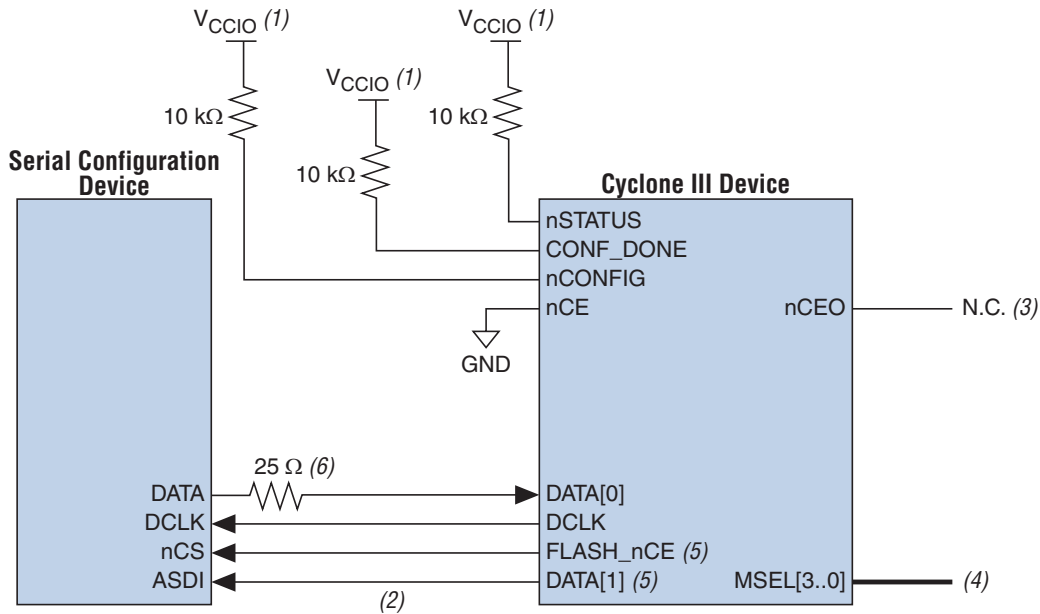

Notes to Figure 10–3:

(1) Connect the pull-up resistors to V_{CCIO} supply of the bank the pin resides in.
(2) Cyclone III devices use the DATA[1] to ASDI path to control the configuration device.
(3) The nCEO pin can be left unconnected or used as a user I/O pin when it does not feed another device's nCE pin.
(4) The MSEL pin settings vary for different configuration voltage standards and POR time. To connect MSEL[3..0], refer to Table 10–6 on page 10–15. Connect the MSEL pins directly to V_{CCIO} or GND.
(5) These are dual-purpose I/O pins. FLASH_nCE pin functions as the nCSO pin in AS configuration scheme. DATA[1] pin functions as the ASDO pin in AS configuration scheme.
(6) Connect the series resistor at the near end of the serial configuration device.

📎 When connecting a serial configuration device to the Cyclone III device in single device AS configuration, you must connect a 25 Ω series resistor at the near end of the serial configuration device for the DATA[0].

📎 In single device AS configuration, the board trace length between the serial configuration device to the Cyclone III device should be within a maximum of 10 inches.

Upon power-up, the Cyclone III devices go through a POR. The POR delay is dependent on the MSEL pin settings which correspond to the configuration scheme that you select. Depending on the configuration scheme, either a fast POR time or a standard POR time is available. The fast POR time is 3 ms < T_{POR} < 9ms for fast configuration time. The standard POR time is 50 ms < T_{POR} < 200ms, which has a lower power ramp rate. During POR, the device resets, holds nSTATUS and CONF_DONE low, and tri-states all user I/O pins. Once the device

successfully exits POR, all user I/O pins continue to be tri-stated. The user I/O pins and dual-purpose I/O pins have weak pull-up resistors which are always enabled (after POR) before and during configuration.

☛ The value of the weak pull-up resistors on the I/O pins that are on before and during configuration can be found in the *DC and Switching Characteristics* chapter of the *Cyclone III Device Handbook*.

The three stages of the configuration cycle are reset, configuration, and initialization. While nCONFIG or nSTATUS are low, the device is in reset. After POR, the Cyclone III devices release nSTATUS, which is pulled high by an external 10 KΩ pull-up resistor, and enters configuration mode.

☞ To begin configuration, power the V_{CCINT}, V_{CCA}, and V_{CCIO} (for the banks where the configuration and JTAG pins reside) voltages to the appropriate voltage levels.

The serial clock (DCLK) generated by the Cyclone III device controls the entire configuration cycle and provides the timing for the serial interface. Cyclone III devices use an internal oscillator to generate DCLK. Cyclone III devices use a 40 MHz oscillator. There is some variation in the internal oscillator frequency because of the process, temperature, and voltage conditions in Cyclone III devices. The internal oscillator is designed such that its maximum frequency is guaranteed to meet EPCS device specifications.

☞ The EPCS1 device does not support any Cyclone III devices because of its insufficient memory capacity.

☛ For information about serial configuration devices, refer to the *Serial Configuration Devices (EPCS1, EPCS4, EPCS16 and EPCS64) Data Sheet* chapter in volume 2 of the *Configuration Handbook*.

Table 10–7 shows the active serial DCLK output frequency.

Table 10–7. Active Serial DCLK Output Frequency   *Note (1)*

Oscillator	Minimum	Typical	Maximum	Units
40 MHz	20	30	40	MHz

Note to Table 10–7:
(1)   These values are preliminary.

In AS configuration scheme, the serial configuration device latches input and control signals on the rising edge of `DCLK` and drives out configuration data on the falling edge. Cyclone III devices drive out control signals on the falling edge of `DCLK` and latch configuration data on the falling edge of `DCLK`.

☞ The `FLASH_nCE` pin and `DATA[1]` pin are dual-purpose I/O pins. The `FLASH_nCE` pin functions as the `nCSO` pin in the AS configuration scheme. The `DATA[1]` pin functions as the `ASDO` pin in the AS configuration scheme.

In configuration mode, the Cyclone III device enables the serial configuration device by driving the `FLASH_nCE` output pin low, which connects to the chip select (`nCS`) pin of the configuration device. The Cyclone III device uses the serial clock (`DCLK`) and serial data output (`DATA[1]`) pins to send operation commands and/or read address signals to the serial configuration device. The configuration device provides data on its serial data output (`DATA`) pin, which connects to the `DATA[0]` input of the Cyclone III device.

After all configuration bits are received by the Cyclone III device, it releases the open-drain `CONF_DONE` pin, which is pulled high by an external 10 KΩ resistor. Initialization begins only after the `CONF_DONE` signal reaches a logic high level. All AS configuration pins (`DATA[0]`, `DCLK`, `FLASH_nCE`, and `DATA[1]`) have weak internal pull-up resistors that are always active. After configuration, these pins are set as input tri-stated and are driven high by the weak internal pull-up resistors. The `CONF_DONE` pin must have an external 10 KΩ pull-up resistor in order for the device to initialize.

In Cyclone III devices, the initialization clock source is either the 10 MHz (typical) internal oscillator (separate from the active serial internal oscillator) or the optional `CLKUSR` pin. By default, the internal oscillator is the clock source for initialization. If the internal oscillator is used, the Cyclone III device provides itself with enough clock cycles for proper initialization. The advantage of using the internal oscillator is you do not need to send additional clock cycles from an external source to the `CLKUSR` pin during the initialization stage. Additionally, you can use the `CLKUSR` pin as a user I/O pin.

You also have the flexibility to synchronize initialization of multiple devices or to delay initialization with the `CLKUSR` option. Using the `CLKUSR` pin allows you to control when your device enters user mode. The device can be delayed from entering user mode for an indefinite amount of time. The **Enable user-supplied start-up clock** (**CLKUSR**) option can be turned on in the Quartus II software from the **General** tab of the **Device & Pin Options** dialog box. When you **Enable** the **user**

supplied start-up clock option, the CLKUSR pin is the initialization clock source. Supplying a clock on CLKUSR does not affect the configuration process. After all configuration data is accepted and CONF_DONE goes high, Cyclone III devices require 3,180 clock cycles to initialize properly and enter user mode. Cyclone III devices support a CLKUSR f_{MAX} of 133 MHz.

An optional INIT_DONE pin is available, which signals the end of initialization and the start of user-mode with a low-to-high transition. The **Enable INIT_DONE Output** option is available in the Quartus II software from the **General** tab of the **Device & Pin Options** dialog box. If the INIT_DONE pin is used, it will be high due to an external 10 KΩ pull-up resistor when nCONFIG is low and during the beginning of configuration. Once the option bit to enable INIT_DONE is programmed into the device (during the first frame of configuration data), the INIT_DONE pin goes low. When initialization is complete, the INIT_DONE pin is released and pulled high. This low-to-high transition signals that the device has entered user mode. When initialization is complete, the device enters user mode. In user mode, the user I/O pins no longer have weak pull-up resistors and function as assigned in your design.

If an error occurs during configuration, Cyclone III devices assert the nSTATUS signal low, indicating a data frame error, and the CONF_DONE signal stays low. If the **Auto-restart configuration after error** option (available in the Quartus II software from the **General** tab of the **Device & Pin Options** dialog box) is turned on, the Cyclone III device resets the configuration device by pulsing FLASH_nCE, releases nSTATUS after a reset time-out period (maximum of 80 μs), and retries configuration. If this option is turned off, the system must monitor nSTATUS for errors and then pulse nCONFIG low for at least 500 ns to restart configuration.

When the Cyclone III device is in user mode, you can initiate reconfiguration by pulling the nCONFIG pin low. The nCONFIG pin should be low for at least 500 ns. When nCONFIG is pulled low, the Cyclone III device is reset. The Cyclone III device also pulls nSTATUS and CONF_DONE low and all I/O pins are tri-stated. When nCONFIG returns to a logic high level and nSTATUS is released by the Cyclone III device, reconfiguration begins.

☞ If you use the optional CLKUSR pin and the nCONFIG pin is pulled low to restart configuration during device initialization, ensure CLKUSR continues to toggle during the time nSTATUS is low (a maximum of 80 μs).

For more information on configuration issues, refer to the *Debugging Configuration Problems* chapter of the *Configuration Handbook* and the FPGA Configuration Troubleshooter on the Altera web site at **www.altera.com**.

Multi-Device AS Configuration

You can configure multiple Cyclone III devices using a single serial configuration device. You can cascade multiple Cyclone III devices using the chip-enable (nCE) and chip-enable-out (nCEO) pins. The first device in the chain must have its nCE pin connected to GND. You must connect its nCEO pin to the nCE pin of the next device in the chain. Use an external 10-kΩ pull-up resistor to pull the nCEO signal high to its V_{CCIO} level to help the internal weak pull-up resistor. When the first device captures all of its configuration data from the bitstream, it drives the nCEO pin low, enabling the next device in the chain. You can leave the nCEO pin of the last device unconnected or use it as a user I/O pin after configuration if the last device in chain is a Cyclone III device. The nCONFIG, nSTATUS, CONF_DONE, DCLK, and DATA[0] pins of each device in the chain are connected (refer to Figure 10–4).

This first Cyclone III device in the chain is the configuration master and controls configuration of the entire chain. You must connect its MSEL pins to select the AS configuration scheme. The remaining Cyclone III devices are configuration slaves and you must connect their MSEL pins to select the PS configuration scheme. Any other Altera device that supports PS configuration can also be part of the chain as a configuration slave. Figure 10–4 shows the pin connections for this setup.

Figure 10–4. Multi-Device AS Configuration
Notes to Figure 10–4:
(1)   Connect the pull-up resistors to V_{CCIO} supply of the bank the pin resides in.
(2)   Connect the pull-up resistor to the V_{CCIO} supply voltage of I/O bank that the nCEO pin resides in.
(3)   You can leave the nCEO pin unconnected or use it as a user I/O pin when it does not feed another device's nCE pin
(4)   The MSEL pin settings vary for different configuration voltage standards and POR time. You must set the Cyclone III master device in AS mode and the slave devices in PS mode. To connect MSEL[3..0] for the master device in AS mode, refer to Table 10–6 on page 10–15. To connect MSEL[3..0] for the slave devices in PS mode, refer to Table 10–10 on page 10–46. Connect the MSEL pins directly to V_{CCIO} or GND.
(5)   These are dual-purpose I/O pins. FLASH_nCE pin functions as the nCSO pin in AS configuration scheme. DATA[1] pin functions as the ASDO pin in AS configuration scheme.
(6)   Connect the series resistor at the near end of the serial configuration device.
(7)   Connect the repeater buffers between the Cyclone III master and slave device(s) for DATA[0] and DCLK. All I/O inputs must maintain a maximum AC voltage of 4.1 V. The output resistance of the repeater buffers has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13.

☞   When connecting a serial configuration device to the Cyclone III device in multi-device AS configuration, you must connect a 25 Ω series resistor at the near end of the serial configuration device for the DATA[0]. Additionally, you must connect the repeater buffers between the Cyclone III master and slave device(s) for DATA[0] and DCLK. All I/O inputs must maintain a maximum AC voltage of 4.1 V. The output resistance of the repeater buffers has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13.

As shown in Figure 10–4, the nSTATUS and CONF_DONE pins on all target devices are connected together with external pull-up resistors. These pins are open-drain bidirectional pins on the devices. When the first device asserts nCEO (after receiving all of its configuration data), it releases its CONF_DONE pin. However, the subsequent devices in the chain keep this shared CONF_DONE line low until they have received their configuration data. When all target devices in the chain have received their configuration data and have released CONF_DONE, the pull-up resistor drives a high level on this line and all devices simultaneously enter initialization mode.

If an error occurs at any point during configuration, the nSTATUS line is driven low by the failing device. If you enable the **Auto-restart configuration after error** option, reconfiguration of the entire chain begins after a reset time-out period (a maximum of 80 μs). If the **Auto-restart configuration after error** option is turned off, the external system must monitor nSTATUS for errors and then pulse nCONFIG low to restart configuration. The external system can pulse nCONFIG if it is under system control rather than tied to V_{CCIO}.

☞ While you can cascade Cyclone III devices, serial configuration devices cannot be cascaded or chained together.

If the configuration bitstream size exceeds the capacity of a serial configuration device, you must select a larger configuration device and/or enable the compression feature. When configuring multiple devices, the size of the bitstream is the sum of the individual devices' configuration bitstreams.

Configuring Multiple Cyclone III Devices with the Same Design

Certain designs require you to configure multiple Cyclone III devices with the same design through a configuration bitstream or SOF. You can do this through one of two methods, as described in this section. For both methods, the serial configuration devices cannot be cascaded or chained together.

Multiple SRAM Object Files

In the first method, two copies of the SRAM Object File (**.sof**) are stored in the serial configuration device. Use the first copy to configure the master Cyclone III device and the second copy to configure all remaining slave devices concurrently. All slave devices must be the same density and package. The setup is similar to Figure 10–4 where the master is set up in active serial mode and the slave devices are set up in passive serial mode.

To configure four identical Cyclone III devices with the same SRAM Object File, you must set up the chain similar to the example shown in Figure 10–5. The first device is the master device and its MSEL pins should be set to select AS configuration. The other three slave devices are set up for concurrent configuration and its MSEL pins should be set to select PS configuration. The nCEO pin from the master device drives the nCE input pins on all three slave devices, as well as the DATA and DCLK pins connect in parallel to all four devices. During the first configuration cycle, the master device reads its configuration data from the serial configuration device while holding nCEO high. After completing its configuration cycle, the master drives nCE low and transmits the second copy of the configuration data to all three slave devices, configuring them simultaneously.

The advantage of using the setup in Figure 10–5 is that you can have a different SRAM Object File for the Cyclone III master device. However, all the Cyclone III slave devices must be configured with the same SRAM Object File. You can either compress or uncompress the SRAM Object Files in this configuration method.

☞ You can still use this method if the master and slave Cyclone III devices use the same SRAM Object File.

Figure 10–5. Multi-Device AS Configuration When Devices Receive the Same Data with Multiple SRAM Object Files
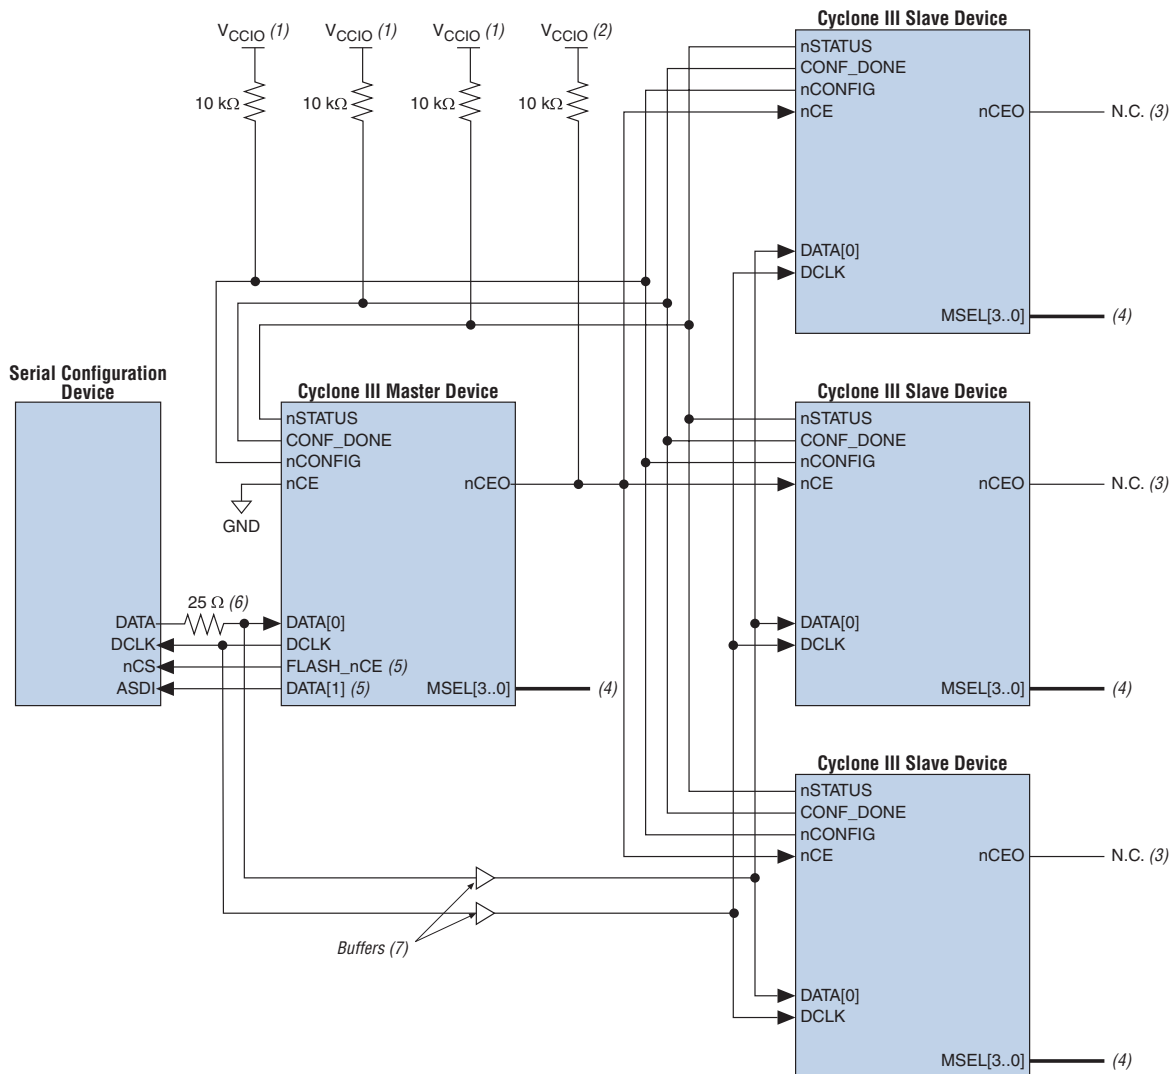

Notes to Figure 10–5:
(1) Connect the pull-up resistors to V_{CCIO} supply of the bank the pin resides in.
(2) Connect the pull-up resistor to the V_{CCIO} supply voltage of I/O bank that the nCEO pin resides in.
(3) The nCEO pin can be left unconnected or used as a user I/O pin when it does not feed another device's nCE pin.
(4) The MSEL pin settings vary for different configuration voltage standards and POR time. You must set the Cyclone III master device in AS mode and the slave devices in PS mode. To connect MSEL[3..0] for the master device in AS mode, refer to Table 10–6 on page 10–15. To connect MSEL[3..0] for the slave devices in PS mode, refer to Table 10–10 on page 10–46. Connect the MSEL pins directly to V_{CCIO} or GND.
(5) These are dual-purpose I/O pins. FLASH_nCE pin functions as the nCSO pin in AS configuration scheme. DATA[1] pin functions as the ASDO pin in AS configuration scheme.
(6) Connect the series resistor at the near end of the serial configuration device.
(7) Connect the repeater buffers between the Cyclone III master and slave device(s) for DATA[0] and DCLK. All I/O inputs must maintain a maximum AC voltage of 4.1 V. The output resistance of the repeater buffers has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13.

Single SRAM Object File

The second method configures both the master and slave Cyclone III devices with the same SRAM Object File. The serial configuration device stores one copy of the SRAM Object File. This setup is shown in Figure 10–6 where the master is setup in AS mode, and the slave devices are setup in PS mode. You must setup one or more slave devices in the chain. All the slave devices must be setup in the same way as shown in Figure 10–6.

Figure 10–6. Multi-Device AS Configuration When Devices Receive the Same Data with a Single SRAM Object File
Notes to Figure 10–6:

(1)   Connect the pull-up resistors to V_{CCIO} supply of the bank the pin resides in.

(2)   The nCEO pin can be left unconnected or used as a user I/O pin when it does not feed another device's nCE pin.

(3)   The MSEL pin settings vary for different configuration voltage standards and POR time. You must set the Cyclone III master device in AS mode and the slave devices in PS mode. To connect MSEL[3..0] for the master device in AS mode, refer to Table 10–6 on page 10–15. To connect MSEL[3..0] for the slave devices in PS mode, refer to Table 10–10 on page 10–46. Connect the MSEL pins directly to V_{CCIO} or GND.

(4)   These are dual-purpose I/O pins. FLASH_nCE pin functions as the nCSO pin in AS configuration scheme. DATA[1] pin functions as the ASDO pin in AS configuration scheme.

(5)   Connect the series resistor at the near end of the serial configuration device.

(6)   Connect the repeater buffers between the Cyclone III master and slave device(s) for DATA[0] and DCLK. All I/O inputs must maintain a maximum AC voltage of 4.1 V. The output resistance of the repeater buffers has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13.

In this setup, all the Cyclone III devices in the chain are connected for concurrent configuration. This can reduce the AS configuration time because all the Cyclone III devices are configured in one configuration cycle. Connect the nCE input pins of all the Cyclone III devices to ground.

You can either leave the nCEO output pins on all the Cyclone III devices unconnected or use the nCEO output pins as normal user I/O pins. The DATA and DCLK pins are connected in parallel to all the Cyclone III devices.

You should put a buffer before the DATA and DCLK output from the master Cyclone III device to avoid signal strength and signal integrity issues. The buffer should not significantly change the DATA-to-DCLK relationships or delay them with respect to other AS signals (ASDI and nCS). Also, the buffer should only drive the slave Cyclone III devices, so that the timing between the master Cyclone III device and serial configuration device is unaffected.

This configuration method supports both compressed and uncompressed SRAM Object Files. Therefore, if the configuration bitstream size exceeds the capacity of a serial configuration device, you can enable the compression feature in the SRAM Object File used or you can select a larger serial configuration device.

Estimating AS Configuration Time

Active serial configuration time is dominated by the time it takes to transfer data from the serial configuration device to the Cyclone III device. This serial interface is clocked by the Cyclone III DCLK output (generated from an internal oscillator). As listed in Table 10–7 on page 10–17, the DCLK minimum frequency when using the 40-MHz oscillator is 20MHz (50 ns). Therefore, the maximum configuration time estimate for an EP3C10 device (3,500,000 bits of uncompressed data) is:

RBF Size × (maximum DCLK period / 1 bit per DCLK cycle) = estimated maximum configuration time

3,500,000 bits × (50 ns / 1 bit) = 175 ms

To estimate the typical configuration time, use the typical DCLK period as listed in Figure 10–7. With a typical DCLK period of 33.33 ns, the typical configuration time is 116.7 ms. Enabling compression reduces the amount of configuration data that is transmitted to the Cyclone III device, which also reduces configuration time. On average, compression reduces configuration time by 50%.

Programming Serial Configuration Devices

Serial configuration devices are non-volatile, flash-memory-based devices. You can program these devices in-system using the USB-Blaster™or ByteBlaster II™ download cable. Alternatively, you can

program them using the Altera Programming Unit (APU), supported third-party programmers, or a microprocessor with the SRunner software driver.

You can perform in-system programming of serial configuration devices via the AS programming interface. During in-system programming, the download cable disables device access to the AS interface by driving the nCE pin high. Cyclone III devices are also held in reset by a low level on nCONFIG. After programming is complete, the download cable releases nCE and nCONFIG, allowing the pull-down and pull-up resistors to drive GND and V_{CC}, respectively. Figure 10–7 shows the download cable connections to the serial configuration device.

☞   For in-system programming of serial configuration device via the AS programming interface, the diodes and capacitors must be placed as close as possible to the Cyclone III device (refer to Figure 10–7.

Altera has developed the Serial FlashLoader (SFL), a JTAG-based in-system programming solution for Altera serial configuration devices. The SFL is a bridge design for the Cyclone III device that uses its JTAG interface to access the EPCS JIC (JTAG Indirect Configuration Device Programming) file and then uses the AS interface to program the EPCS device. Both the JTAG interface and AS interface are bridged together inside the SFL design.

For more information about the Serial FlashLoader (SFL), refer to the *AN 370: Using the Serial FlashLoader with Quartus II Software* application note on the Altera web site at **www.altera.com**.

For more information about the USB-Blaster download cable, refer to the *USB-Blaster USB Port Download Cable Data Sheet*. For more information about the ByteBlaster II cable, refer to the *ByteBlaster II Download Cable Data Sheet*.

Figure 10–7. In-System Programming of Serial Configuration Devices
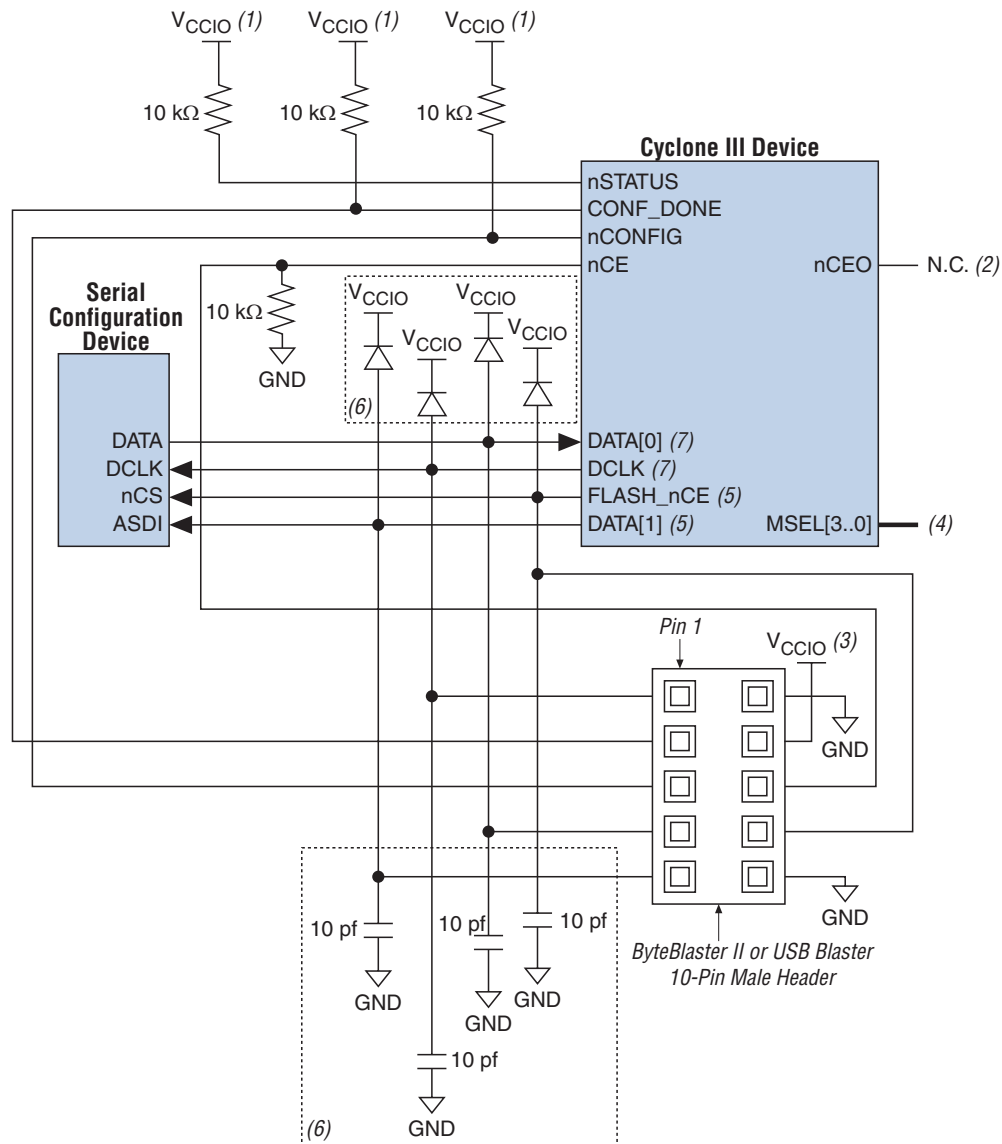

Notes to Figure 10–7:

(1)   Connect these pull-up resistors to the V_{CCIO} supply of the bank in which the pin resides.

(2)   The nCEO pin can be left unconnected or used as a user I/O pin when it does not feed other device's nCE pin.

(3)   Power up the ByteBlaster II or USB Blaster cable's V_{CC} with the V_{CCIO} supply.

(4)   The MSEL pin settings vary for different configuration voltage standards and POR time. To connect MSEL[3..0], refer to Table 10–6 on page 10–15. Connect the MSEL pins directly to V_{CCIO} or ground.

(5)   These are dual-purpose I/O pins. FLASH_nCE pin functions as the nCSO pin in AS configuration scheme. DATA[1] pin functions as the ASDO pin in AS configuration scheme.

(6)   The diodes and capacitors must be placed as close as possible to the Cyclone III device.

(7)   When cascading Cyclone III devices in a multi-device AS configuration, connect the repeater buffers between the Cyclone III master and slave device(s) for DATA[0] and DCLK. All I/O inputs must maintain a maximum AC voltage of 4.1 V. The output resistance of the repeater buffers has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13.

You can use the Quartus II software with the APU and the appropriate configuration device programming adapter to program serial configuration devices. All serial configuration devices are offered in an 8-pin or 16-pin small outline integrated circuit (SOIC) package.

In production environments, serial configuration devices can be programmed using multiple methods. Altera programming hardware or other third-party programming hardware can be used to program blank serial configuration devices before they are mounted onto printed circuit boards (PCBs). Alternatively, you can use an on-board microprocessor to program the serial configuration device in-system by porting the reference C-based software driver provided by Altera (that is, the SRunner software driver).

A serial configuration device can be programmed in-system by an external microprocessor using SRunner. SRunner is a software driver developed for embedded serial configuration device programming, which can be easily customized to fit in different embedded systems. SRunner is able to read a raw programming data (.**rpd**) file and write to the serial configuration devices. The serial configuration device programming time using SRunner is comparable to the programming time with the Quartus II software.

For more information about SRunner, refer to the *AN 418: SRunner: An Embedded Solution for Serial Configuration Device Programming* application note and the source code on the Altera web site at **www.altera.com**.

For more information on programming serial configuration devices, refer to the *Serial Configuration Devices (EPCS1, EPCS4, EPCS16 and EPCS64) Data Sheet* in the *Configuration Handbook*.

Active Parallel Configuration (Supported Flash Memories)

Cyclone III devices offer the AP configuration scheme for Altera's devices. In the AP configuration scheme, Cyclone III devices are configured using commodity 16-bit parallel flash memory. These external non-volatile configuration devices are industry standard microprocessor flash memories. The flash memories provide a fast interface to access configuration data. The speedup in configuration time is mainly due to the 16-bit wide parallel data bus which is used to retrieve data from the flash.

Some of the smaller Cyclone III devices or package options do not support the AP configuration scheme and do not have the MSEL[3] pin. For more information, refer to .

During device configuration, Cyclone III devices read configuration data via the parallel interface, and configure their SRAM cells. This scheme is referred to as the AP configuration scheme because the device controls the configuration interface. This scheme contrasts with the FPP configuration scheme, where the external host controls the interface.

☞   The Cyclone III remote system upgrade feature is available when configuring your Cyclone III device using the AP configuration scheme.

Table 10–8 shows the MSEL pin settings when using the AP configuration scheme with different configuration voltage standard.

Table 10–8. Cyclone III MSEL Pin Settings for AP Configuration Schemes (Part 1 of 2)					
Configuration Scheme	**MSEL3** *(5)*	**MSEL2** *(5)*	**MSEL1**	**MSEL0**	**Configuration Voltage Standard** *(4)*
Intel Active Parallel × 16 Fast (AP Fast POR) *(1)*, *(2)*, *(3)*	0	1	0	1	3.3 V *(6)*
Intel Active Parallel × 16 Fast (AP Fast POR) *(1)*, *(2)*, *(3)*	0	1	1	0	1.8 V
Intel Active Parallel × 16 (AP Standard POR) *(1)*, *(2)*, *(3)*	0	1	1	1	3.3 V *(6)*
Intel Active Parallel × 16 (AP Standard POR) *(1)*, *(2)*, *(3)*	1	0	0	0	1.8 V
Spansion Active Parallel × 16 Fast (AP Fast POR) *(1)*, *(2)*, *(3)*	1	0	0	1	1.8 V

Table 10–8. Cyclone III MSEL Pin Settings for AP Configuration Schemes (Part 2 of 2)					
Configuration Scheme	**MSEL3** *(5)*	**MSEL2** *(5)*	**MSEL1**	**MSEL0**	**Configuration Voltage Standard** *(4)*
Spansion Active Parallel × 16 (AP Standard POR) *(1)*, *(2)*, *(3)*	1	0	1	0	1.8 V
Intel Active Parallel x16 (AP Standard POR) *(1)*, *(2)*, *(3)*	1	0	1	1	3.0/2.5 V *(6)*

Notes to Table 10–8:

(1)   These schemes support the remote system upgrade feature. Remote update mode is supported when using remote system upgrade feature. You can enable or disable remote update mode with an option setting in the Quartus II software. For more information about the remote system upgrade feature, refer to the *Remote System Upgrade with Cyclone III Devices* chapter in the *Cyclone III Device Handbook*.

(2)   Some of the smaller Cyclone III devices or package options do not support the AP configuration scheme. For more information, refer to Table 10–2 on page 10–5.

(3)   In the AP configuration scheme, the commodity parallel flash is used as configuration memory. For information about the supported families for the commodity parallel flash, refer to Table 10–9 on page 10–32.

(4)   Configuration voltage standard applied to V_{CCIO}.

(5)   Some of the smaller Cyclone III devices or package options do not support the AP configuration scheme and do not have the MSEL[3] pin. For information about the supported configuration schemes across device densities and package options, refer to Table 10–2 on page 10–5.

(6)   You must follow specific requirements when interfacing Cyclone III devices with 2.5V/3.0V/3.3V configuration voltage standards. For information on the requirements, refer to "Configuration and JTAG Pin I/O Requirements" on page 10–13.

AP Configuration Supported Flash Memories

The AP configuration controller in Cyclone III devices is designed to interface with the StrataFlash® Embedded Memory (P30) flash family from Intel and the S29WSxxxN MirrorBit™ flash family from Spansion, which are two industry standard flash families. Unlike serial configuration devices, both of the flash families supported in AP configuration scheme are designed to interface with microprocessors. By configuring from a industry standard microprocessor flash which allows access to the flash once in user mode, the AP configuration scheme allows you to combine configuration data and user data (microprocessor boot code) on the same flash memory.

The Intel P30 flash family and the Spansion S29WS-N flash family are similar because both support a continuous synchronous burst read mode at 40MHz DCLK frequency for reading data from the flash. Additionally, the Intel P30 and Spansion S29WS-N flash families have a near identical pin-out and adopt similar protocols for data access.

☞   Cyclone III devices use a 40 MHz oscillator for the AP configuration scheme.

Table 10–9 shows the supported families of the commodity parallel flash for the AP configuration scheme.

Table 10–9. Cyclone III Supported Commodity Flash for AP Configuration Schemes *Note (1)*

Flash Memory Density	Intel P30 Flash Family *(2)*, *(4)*	Spansion S29WS-N Flash Family *(3)*, *(5)*
64 Mbit	✓	
128 Mbit	✓	✓
256 Mbit	✓	✓

Notes to Table 10–9:
(1) The AP configuration scheme only support flash memory speed grades of 40 MHz and above. Therefore, you must refer to the respective flash datasheets to check for the supported speed grades and package options.
(2) For information on the operation of the StrataFlash Embedded Memory (P30) flash memories from Intel, search for the key word *P30* on the Intel web site at **www.intel.com** to obtain the P30 family datasheet.
(3) For information on the operation of the S29WSxxxN MirrorBit flash memories from Spansion, search for the key word *S29WS-N* on the Spansion web site at **www.spansion.com** to obtain the S29WS-N family datasheet.
(4) Both 3.3 V and 1.8 V I/O options are supported for Intel P30 flash family.
(5) Only 1.8 V I/O option is supported for Spansion S29WS-N flash family.

AP configuration of Cyclone III devices supports the Intel P30 family 64 Mbit, 128 Mbit and 256 Mbit flash memories. Configuring Cyclone III devices from the Intel P30 family 512 Mbit and 1 Gbit flash memories are possible, but you need to properly drive the extra address and chip select pins as required by these flash memories.

☞ You must refer to the respective flash datasheets to check for the supported speed grades and package options. For example, the Intel P30 family only has a single speed grade at 40MHz. However, it does not support 40 MHz on the TSOP packages. Therefore, the P30 FBGA packages is supported for the AP configuration scheme, and the TSOP packages is not supported.

In addition, AP configuration of Cyclone III devices supports the 128 Mbit and 256 Mbit flash memories of the Spansion S29WS-N family. The Spansion S29WS-N family supports the 80 MHz (0S part identifier), 66 MHz (0P part identifier) and 54 MHz (0L part identifier) speed grades. The AP configuration scheme in Cyclone III devices supports all three speed grades. However, AP configuration for all three speed grades should be capped at 40 MHz. The advantage of the faster speed grades is realized when your design in the Cyclone III devices access the flash memory in user mode.

For information on the operation of the StrataFlash Embedded Memory (P30) flash memories from Intel, search for the key word "P30" on the Intel web site at **www.intel.com** to obtain the P30 family datasheet.

For information on the operation of the S29WSxxxN MirrorBit flash memories from Spansion, search for the key word "S29WS-N" on the Spansion web site at **www.spansion.com** to obtain the S29WS-N family datasheet. Refer to the 128N or 256N datasheet.

Single Device AP Configuration

The three groups of interface pins supported in the Intel P30 and Spansion S29WS-N flash memories are the control pins, the address pins, and the data pins. In the AP configuration scheme, both of the supported parallel flash memories accept DCLK, active-low reset (RST# or RESET#), active-low chip enable (CE#), active-low output enable (OE#), active-low address valid (ADV# or AVD#), and active-low write enable (WE#) as control signals from the Cyclone III device. The supported parallel flash memories output a control signal (WAIT or RDY) to the Cyclone III device to indicate when synchronous data is ready on the data bus. The Cyclone III device has a 24-bit address bus which connects to the address bus (A[24:1] or A[23..0]) of the flash memory. A 16-bit bidirectional data bus (DATA[15..0]) provides data transfer between the Cyclone III device and the flash memory.

The control signals from the Cyclone III device to the flash memory include DCLK, nRESET, FLASH_nCE, nOE, nAVD, and nWE. The interface for the Intel P30 flash memory and the Spansion S29WS-N flash memory connects to Cyclone III device pins, as shown in Figure 10–8 and Figure 10–9 respectively.

Figure 10–8. Single Device AP Configuration Using Intel P30 Flash Memory
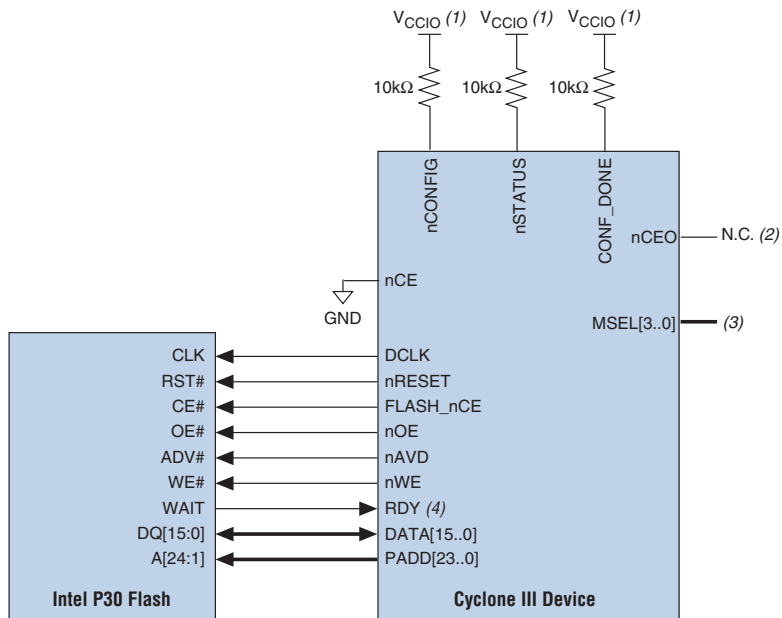

Notes to Figure 10–8:

(1)   Connect the pull-up resistors to V$_{CCIO}$ supply of the bank the pin resides in.

(2)   The nCEO pin can be left unconnected or used as a user I/O pin when it does not feed another device's nCE pin.

(3)   The MSEL pin settings vary for different configuration voltage standards and POR time. To connect MSEL[3..0], refer to Table 10–8 on page 10–30. Connect the MSEL pins directly to V$_{CCIO}$ or GND.

(4)   The current implementation for AP configuration ignores the RDY pin. However, it is recommended that you connect this pin.

Figure 10–9. Single Device AP Configuration Using Spansion S29WS-N Flash Memory
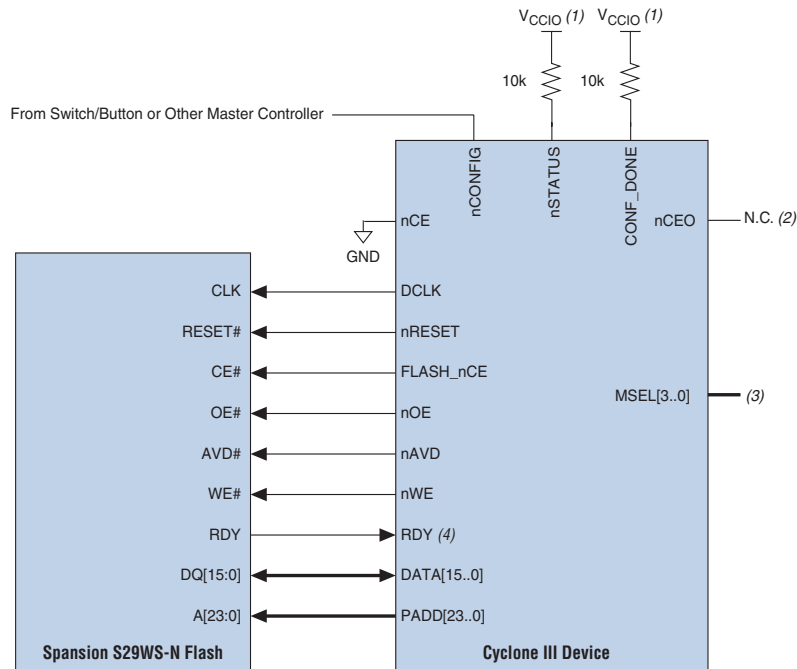

Notes to *Figure 10–9*:

(1)   Connect the pull-up resistors to V_{CCIO} supply of the bank the pin resides in.

(2)   The nCEO pin can be left unconnected or used as a user I/O pin when it does not feed another device's nCE pin.

(3)   The MSEL pin settings vary for different configuration voltage standards and POR time. To connect MSEL[3..0], refer to Table 10–8 on page 10–30. Connect the MSEL pins directly to V_{CCIO} or GND.

(4)   The current implementation for AP configuration ignores the RDY pin. However it is recommended that you connect this pin.

☞   In single device AP configuration, the board trace length between supported parallel flash to the Cyclone III device should be within a maximum of 6 inches.

The default read mode of the supported parallel flash memory is asynchronous, and all writes to the parallel flash memory are asynchronous. Both of the parallel flash families support a synchronous read mode, with data supplied on the positive edge of DCLK. nRESET is an active-low hard reset, FLASH_nCE is an active-low chip enable, nOE is an active-low output enable for the DATA[15..0] bus and WAIT/RDY pin, nAVD is an active-low address valid signal and is used to write addresses into the flash, and nWE is an active-low write enable and is used to write data into the flash. The PADD[23..0] bus is the address bus supplied to the flash. The DATA[15..0] bus is a bidirectional bus used to supply and read data to and from the flash, with the flash output controlled by nOE.

Upon power-up, the Cyclone III devices go through a POR. The POR delay is dependent on the MSEL pin settings which correspond to the configuration scheme that you select. Depending on the configuration scheme, either a fast POR time or a standard POR time is available. The fast POR time is $3ms < T_{POR} < 9ms$ for fast configuration time. The standard POR time is $50ms < T_{POR} < 200ms$, which has a lower power ramp rate. During POR, the device resets, holds nSTATUS and CONF_DONE low, and tri-states all user I/O pins. Once the device successfully exits POR, all user I/O pins continue to be tri-stated. The user I/O pins and dual-purpose I/O pins have weak pull-up resistors which are always enabled (after POR) before and during configuration.

The value of the weak pull-up resistors on the I/O pins that are on before and during configuration can be found in the *DC and Switching Characteristics* chapter of the *Cyclone III Device Handbook*.

The three stages of the configuration cycle are reset, configuration, and initialization. While nCONFIG or nSTATUS are low, the device is in reset. After POR, the Cyclone III devices release nSTATUS, which is pulled high by an external 10 KΩ pull-up resistor, and enters configuration mode.

To begin configuration, power the V_{CCINT}, V_{CCA}, and V_{CCIO} (for the banks where the configuration and JTAG pins reside) voltages to the appropriate voltage levels.

The serial clock (DCLK) generated by the Cyclone III device controls the entire configuration cycle and provides the timing for the parallel interface. Cyclone III devices use an internal oscillator to generate DCLK. Cyclone III devices use a 40 MHz oscillator for the AP configuration scheme. The oscillator is the same oscillator used in the AS configuration scheme and the active DCLK output frequency is as shown in Table 10–7 on page 10–17.

After all configuration bits are received by the Cyclone III device, it releases the open-drain CONF_DONE pin, which is pulled high by an external 10 KΩ resistor. Initialization begins only after the CONF_DONE signal reaches a logic high level. The CONF_DONE pin must have an external 10 KΩ pull-up resistor in order for the device to initialize.

In Cyclone III devices, the initialization clock source is either the 10 MHz (typical) internal oscillator (separate from the active serial internal oscillator) or the optional CLKUSR pin. By default, the internal oscillator is the clock source for initialization. If the internal oscillator is used, the Cyclone III device provides itself with enough clock cycles for proper initialization. The advantage of using the internal oscillator is you do not

need to send additional clock cycles from an external source to the CLKUSR pin during the initialization stage. Additionally, you can use the CLKUSR pin as a user I/O pin.

You also have the flexibility to synchronize initialization of multiple devices or to delay initialization with the CLKUSR option. Using the CLKUSR pin allows you to control when your device enters user mode. The device can be delayed from entering user mode for an indefinite amount of time. The **Enable user-supplied start-up clock (CLKUSR)** option can be turned on in the Quartus II software from the General tab of the **Device & Pin Options** dialog box. When you click **Enable user-supplied start-up clock (CLKUSR)**, the CLKUSR pin is the initialization clock source. Supplying a clock on CLKUSR does not affect the configuration process. After all configuration data has been accepted and CONF_DONE goes high, Cyclone III devices require 3,180 clock cycles to initialize properly and enter user mode. Cyclone III devices support a CLKUSR fMAX of 133 MHz.

An optional INIT_DONE pin is available, which signals the end of initialization and the start of user-mode with a low-to-high transition. The **Enable INIT_DONE Output** option is available in the Quartus II software from the General tab of the **Device & Pin Options** dialog box. If the INIT_DONE pin is used, it will be high due to an external 10 KΩ pull-up resistor when nCONFIG is low and during the beginning of configuration. Once the option bit to enable INIT_DONE is programmed into the device (during the first frame of configuration data), the INIT_DONE pin goes low. When initialization is complete, the INIT_DONE pin is released and pulled high. This low-to-high transition signals that the device has entered user mode. When initialization is complete, the device enters user mode. In user mode, the user I/O pins no longer have weak pull-up resistors and function as assigned in your design.

If an error occurs during configuration, Cyclone III devices assert the nSTATUS signal low, indicating a data frame error, and the CONF_DONE signal stays low. If the **Auto-restart configuration after error** option (available in the Quartus II software from the **General** tab of the **Device & Pin Options** dialog box) is turned on, the Cyclone III device resets the configuration device by pulsing FLASH_nCE, releases nSTATUS after a reset time-out period (maximum of 80 µs), and retries configuration. If this option is turned off, the system must monitor nSTATUS for errors and then pulse nCONFIG low for at least 500 ns to restart configuration.

When the Cyclone III device is in user mode, you can initiate reconfiguration by pulling the nCONFIG pin low. The nCONFIG pin should be low for at least 500 ns. When nCONFIG is pulled low, the Cyclone III device is reset. The Cyclone III device also pulls nSTATUS and

`CONF_DONE` low and all I/O pins are tri-stated. When `nCONFIG` returns to a logic high level and `nSTATUS` is released by the Cyclone III device, reconfiguration begins.

☞ If you use the optional `CLKUSR` pin and the `nCONFIG` pin is pulled low to restart configuration during device initialization, ensure `CLKUSR` continues to toggle during the time `nSTATUS` is low (a maximum of 80 µs).

For more information on configuration issues, refer to the *Debugging Configuration Problems* chapter of the *Configuration Handbook* and the FPGA Configuration Troubleshooter on the Altera web site (**www.altera.com**).

Multi-Device AP Configuration

You can configure multiple Cyclone III devices using a single parallel flash. You can cascade multiple Cyclone III devices using the chip-enable (`nCE`) and chip-enable-out (`nCEO`) pins. The first device in the chain must have its `nCE` pin connected to GND. You must connect its `nCEO` pin to the `nCE` pin of the next device in the chain. Use an external 10-kΩ pull-up resistor to pull the `nCEO` signal high to its V_{CCIO} level to help the internal weak pull-up resistor. When the first device captures all of its configuration data from the bitstream, it drives the `nCEO` pin low, enabling the next device in the chain. You can leave the `nCEO` pin of the last device unconnected or use it as a user I/O pin after configuration if the last device in the chain is a Cyclone III device. The `nCONFIG`, `nSTATUS`, `CONF_DONE`, `DCLK`, `DATA[15..8]`, and `DATA[7..0]` pins of each device in the chain are connected (refer to Figure 10–10 and Figure 10–11).

This first Cyclone III device in the chain is the configuration master and controls configuration of the entire chain. You must connect its MSEL pins to select the AP configuration scheme. The remaining Cyclone III devices are configuration slaves and you must connect their MSEL pins to select the FPP configuration scheme. Any other Altera device that supports FPP configuration can also be part of the chain as a configuration slave (refer to Figure 10–10 and Figure 10–11).

The two configurations for the `DATA[15..0]` bus in multi-device AP configuration are the byte-wide multi-device AP configuration and the word-wide multi-device AP configuration.

Byte-Wide Multi-Device AP Configuration

The first method is the byte-wide multi-device AP configuration and is the simpler form. In the byte-wide multi-device AP configuration, the least significant byte DATA[7..0] from the flash and master device set to AP configuration scheme is connected to each of the slave devices set to FPP configuration scheme, as shown in Figure 10–10.

Figure 10–10. Byte-Wide Multi-Device AP Configuration
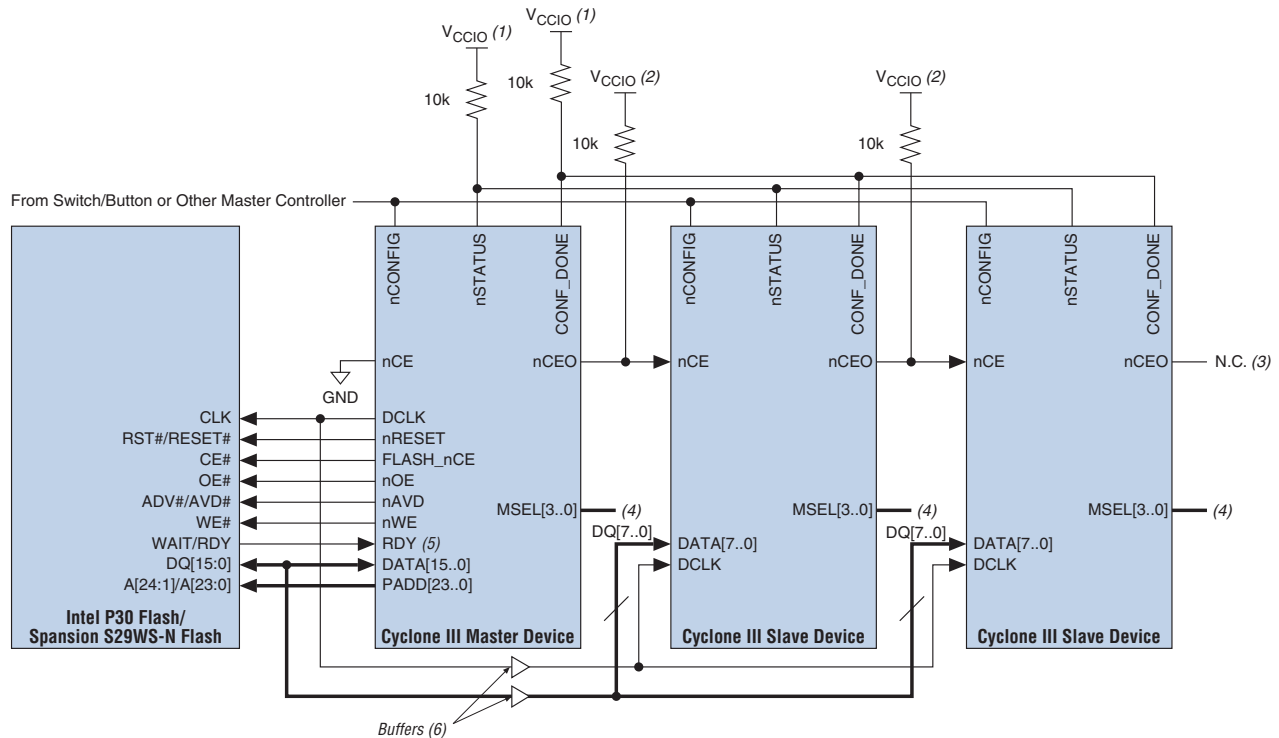

Notes to Figure 10–10:
(1) Connect the pull-up resistors to V_{CCIO} supply of the bank the pin resides in.
(2) Connect the pull-up resistor to the V_{CCIO} supply voltage of I/O bank that the nCEO pin resides in.
(3) The nCEO pin can be left unconnected or used as a user I/O pin when it does not feed another device's nCE pin.
(4) The MSEL pin settings vary for different configuration voltage standards and POR time. You must set the Cyclone III master device in AP mode and the slave devices in FPP mode. To connect MSEL[3..0] for the master device in AP mode, refer to Table 10–8 on page 10–30. To connect MSEL[3..0] for the slave devices in FPP mode, refer to Table 10–12 on page 10–61. Connect the MSEL pins directly to V_{CCIO} or GND.
(5) The current implementation for AP configuration ignores the RDY pin. However it is recommended that you connect this pin.
(6) Connect the repeater buffers between the Cyclone III master and slave device(s) for DATA[15..0] and DCLK. All I/O inputs must maintain a maximum AC voltage of 4.1V. The output resistance of the repeater buffers has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13.

Word-Wide Multi-Device AP Configuration

In the second method, the more efficient setup is where some of the slave devices are connected to the least significant byte `DATA[7..0]` and the remaining slave devices are connected to the most significant byte `DATA[15..8]`. In the word-wide multi-device AP configuration, the `nCEO` pin of the master device enables two separate daisy-chains of slave devices, allowing both chains to be programmed concurrently, as shown in Figure 10–11.

Figure 10–11. Word-Wide Multi-Device AP Configuration
Notes to Figure 10–11:

(1)   Connect the pull-up resistors to V_{CCIO} supply of the bank the pin resides in.

(2)   Connect the pull-up resistor to the V_{CCIO} supply voltage of I/O bank that the nCEO pin resides in.

(3)   The nCEO pin can be left unconnected or used as a user I/O pin when it does not feed another device's nCE pin.

(4)   The MSEL pin settings vary for different configuration voltage standards and POR time. You must set the Cyclone III master device in AP mode and the slave devices in FPP mode. To connect MSEL[3..0] for the master device in AP mode, refer to Table 10–8 on page 10–30. To connect MSEL[3..0] for the slave devices in FPP mode, refer to Table 10–12 on page 10–61. Connect the MSEL pins directly to V_{CCIO} or GND.

(5)   Currently the RDY pin does not listen during configuration. However it is recommended that you connect this pin.

(6)   Connect the repeater buffers between the Cyclone III master and slave device(s) for DATA[15..0] and DCLK. All I/O inputs must maintain a maximum AC voltage of 4.1V. The output resistance of the repeater buffers has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13.

☞ In multi-device AP configuration, the board trace length between the parallel flash to the master Cyclone III device should be within maximum of 6 inches. Additionally, you must connect the repeater buffers between the Cyclone III master and slave device(s) for DATA[15..0] and DCLK. All I/O inputs must maintain a maximum AC voltage of 4.1 V. The output resistance of the repeater buffers has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13.

As shown in Figure 10–10 and Figure 10–11, the nSTATUS and CONF_DONE pins on all target devices are connected together with external pull-up resistors. These pins are open-drain bidirectional pins on the devices. When the first device asserts nCEO (after receiving all of its configuration data), it releases its CONF_DONE pin. However, the subsequent devices in the chain keep this shared CONF_DONE line low until they have received their configuration data. When all target devices in the chain have received their configuration data and have released CONF_DONE, the pull-up resistor drives a high level on this line and all devices simultaneously enter initialization mode.

If an error occurs at any point during configuration, the nSTATUS line is driven low by the failing device. If you enable the Auto-restart configuration after error option, reconfiguration of the entire chain begins after a reset time-out period (a maximum of 80 s). If the Auto-restart configuration after error option is turned off, the external system must monitor nSTATUS for errors and then pulse nCONFIG low to restart configuration. The external system can pulse nCONFIG if it is under system control rather than tied to V_{CCIO}.

Configuring With Multiple Bus Masters

Similar to AS configuration scheme, AP configuration scheme supports multiple bus masters for the parallel flash. For another master to take control of the AP configuration bus, it must assert nCONFIG low for at least 500 ns to reset the master Cyclone III device and over-ride the weak 10 kΩ pull-down resistor on the nCE pin. This resets the master Cyclone III device and causes it to tri-state its AP configuration bus. The other master then takes control of the AP configuration bus. Once the other master is done, it must release the AP configuration bus, then release the nCE pin, and finally pulse nCONFIG low to restart reconfiguration.

In the AP configuration scheme, multiple masters can share the parallel flash. Similar to the AS configuration scheme, the bus control is negotiated by the nCE pin. The AP configuration with multiple bus masters is shown in Figure 10–12.

Figure 10–12. AP Configuration With Multiple Bus Masters
Notes to Figure 10–12:
(1)   Connect the pull-up resistors to V_{CCIO} supply of the bank the pin resides in.
(2)   The nCEO pin can be left unconnected or used as a user I/O pin when it does not feed another device's nCE pin.
(3)   The MSEL pin settings vary for different configuration voltage standards and POR time. To connect MSEL[3..0], refer to Table 10–8 on page 10–30. Connect the MSEL pins directly to V_{CCIO} or GND.
(4)   The current implementation for AP configuration ignores the RDY pin. However it is recommended that you connect this pin.
(5)   When cascading Cyclone III devices in a multi-device AP configuration, connect the repeater buffers between the Cyclone III master and slave device(s) for DATA[15..0] and DCLK. All I/O inputs must maintain a maximum AC voltage of 4.1 V. The output resistance of the repeater buffers has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13.
(6)   The other master device has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13.
(7)   The other master device can pulse nCONFIG if it is under system control rather than tied to V_{CCIO}.

Estimating AP Configuration Time

Active parallel configuration time is dominated by the time it takes to transfer data from the parallel flash to the Cyclone III device. This parallel interface is clocked by the Cyclone III DCLK output (generated from an internal oscillator). As listed in Table 10–7 on page 10–17, the DCLK minimum frequency when using the 40-MHz oscillator is 20MHz (50 ns). In the word-wide cascade programming, the DATA[15..0] bus transfers a 16-bit word and essentially cuts configuration time to approximately

1/16 that of the AS configuration time. Therefore, the maximum configuration time estimate for an EP3C10 device (3,500,000 bits of uncompressed data) is:

RBF Size × (maximum `DCLK` period / 16 bit per `DCLK` cycle) = estimated maximum configuration time

3,500,000 bits × (50 ns / 16 bit) = 10.9 ms

To estimate the typical configuration time, use the typical `DCLK` period as listed in Table 10–7 on page 10–17. With a typical `DCLK` period of 33.33ns, the typical configuration time is 7.3 ms.

Programming Parallel Flash Memories

The supported parallel flash memories are external non-volatile configuration devices. They are industry standard microprocessor flash memories.

For information on the supported families for the commodity parallel flash, refer to Table 10–9 on page 10–32.

Cyclone III devices in a single device chain or in a multiple device chain support in-system programming of a parallel flash using the JTAG interface via the flash loader megafunction. The board's intelligent host or download cable can use the four JTAG pins on the Cyclone III device to program the parallel flash in system, even if the host or download cable cannot access the parallel flash's configuration pins.

☞ The flash loader design supporting AP flash programming is a new megafunction in Quartus II software. Please contact Altera Technical Support for more information on the new megafunction.

In the AP configuration scheme, the default configuration boot address is 0×010000 in the supported parallel flash memory. This allows special parameter blocks within the flash memory map to be used by the system. The parameter blocks can be at the top or bottom of the memory map. The configuration boot address in the AP configuration scheme is shown in Figure 10–13. You can change the default configuration default boot address to any desired address using the JTAG instruction `APFC_BOOT_ADDR`.

Figure 10–13. Configuration Boot Address in AP Flash Memory Map
For information about the operation of the StrataFlash Embedded Memory (P30) flash memories from Intel, search for the key word "P30" on the Intel web site at **www.intel.com** to obtain the P30 family datasheet.

For information about the operation of the S29WSxxxN MirrorBit flash memories from Spansion, search for the key word "S29WS-N" on the Spansion web site at **www.spansion.com** to obtain the S29WS-N family datasheet. Refer to the 128N or 256N datasheet.

Passive Serial Configuration

You can perform PS configuration on Cyclone III devices with an external intelligent host, such as a MAX II device, microprocessor with flash memory, or a download cable. In the PS scheme, an external host controls configuration. Configuration data is clocked into the target Cyclone III device via the `DATA[0]` pin at each rising edge of `DCLK`.

☞   The Cyclone III decompression feature is available when configuring your Cyclone III device with the PS configuration scheme.

Table 10–10 shows the MSEL pin settings when using the PS configuration scheme with different configuration voltage standards.

Table 10–10. Cyclone III MSEL Pin Settings for PS Configuration Schemes

Configuration Scheme	MSEL3	MSEL2	MSEL1	MSEL0	Configuration Voltage Standard (2)
Passive Serial Standard (PS Standard POR) (1)	0	0	0	0	3.3/2.5 V (3)
Passive Serial Fast (PS Fast POR) (1)	1	1	0	0	3.3/2.5 V (3)

Notes to Table 10–10:
(1)   These schemes support data decompression.
(2)   Configuration voltage standard applied to V_{CCIO}.
(3)   You must follow specific requirements when interfacing Cyclone III devices with 2.5V / 3.0V / 3.3V configuration voltage standards. For information on the requirements, refer to "Configuration and JTAG Pin I/O Requirements" on page 10–13.

If your system already contains a common flash interface (CFI) flash memory, you can utilize it for the Cyclone III device configuration storage as well. The MAX II PFL feature provides an efficient method to program CFI flash memory devices through the JTAG interface and the logic to control configuration from the flash memory device to the Cyclone III device. Both PS and FPP configuration schemes are supported using this PFL feature.

👣   For more information about PFL, refer to the *AN 386: Using the MAX II Parallel Flash Loader with the Quartus II Software* application note on the Altera website at **www.altera.com**.

PS Configuration Using a MAX II Device as an External Host

In the PS configuration scheme, you can use a MAX II device as an intelligent host that controls the transfer of configuration data from a storage device, such as flash memory, to the target Cyclone III device. You

can store configuration data RBF, HEX, or TTF format. Figure 10–14 shows the configuration interface connections between a Cyclone III device and a MAX II device for single device configuration.

Figure 10–14. Single Device PS Configuration Using an External Host
Notes to Figure 10–14:
(1)   Connect the pull-up resistor to a supply that provides an acceptable input signal for the device. V_{CC} should be high enough to meet the V_{IH} specification of the I/O on the device and the external host.
(2)   The nCEO pin can be left unconnected or used as a user I/O pin when it does not feed other device's nCE pin.
(3)   The MSEL pin settings vary for different configuration voltage standards and POR time. To connect MSEL[3..0], refer to Table 10–10 on page 10–46. Connect the MSEL pins directly to V_{CCIO} or ground.
(4)   All I/O inputs must maintain a maximum AC voltage of 4.1 V. The DATA[0] and DCLK has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13.

☞   All I/O inputs must maintain a maximum AC voltage of 4.1 V. In single device PS configuration, the DATA[0] and DCLK has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13.

Upon power-up, the Cyclone III devices go through a POR. The POR delay is dependent on the MSEL pin settings which correspond to the configuration scheme that you select. Depending on the configuration scheme, either a fast POR time or a standard POR time is available. The fast POR time is 3ms < T_{POR} < 9 ms for fast configuration time. The standard POR time is 50ms < T_{POR} < 200ms which has a lower power ramp rate. During POR, the device resets, holds nSTATUS low, and tri-states all user I/O pins. Once the device successfully exits POR, all user I/O pins continue to be tri-stated. The user I/O pins and dual-purpose I/O pins have weak pull-up resistors which are always enabled (after POR) before and during configuration.

👣   For information about the value of the weak pull-up resistors on the I/O pins that are on before and during configuration can be found in the *DC and Switching Characteristics* chapter of the *Cyclone III Device Handbook*.

The three stages of the configuration cycle are reset, configuration, and initialization. While nCONFIG or nSTATUS are low, the device is in reset. To initiate configuration, the MAX II device must generate a low-to-high transition on the nCONFIG pin.

☞ To begin configuration, power the V_{CCINT}, V_{CCA}, and V_{CCIO} (for the banks where the configuration and JTAG pins reside) voltages to the appropriate voltage levels.

When nCONFIG goes high, the device comes out of reset and releases the open-drain nSTATUS pin, which is then pulled high by an external 10 KΩ pull-up resistor. Once nSTATUS is released, the device is ready to receive configuration data and the configuration stage begins. When nSTATUS is pulled high, the MAX II device should place the configuration data one bit at a time on the DATA[0] pin. If you are using configuration data in either a RBF, TTF, or HEX file, you must send the least significant bit (LSB) of each data byte first. For example, if the RBF contains the byte sequence 02 1B EE 01 FA, the serial bitstream you should transmit to the device is:

0100-0000 1101-1000 0111-0111 1000-0000 0101-1111.

The Cyclone III devices receive configuration data on the DATA[0] pin and the clock is received on the DCLK pin. Data is latched into the device on the rising edge of DCLK. Data is continuously clocked into the target device until CONF_DONE goes high. After the device has received all configuration data successfully, it releases the open-drain CONF_DONE pin, which is pulled high by an external 10 KΩ pull-up resistor. A low-to-high transition on CONF_DONE indicates configuration is complete and initialization of the device can begin. The CONF_DONE pin must have an external 10 KΩ pull-up resistor in order for the device to initialize.

In Cyclone III devices, the initialization clock source is either the internal oscillator (typically 10MHz) or the optional CLKUSR pin. By default, the internal oscillator is the clock source for initialization. If the internal oscillator is used, the Cyclone III device provides itself with enough clock cycles for proper initialization. Therefore, if the internal oscillator is the initialization clock source, sending the entire configuration file to the device is sufficient to configure and initialize the device. Driving DCLK to the device after configuration is complete does not affect device operation. Additionally, if you use the internal oscillator as the clock source, you can use the CLKUSR pin as a user I/O pin.

You also have the flexibility to synchronize initialization of multiple devices or to delay initialization with the CLKUSR option. The **Enable user-supplied start-up clock** (**CLKUSR**) option can be turned on in the Quartus II software from the **General** tab of the **Device & Pin Options**

dialog box. Supplying a clock on CLKUSR does not affect the configuration process. After all the configuration data is accepted and CONF_DONE goes high, CLKUSR is enabled after the time specified as t_{CD2CU}. After this time period elapses, Cyclone III devices require 3,180 clock cycles to initialize properly and enter user mode. Cyclone III devices support a CLKUSR f_{MAX} of 133 MHz.

An optional INIT_DONE pin is available, which signals the end of initialization and the start of user-mode with a low-to-high transition. The **Enable INIT_DONE Output** option is available in the Quartus II software from the **General** tab of the **Device & Pin Options** dialog box. If you use the INIT_DONE pin, it will be high due to an external 10 KΩ pull-up resistor when nCONFIG is low and during the beginning of configuration. Once the option bit to enable INIT_DONE is programmed into the device (during the first frame of configuration data), the INIT_DONE pin goes low. When initialization is complete, the INIT_DONE pin is released and pulled high. The MAX II device must be able to detect this low-to-high transition which signals the device has entered user mode. When initialization is complete, the device enters user mode. In user mode, the user I/O pins no longer have weak pull-up resistors and function as assigned in your design.

To ensure DCLK and DATA[0] are not left floating at the end of configuration, the MAX II device must drive them either high or low, whichever is convenient on your board. The DATA[0] pin is available as a user I/O pin after configuration. When you choose the PS scheme in the Quartus II software, the DATA[0] pin is tri-stated, by default, in user mode and should be driven by the MAX II device. To change this default option in the Quartus II software, select the **Dual-Purpose Pins** tab of the **Device & Pin Options** dialog box.

The configuration clock (DCLK) speed must be below the specified system frequency to ensure correct configuration (refer to Table 10–11 on page 10–54). No maximum DCLK period exists, which means you can pause configuration by halting DCLK for an indefinite amount of time.

If an error occurs during configuration, the device drives its nSTATUS pin low, resetting itself internally. The low signal on the nSTATUS pin also alerts the MAX II device that there is an error. If the **Auto-restart configuration after error** option (available in the Quartus II software from the **General** tab of the **Device & Pin Options** dialog box) is turned on, the Cyclone III device releases nSTATUS after a reset time-out period (maximum of 80 μs). After nSTATUS is released and pulled high by a pull-up resistor, the MAX II device can try to reconfigure the target device without needing to pulse nCONFIG low. If this option is turned off, the MAX II device must generate a low-to-high transition (with a low pulse of at least 500 ns) on nCONFIG to restart the configuration process.

The MAX II device can also monitor the CONF_DONE and INIT_DONE pins to ensure successful configuration. The CONF_DONE pin must be monitored by the MAX II device to detect errors and determine when programming completes. If all configuration data is sent, but CONF_DONE or INIT_DONE have not gone high, the MAX II device must reconfigure the target device.

☞   If the optional CLKUSR pin is being used and nCONFIG is pulled low to restart configuration during device initialization, you need to ensure that CLKUSR continues toggling during the time nSTATUS is low (maximum of 80 µs).

When the device is in user-mode, you can initiate a reconfiguration by transitioning the nCONFIG pin low-to-high. The nCONFIG pin must be low for at least 500 µs. When nCONFIG is pulled low, the device also pulls nSTATUS and CONF_DONE low and tri-states all I/O pins. Once nCONFIG returns to a logic high level and nSTATUS is released by the device, reconfiguration begins.

For more information about configuration issues, refer the *Debugging Configuration Problems* chapter of the *Configuration Handbook* and the FPGA Configuration Troubleshooter on the Altera web site at **www.altera.com**.

Figure 10–15 shows how to configure multiple devices using a MAX II device. This circuit is similar to the PS configuration circuit for a single device, except Cyclone III devices are cascaded for multi-device configuration.

Figure 10–15. Multi-Device PS Configuration Using an External Host
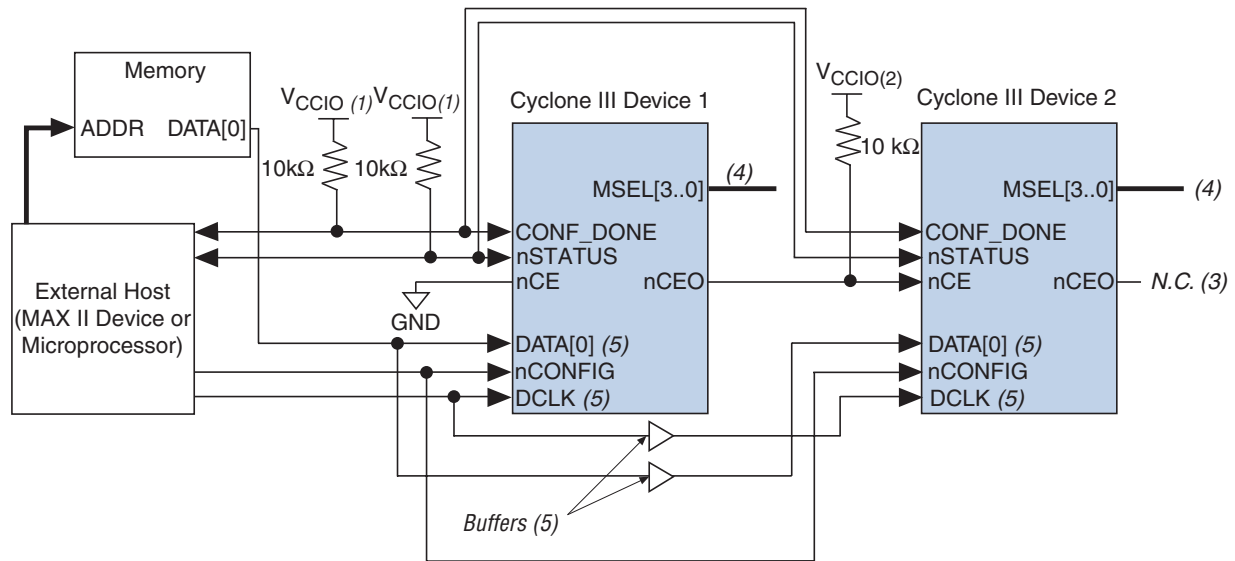

Notes to Figure 10–15:
(1) The pull-up resistor should be connected to a supply that provides an acceptable input signal for all devices in the chain. V_{CC} should be high enough to meet the V_{IH} specification of the I/O on the device and the external host.
(2) Connect the pull-up resistor to the V_{CCIO} supply voltage of I/O bank that the nCEO pin resides in.
(3) The nCEO pin can be left unconnected or used as a user I/O pin when it does not feed other device's nCE pin.
(4) The MSEL pin settings vary for different configuration voltage standards and POR time. To connect MSEL[3..0], refer to Table 10–10 on page 10–46. Connect the MSEL pins directly to V_{CCIO} or ground.
(5) All I/O inputs must maintain a maximum AC voltage of 4.1 V. The DATA[0] and DCLK has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13.

☞ All I/O inputs must maintain a maximum AC voltage of 4.1 V. In multi-device PS configuration, the DATA[0] and DCLK has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13. You must connect the repeater buffers between the Cyclone III master and slave device(s) for DATA[0] and DCLK.

In multi-device PS configuration, the first device's nCE pin is connected to GND while its nCEO pin is connected to nCE of the next device in the chain. The last device's nCE input comes from the previous device, while its nCEO pin is left floating. After the first device completes configuration in a multi-device configuration chain, its nCEO pin drives low to activate the second device's nCE pin, which prompts the second device to begin configuration. The second device in the chain begins configuration within one clock cycle. Therefore, the transfer of data destinations is transparent to the MAX II device. All other configuration pins (nCONFIG, nSTATUS, DCLK, DATA[0], and CONF_DONE) are connected to every device in the chain. Configuration signals can require buffering to ensure signal

integrity and prevent clock skew problems. Ensure that the DCLK and DATA lines are buffered. Because all device CONF_DONE pins are tied together, all devices initialize and enter user mode at the same time.

If any device detects an error, configuration stops for the entire chain and the entire chain must be reconfigured because all nSTATUS and CONF_DONE pins are tied together. For example, if the first device flags an error on nSTATUS, it resets the chain by pulling its nSTATUS pin low. This behavior is similar to a single device detecting an error.

If the **Auto-restart configuration after error** option is turned on, the devices release their nSTATUS pins after a reset time-out period (maximum of 80 μs). After all nSTATUS pins are released and pulled high, the MAX II device can try to reconfigure the chain without needing to pulse nCONFIG low. If this option is turned off, the MAX II device must generate a low-to-high transition (with a low pulse of at least 500 ns) on nCONFIG to restart the configuration process.

In your system, you can have multiple devices that contain the same configuration data. To support this configuration scheme, all device nCE inputs are tied to GND, while nCEO pins are left floating. All other configuration pins (nCONFIG, nSTATUS, DCLK, DATA[0], and CONF_DONE) are connected to every device in the chain. Configuration signals can require buffering to ensure signal integrity and prevent clock skew problems. Ensure that the DCLK and DATA lines are buffered. Devices must be the same density and package. All devices will start and complete configuration at the same time. Figure 10–16 shows multi-device PS configuration when both Cyclone III devices are receiving the same configuration data.

Figure 10–16. Multi-Device PS Configuration When Both Devices Receive the Same Data
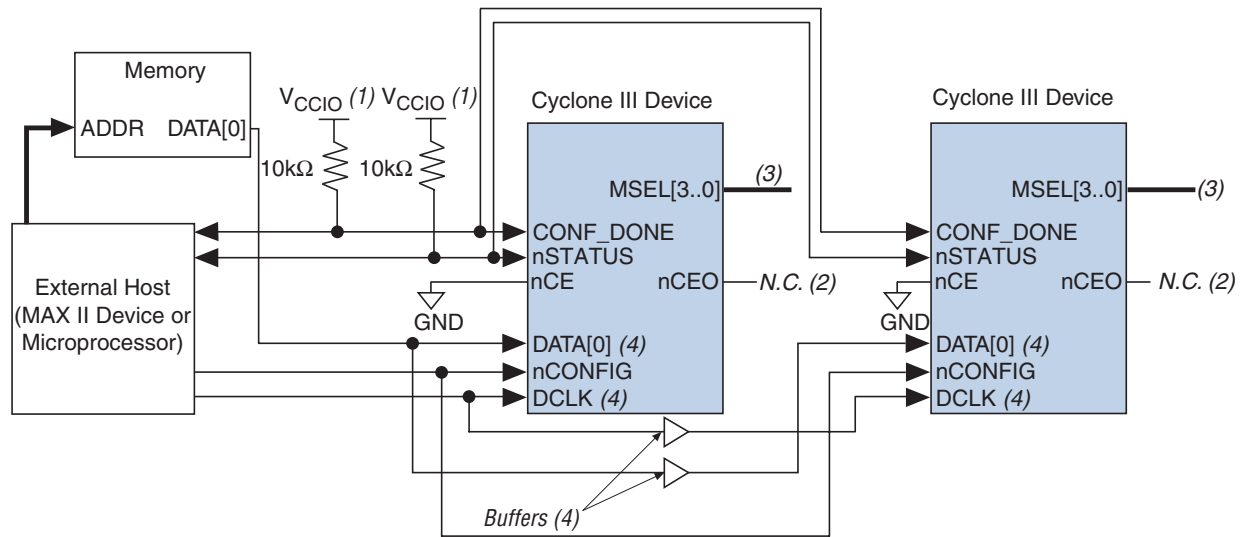

Notes to Figure 10–16:
(1) The pull-up resistor should be connected to a supply that provides an acceptable input signal for all devices in the chain. V_{CC} should be high enough to meet the V_{IH} specification of the I/O on the device and the external host.
(2) The nCEO pins of both devices can be left unconnected or used as user I/O pins when configuring the same configuration data into multiple devices.
(3) The MSEL pin settings vary for different configuration voltage standards and POR time. To connect MSEL[3..0], refer to Table 10–10 on page 10–46. Connect the MSEL pins directly to V_{CCIO} or ground.
(4) All I/O inputs must maintain a maximum AC voltage of 4.1 V. The DATA[0] and DCLK has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13.

You can use a single configuration chain to configure Cyclone III devices with other Altera devices. To ensure that all devices in the chain complete configuration at the same time or that an error flagged by one device initiates reconfiguration in all devices, all of the device CONF_DONE and nSTATUS pins must be tied together.

For more information about configuring multiple Altera devices in the same configuration chain, refer to *Configuring Mixed Altera FPGA Chains* in the *Configuration Handbook*.

PS Configuration Timing

A PS configuration must meet the setup and hold timing parameters and the maximum clock frequency. When using a microprocessor or another intelligent host to control the PS interface, ensure that you meet these timing requirements.

Figure 10–17 shows the timing waveform for PS configuration when using a MAX II device as an external host.

Figure 10–17. PS Configuration Timing Waveform   *Note (1)*
Notes to Figure 10–17:
(1)   The beginning of this waveform shows the device in user mode. In user mode, nCONFIG, nSTATUS and CONF_DONE are at logic high levels. When nCONFIG is pulled low, a reconfiguration cycle begins.
(2)   Upon power-up, the Cyclone III device holds nSTATUS low for the time of the POR delay.
(3)   Upon power-up, before and during configuration, CONF_DONE is low.
(4)   In user mode, drive DCLK either high or low when using the PS configuration scheme, whichever is more convenient. When using the AS configuration scheme, DCLK is a Cyclone III output pin and should not be driven externally.
(5)   Do not leave the DATA[0] pin floating after configuration. Drive it high or low, whichever is more convenient.

Table 10–11 defines the timing parameters for Cyclone III devices for PS configuration.

Table 10–11. PS Timing Parameters for Cyclone III Devices   (Part 1 of 2)   Note (1)

Symbol	Parameter	Minimum	Maximum	Units
t_{CF2CD}	nCONFIG low to CONF_DONE low		500	ns
t_{CF2ST0}	nCONFIG low to nSTATUS low		500	ns
t_{CFG}	nCONFIG low pulse width	500		ns
t_{STATUS}	nSTATUS low pulse width	70	230 *(2)*	µs
t_{CF2ST1}	nCONFIG high to nSTATUS high		230 *(2)*	µs
t_{CF2CK}	nCONFIG high to first rising edge on DCLK	230 *(2)*		µs
t_{ST2CK}	nSTATUS high to first rising edge of DCLK	230 *(2)*		µs
t_{DSU}	Data setup time before rising edge on DCLK	5		ns

Symbol	Parameter	Minimum	Maximum	Units
t_{DH}	Data hold time after rising edge on `DCLK`	0		ns
t_{CH}	`DCLK` high time	3.2		ns
t_{CL}	`DCLK` low time	3.2		ns
t_{CLK}	`DCLK` period	7.5		ns
f_{MAX}	`DCLK` frequency		133	MHz
t_{CD2UM}	`CONF_DONE` high to user mode *(3)*	300	650	µs
t_{CD2CU}	`CONF_DONE` high to `CLKUSR` enabled	4 × maximum `DCLK` period		
t_{CD2UMC}	`CONF_DONE` high to user mode with `CLKUSR` option on	t_{CD2CU} + (3,180 × `CLKUSR` period)		

Table 10–11. PS Timing Parameters for Cyclone III Devices   (Part 2 of 2)   Note (1)

Notes to Table 10–11:
(1)   This information is preliminary.
(2)   This value is applicable if users do not delay configuration by extending the `nCONFIG` or `nSTATUS` low pulse width.
(3)   The minimum and maximum numbers apply only if the internal oscillator is chosen as the clock source for starting the device.

For more information about device configuration options and how to create configuration files, refer to the *Software Settings* section in volume 2 of the *Configuration Handbook.*

PS Configuration Using a Microprocessor

In the PS configuration scheme, a microprocessor can control the transfer of configuration data from a storage device, such as flash memory, to the target Cyclone III device.

All information "PS Configuration Using a MAX II Device as an External Host" on page 10–46 is also applicable when using a microprocessor as an external host. Refer to that section for all configuration and timing information.

The MicroBlaster™ software driver enables you to configure Altera FPGAs, including Cyclone III devices, through the ByteBlaster II or ByteBlasterMV cable in PS mode. The MicroBlaster software driver supports a RBF programming input file and is targeted for embedded PS configuration. The source code is developed for the Windows NT operating system. You can customize it to run on other operating systems.

For more information about the MicroBlaster software driver, refer to the *AN 423: Configuring the MicroBlaster Passive Serial Software Driver* application note and source files on the Altera web site at **www.altera.com**.

☞ If you turn on the **Enable user-supplied start-up clock (CLKUSR)** option in the Quartus II software, the Cyclone III devices does not enter user mode after the MicroBlaster has transmitted all the configuration data in the RBF file. You need to supply enough initialization clock cycles to the CLKUSR pin to enter user mode.

PS Configuration Using a Download Cable

In this section, the generic term "download cable" includes the Altera USB-Blaster universal serial bus (USB) port download cable, MasterBlaster™ serial/USB communications cable, ByteBlaster II parallel port download cable, and the ByteBlaster MV parallel port download cable.

In PS configuration with a download cable, an intelligent host (such as a PC) transfers data from a storage device to the device via the USB Blaster, MasterBlaster, ByteBlaster II, or ByteBlasterMV cable.

Upon power-up, the Cyclone III devices go through a POR. The POR delay is dependent on the MSEL pin settings which correspond to the configuration scheme that you select. Depending on the configuration scheme, either a fast POR time or a standard POR time is available. The fast POR time is 3ms < T_{POR} < 9ms for fast configuration time. The standard POR time is 50ms < T_{POR} < 200ms which has a lower power ramp rate. During POR, the device resets, holds nSTATUS low, and tri-states all user I/O pins. Once the device successfully exits POR, all user I/O pins continue to be tri-stated. The user I/O pins and dual-purpose I/O pins have weak pull-up resistors which are always enabled (after POR) before and during configuration.

For information about the value of the weak pull-up resistors on the I/O pins that are on before and during configuration, refer to the *DC and Switching Characteristics* chapter of the *Cyclone III Device Handbook.*

The three stages of the configuration cycle are reset, configuration, and initialization. While nCONFIG or nSTATUS are low, the device is in reset. To initiate configuration in this scheme, the download cable generates a low-to-high transition on the nCONFIG pin.

☞   To begin configuration, power the V_{CCINT}, V_{CCA}, and V_{CCIO} (for the banks where the configuration and JTAG pins reside) voltages to the appropriate voltage levels.

When nCONFIG goes high, the device comes out of reset and releases the open-drain nSTATUS pin, which is then pulled high by an external 10 KΩ pull-up resistor. Once nSTATUS is released the device is ready to receive configuration data and the configuration stage begins. The programming hardware or download cable then places the configuration data one bit at a time on the device's DATA[0] pin. The configuration data is clocked into the target device until CONF_DONE goes high. The CONF_DONE pin must have an external 10 KΩ pull-up resistor in order for the device to initialize.

When you use a download cable, setting the **Auto-restart configuration after error** option does not affect the configuration cycle because you must manually restart configuration in the Quartus II software when an error occurs. Additionally, the **Enable user-supplied start-up clock (CLKUSR)** option has no affect on the device initialization because this option is disabled in the SRAM Object File when programming the device using the Quartus II programmer and download cable. Therefore, if you turn on the CLKUSR option, you do not need to provide a clock on CLKUSR when you are configuring the device with the Quartus II programmer and a download cable. Figure 10–18 shows PS configuration for Cyclone III devices using a USB Blaster, MasterBlaster, ByteBlaster II, or ByteBlasterMV cable.

Figure 10–18. PS Configuration Using a USB Blaster, MasterBlaster, ByteBlaster II or ByteBlasterMV Cable
Notes to Figure 10–18:

(1) The pull-up resistor should be connected to the same supply voltage as the V_{CCA} supply.

(2) The pull-up resistors on DATA[0] and DCLK are only needed if the download cable is the only configuration scheme used on your board. This is to ensure that DATA[0] and DCLK are not left floating after configuration. For example, if you are also using a configuration device, the pull-up resistors on DATA[0] and DCLK are not needed.

(3) Pin 6 of the header is a V_{IO} reference voltage for the MasterBlaster output driver. V_{IO} should match the device's V_{CCA}. Refer to the *MasterBlaster Serial/USB Communications Cable Data Sheet* for this value. In the ByteBlasterMV, this pin is a no connect. In the USB-Blaster and ByteBlaster II, this pin is connected to nCE when it is used for AS programming, otherwise it is a no connect.

(4) The nCEO pin can be left unconnected or used as a user I/O pin when it does not feed other device's nCE pin.

(5) The MSEL pin settings vary for different configuration voltage standards and POR time. To connect MSEL[3..0], refer to Table 10–10 on page 10–46 for PS Configuration Schemes. Connect the MSEL pins directly to V_{CCIO} or GND.

(6) Power up the ByteBlaster II, USB-Blaster, or ByteBlasterMV cable's V_{CC} with a 2.5V supply from V_{CCA}. Third-party programmers must switch to 2.5V. Pin 4 of the header is a V_{CC} power supply for the MasterBlaster cable. The MasterBlaster cable can receive power from either 5.0- or 3.3-V circuit boards, DC power supply, or 5.0 V from the USB cable. Refer to the *MasterBlaster Serial/USB Communications Cable Data Sheet* for this value.

☞ Power up the ByteBlaster II, USB Blaster or ByteBlasterMV cable's V_{CC} with a 2.5V supply from V_{CCA}. Third-party programmers must switch to 2.5V. Pin 4 of the header is a V_{CC} power supply for the MasterBlaster cable. The MasterBlaster cable can receive power from either 5.0- or 3.3-V circuit boards, DC power supply, or 5.0 V from the USB cable. Refer to the *MasterBlaster Serial/USB Communications Cable Data Sheet* for this value.

You can use a download cable to configure multiple Cyclone III devices by connecting each device's nCEO pin to the subsequent device's nCE pin. The first device's nCE pin is connected to GND while its nCEO pin is connected to the nCE of the next device in the chain. The last device's nCE input comes from the previous device, while its nCEO pin is left floating. All other configuration pins, nCONFIG, nSTATUS, DCLK, DATA[0], and CONF_DONE are connected to every device in the chain. Because all CONF_DONE pins are tied together, all devices in the chain initialize and enter user mode at the same time.

In addition, the entire chain halts configuration if any device detects an error because the nSTATUS pins are tied together. The **Auto-restart configuration after error** option does not affect the configuration cycle because you must manually restart configuration in the Quartus II software when an error occurs.

Figure 10–19 shows how to configure multiple Cyclone III devices with a download cable.

Figure 10–19. Multi-Device PS Configuration Using a USB Blaster, MasterBlaster, ByteBlaster II or ByteBlasterMV Cable
Notes to Figure 10–19:

(1) The pull-up resistor should be connected to the same supply voltage as the V_{CCA} supply.

(2) The pull-up resistors on DATA[0] and DCLK are only needed if the download cable is the only configuration scheme used on your board. This is to ensure that DATA[0] and DCLK are not left floating after configuration. For example, if you are also using a configuration device, the pull-up resistors on DATA[0] and DCLK are not needed.

(3) Pin 6 of the header is a V_{IO} reference voltage for the MasterBlaster output driver. V_{IO} should match the device's V_{CCA}. Refer to the MasterBlaster Serial/USB Communications Cable Data Sheet for this value. In the ByteBlasterMV, this pin is a no connect. In the USB-Blaster and ByteBlaster II, this pin is connected to nCE when it is used for AS programming, otherwise it is a no connect.

(4) Connect the pull-up resistor to the V_{CCIO} supply voltage of I/O bank that the nCEO pin resides in.

(5) The nCEO pin of the last device in chain can be left unconnected or used as a user I/O pin.

(6) The MSEL pin settings vary for different configuration voltage standards and POR time. To connect MSEL[3..0], refer to Table 10–10 on page 10–46 for PS Configuration Schemes. Connect the MSEL pins directly to V_{CCIO} or GND.

(7) Power up the ByteBlaster II, USB Blaster, or ByteBlasterMV cable's V_{CC} with a 2.5V supply from V_{CCA}. Third-party programmers must switch to 2.5 V. Pin 4 of the header is a V_{CC} power supply for the MasterBlaster cable. The MasterBlaster cable can receive power from either 5.0- or 3.3-V circuit boards, DC power supply, or 5.0 V from the USB cable. Refer to the *MasterBlaster Serial/USB Communications Cable Data Sheet* for this value.

For more information on how to use the USB Blaster, MasterBlaster, ByteBlaster II or ByteBlasterMV cables, refer to the following data sheets:

■ *USB-Blaster USB Port Download Cable Data Sheet*
■ *MasterBlaster Serial/USB Communications Cable Data Sheet*
■ *ByteBlaster II Parallel Port Download Cable Data Sheet*
■ *ByteBlasterMV Parallel Port Download Cable Data Sheet*

Fast Passive Parallel Configuration

FPP configuration in Cyclone III devices is designed to meet the continuously increasing demand for faster configuration times. Cyclone III devices are designed with the capability of receiving byte-wide configuration data per clock cycle.

Table 10–12 shows the MSEL pin settings when using the FPP configuration scheme with different configuration voltage standard.

Table 10–12. Cyclone III MSEL Pin Settings for FPP Configuration Schemes

Configuration Scheme	MSEL3	MSEL2	MSEL1	MSEL0	Configuration Voltage Standard *(2)*
Fast Passive Parallel Fast (FPP Fast POR) *(1)*	1	1	1	0	3.3/2.5 V *(3)*
Fast Passive Parallel Fast (FPP Fast POR) *(1)*	1	1	1	1	1.8/1.5 V

Notes to Table 10–12:
(1) Some of the smaller Cyclone III devices or package options do not support the FPP configuration scheme. For more information, refer to Table 10–2.
(2) Configuration voltage standard applied to V_{CCIO}.
(3) You must follow specific requirements when interfacing Cyclone III devices with 2.5V / 3.0V / 3.3V configuration voltage standards. For information on the requirements, refer to "Configuration and JTAG Pin I/O Requirements" on page 10–13.

You can perform FPP configuration of Cyclone III devices with an intelligent host, such as a MAX II device or microprocessor with flash memory.

If your system already contains a CFI flash memory, you can utilize it for the Cyclone III device configuration storage as well. The MAX II PFL feature in MAX II devices provides an efficient method to program CFI flash memory devices through the JTAG interface and the logic to control configuration from the flash memory device to the Cyclone III device. Both PS and FPP configuration schemes are supported using this PFL feature.

For more information about PFL, refer to the *AN 386: Using the MAX II Parallel Flash Loader with the Quartus II Software* application note on the Altera web site at **www.altera.com**.

FPP Configuration Using a MAX II Device as an External Host

FPP configuration using an external host provides a fast method to configure Cyclone III devices. In the FPP configuration scheme, you can use a MAX II device as an intelligent host that controls the transfer of configuration data from a storage device, such as flash memory, to the target Cyclone III device. You can store configuration data in RBF, HEX, or TTF format. When using a MAX II device as an intelligent host, a design that controls the configuration process, such as fetching the data from flash memory and sending it to the device, must be stored in the MAX II device.

Figure 10–20 shows the configuration interface connections between the Cyclone III device and a MAX II device for single device configuration.

Figure 10–20. Single Device FPP Configuration Using an External Host
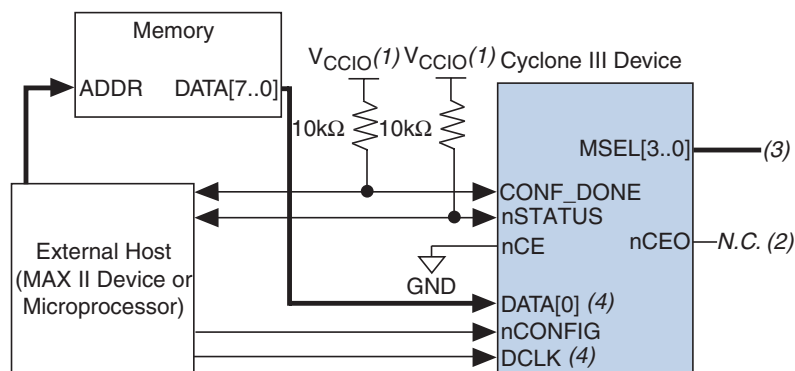

Notes to Figure 10–20:

(1) Connect the pull-up resistor to a supply that provides an acceptable input signal for the device. V_{CC} should be high enough to meet the V_{IH} specification of the I/O on the device and the external host.

(2) The nCEO pin can be left unconnected or used as a user I/O pin when it does not feed other device's nCE pin.

(3) The MSEL pin settings vary for different configuration voltage standards and POR time. To connect MSEL[3..0], refer to Table 10–12. Connect the MSEL pins directly to V_{CCIO} or GND.

(4) All I/O inputs must maintain a maximum AC voltage of 4.1 V. The DATA[7..0] and DCLK has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13.

☞ All I/O inputs must maintain a maximum AC voltage of 4.1 V. In single device FPP configuration, the DATA[7..0] and DCLK has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13.

Upon power-up, the Cyclone III devices go through a POR. The POR delay is dependent on the MSEL pin settings which correspond to the configuration scheme that you select. Depending on the configuration scheme, either a fast POR time or a standard POR time is available. The fast POR time is 3ms < T_{POR} < 9ms for fast configuration time. The standard POR time is 50ms < T_{POR} < 200ms which has a lower power ramp rate. During POR, the device resets, holds nSTATUS low, and tri-states all user I/O pins. Once the device successfully exits POR, all user I/O pins continue to be tri-stated. The user I/O pins and dual-purpose I/O pins have weak pull-up resistors which are always enabled (after POR) before and during configuration.

For more information about the value of the weak pull-up resistors on the I/O pins that are on before and during configuration, refer to the *DC and Switching Characteristics* chapter in the *Cyclone III Device Handbook*.

The three stages in the configuration cycle are reset, configuration, and initialization. While nCONFIG or nSTATUS are low, the device is in the reset stage. To initiate configuration, the MAX II device must drive the nCONFIG pin from low-to-high.

☞ To begin configuration, power the V_{CCINT}, V_{CCA}, and V_{CCIO} (for the banks where the configuration and JTAG pins reside) voltages to the appropriate voltage levels.

When nCONFIG goes high, the device comes out of reset and releases the open-drain nSTATUS pin, which is then pulled high by an external 10 KΩ pull-up resistor. Once nSTATUS is released, the device is ready to receive configuration data and the configuration stage begins. When nSTATUS is pulled high, the MAX II device places the configuration data one byte at a time on the DATA[7..0] pins.

The Cyclone III devices receive configuration data on the DATA[7..0] pins and the clock is received on the DCLK pin. Data is latched into the device on the rising edge of DCLK. Data is continuously clocked into the target device until CONF_DONE goes high. The CONF_DONE pin goes high one byte early in FPP configuration mode. The last byte is required for serial configuration (AS and PS) modes. After the device has received the next to last byte of the configuration data successfully, it releases the open-drain CONF_DONE pin, which is pulled high by an external 10 KΩ pull-up resistor. A low-to-high transition on CONF_DONE indicates configuration is complete and initialization of the device can begin. The CONF_DONE pin must have an external 10 KΩ pull-up resistor in order for the device to initialize.

In Cyclone III devices, the initialization clock source is either the internal oscillator (typically 10MHz) or the optional CLKUSR pin. By default, the internal oscillator is the clock source for initialization. If the internal oscillator is used, the Cyclone III device provides itself with enough clock cycles for proper initialization. Therefore, if the internal oscillator is the initialization clock source, sending the entire configuration file to the device is sufficient to configure and initialize the device. Driving DCLK to the device after configuration is complete does not affect device operation. Additionally, if you use the internal oscillator as the clock source, you can use the CLKUSR pin as a user I/O pin.

You can also synchronize initialization of multiple devices or to delay initialization with the CLKUSR option. The **Enable user-supplied start-up clock** (**CLKUSR**) option can be turned on in the Quartus II software from the **General** tab of the **Device & Pin Options** dialog box. Supplying a clock on CLKUSR does not affect the configuration process. The CONF_DONE pin goes high one byte early in FPP configuration mode.

The last byte is required for serial configuration (AS and PS) modes. After the CONF_DONE pin transitions high, CLKUSR is enabled after the time specified as t_{CD2CU}. After this time period elapses, Cyclone III devices require 3,180 clock cycles to initialize properly and enter user mode. Cyclone III devices support a CLKUSR f_{MAX} of 133 MHz.

An optional INIT_DONE pin is available, which signals the end of initialization and the start of user-mode with a low-to-high transition. This **Enable INIT_DONE Output** option is available in the Quartus II software from the **General** tab of the **Device & Pin Options** dialog box. If the INIT_DONE pin is used, it is high because of an external 10 KΩ pull-up resistor when nCONFIG is low and during the beginning of configuration. Once the option bit to enable INIT_DONE is programmed into the device (during the first frame of configuration data), the INIT_DONE pin goes low. When initialization is complete, the INIT_DONE pin is released and pulled high. The MAX II device must be able to detect this low-to-high transition, which signals the device has entered user mode. When initialization is complete, the device enters user mode. In user-mode, the user I/O pins no longer have weak pull-up resistors and function as assigned in your design.

To ensure DCLK and DATA[7..0] are not left floating at the end of configuration, the MAX II device must drive them either high or low, whichever is convenient on your board. The DATA[7..0] pins are available as user I/O pins after configuration. When you select the FPP scheme in the Quartus II software, these I/O pins are tri-stated in user mode by default. To change this default option in the Quartus II software, select the **Dual-Purpose Pins** tab of the **Device & Pin Options** dialog box.

The configuration clock (DCLK) speed must be below the specified frequency to ensure correct configuration. No maximum DCLK period exists, which means you can pause configuration by halting DCLK for an indefinite amount of time.

If an error occurs during configuration, the device drives its nSTATUS pin low, resetting itself internally. The low signal on the nSTATUS pin also alerts the MAX II device that there is an error. If the **Auto-restart configuration after error** option (available in the Quartus II software from the **General** tab of the **Device & Pin Options** dialog box is turned on, the device releases nSTATUS after a reset time-out period (maximum of 80 μs). After nSTATUS is released and pulled high by a pull-up resistor, the MAX II device can try to reconfigure the target device without needing to pulse nCONFIG low. If this option is turned off, the MAX II device must generate a low-to-high transition (with a low pulse of at least 500 ns) on CONFIG to restart the configuration process.

The MAX II device can also monitor the CONF_DONE and INIT_DONE pins to ensure successful configuration. The CONF_DONE pin must be monitored by the MAX II device to detect errors and determine when programming completes. If all configuration data is sent, but the CONF_DONE or INIT_DONE signals have not gone high, the MAX II device will reconfigure the target device.

☞   If the optional CLKUSR pin is used and nCONFIG is pulled low to restart configuration during device initialization, you need to ensure CLKUSR continues toggling during the time nSTATUS is low (maximum of 80 μs).

When the device is in user-mode, initiating a reconfiguration is done by transitioning the nCONFIG pin low-to-high. The nCONFIG pin should be low for at least 500 ns. When nCONFIG is pulled low, the device also pulls nSTATUS and CONF_DONE low and all I/O pins are tri-stated. When nCONFIG returns to a logic high level and nSTATUS is released by the device, reconfiguration begins.

For more information about configuration issues, refer to the *Debugging Configuration Problems* chapter of the *Configuration Handbook* and the FPGA Configuration Troubleshooter on the Altera web site at **www.altera.com**.

Figure 10–21 shows how to configure multiple devices using a MAX II device. This circuit is similar to the FPP configuration circuit for a single device, except the Cyclone III devices are cascaded for multi-device configuration.

Figure 10–21. Multi-Device FPP Configuration Using an External Host
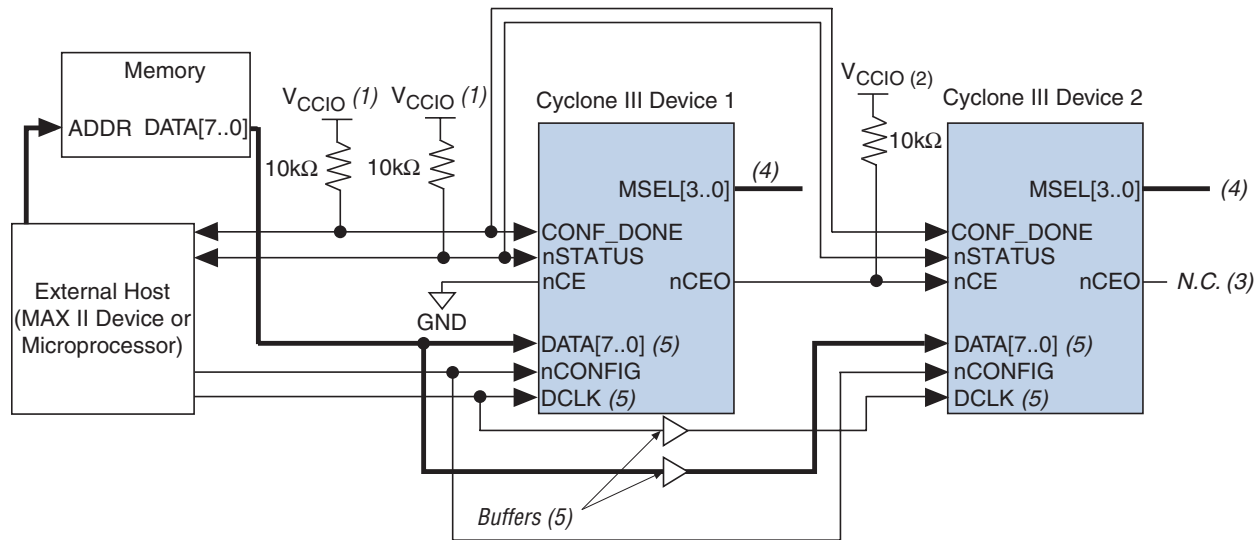

Notes to Figure 10–21:
(1) The pull-up resistor should be connected to a supply that provides an acceptable input signal for all devices in the chain. V_{CC} should be high enough to meet the V_{IH} specification of the I/O on the device and the external host.
(2) Connect the pull-up resistor to the V_{CCIO} supply voltage of I/O bank that the nCEO pin resides in.
(3) The nCEO pin can be left unconnected or used as a user I/O pin when it does not feed other device's nCE pin.
(4) The MSEL pin settings vary for different configuration voltage standards and POR time. To connect MSEL[3..0], refer to Table 10–12 on page 10–61. Connect the MSEL pins directly to V_{CCIO} or ground.
(5) All I/O inputs must maintain a maximum AC voltage of 4.1 V. The DATA[7..0] and DCLK has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13.

☞ All I/O inputs must maintain a maximum AC voltage of 4.1 V. In multi-device FPP configuration, the DATA[7..0] and DCLK has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13. You must connect the repeater buffers between the Cyclone III master and slave device(s) for DATA[7..0] and DCLK.

In multi-device FPP configuration, the first device's nCE pin is connected to GND while its nCEO pin is connected to the nCE pin of the next device in the chain. The last device's nCE input comes from the previous device, while its nCEO pin is left floating. After the first device completes configuration in a multi-device configuration chain, its nCEO pin drives low to activate the second device's nCE pin, which prompts the second device to begin configuration. The second device in the chain begins configuration within one clock cycle; therefore, the transfer of data destinations is transparent to the MAX II device. All other configuration pins (nCONFIG, nSTATUS, DCLK, DATA[7..0], and CONF_DONE) are connected to every device in the chain. The configuration signals may require buffering to ensure signal integrity and prevent clock skew

problems. Ensure that the DCLK and DATA lines are buffered. All devices initialize and enter user mode at the same time because all device CONF_DONE pins are tied together.

All nSTATUS and CONF_DONE pins are tied together and if any device detects an error, configuration stops for the entire chain and the entire chain must be reconfigured. For example, if the first device flags an error on nSTATUS, it resets the chain by pulling its nSTATUS pin low. This behavior is similar to a single device detecting an error.

If the **Auto-restart configuration after error** option is turned on, the devices release their nSTATUS pins after a reset time-out period (maximum of 80 μs). After all nSTATUS pins are released and pulled high, the MAX II device can try to reconfigure the chain without pulsing nCONFIG low. If this option is turned off, the MAX II device must generate a low-to-high transition (with a low pulse of at least 500 μs) on nCONFIG to restart the configuration process.

If a system has multiple devices that contain the same configuration data, tie all device nCE inputs to GND, and leave nCEO pins floating. All other configuration pins (nCONFIG, nSTATUS, DCLK, DATA[7..0], and CONF_DONE) are connected to every device in the chain. Configuration signals may require buffering to ensure signal integrity and prevent clock skew problems. Ensure that the DCLK and DATA lines are buffered. Devices must be the same density and package. All devices start and complete configuration at the same time. Figure 10–22 shows multi-device FPP configuration when both Cyclone III devices are receiving the same configuration data.

Figure 10–22. Multi-Device FPP Configuration Using an External Host When Both Devices Receive the Same Data
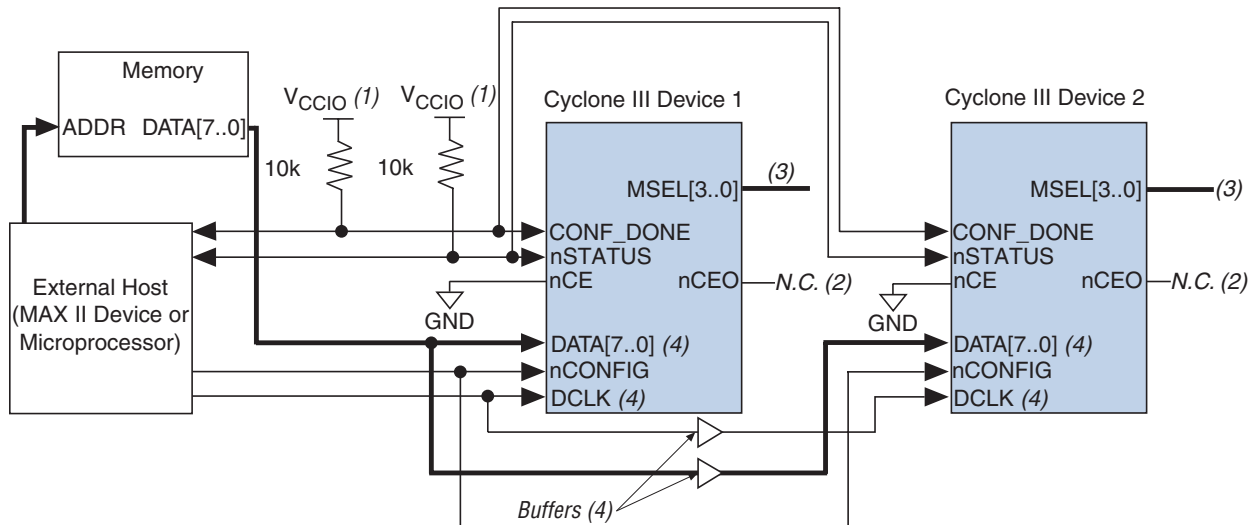

Notes to *Figure 10–22:*
(1) The pull-up resistor should be connected to a supply that provides an acceptable input signal for all devices in the chain. V_{CC} should be high enough to meet the V_{IH} specification of the I/O on the device and the external host.
(2) The nCEO pins of both devices can be left unconnected or used as user I/O pins when configuring the same configuration data into multiple devices.
(3) The MSEL pin settings vary for different configuration voltage standards and POR time. To connect MSEL[3..0], refer to Table 10–12. Connect the MSEL pins directly to V_{CCIO} or GND.
(4) All I/O inputs must maintain a maximum AC voltage of 4.1 V. The DATA[7..0] and DCLK has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13.

You can use a single configuration chain to configure Cyclone III devices with other Altera devices that support FPP configuration. To ensure that all devices in the chain complete configuration at the same time or that an error flagged by one device initiates reconfiguration in all devices, tie all of the device CONF_DONE and nSTATUS pins together.

For more information on configuring multiple Altera devices in the same configuration chain, refer to *Configuring Mixed Altera device Chains* in the *Configuration Handbook.*

FPP Configuration Timing

Figure 10–23 shows the timing waveform for FPP configuration when using a MAX II device as an external host.

Figure 10–23. FPP Configuration Timing Waveform   *Note (1)*
Notes to Figure 10–23:
(1)   The beginning of this waveform shows the device in user-mode. In user-mode, nCONFIG, nSTATUS, and CONF_DONE are at logic high levels. When nCONFIG is pulled low, a reconfiguration cycle begins.
(2)   Upon power-up, the Cyclone III device holds nSTATUS low for the time of the POR delay.
(3)   Upon power-up, before and during configuration, CONF_DONE is low.
(4)   DCLK should not be left floating after configuration. It should be driven high or low, whichever is more convenient.
(5)   DATA[7..0] are available as user I/O pins after configuration and the state of these pins depends on the dual-purpose pin settings.

Table 10–13 defines the timing parameters for Cyclone III devices for FPP configuration.

Table 10–13. FPP Timing Parameters for Cyclone III Devices   (Part 1 of 2)   Note (1)

Symbol	Parameter	Min	Max	Units
t_{CF2CD}	nCONFIG low to CONF_DONE low		500	ns
t_{CF2ST0}	nCONFIG low to nSTATUS low		500	ns
t_{CFG}	nCONFIG low pulse width	500		ns
t_{STATUS}	nSTATUS low pulse width	70	230 *(2)*	µs
t_{CF2ST1}	nCONFIG high to nSTATUS high		230 *(2)*	µs
t_{CF2CK}	nCONFIG high to first rising edge on DCLK	230 *(2)*		µs
t_{ST2CK}	nSTATUS high to first rising edge of DCLK	2		µs
t_{DSU}	Data setup time before rising edge on DCLK	5		ns
t_{DH}	Data hold time after rising edge on DCLK	0		ns

Table 10–13. FPP Timing Parameters for Cyclone III Devices   (Part 2 of 2)   Note (1)

Symbol	Parameter	Min	Max	Units
t_{CH}	DCLK high time	3.2		ns
t_{CL}	DCLK low time	3.2		ns
t_{CLK}	DCLK period	7.5		ns
f_{MAX}	DCLK frequency		133	MHz
t_{CD2UM}	CONF_DONE high to user mode *(3)*	300	650	μs
t_{CD2CU}	CONF_DONE high to CLKUSR enabled	4 × maximum DCLK period		
t_{CD2UMC}	CONF_DONE high to user mode with CLKUSR option on	t_{CD2CU}+(3,180× CLKUSR period)		

Notes to Table 10–13:
(1)   This information is preliminary.
(2)   This value is applicable if users do not delay configuration by extending the nCONFIG or nSTATUS low pulse width.
(3)   The minimum and maximum numbers apply only if the internal oscillator is chosen as the clock source for starting up the device.

For more information about device configuration options and how to create configuration files, refer to the *Software Settings* section in volume 2 of the *Configuration Handbook.*

FPP Configuration Using a Microprocessor

In the FPP configuration scheme, a microprocessor can control the transfer of configuration data from a storage device, such as flash memory, to the target Cyclone III device.

All information in "FPP Configuration Using a MAX II Device as an External Host" on page 10–62 is also applicable when using a microprocessor as an external host. Refer to that section for all configuration and timing information.

JTAG Configuration

JTAG has developed a specification for boundary-scan testing. This boundary-scan test (BST) architecture offers the capability to efficiently test components on PCBs with tight lead spacing. The BST architecture can test pin connections without using physical test probes and capture functional data while a device is operating normally. You can also use the JTAG circuitry to shift configuration data into the device. The Quartus II software automatically generates SRAM Object Files that can be used for JTAG configuration with a download cable in the Quartus II software programmer.

For more information on JTAG boundary-scan testing, refer to the following documents:

- *IEEE 1149.1 (JTAG) Boundary-Scan Testing for Cyclone III Devices* chapter in the *Cyclone III Device Handbook.*
- *Jam Programming and Testing Language Specification*

Cyclone III devices are designed such that JTAG instructions have precedence over any device configuration modes. Therefore, JTAG configuration can take place without waiting for other configuration modes to complete. For example, if you attempt JTAG configuration of Cyclone III devices during PS configuration, PS configuration terminates and JTAG configuration begins. If the Cyclone III MSEL pins are set to AS mode, the Cyclone III device does not output a DCLK signal when JTAG configuration takes place.

☞ You cannot use the Cyclone III decompression feature if you are configuring your Cyclone III device when using JTAG-based configuration.

The four required pins for a device operating in JTAG mode are TDI, TDO, TMS, and TCK. The TCK pin has an internal weak pull-down resistor, while the TDI, and TMS pins have weak internal pull-up resistors (typically 25 kΩ). The TDO output pin is powered by V_{CCIO} in I/O bank 1. All of the JTAG input pins are powered by the V_{CCIO} pin. All the JTAG pins support only LVTTL I/O standard. All user I/O pins are tri-stated during JTAG configuration. Table 10–14 explains each JTAG pin's function.

☞ The TDO output is powered by the V_{CCIO} power supply of I/O bank 1. For recommendations on how to connect a JTAG chain with multiple voltages across the devices in the chain, refer to the *IEEE 1149.1 (JTAG) Boundary Scan Testing for Cyclone III Devices* chapter in the *Cyclone III Device Handbook*.

Table 10–14. Dedicated JTAG Pins		
Pin Name	**Pin Type**	**Description**
TDI	Test data input	Serial input pin for instructions as well as test and programming data. Data is shifted in on the rising edge of TCK. If the JTAG interface is not required on the board, the JTAG circuitry can be disabled by connecting this pin to V_{CC}.
TDO	Test data output	Serial data output pin for instructions as well as test and programming data. Data is shifted out on the falling edge of TCK. The pin is tri-stated if data is not being shifted out of the device. If the JTAG interface is not required on the board, the JTAG circuitry can be disabled by leaving this pin unconnected.

Table 10–14. Dedicated JTAG Pins		
Pin Name	**Pin Type**	**Description**
TMS	Test mode select	Input pin that provides the control signal to determine the transitions of the TAP controller state machine. Transitions within the state machine occur on the rising edge of TCK. Therefore, TMS must be set up before the rising edge of TCK. TMS is evaluated on the rising edge of TCK. If the JTAG interface is not required on the board, the JTAG circuitry can be disabled by connecting this pin to VCC.
TCK	Test clock input	The clock input to the BST circuitry. Some operations occur at the rising edge, while others occur at the falling edge. If the JTAG interface is not required on the board, the JTAG circuitry can be disabled by connecting this pin to GND.

You can download data to the device on the PCB through the USB Blaster, MasterBlaster, ByteBlaster II, or ByteBlasterMV download cable during JTAG configuration. Configuring devices through a cable is similar to programming devices in-system. Figure 10–24 shows JTAG configuration of a single Cyclone III device.

Figure 10–24. JTAG Configuration of a Single Device Using a Download Cable
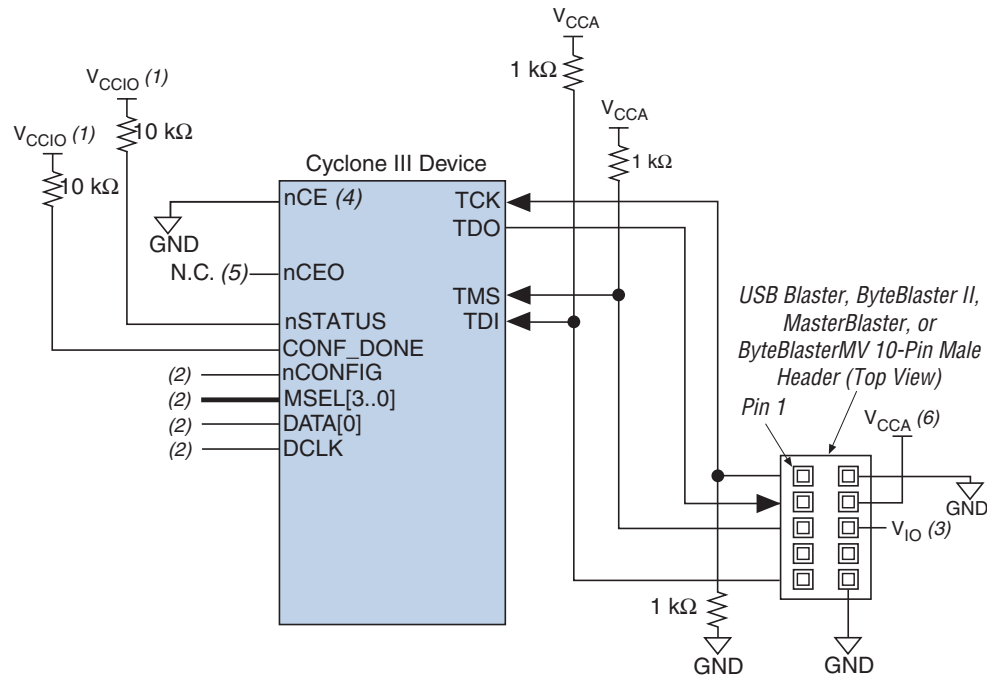

Notes to Figure 10–24:
(1) The pull-up resistor should be connected to the same supply voltage as the USB-Blaster, MasterBlaster (V_{IO} pin), ByteBlaster II, or ByteBlasterMV cable.
(2) Connect the `nCONFIG` and `MSEL[3..0]` pins to support a non-JTAG configuration scheme. If only JTAG configuration is used, connect the `nCONFIG` pin to V_{CC}, and the `MSEL[3..0]` pins to ground. In addition, pull `DCLK` and `DATA[0]` to either high or low, whichever is convenient on your board.
(3) Pin 6 of the header is a V_{IO} reference voltage for the MasterBlaster output driver. V_{IO} should match the device's V_{CCA}. Refer to the *MasterBlaster Serial/USB Communications Cable Data Sheet* for this value. In the ByteBlasterMV, this pin is a no connect. In the USB-Blaster and ByteBlaster II, this pin is connected to `nCE` when it is used for AS programming, otherwise it is a no connect.
(4) `nCE` must be connected to GND or driven low for successful JTAG configuration.
(5) The `nCEO` pin can be left unconnected or used as a user I/O pin when it does not feed other device's `nCE` pin.
(6) Power up the ByteBlaster II, USB Blaster, or ByteBlasterMV cable's V_{CC} with a 2.5V supply from V_{CCA}. Third-party programmers must switch to 2.5V. Pin 4 of the header is a V_{CC} power supply for the MasterBlaster cable. The MasterBlaster cable can receive power from either 5.0- or 3.3-V circuit boards, DC power supply, or 5.0 V from the USB cable. Refer to the *MasterBlaster Serial/USB Communiaties Cable Data Sheet* for this value.

☞ Power up the ByteBlaster II, USB Blaster, or ByteBlasterMV cable's V_{CC} with a 2.5V supply from V_{CCA}. Third-party programmers must switch to 2.5V. Pin 4 of the header is a V_{CC} power supply for the MasterBlaster cable. The MasterBlaster cable can receive power from either 5.0- or 3.3-V circuit boards, DC power supply, or 5.0 V from the USB cable. Refer to the *MasterBlaster Serial/USB Communications Cable Data Sheet* for this value.

To configure a single device in a JTAG chain, the programming software places all other devices in bypass mode. In bypass mode, devices pass programming data from the TDI pin to the TDO pin through a single bypass register without being affected internally. This scheme enables the programming software to program or verify the target device. Configuration data driven into the device appears on the TDO pin one clock cycle later.

The Quartus II software verifies successful JTAG configuration upon completion. At the end of configuration, the software checks the state of CONF_DONE through the JTAG port. When Quartus II generates a (.**jam**) file for a multi-device chain, it contains instructions so that all the devices in the chain are initialized at the same time. If CONF_DONE is not high, the Quartus II software indicates that configuration has failed. If CONF_DONE is high, the software indicates that configuration was successful. After the configuration bitstream is transmitted serially via the JTAG TDI port, the TCK port is clocked an additional 3,180 cycles to perform device initialization.

Cyclone III devices have dedicated JTAG pins that always function as JTAG pins. Not only can you perform JTAG testing on Cyclone III devices before and after, but also during configuration. Cyclone III devices support the BYPASS, IDCODE, and SAMPLE instructions during configuration without interrupting configuration. All other JTAG instructions may only be issued by first interrupting configuration and reprogramming I/O pins using the ACTIVE_DISENGAGE and CONFIG_IO instructions.

The CONFIG_IO instruction allows I/O buffers to be configured via the JTAG port and when issued after the ACTIVE_DISENGAGE instruction, interrupts configuration. This instruction allows you to perform board-level testing prior to configuring the Cyclone III device or waiting for a configuration device to complete configuration. In Cyclone III devices, prior to issuing the CONFIG_IO instruction, you must issue the ACTIVE_DISENGAGE instruction. This is because in Cyclone III devices, the CONFIG_IO instruction does not hold nSTATUS low until reconfiguration, so you must disengage the active configuration mode controller when active configuration is interrupted. The ACTIVE_DISENGAGE instruction places the active configuration mode controllers in an idle state prior to JTAG programming. Additionally, the ACTIVE_ENGAGE instruction allows you to re-engage an already disengaged active configuration mode controller.

☞ You must follow a specific flow when executing the CONFIG_IO, ACTIVE_DISENGAGE, and ACTIVE_ENGAGE JTAG instructions in Cyclone III devices. For information on the instruction flow, refer to "JTAG Configuration" on page 10–70

The chip-wide reset (DEV_CLRn) and chip-wide output enable (DEV_OE) pins on Cyclone III devices do not affect JTAG boundary-scan or programming operations. Toggling these pins does not affect JTAG operations (other than the usual boundary-scan operation).

When designing a board for JTAG configuration of Cyclone III devices, consider the dedicated configuration pins. Table 10–15 shows how these pins should be connected during JTAG configuration.

Table 10–15. Dedicated Configuration Pin Connections During JTAG Configuration	
Signal	**Description**
nCE	On all Cyclone III devices in the chain, nCE should be driven low by connecting it to ground, pulling it low via a resistor, or driving it by some control circuitry. For devices that are also in multi-device AS, AP, PS, or FPP configuration chains, the nCE pins should be connected to GND during JTAG configuration or JTAG configured in the same order as the configuration chain.
nCEO	On all Cyclone III devices in the chain, nCEO can be left floating or connected to the nCE of the next device.
MSEL[3..0]	These pins must not be left floating. These pins support whichever non-JTAG configuration is used in production. If only JTAG configuration is used, tie these pins to GND.
nCONFIG	Driven high by connecting to V_{CC}, pulling up via a resistor, or driven high by some control circuitry.
nSTATUS	Pull to V_{CC} via a 10 KΩ resistor. When configuring multiple devices in the same JTAG chain, each nSTATUS pin should be pulled up to V_{CC} individually.
CONF_DONE	Pull to V_{CC} via a 10 KΩ resistor. When configuring multiple devices in the same JTAG chain, each CONF_DONE pin should be pulled up to V_{CC} individually. CONF_DONE going high at the end of JTAG configuration indicates successful configuration.
DCLK	Should not be left floating. Drive low or high, whichever is more convenient on your board.

When programming a JTAG device chain, one JTAG-compatible header is connected to several devices. The number of devices in the JTAG chain is limited only by the drive capability of the download cable. When four or more devices are connected in a JTAG chain, Altera recommends buffering the TCK, TDI, and TMS pins with an on-board buffer.

JTAG-chain device programming is ideal when the system contains multiple devices, or when testing your system using JTAG BST circuitry. Figure 10–25 shows a multi-device JTAG configuration.

Figure 10–25. JTAG Configuration of Multiple Devices Using a Download Cable
Notes to Figure 10–25:

(1) The pull-up resistor should be connected to the same supply voltage as the USB-Blaster, MasterBlaster (V_{IO} pin), ByteBlaster II or ByteBlasterMV cable.

(2) Connect the nCONFIG and MSEL[3..0] pins to support a non-JTAG configuration scheme. If only JTAG configuration is used, connect the nCONFIG pin to V_{CC}, and the MSEL[3..0] pins to ground. In addition, pull DCLK and DATA[0] to either high or low, whichever is convenient on your board.

(3) Pin 6 of the header is a V_{IO} reference voltage for the MasterBlaster output driver. V_{IO} should match the device's V_{CCA}. Refer to the *MasterBlaster Serial/USB Communications Cable Data Sheet* for this value. In the ByteBlasterMV cable, this pin is a no connect. In the USB-Blaster and ByteBlaster II cable, this pin is connected to nCE when it is used for AS programming, otherwise it is a no connect.

(4) nCE must be connected to ground or driven low for successful JTAG configuration.

(5) Power up the ByteBlaster II, USB Blaster, or ByteBlasterMV cable's V_{CC} with a 2.5V supply from V_{CCA}. Third-party programmers must switch to 2.5 V. Pin 4 of the header is a V_{CC} power supply for the MasterBlaster cable. The MasterBlaster cable can receive power from either 5.0- or 3.3-V circuit boards, DC power supply, or 5.0 V from the USB cable. Refer to the *MasterBlaster Serial/USB Communications Data Sheet* for this value.

☞ Power up the ByteBlaster II or USB Blaster cable's V_{CC} with a 2.5V supply from V_{CCA}. Third-party programmers must switch to 2.5V.

☞ All I/O inputs must maintain a maximum AC voltage of 4.1V. If a non-Cyclone III device is cascaded in the JTAG-chain, TDO of the non-Cyclone III device driving into TDI of Cyclone III has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13.

The nCE pin must be connected to GND or driven low during JTAG configuration. In multi-device AS, AP, PS, and FPP configuration chains, the first device's nCE pin is connected to GND while its nCEO pin is connected to the nCE pin of the next device in the chain. The last device's

input for the nCE pin comes from the previous device, while its nCEO pin is left floating. In addition, the CONF_DONE and nSTATUS signals are all shared in multi-device AS, AP, PS, and FPP configuration chains so the devices can enter user mode at the same time after configuration is complete. When the CONF_DONE and nSTATUS signals are shared among all the devices, every device must be configured when JTAG configuration is performed.

If you only use JTAG configuration, Altera recommends that you connect the circuitry as shown in Figure 10–25, where each of the CONF_DONE and nSTATUS signals are isolated so that each device can enter user mode individually.

After the first device completes configuration in a multi-device configuration chain, its nCEO pin drives low to activate the second device's nCE pin, which prompts the second device to begin configuration. Therefore, if these devices are also in a JTAG chain, make sure the nCE pins are connected to GND during JTAG configuration or that the devices are JTAG configured in the same order as the configuration chain. As long as the devices are JTAG configured in the same order as the multi-device configuration chain, the nCEO of the previous device drives the nCE pin of the next device low when it has successfully been JTAG configured.

You can place other Altera devices that have JTAG support in the same JTAG chain for device programming and configuration.

☞ JTAG configuration allows an unlimited number of Cyclone III devices to be cascaded in a JTAG chain.

For more information about configuring multiple Altera devices in the same configuration chain, refer to the *Configuring Mixed Altera Device Chains* chapter in the *Configuration Handbook*.

Figure 10–26 shows JTAG configuration of a Cyclone III device with a microprocessor.

Figure 10–26. JTAG Configuration of a Single Device Using a Microprocessor
Notes to Figure 10–26:
(1) The pull-up resistor should be connected to a supply that provides an acceptable input signal for all devices in the chain.
(2) Connect the nCONFIG and MSEL[3..0] pins to support a non-JTAG configuration scheme. If only JTAG configuration is used, connect the nCONFIG pin to V_{CC}, and the MSEL[3..0] pins to ground. In addition, pull DCLK and DATA[0] to either high or low, whichever is convenient on your board.
(3) nCE must be connected to GND or driven low for successful JTAG configuration.
(4) All I/O inputs must maintain a maximum AC voltage of 4.1 V. Signals driving into TDI, TMS, and TCK has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13.

☞   All I/O inputs must maintain a maximum AC voltage of 4.1 V. Signals driving into TDI, TMS, and TCK has to fit the maximum overshoot equation outlined in "Configuration and JTAG Pin I/O Requirements" on page 10–13.

Jam STAPL

Jam STAPL, JEDEC standard JESD-71, is a standard file format for in-system programmability (ISP) purposes. Jam STAPL supports programming or configuration of programmable devices and testing of electronic systems, using the IEEE 1149.1 JTAG interface. Jam STAPL is a freely licensed open standard.

The Jam Player provides an interface for manipulating the IEEE Std. 1149.1 JTAG TAP state machine.

👣   For more information about JTAG and Jam STAPL in embedded environments, refer to the *AN 122: Using Jam STAPL for ISP and ICR via an Embedded Processor*. To download the jam player, visit the Altera web site at **www.altera.com.**

Configuring Cyclone III Devices with JRunner

☞ This section provides preliminary information on the JRunner. The JRunner software driver support for Cyclone III devices will be available soon. Please contact Altera Technical Support for more information.

JRunner is a software driver that allows you to configure Cyclone III devices through the ByteBlaster II or ByteBlasterMV cables in JTAG mode. The programming input file supported is in RBF format. JRunner also requires a Chain Description File (**.cdf**) generated by the Quartus II software. JRunner is targeted for embedded JTAG configuration. The source code has been developed for the Windows NT operating system (OS). You can customize the code to make it run on your embedded platform.

☞ The RBF used by the JRunner software driver can not be a compressed RBF because JRunner uses JTAG-based configuration. During JTAG-based configuration, the real-time decompression feature is not available.

For more information about the JRunner software driver, refer to the *AN 414: JRunner Software Driver: An Embedded Solution for PLD JTAG Configuration* application note and the source files on the Altera web site at **www.altera.com**.

Combining JTAG and Active Serial Configuration Schemes

You can combine the AS configuration scheme with JTAG-based configuration (Figure 10–27). This setup uses two 10-pin download cable headers on the board. One download cable is used in JTAG mode to configure the Cyclone III device directly via the JTAG interface. The other download cable is used in AS mode to program the serial configuration device in-system via the AS programming interface. The MSEL[3..0] pins should be set to select the AS configuration mode (refer to Table 10–6 on page 10–15). If you try configuring the device using both schemes simultaneously, JTAG configuration takes precedence and AS configuration terminates.

Figure 10–27. Combining JTAG and AS Configuration Schemes
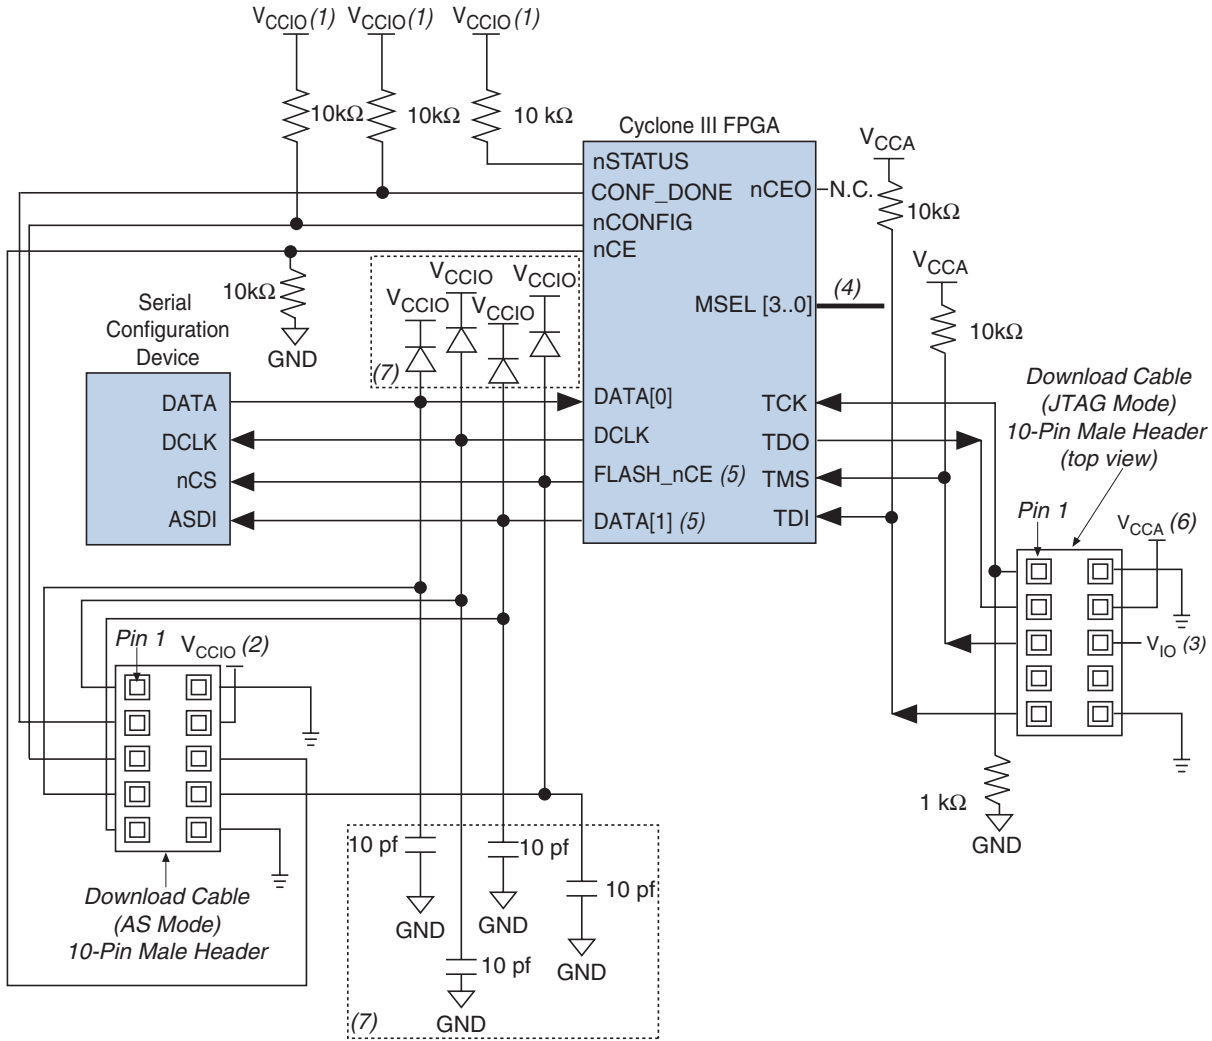

Notes to Figure 10–27:
(1) Connect these pull-up resistors to the V_{CCIO} supply of the bank in which the pin resides.
(2) Power up the ByteBlaster II or USB Blaster cable's V_{CC} with the V_{CCIO} supply.
(3) Pin 6 of the header is a V_{IO} reference voltage for the MasterBlaster output driver. V_{IO} should match the device's V_{CCA}. Refer to the *MasterBlaster Serial/USB Communications Cable Data Sheet* for this value. In the ByteBlasterMV, this pin is a no connect. In the USB-Blaster and ByteBlaster II, this pin is connected to nCE when it is used for AS programming, otherwise it is a no connect.
(4) The MSEL pin settings vary for different configuration voltage standards and POR time. To connect MSEL[3..0], refer to Table 10–6 on page 10–15 for AS Configuration Schemes. Connect the MSEL pins directly to V_{CCIO} or GND.
(5) These are dual-purpose I/O pins. The FLASH_nCE pin functions as the nCSO pin in AS configuration scheme. The DATA[1] pin functions as the ASDO pin in AS configuration scheme.
(6) Power up the ByteBlaster II, USB Blaster, or ByteBlasterMV cable's V_{CC} with a 2.5V supply from V_{CCA}. Third-party programmers must switch to 2.5 V. Pin 4 of the header is a V_{CC} power supply for the MasterBlaster cable. The MasterBlaster cable can receive power from either 5.0- or 3.3-V circuit boards, DC power supply, or 5.0 V from the USB cable. Refer to the *MasterBlaster Serial/USB Communications Cable Data Sheet* for this value.
(7) The diodes and capacitors must be placed as close as possible to the Cyclone III device.

Cyclone III JTAG Instructions

This section describes some JTAG instructions for Cyclone III devices. These instructions are CONFIG_IO, ACTIVE_DISENGAGE, ACTIVE_ENGAGE, EN_ACTIVE_CLK, DIS_ACTIVE_CLK, and APFC_BOOT_ADDR.

For information on the JTAG binary instruction code, refer to the *IEEE 1149.1 (JTAG) Boundary Scan Testing for Cyclone III Devices* chapter in the *Cyclone III Device Handbook.*

I/O Reconfiguration

The CONFIG_IO instruction is used to reconfigure the I/O configuration shift register (IOCSR) chain. This instruction allows you to perform board-level testing prior to configuring the Cyclone III device or waiting for a configuration device to complete configuration. Once configuration has been interrupted and JTAG testing is complete, the part must be reconfigured via JTAG (PULSE_NCONFIG instruction) or by pulsing nCONFIG pin low.

You can issue the CONFIG_IO instruction any time during user mode. The CONFIG_IO instruction cannot be issued while nCONFIG pin is asserted low (during power up) or immediately after issuing a JTAG instruction that triggers reconfiguration. Refer to Table 10–16 on page 10–82 on the wait-time for issuing the CONFIG_IO instruction.

You must meet the following timing restrictions when using CONFIG_IO instruction:

- CONFIG_IO instruction cannot be issued during nCONFIG pin low
- Must observe 200 μs minimum wait time after, either one of the following conditions:
    - nCONFIG pin goes high
    - issuing PULSE_NCONFIG instruction
    - issuing ACTIVE_ENGAGE instruction, before issuing CONFIG_IO instruction
- Must wait 200 μs after power up, with nCONFIG pin high before issuing CONFIG_IO instruction (or wait for nSTATUS pin goes high).

Table 10–16. Wait Time for Issuing CONFIG_IO Instruction

Wait Time	TIme
Wait time after `nCONFIG` pin is released.	200 µs
Wait time after `PULSE_NCONFIG` or `ACTIVE_ENGAGE` is issued	200 µs

The `ACTIVE_DISENGAGE` instruction can be used together with `CONFIG_IO` instruction to interrupt configuration. Table 10-17 shows the sequence of instructions to use for various CONFIG_IO usage scenarios.

Table 10–17. JTAG CONFIG_IO (Without JTAG_PROGRAM) Instruction Flows Note (1), (2)

JTAG Instruction	Native configuration scheme and current state of the Cyclone III device											
	Prior to user mode (interrupting native configuration)				User mode				Power up			
	PS	FPP	AS	AP	PS	FPP	AS	AP	PS	FPP	AS	AP
`ACTIVE_DISENGAGE`	O	O	O	O	O	O	O	O	-	-	-	-
`CONFIG_IO`	R	R	R	R	R	R	R	R	NA	NA	NA	NA
JTAG Boundary Scan Instructions (no `JTAG_PROGRAM`)	O	O	O	O	O	O	O	O	-	-	-	-
`ACTIVE_ENGAGE`	A	A	R	R	A	A	R	R	-	-	-	-
`PULSE_NCONFIG`			O	O			O	O	-	-	-	-
Pulse `nCONFIG` pin			O	O			O	O	-	-	-	-
JTAG TAP Reset	R	R	R	R	R	R	R	R	-	-	-	-

Notes to Table 10–17 :
(1) "R" indicates required, "O" indicates optional, "A" indicates any of these instructions, and "NA" indicates not allowed.
(2) Required if `ACTIVE_ENGAGE` is used.

The instructions `ACTIVE_DISENGAGE` and `ACTIVE_ENGAGE` are unique to Cyclone III devices, and are related to the change to `CONFIG_IO` instruction. Unlike Cyclone II devices, the `CONFIG_IO` instruction does not control the `nSTATUS` pin in Cyclone III devices. Since in Cyclone III devices, the `CONFIG_IO` instruction does not hold `nSTATUS` pin low until

reconfiguration, you must disengage the active configuration (AS, and AP) controllers when active configuration is interrupted. You must issue the `ACTIVE_DISENGAGE` instruction alone or prior to `CONFIG_IO` instruction if the `JTAG_PROGRAM` instruction is to be issued later (refer to Table 10–18). This puts the AP controller into the "chill-out" state, and the AS controller into the "idle" state. The active configuration controller will be enabled when Cyclone III devices completes reconfiguration using `JTAG_PROGRAM` instruction.

☞ While executing the CONFIG_IO instruction, all user IOs are tri-stated.

If reconfiguration after interruption is done using native modes (rather than using `JTAG_PROGRAM`), then it is not necessary to issue `ACTIVE_DISENGAGE` instruction prior to `CONFIG_IO`. You can initiate reconfiguration by either pulling `nCONFIG` pin low for at least 500 ns, or issuing `PULSE_NCONFIG` instruction. In the case `ACTIVE_DISENGAGE` instruction was issued and `JTAG_PROGRAM` instruction is unsuccessful to usermode, you must issue the `ACTIVE_ENGAGE` instruction to reactivate the active configuration (AS, and AP) controller. Issuing `ACTIVE_ENGAGE` instruction also will trigger reconfiguration in native modes, therefore it is not necessary to pull `nCONFIG` pin low or issuing `PULSE_NCONFIG` instruction.

ACTIVE_DISENGAGE

The `ACTIVE_DISENGAGE` is a unique JTAG instruction on Cyclone III devices that places the active configuration (AS, and AP) controllers into an "idle" state prior to JTAG programming. The active configuration controllers are the AS controller when the MSEL pins are set to AS configuration scheme, and the AP controller when the MSEL pins are set to AP configuration scheme. The two purposes of placing the active controllers in an idle state is to ensure that they are not trying to configure the device in their respective native modes during JTAG programming and to allow the controllers to properly recognize a successful JTAG programming that results in the device reaching usermode.

The new `ACTIVE_DISENGAGE` instruction is required before JTAG Programming regardless of the current state of the Cyclone III device if the MSEL pins are set to an active configuration mode. The `ACTIVE_DISENGAGE` instruction can be issued during a passive configuration scheme (PS, or FPP), it will just have no effect on the Cyclone III device. Similarly, the `CONFIG_IO` instruction can be issued after an `ACTIVE_DISENGAGE` instruction, but is no longer required to properly halt native configuration. Refer to Table 10–18 for a summary of

the required, recommended and optional instructions for each native configuration mode. The ordering of the required instructions is a hard requirement and must be met to ensure functionality.

Table 10–18. JTAG Programming Instruction Flows Note (1)												
JTAG Instruction	**Native configuration scheme and current state of the Cyclone III device**											
	Prior to user mode (interrupting native configuration)				**User mode**				**Power up**			
	PS	**FPP**	**AS**	**AP**	**PS**	**FPP**	**AS**	**AP**	**PS**	**FPP**	**AS**	**AP**
ACTIVE_DISENGAGE	O	O	R	R	O	O	O	R	O	O	R	R
CONFIG_IO	Rc	Rc	O	O	O	O	O	O	NA	NA	NA	NA
Other JTAG instructions	O	O	O	O	O	O	O	O	O	O	O	O
JTAG_PROGRAM	R	R	R	R	R	R	R	R	R	R	R	R
CHECK_STATUS	Rc	Rc	Rc	Rc	Rc	Rc	Rc	Rc	Rc	Rc	Rc	Rc
JTAG_STARTUP	R	R	R	R	R	R	R	R	R	R	R	R
JTAG TAP Reset/ other instruction	R	R	R	R	R	R	R	R	R	R	R	R

Note to Table 10–18:
(1)　"R" indicates required, "O" indicates optional, "Rc" indicates recommended, and "NA" indicates not allowed.

The effect of the ACTIVE_DISENGAGE instruction is similar but not the same to the AS and AP controllers. In AS configuration scheme, ACTIVE_DISENGAGE will hold the AS controller in the "idle" state. In AP configuration scheme, ACTIVE_DISENGAGE will cause the AP controller to enter the "chill-out" state. If a successful JTAG programming is executed, the active controllers will automatically be "re-engaged" once usermode is reached via JTAG programming. This causes the active controllers to transition to their respective usermode states.

If JTAG programming is not successful in getting the Cyclone III device to usermode, and the user wishes to "re-engage" the native active programming, the methods available to achieve this are different for AS and AP configuration schemes. When in AS configuration scheme, you can re-engage the AS controller either by moving the JTAG TAP controller to the RESET state, or by issuing the ACTIVE_ENGAGE instruction. When in AP configuration scheme, the only way to re-engage the AP controller is to issue the ACTIVE_ENGAGE instruction. In this case, asserting the nCONFIG pin will not re-engage either active controller.

ACTIVE_ENGAGE

The new instruction ACTIVE_ENGAGE enables you to "re-engage" an already disengaged active controller. You can issue this instruction any time (during configuration or user mode) and it will "re-engage" an already disengaged active controller as well as trigger reconfiguration of the Cyclone III device in active mode specified by MSEL pin settings.

It will act as PULSE_NCONFIG instruction when the device is in passive configuration schemes (PS, or FPP). The nCONFIG pin is disabled when the ACTIVE_ENGAGE instruction is issued.

Overriding the Internal Oscillator

This feature allows you to override the internal oscillator during active configuration. The active configuration (AS, and AP) controllers use the internal oscillator as the clock source. You can change the clock source to CLKUSR through JTAG instruction.

The JTAG instructions EN_ACTIVE_CLK and DIS_ACTIVE_CLK will toggle on or off whether the active clock is sourced from the CLKUSR pin or the internal configuration oscillator. To source the active clock from the CLKUSR pin, you can issue the EN_ACTIVE_CLK instruction. This will cause the CLKUSR pin to become the active clock source. Normally, test instruments use this when it wants to drive its own clock to control the AS state machine.

To revert the clock source back to the configuration oscillator, you can issue the DIS_ACTIVE_CLK instruction. Consequently, a power-on reset (POR) will revert the clock source back to the configuration oscillator. Toggling the nCONFIG pin or driving the JTAG state machine to the Reset state will not revert the clock source.

Table 10–19 shows the CLKUSR input frequency range for the active clock.

Table 10–19. CLKUSR Input Frequency for Active Clock *Note (1)*			
Minimum	Typical	Maximum	Units
TBD	TBD	TBD	TBD
Notes to Table 10–19: (1) These values are preliminary.			

EN_ACTIVE_CLK

The EN_ACTIVE_CLK instruction causes the CLKUSR pin signal to replace the internal oscillator as the source of clock. After this instruction is issued, other JTAG instructions can be issued while CLKUSR pin signal remains as the clock source. The clock source is only reverted back to the internal oscillator by issuing the DIS_ACTIVE_CLK instruction or a power-on reset (POR).

DIS_ACTIVE_CLK

The DIS_ACTIVE_CLK instruction breaks the CLKUSR enable latch set by EN_ACTIVE_CLK instruction and cause the clock source to revert back to the internal oscillator.

Changing the Start Boot Address of AP Flash

In AP configuration scheme, you can change the default configuration boot address of the parallel flash memory to any desired address using the JTAG instruction APFC_BOOT_ADDR.

APFC_BOOT_ADDR

The APFC_BOOT_ADDR instruction defines a start boot address for the parallel flash memory in the AP configuration scheme.

This instruction shifts in a start boot address for the AP flash. When this instruction becomes the active instruction, TDI and TDO are connected through a 22-bit active boot address shift register. The shifted in boot address bits get loaded into the 22-bit AP boot address update register, which feeds into the AP controller. The content of the AP boot address update register can be captured, and shifted out of the active boot address shift register from TDO.

The boot address in the boot address shift register and update register are shifted to the right (towards LSB direction) by two bits versus intended boot address. The reason for this is that the two LSB of the address are not accessible. When this boot address is fed into the AP controller, two 0's are attached in the end as least significant bits therefore pushing the shifted-in boot address to the left by two bits, which becomes the actual AP boot address the AP controller gets.

When the remote update feature is enabled, the APFC_BOOT_ADDR instruction sets the boot address for the factory configuration only.

Device Configuration Pins

The following tables describe the connections and functionality of all the configuration related pins on the Cyclone III devices. Table 10–20 summarizes the Cyclone III pin configuration.

	Table 10–20. Cyclone III Configuration Pin Summary (Part 1 of 2)				
Bank	**Description**	**Input/Output**	**Dedicated**	**Powered By**	**Configuration Mode**
1	FLASH_nCE, nCSO	Output		V_{CCIO}	AS, AP
6	CRC_ERROR	Output		V_{CCIO}	Optional, all modes
1	DATA[0]	Input		V_{CCIO}	PS, FPP, AS
		Bidirectional		V_{CCIO}	AP
1	DATA[1], ASDO	Input		V_{CCIO}	FPP
		Output		V_{CCIO}	AS
		Bidirectional		V_{CCIO}	AP
8	DATA[7..2]	Input		V_{CCIO}	FPP
		Bidirectional		V_{CCIO}	AP
8	DATA[15..8]	Bidirectional		V_{CCIO}	AP
6	INIT_DONE	Output		Pull-up	Optional, all modes
1	nSTATUS	Bidirectional	Yes	Pull-up	All modes
1	nCE	Input	Yes	V_{CCIO}	All modes
1	DCLK	Input	Yes	V_{CCIO}	PS, FPP
		Output		V_{CCIO}	AS, AP
6	CONF_DONE	Bidirectional	Yes	Pull-up	All modes
1	TDI	Input	Yes	V_{CCIO}	JTAG
1	TMS	Input	Yes	V_{CCIO}	JTAG
1	TCK	Input	Yes	V_{CCIO}	JTAG
1	nCONFIG	Input	Yes	V_{CCIO}	All modes
6	CLKUSR	Input		V_{CCIO}	Optional
6	nCEO	Output		V_{CCIO}	Optional, all modes
6	MSEL[3..0]	Input	Yes	V_{CCINT}	All modes
1	TDO	Output	Yes	V_{CCIO}	JTAG

Table 10–20. Cyclone III Configuration Pin Summary (Part 2 of 2)

Table 10–21 describes the dedicated configuration pins, which are required to be connected properly on your board for successful configuration. Some of these pins may not be required for your configuration schemes.

Table 10–21. Dedicated Configuration Pins on the Cyclone III Device (Part 1 of 7)

Pin Name	User Mode	Configuration Scheme	Pin Type	Description
MSEL[3..0]	N/A	All	Input	4-bit configuration input that sets the Cyclone III device configuration scheme. Some of the smaller devices or package options do not support the AP configuration scheme and do not have the MSEL[3] pin. Refer to Table 10–1 for the appropriate connections. These pins must be hard-wired to V_{CCIO} or GND. The MSEL[3..0] pins have internal 5-kΩ pull-down resistors that are always active.
nCONFIG	N/A	All	Input	Configuration control input. Pulling this pin low during user-mode will cause the Cyclone III device to lose its configuration data, enter a reset state, and tri-state all I/O pins. Returning this pin to a logic high level will initiate a reconfiguration.

Table 10–21. Dedicated Configuration Pins on the Cyclone III Device (Part 2 of 7)				
Pin Name	**User Mode**	**Configuration Scheme**	**Pin Type**	**Description**
nSTATUS	N/A	All	Bidirectional open-drain	The Cyclone III device drives nSTATUS low immediately after power-up and releases it after the POR time. Status output. If an error occurs during configuration, nSTATUS is pulled low by the target device. Status input. If an external source (for example, another Cyclone III device) drives the nSTATUS pin low during configuration or initialization, the target device enters an error state. Driving nSTATUS low after configuration and initialization does not affect the configured device. If a configuration device is used, driving nSTATUS low will cause the configuration device to attempt to configure the device, but since the device ignores transitions on nSTATUS in user-mode, the device does not reconfigure. To initiate a reconfiguration, nCONFIG must be pulled low.
CONF_DONE	N/A	All	Bidirectional open-drain	Status output. The target Cyclone III device drives the CONF_DONE pin low before and during configuration. Once all configuration data is received without error and the initialization cycle starts, the target device releases CONF_DONE. Status input. After all data is received and CONF_DONE goes high, the target device initializes and enters user mode. The CONF_DONE pin must have an external 10 KΩ pull-up resistor in order for the device to initialize. Driving CONF_DONE low after configuration and initialization does not affect the configured device.

Table 10–21. Dedicated Configuration Pins on the Cyclone III Device (Part 3 of 7)				
Pin Name	**User Mode**	**Configuration Scheme**	**Pin Type**	**Description**
nCE	N/A	All	Input	Active-low chip enable. The nCE pin activates the Cyclone III device with a low signal to allow configuration. The nCE pin must be held low during configuration, initialization, and user-mode. In single device configuration, it should be tied low. In multi-device configuration, nCE of the first device is tied low while its nCEO pin is connected to nCE of the next device in the chain. The nCE pin must also be held low for successful JTAG programming of the device.
nCEO	N/A if option is on. I/O if option is off.	All	Output	Output that drives low when Cyclone III device configuration is complete. In single device configuration, you can leave this pin floating or use it as a user I/O pin after configuration. In multi-device configuration, this pin feeds the next device's nCE pin. The nCEO of the last device in the chain can be left floating or used as a user I/O pin after configuration. If you use the nCEO pin to feed next device's nCE pin, use an external 10-kΩ pull-up resistor to pull the nCEO pin high to the V_{CCIO} voltage of its I/O bank to help the internal weak pull-up resistor. Use the Quartus II software to make this pin a user I/O pin.
FLASH_nCE, nCSO	N/A in AS or AP modes. I/O in other modes	AS, AP	Output	Output control signal from the Cyclone III device to the serial configuration device in AS mode that enables the configuration device. FLASH_nCE pin functions as the nCSO pin in AS mode. Output control signal from the Cyclone III device to the parallel flash in AP mode that enables the flash. Connects to the CE# pin on both the Intel P30 and the Spansion S29WS-N flash. In AS or AP mode, FLASH_nCE has an internal pull-up resistor that is always active.

Table 10–21. Dedicated Configuration Pins on the Cyclone III Device (Part 4 of 7)				
Pin Name	**User Mode**	**Configuration Scheme**	**Pin Type**	**Description**
DCLK	N/A	PS, FPP, AS, AP	Input (PS, FPP). Output (AS, AP)	In PS and FPP configuration, DCLK is the clock input used to clock data from an external source into the target Cyclone III device. Data is latched into the device on the rising edge of DCLK. In AS and AP mode, DCLK is an output from the Cyclone III device that provides timing for the configuration interface. Optionally, in AS and AP mode, DCLK can be controlled by the core in user-mode. In AS mode, DCLK has an internal pull-up resistor (typically 25 kΩ) that is always active. After configuration, this pin is tri-stated. In schemes that use a configuration device, DCLK will be driven low after configuration is done. In schemes that use a control host, DCLK should be driven either high or low, whichever is more convenient. Toggling this pin after configuration does not affect the configured device.
DATA[0]	N/A in AS mode. I/O in non-AS mode	PS, FPP, AS, AP	Input (PS, FPP, AS). Bidirectional open-drain (AP)	Data input. In serial configuration modes, bit-wide configuration data is presented to the target Cyclone III device on the DATA[0] pin. In AS mode, DATA[0] has an internal pull-up resistor that is always active. After AS configuration, DATA[0] is a dedicated input pin with optional user control. After PS or FPP configuration, DATA[0] is available as a user I/O pin and the state of this pin depends on the **Dual-Purpose Pin** settings. After AP configuration, DATA[0] is a dedicated bidirectional pin with optional user control.

Table 10–21. Dedicated Configuration Pins on the Cyclone III Device (Part 5 of 7)				
Pin Name	**User Mode**	**Configuration Scheme**	**Pin Type**	**Description**
DATA[1], ASDO	N/A in AS mode. I/O in non-AS mode	FPP, AS, AP	Input (FPP). Output (AS). Bidirectional open-drain (AP)	Data input in non-AS mode. Byte-wide or word-wide configuration data is presented to the target Cyclone III device on DATA[7..0] or DATA[15..0] respectively. Control signal from the Cyclone III device to the serial configuration device in AS mode used to read out configuration data. The DATA[1] pin functions as the ASDO pin in AS mode. In AS mode, DATA[1] has an internal pull-up resistor that is always active. After AS configuration, DATA[1] is a dedicated output pin with optional user control. In PS configuration scheme, DATA[1] functions as user I/O pin during configuration, which means it is tri-stated. After FPP configuration, DATA[1] is available as a user I/O pin and the state of this pin depends on the **Dual-Purpose Pin** settings. After AP configuration, DATA[1] is a dedicated bidirectional pin with optional user control.
DATA[7..2]	I/O	FPP, AP	Inputs (FPP). Bidirectional open-drain (AP)	Data inputs. Byte-wide or word-wide configuration data is presented to the target Cyclone III device on DATA[7..0] or DATA[15..0] respectively. In AS or PS configuration schemes, they function as user I/O pins during configuration, which means they are tri-stated. After FPP configuration, DATA[7..2] are available as user I/O pins and the state of these pin depends on the **Dual-Purpose Pin** settings. After AP configuration, DATA[7..2] are dedicated bidirectional pins with optional user control.

Table 10–21. Dedicated Configuration Pins on the Cyclone III Device (Part 6 of 7)				
Pin Name	**User Mode**	**Configuration Scheme**	**Pin Type**	**Description**
DATA[15..8]	I/O	AP	Bidirectional open-drain	Data inputs. Word-wide configuration data is presented to the target Cyclone III device on DATA[15..0]. In PS, FPP or AS configuration schemes, they function as user I/O pins during configuration, which means they are tri-stated. After AP configuration, DATA[15:8] are dedicated bidirectional pins with optional user control.
PADD[23..0]	N/A in AP mode. I/O in non-AP mode	AP	Output	24-bit address bus from the Cyclone III device to the parallel flash in AP mode. Connects to the A[24:1] bus on the Intel P30 or the A[23..0] bus on the Spansion S29WS-N flash.
nRESET	N/A in AP mode. I/O in non-AP mode	AP	Output	Active-low reset output. Driving the nRESET pin low resets the parallel flash. Connects to the RST# pin on the Intel P30 or the RESET# pin on the Spansion S29WS-N flash.
nAVD	N/A in AP mode. I/O in non-AP mode	AP	Output	Active-low address valid output. Driving the nAVD pin low during read or write operation indicates to the parallel flash that valid address is present on the PADD[23..0] address bus. Connects to the ADV# pin on the Intel P30 or the AVD# pin on the Spansion S29WS-N flash.
nOE	N/A in AP mode. I/O in non-AP mode	AP	Output	Active-low output enable to the parallel flash. Driving the nOE pin low during read operation enables the parallel flash outputs (DATA[15..0] and RDY). Connects to the OE# pin on both the Intel P30 and the Spansion S29WS-N flash.

Table 10–21. Dedicated Configuration Pins on the Cyclone III Device (Part 7 of 7)				
Pin Name	**User Mode**	**Configuration Scheme**	**Pin Type**	**Description**
nWE	N/A in AP mode. I/O in non-AP mode	AP	Output	Active-low write enable to the parallel flash. Driving the nWE pin low during write operation indicates to the parallel flash that data on the DATA[15..0] bus is valid. Connects to the WE# pin on both the Intel P30 and the Spansion S29WS-N flash.
RDY	N/A in AP mode. I/O in non-AP mode	AP	Input	The current implementation for AP configuration ignores the RDY pin. However it is recommended that you connect this pin. Connects to the WAIT pin on the Intel P30 or the RDY pin on the Spansion S29WS-N flash.

Table 10–22 describes the optional configuration pins. If these optional configuration pins are not enabled in the Quartus II software, they are available as general-purpose user I/O pins. Therefore, during configuration, these pins function as user I/O pins and are tri-stated with weak pull-up resistors.

Table 10–22. Optional Configuration Pins (Part 1 of 2)			
Pin Name	**User Mode**	**Pin Type**	**Description**
CLKUSR	N/A if option is on. I/O if option is off.	Input	Optional user-supplied clock input synchronizes the initialization of one or more devices. This pin is enabled by turning on the **Enable user-supplied start-up clock** (**CLKUSR**) option in the Quartus II software.
INIT_DONE	N/A if option is on. I/O if option is off.	Output open-drain	Status pin can be used to indicate when the device has initialized and is in user-mode. When nCONFIG is low and during the beginning of configuration, the INIT_DONE pin is tri-stated and pulled high due to an external 10 KΩ pull-up resistor. Once the option bit to enable INIT_DONE is programmed into the device (during the first frame of configuration data), the INIT_DONE pin will go low. When initialization is complete, the INIT_DONE pin will be released and pulled high and the device enters user-mode. Thus, the monitoring circuitry must be able to detect a low-to-high transition. This pin is enabled by turning on the **Enable INIT_DONE output** option in the Quartus II software.

Table 10–22. Optional Configuration Pins   (Part 2 of 2)

Pin Name	User Mode	Pin Type	Description
DEV_OE	N/A if option is on. I/O if option is off.	Input	Optional pin that allows the user to override all tri-states on the device. When this pin is driven low, all I/O pins are tri-stated; when this pin is driven high, all I/O pins behave as programmed. This pin is enabled by turning on the **Enable device-wide output enable** (**DEV_OE**) option in the Quartus II software.
DEV_CLRn	N/A if option is on. I/O if option is off.	Input	Optional pin that allows you to override all clears on all device registers. When this pin is driven low, all registers are cleared; when this pin is driven high, all registers behave as programmed. This pin is enabled by turning on the **Enable device-wide reset** (**DEV_CLRn**) option in the Quartus II software.

Table 10–23 describes the dedicated JTAG pins. JTAG pins must be kept stable before and during configuration to prevent accidental loading of JTAG instructions. The TDI and TMS have weak internal pull-up resistors, while TCK has a weak internal pull-down resistor. If you plan to use the SignalTap® II Embedded Logic Array Analyzer, you need to connect the JTAG pins of the Cyclone III device to a JTAG header on your board.

Table 10–23. Dedicated JTAG Pins   (Part 1 of 2)

Pin Name	User Mode	Pin Type	Description
TDI	N/A	Input	Serial input pin for instructions as well as test and programming data. Data is shifted in on the rising edge of TCK. The TDI pin is powered by the V_{CCIO} supply. If the JTAG interface is not required on the board, the JTAG circuitry can be disabled by connecting this pin to V_{CC}.
TDO	N/A	Output	Serial data output pin for instructions as well as test and programming data. Data is shifted out on the falling edge of TCK. The pin is tri-stated if data is not being shifted out of the device. The TDO pin is powered by V_{CCIO} in I/O bank 1. For recommendations on connecting a JTAG chain with multiple voltages across the devices in the chain, refer to the *IEEE 1149.1 (JTAG) Boundary Scan Testing for Cyclone III Devices* chapter in the *Cyclone III Device Handbook*. If the JTAG interface is not required on the board, the JTAG circuitry can be disabled by leaving this pin unconnected.

Table 10–23. Dedicated JTAG Pins (Part 2 of 2)			
Pin Name	**User Mode**	**Pin Type**	**Description**
TMS	N/A	Input	Input pin that provides the control signal to determine the transitions of the TAP controller state machine. Transitions within the state machine occur on the rising edge of TCK. Therefore, TMS must be set up before the rising edge of TCK. TMS is evaluated on the rising edge of TCK. The TMS pin is powered by the V_{CCIO} supply. If the JTAG interface is not required on the board, the JTAG circuitry can be disabled by connecting this pin to V_{CC}.
TCK	N/A	Input	The clock input to the BST circuitry. Some operations occur at the rising edge, while others occur at the falling edge. The TCK pin is powered by the V_{CCIO} supply. If the JTAG interface is not required on the board, the JTAG circuitry can be disabled by connecting TCK to GND.

Conclusion

Cyclone III devices can be configured in a number of different schemes to fit your system's need. In addition, configuration data decompression and remote system upgrade support supplement the Cyclone III configuration solution.

CIII51011-1.0

Introduction

Cyclone® III devices offer hot socketing, also known as hot plug-in, hot insertion, or hot swap, and power sequencing support without the use of any external devices. You can insert or remove a Cyclone III board in a system during system operation without causing undesirable effects to the board or to the running system bus.

The hot socketing feature removes complexity when using Cyclone III devices on printed circuit boards (PCBs) containing a mixture of 3.0, 3.3, 2.5, 1.8, 1.5, and 1.2 V devices. With the Cyclone III hot socketing feature, you no longer need to ensure a proper power-up sequence for each device on the board.

The Cyclone III hot-socketing feature provides:

- Board or device insertion and removal without external components or board manipulation
- Support for any power-up sequence
- Non-intrusive I/O buffers to system buses during hot insertion

This chapter also discusses the power-on reset (POR) circuitry in Cyclone III devices. The POR circuitry keeps the devices in the reset state until the V_{CC} is within operating range.

Cyclone III Hot-Socketing Specifications

Cyclone III devices offer hot-socketing capability with all three features listed above without any external components or special design requirements. The hot-socketing feature in Cyclone III devices offers the following:

- The device can be driven before power-up without any damage to the device itself.
- I/O pins remain tri-stated during power-up. The device does not drive out before or during power-up, thereby affecting other buses in operation.

Devices Can Be Driven Before Power-Up

You can drive signals into the I/O pins, dedicated input pins, and dedicated clock pins of Cyclone III devices before or during power-up or power-down without damaging the device. Cyclone III devices support any power-up or power-down sequence (V_{CCIO} and V_{CCINT}) to simplify system level design.

I/O Pins Remain Tri-Stated During Power-Up

A device that does not support hot socketing may interrupt system operation or cause contention by driving out before or during power-up. In a hot-socketing situation, the output buffers of the Cyclone III device are turned off during system power-up or power-down. A Cyclone III device also does not drive out until the device is configured and has attained proper operating conditions.

You can power up or power down the V_{CCIO}, V_{CCA}, and V_{CCINT} pins in any sequence. The maximum power ramp rate for fast POR time is 3 ms, and 50 ms for standard POR time, respectively. The minimum power ramp rate is 50 us. V_{CCIO} for all I/O banks should be powered-up during device operation. All V_{CCA} pins must be powered to 2.5-V (even when PLLs are not used), and must be powered-up and powered-down at the same time. V_{CCD_PLL} must always be connected to V_{CCINT} through a decoupling capacitor and ferrite bead. During hot socketing, the I/O pin capacitance is less than 15 pF and the clock pin capacitance is less than 20 pF. Cyclone III devices meet the following hot socketing specification:

■   The hot-socketing DC specification is $\mid I_{IOPIN} \mid$ < 300 uA.
■   The hot-socketing AC specification is $\mid I_{IOPIN} \mid$ < 8 mA for the ramp rate of 10 ns or more.

For ramp rates faster than 10 ns on I/O pins, $\mid I_{IOPIN} \mid$ can be obtained with the equation I=C dv/dt, where C is the I/O pin capacitance and dv/dt is the slew rate. The hot-socketing specification takes into account the pin capacitance but not board trace and external loading capacitance. You must consider additional or separate capacitance for trace, connector, and loading.

I_{IOPIN} is the current for any user I/O pin on the device. The DC specification applies when all V_{CC} supplied to the device is stable in the powered-up or powered-down conditions.

A possible concern for semiconductor devices in general regarding hot socketing is the potential for latch-up. Latch-up can occur when electrical subsystems are hot socketed into an active system. During hot socketing, the signal pins may be connected and driven by the active system before

the power supply can provide current to the device's V_{CC} and ground planes. This condition can lead to latch-up and cause a low-impedance path from V_{CC} to ground within the device. As a result, the device extends a large amount of current, possibly causing electrical damage.

By design of the I/O buffers and hot socketing circuitry, Altera® ensures that Cyclone III devices are immune to latch-up during hot socketing.

Hot-Socketing Feature Implementation in Cyclone III Devices

The hot-socketing feature disables the output buffer during power-up (either V_{CCINT} or V_{CCIO} supplies) or power-down. The hot-socket circuit generates an internal HOTSCKT signal when either V_{CCINT} or V_{CCIO} is below the threshold voltage. Designs cannot use the HOTSCKT signal for other purposes. The HOTSCKT signal cuts off the output buffer to ensure that no DC current (except for weak pull-up leakage current) leaks through the pin. When V_{CC} ramps up slowly, V_{CC} is still relatively low, even after the internal POR signal (not available to the FPGA fabric used by customer designs) is released and the configuration is finished. The CONF_DONE, nCEO, and nSTATUS pins would fail to respond, as the output buffer cannot drive out because the hot-socketing circuitry keeps the I/O pins tri-stated at this low V_{CC} voltage. Therefore, the hot-socketing circuit has been removed on these configuration output or bidirectional pins to ensure that they are operational during configuration. These pins are expected to drive out during power-up and power-down sequences.

Each I/O pin has the circuitry shown in Figure 11–1.

Figure 11–1. Hot Socketing Circuit Block Diagram for Cyclone III Devices

The POR circuit monitors the V_{CCINT}, V_{CCIO}, and V_{CCA}. voltage level and keeps I/O pins tri-stated until the device is in user mode. The weak pull-up resistor (R) from the I/O pin to V_{CCIO} keeps the I/O pins from floating. The voltage tolerance control circuit permits the I/O pins to be driven by 3.3 V before V_{CCIO} and/or V_{CCINT} are powered, and it prevents the I/O pins from driving out when the device is not in user mode. The hot socket circuit prevents I/O pins from internally powering V_{CCIO} and V_{CCINT} when driven by external signals before the device is powered.

Figure 11–2 shows a transistor level cross section of the Cyclone III device I/O buffers. This design ensures that the output buffers do not drive when V_{CCIO} is powered before V_{CCINT} or if the I/O pad voltage is higher than V_{CCIO}. This also applies for sudden voltage spikes during hot socketing. There is no current path from signal I/O pins to V_{CCINT} or V_{CCIO} during hot socketing. The V_{PAD} leakage current charges the voltage tolerance control circuit capacitance.

Figure 11–2. Transistor Level Diagram of FPGA Device I/O Buffers
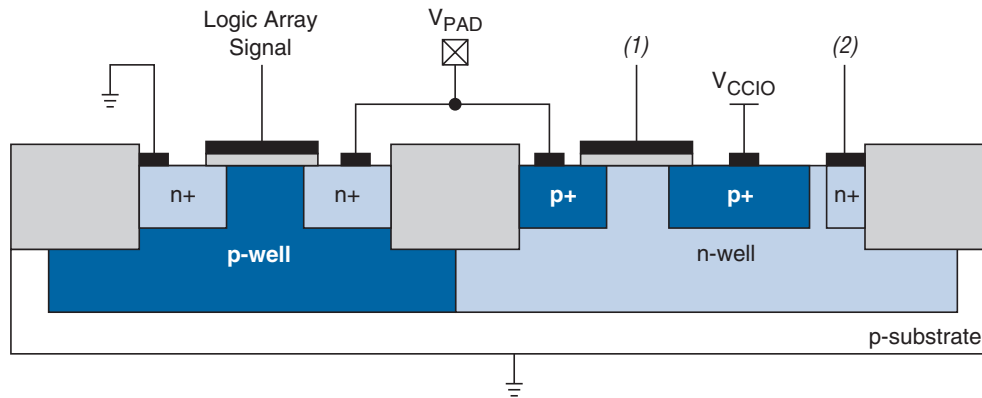

Note to Figure 11–2:
(1)   This is the logic array signal or the larger of either the V_{CCIO} or V_{PAD} signal.
(2)   This is the larger of either the V_{CCIO} or V_{PAD} signal.

Power-On Reset Circuitry

Cyclone III devices contain POR circuitry to keep the device in a reset state until the power supply voltage levels have stabilized during power-up. The POR circuit monitors the V_{CCINT}, V_{CCIO}, and V_{CCA} pin and tri-states all user I/O pins until the V_{CC} reaches the recommended operating levels. In addition, the POR circuitry also ensures the V_{CCIO} level of I/O banks 1, 6, 7, and 8 that contains configuration pins reach an acceptable level before configuration is triggered.

After the Cyclone III device enters user mode, the POR circuit continues to monitor the V_{CCINT} and V_{CCA} pin so that a brown-out condition during user mode can be detected. If the V_{CCINT} and V_{CCA} voltage sags below the POR trip point during user mode, the POR circuit resets the device. If the V_{CCIO} voltage sags during user mode, the POR circuit does not reset the device.

Wake-Up Time for Cyclone III Devices

In some applications, it may be necessary for a device to wake up very quickly in order to begin operation. The Cyclone III device offers the Fast-On feature to support fast wake-up time applications. For Cyclone III devices, MSEL[3..0] pin settings determine the POR time (t_{POR}) of the device. The fast POR ranges from 3 ms to 9 ms while the standard POR ranges from 50 ms to 200 ms.

For more information about the `MSEL[3..0]` pin settings, refer to the *Configuring Cyclone III Devices* chapter in volume 1 of the *Cyclone III Device Handbook*.

For Cyclone III devices, wake-up time consists of power-up, POR, configuration, and initialization. The device must properly go through all four stages to configure correctly and begin operation. You can calculate wake-up time using the following equation:

Wake-Up Time = V_{CC} Ramp Time + POR Time + Configuration Time + Initialization Time

Figure 11–3 illustrates the components of wake-up time.

Figure 11–3. Cyclone III Wake-Up Time
The V_{CC} ramp time and POR time depend on the power supply used in your system and the device `MSEL[3..0]` pin settings.

Configuration time depends on the configuration scheme you chose and the configuration file size. You can calculate configuration time by multiplying the number of bits in the configuration file with the period of the configuration clock. For fast configuration times, you should either use a fast passive parallel (FPP) configuration scheme with maximum DCLK frequency of 100 MHz or an active parallel (AP) configuration scheme with maximum DCLK frequency of 40 MHz. In addition, you can

use passive serial (PS) with compression to reduce the configuration file size and speed up the configuration time. Passive parallel configuration mode does not support compression. The t_{CD2UM} or t_{CD2UMC} parameters determine the initialization time.

For more information about the t_{CD2UM} or t_{CD2UMC} parameters and configuration schemes, refer to the *Configuring Cyclone III Devices* chapter in volume 1 of the *Cyclone III Device Handbook*.

If you cannot meet the maximum V_{CC} ramp time requirement, you must use an external component to hold nCONFIG low until the power supplies have reached their minimum recommended operating levels. Otherwise, the device may not properly configure and enter user mode.

Conclusion

Cyclone III devices offer hot socketing allowing the device to power-up successfully without any power-sequencing. The POR circuitry keeps the devices in the reset state until the V_{CC} is within operating range.

CIII51012-1.0

Introduction

System designers face difficult challenges such as shortened design cycles, evolving standards, and system deployments in remote locations. Cyclone® III devices help overcome these challenges with their inherent re-programmability and dedicated circuitry to perform remote system upgrades. Remote system upgrades help deliver feature enhancements and bug fixes without costly recalls, reduce time-to-market, and extend product life.

Cyclone III devices feature dedicated remote system update circuitry. Soft logic (either the Nios II® embedded processor or user logic) implemented in a Cyclone III device can download a new configuration image from a remote location, store it in configuration memory (such as a serial configuration device), and direct the dedicated remote system update circuitry to initiate a reconfiguration cycle. The dedicated circuitry performs error detection during and after the configuration process, recovers from any error condition by reverting back to a safe configuration image, and provides error status information. This dedicated remote system upgrade circuitry is unique to Cyclone III devices and helps to avoid system downtime.

Remote system upgrade is supported in Cyclone III active serial (AS) and active parallel (AP) configuration schemes. Remote system upgrade can also be implemented in conjunction with advanced Cyclone III features such as real-time decompression of configuration data in an AS configuration scheme.

This chapter describes the functionality and implementation of the dedicated remote system upgrade circuitry. It also defines several concepts related to remote system upgrade, including factory configuration, application configuration, remote update mode, and user watchdog timer.

Functional Description

The dedicated remote system upgrade circuitry in Cyclone III devices manages remote configuration and provides error detection, recovery, and status information. User logic or a Nios II processor implemented in the Cyclone III device logic array provides access to the remote configuration data source and an interface to the system's configuration memory.

The Cyclone III device's remote system upgrade process involves the following steps:

1. A Nios II processor (or user logic) implemented in the Cyclone III device logic array receives new configuration data from a remote location. The connection to the remote source is a communication protocol such as the transmission control protocol/Internet protocol (TCP/IP), peripheral component interconnect (PCI), user datagram protocol (UDP), universal asynchronous receiver/transmitter (UART), or a proprietary interface.

2. The Nios II processor (or user logic) writes this new configuration data into a non-volatile configuration memory. The non-volatile configuration memory can be the serial configuration device (in the AS configuration scheme), or the supported parallel flash memory (in the AP configuration scheme).

3. The Nios II processor (or user logic) initiates a reconfiguration cycle with the new or updated configuration data.

4. The dedicated remote system upgrade circuitry detects and recovers from any error(s) that might occur during or after the reconfiguration cycle, and provides error status information to the user design.

Figure 12–1 shows the steps required for performing remote configuration updates. (The numbers in the figure below coincide with the steps above.)

Figure 12–1. Functional Diagram of Cyclone III Remote System Upgrade
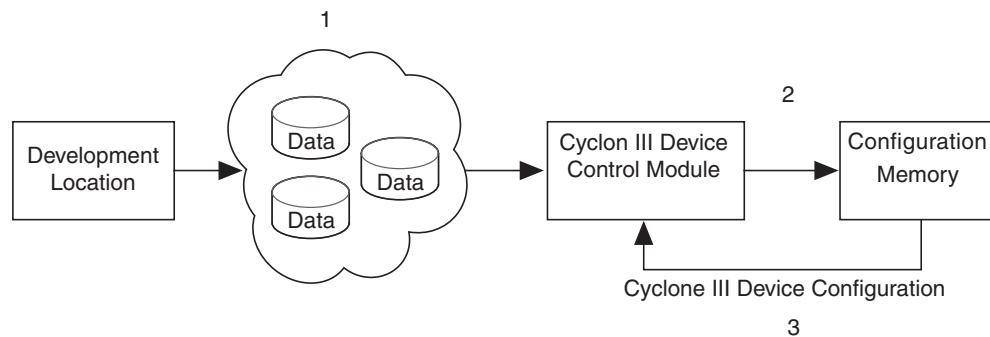

Cyclone III devices only support remote system upgrade in the AS and AP configuration schemes.

■ The serial configuration device uses the AS configuration scheme to configure the Cyclone III device.
■ The supported parallel flash uses the AP configuration scheme to configure the Cyclone III device.

Figure 12–2 shows the block diagrams for implementing remote system upgrade with the Cyclone III AS and AP configuration schemes.

Figure 12–2. Remote System Upgrade Block Diagrams for Cyclone III AS and AP Configuration Schemes
For information about programming the serial configuration device or programming the supported parallel flash memory, refer to the *Configuring Cyclone III Devices* chapter of the *Cyclone III Device Handbook*.

You must set the mode select pins (MSEL[3..0]) to the AS or AP configuration scheme to use the remote system upgrade in your system. Table 12–1 lists the MSEL pin settings for Cyclone III devices in remote system upgrade mode. The MSEL pin settings in remote system upgrade mode is the same as in the standard configuration mode. Standard configuration mode refers to normal Cyclone III device configuration mode with no support for remote system upgrades, and the remote system upgrade circuitry is disabled. When using remote system upgrade in Cyclone III devices, you must enable the remote update mode option setting in the Quartus® II software.

For more information about standard configuration schemes supported in Cyclone III devices, refer to the *Configuring Cyclone III Devices* chapter in the *Cyclone III Device Handbook*.

Table 12–1. Cyclone III Remote System Upgrade Modes

Configuration Scheme	Configuration Voltage Standard (5)	MSEL[3..0]	Remote Update Mode Option Setting (1)	Remote System Upgrade Mode
Active Serial Standard (AS Standard POR) (2), (3)	3.3 V	0010	Disable	Standard
		0010	Enable	Remote update
Active Serial Fast (AS Fast POR) (2), (3)	3.3 V	1101	Disable	Standard
		1101	Enable	Remote update

Notes to Table 12–1:

(1) You can enable or disable the remote update mode with an option setting in the Quartus II software.
(2) These schemes support data decompression.
(3) The EPCS16 and EPCS64 devices support up to a 40 MHz `DCLK` and are supported in Cyclone III devices. Existing batches of EPCS4 devices manufactured on 0.15 µm process geometry support up to a 40 MHz `DCLK` and are supported in Cyclone III devices. However, batches of EPCS4 devices manufactured on 0.18 µm process geometry do not support AS configuration in Cyclone III devices. For more information, refer to the *Configuring Cyclone III Devices* chapter in the *Cyclone III Device Handbook*.
(4) In the AP configuration scheme, the commodity parallel flash is used as configuration memory. For information on the supported families for the commodity parallel flash, refer to the *Configuring Cyclone III Devices* chapter in the *Cyclone III Device Handbook*.
(5) Configuration voltage standard applied to V_{CCIO}.

Configuration Image Types

When using remote system upgrade, Cyclone III device configuration bitstreams are classified as factory configuration images or application configuration images. An image, also referred to as a configuration, is a design loaded into the device that performs certain user-defined functions. Each device in your system requires one factory image and one or more application images. The factory image is a user-defined fall-back, or safe, configuration and is responsible for administering remote updates in conjunction with the dedicated circuitry. Application images implement user-defined functionality in the target Cyclone III device.

A remote system update involves storing a new application configuration image or updating an existing one via the remote communication interface. After an application configuration image is stored or updated remotely, the user design in the Cyclone III device initiates a reconfiguration cycle with the new image. Any errors during or after this cycle are detected by the dedicated remote system upgrade circuitry, and cause the device to automatically revert to the factory image. The factory image then performs error processing and recovery. While error processing functionality is limited to the factory configuration, both factory and application configurations can download and store remote updates and initiate system reconfiguration.

Remote System Upgrade Mode

The remote update mode allows you to determine the functionality of your system upon power up and offer various features.

Overview

In remote update mode, the Cyclone III device loads the factory configuration image upon power up. The user-defined factory configuration determines which application configuration is to be loaded and triggers a reconfiguration cycle.

When used with serial configuration devices or with supported parallel flash memories, the remote update mode allows an application configuration to start at any flash sector boundary. Additionally, the remote update mode features a user watchdog timer that can detect functional errors in an application configuration.

Remote Update Mode

When a Cyclone III device is first powered up in remote update in the AS configuration scheme, it loads the factory configuration located at address `boot_address[23:0] = 24b'0`. You should always store the factory configuration image for your system at boot address `24b'0` when

using the AS configuration scheme. A factory configuration image is a bitstream for the Cyclone III device(s) in your system that is programmed during production and is the fall-back image when an error occurs. This image is stored in non-volatile memory and is never updated or modified using remote access. This corresponds to the start address location 0x000000 in the serial configuration device.

Upon power up in remote update in the AP configuration scheme, the Cyclone III device loads the default factory configuration located at address `boot_address[23:0] = 24'h010000 = 24'b1 0000 0000 0000 0000`. You can change the default factory configuration address to any desired address using the JTAG instruction `APFC_BOOT_ADDR`. The factory configuration image is stored in non-volatile memory and is never updated or modified using remote access. This corresponds to the default start address location 0x010000 (or the updated address if the default address is changed) in the supported parallel flash memory.

For information about the application of the JTAG instruction `APFC_BOOT_ADDR` in AP configuration scheme, refer to the *Configuring Cyclone III Devices* chapter in the *Cyclone III Device Handbook*.

The factory configuration image is user designed and contains soft logic to:

- Process any errors based on status information from the dedicated remote system upgrade circuitry
- Communicate with the remote host and receive new application configurations, and store this new configuration data in the local non-volatile memory device
- Determine which application configuration is to be loaded into the Cyclone III device
- Enable or disable the user watchdog timer and load its time-out value (optional).
- Instruct the dedicated remote system upgrade circuitry to initiate a reconfiguration cycle

Figure 12–3 shows the transitions between the factory and application configurations in remote update mode.

Figure 12–3. Transitions Between Configurations in Remote Update Mode
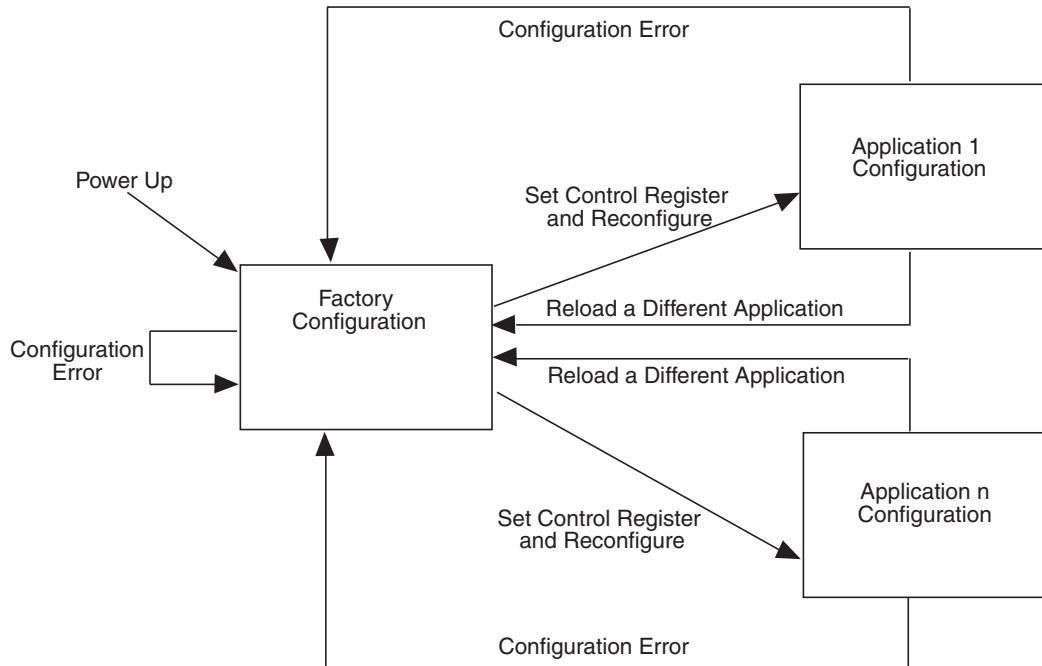

After power up or a configuration error, the factory configuration logic writes the remote system upgrade control register to specify the address of the application configuration to be loaded. The factory configuration also specifies whether or not to enable the user watchdog timer for the application configuration and, if enabled, specify the timer setting.

The user watchdog timer ensures that the application configuration is valid and functional. After confirming the system is healthy, the user-designed application configuration must reset the timer periodically during user-mode operation of an application configuration. This timer reset logic should be a user-designed hardware and/or software health monitoring signal that indicates error-free system operation. If the user application configuration detects a functional problem or if the system hangs, the timer is not reset in time and the dedicated circuitry updates the remote system upgrade status register, triggering the device to load the factory configuration. The user watchdog timer is automatically disabled for factory configurations.

☞ Only valid application configurations designed for remote update mode include the logic to reset the timer in user mode.

For more information about the user watchdog timer, refer to the "User Watchdog Timer" on page 12–16.

If there is an error while loading the application configuration, the remote system upgrade status register is written by the Cyclone III device's dedicated remote system upgrade circuitry, specifying the cause of the reconfiguration. The following actions cause the remote system upgrade status register to be written:

■ nSTATUS driven low externally
■ Internal CRC error
■ User watchdog timer timeout
■ A configuration reset (logic array nCONFIG signal or external nCONFIG pin assertion)

Cyclone III devices automatically load the factory configuration located at address boot_address[23:0] = 24'b0 for the AS configuration scheme, and default address boot_address[23:0] = 24'h010000 (or the updated address if the default address is changed) for the AP configuration scheme. This user-designed factory configuration reads the remote system upgrade status register to determine the reason for reconfiguration. Then the factory configuration takes the appropriate error recovery steps and writes to the remote system upgrade control register to determine the next application configuration to be loaded.

When Cyclone III devices successfully load the application configuration, they enter into user mode. In user mode, the soft logic (Nios II processor or state machine and the remote communication interface) assists the Cyclone III device in determining when a remote system update is arriving. When a remote system update arrives, the soft logic receives the incoming data, writes it to the configuration memory device, and triggers the device to load the factory configuration. The factory configuration reads the remote system upgrade status register, determines the valid application configuration to load, writes the remote system upgrade control register accordingly, and initiates system reconfiguration.

Dedicated Remote System Upgrade Circuitry

This section explains the implementation of the Cyclone III remote system upgrade dedicated circuitry. The remote system upgrade circuitry is implemented in hard logic. This dedicated circuitry interfaces to the user-defined factory application configurations implemented in the Cyclone III device logic array to provide the complete remote configuration solution. The remote system upgrade circuitry contains the remote system upgrade registers, a watchdog timer, and state machines that control those components. Figure 12–4 shows the remote system upgrade block's data path.

Figure 12–4. Remote System Upgrade Circuit Data Path
Remote System Upgrade Registers

The remote system upgrade block contains a series of registers that store the configuration addresses, watchdog timer settings, and status information. These registers are detailed in Table 12–2.

Table 12–2. Remote System Upgrade Registers	
Register	**Description**
Shift register	This register is accessible by the logic array and allows the update, status, and control registers to be written and sampled by user logic. Write access is enabled in remote update mode for factory configurations to allow writes to the update register. Write access is disabled for all application configurations in remote update mode.
Control register	This register contains the current configuration address, the user watchdog timer settings, one option bit for checking early CONF_DONE, and one option bit for selecting the internal oscillator as the startup state machine clock. During a read operation in an application configuration, this register is read into the shift register. When a reconfiguration cycle is initiated, the contents of the update register are written into the control register.
Update register	This register contains data similar to that in the control register. However, it can only be updated by the factory configuration by shifting data into the shift register and issuing an update operation. When a reconfiguration cycle is triggered by the factory configuration, the control register is updated with the contents of the update register. During a read in a factory configuration, this register is read into the shift register.
Status register	This register is written to by the remote system upgrade circuitry on every reconfiguration to record the cause of the reconfiguration. This information is used by the factory configuration to determine the appropriate action following a reconfiguration. During a capture cycle, this register is read into the shift register.

The remote system upgrade control and status registers are clocked by the 10-MHz internal oscillator (the same oscillator that controls the user watchdog timer). However, the remote system upgrade shift and update registers are clocked by the user clock input (RU_CLK).

Remote System Upgrade Control Register

The remote system upgrade control register stores the application configuration address, the user watchdog timer settings, and option bits for application configuration. In remote update mode for the AS configuration scheme, the control register address bits are set to all zeros (24'b0) at power up to load the AS factory configuration. In remote update mode for the AP configuration scheme, the control register address bits are set to 24'h010000 (24'b1 0000 0000 0000 0000) at power up to load the AP default factory configuration. However, for the AP configuration scheme, you can change the default factory configuration address to any desired address using the JTAG instruction APFC_BOOT_ADDR. Additionally, a factory configuration in remote update mode has write access to this register.

For information on the application of the JTAG instruction APFC_BOOT_ADDR in the AP configuration scheme, refer to the *Configuring Cyclone III Devices* chapter in the *Cyclone III Device Handbook*.

The control register bit positions are shown in Figure 12–5 and defined in Table 12–3. In the figure, the numbers show the bit position of a setting within a register. For example, bit number 35 is the enable bit for the watchdog timer.

Figure 12–5. Remote System Upgrade Control Register

38	37	36	35	34	33	12	11	0
Rsv2	Cd_early	Osc_int	Wd_en	Rsv1	Ru_address[21..0]		Wd_timer[11..0]	

The early CONF_DONE check (Cd_early) option bit, when enabled, ensures that there is a valid configuration at the boot address specified by the factory configuration and that it is of the proper size. The internal oscillator as startup state machine clock (Osc_int) option bit, when enabled, ensures a functional startup clock to eliminate the hanging of startup. When all option bits are turned on, they provide complete coverage for the programming and startup portions of the application configuration. It is strongly recommended that you turn on both the Cd_early and Osc_int option bits.

☞ The Cd_early and Osc_int option bits for the application configuration should be turned on by the factory configuration.

Table 12–3. Remote System Upgrade Control Register Contents

Control Register Bit	Value	Definition
`Wd_timer[11..0]`	12'b000000000000	User watchdog time-out value (most significant 12 bits of 29-bit count value: `{Wd_timer[11..0],17'b0}`)
`Ru_address[21..0]`	22'b0000000000000000000000	AS and AP configuration address (most significant 22 bits of 24-bit boot address value: `boot_address[23:0] = {Ru_address[21..0],2'b0}`)
`Rsv1`	1'b0	Reserved bit
`Wd_en`	1'b1	User watchdog timer enable bit
`Osc_int` *(1)*	1'b1	Internal oscillator as startup state machine clock enable bit
`Cd_early` *(1)*	1'b1	Early `CONF_DONE` check
`Rsv2`	1'b1	Reserved bit

Note to Table 12–3:

(1) Option bit for the application configuration.

Remote System Upgrade Status Register

The remote system upgrade status register specifies the reconfiguration trigger condition. The various trigger and error conditions include:

■ CRC (cyclic redundancy check) error during application configuration
■ `nSTATUS` assertion by an external device due to an error
■ Cyclone III device logic array triggered a reconfiguration cycle, possibly after downloading a new application configuration image
■ External configuration reset (`nCONFIG`) assertion
■ User watchdog timer time out

Table 12–4 describes the contents of the current state logic in the status register, when the RSU master state machine is in factory configuration and the MSEL pin settings are set to AS or AP scheme. The status register bit in the table shows the bit positions within a 32-bit logic.

Table 12–4. Remote System Upgrade Current State Logic (Factory) Contents In Status Register Notes (1), (2)

Status Register Bit	Definition	Description
31:30	Master State Machine current state	The current state of the RSU master state machine
29:24	Reserved bits	Padding bits that are set to all 0's
23:0	Boot address	The current 24-bit boot address that was used by the AS or AP configuration scheme as the start address to load the current configuration

Notes to Table 12–4:
(1)   The RSU master state machine is in factory configuration.
(2)   The MSEL pin settings are in the AS or AP configuration scheme.

Table 12–5 describes the contents of the current state logic in the status register when the RSU master state machine is in application configuration 1. The status register bit in the table shows the bit positions within a 32-bit logic.

Table 12–5. Remote System Upgrade Current State Logic (Application 1) Contents In Status Register Notes (1), (2)

Status Register Bit	Definition	Description
31:30	Master State Machine current state	The current state of the RSU master state machine
29	User watchdog timer enable bit	The current state of the user watchdog enable, which is active high
28:0	User watchdog timer time-out value	The current, entire 29-bit watchdog time-out value

Notes to Table 12–5:
(1)   The RSU master state machine is in application configuration 1.
(2)   The MSEL pin settings do not matter.

Table 12–6 describes the contents of the current state logic in the status register when the RSU master state machine is in application configuration 2 and the MSEL pin settings are set to AS or AP scheme. The status register bit in Table 12–6 shows the bit positions within a 32-bit logic.

Table 12–6. Remote System Upgrade Current State Logic (Application 2) Contents In Status Register *Notes (1), (2)*

Status Register Bit	Definition	Description
31:30	Master State Machine current state	The current state of the RSU master state machine.
29:24	Reserved bits	Padding bits that are set to all 0's.
23:0	Boot address	The current 24-bit boot address that was used by the AS or AP configuration scheme as the start address to load the current configuration.

Notes to Table 12–6:
(1) The RSU master state machine is in application configuration 2.
(2) The MSEL pin settings are in the AS or AP configuration scheme.

The previous two application configurations are available in the previous state registers (previous state register 1 and previous state register 2), but only for debug purposes. Table 12–7 describes the contents of the previous state register 1 in the status register when the MSEL pin settings are set to AS or AP scheme. The status register bit in the table shows the bit positions within a 31-bit register.

Table 12–7. Remote System Upgrade Previous State Register 1 Contents In Status Register *Note (1)*

Status Register Bit	Definition	Description
30	nCONFIG source	One-hot, active high field that describes the reconfiguration source that caused the Cyclone III device to leave the previous application configuration. In the event of a tie, the higher bit order indicates precedence. For example, if nCONFIG and RSU nCONFIG reach the reconfiguration state machine at the same time, the nCONFIG precedes the RSU nCONFIG.
29	CRC error source	
28	nSTATUS source	
27	User watchdog timer source	
26	RSU nCONFIG source	
25:24	Master State Machine current state	The state of the master state machine when the reconfiguration event occurred that caused the Cyclone III device to leave the previous application configuration.
23:0	Boot address	The address used by the AS or AP configuration scheme to load the previous application configuration.

Note to Table 12–7:
(1) The MSEL pin settings are in the AS or AP configuration scheme.

Table 12–8 describes the contents of the previous state register 2 in the status register when the MSEL pin settings are set to AS or AP scheme. The status register bit in the table shows the bit positions within a 31-bit register. Table 12–8 has the same bit definitions as Table 12–7, except all fields reflect the current state when a reconfiguration source caused the Cyclone III device to leave the application configuration before the previous application configuration.

Table 12–8. Remote System Upgrade Previous State Register 2 Contents In Status Register Notes (1), (2)		
Status Register Bit	**Definition**	**Description**
30	nCONFIG source	One-hot, active high field that describes the reconfiguration source that caused the Cyclone III device to leave the previous application configuration. In the event of a tie, the higher bit order indicates precedence. For example, if nCONFIG and RSU nCONFIG reach the reconfiguration state machine at the same time, the nCONFIG precedes the RSU nCONFIG.
29	CRC Error source	
28	nSTATUS source	
27	User watchdog timer source	
26	RSU nCONFIG source	
25:24	Master State Machine current state	The state of the master state machine when the reconfiguration event occurred that caused the Cyclone III device to leave the previous application configuration.
23:0	Boot address	The address used by the AS or AP configuration scheme to load the previous application configuration.

Notes to Table 12–8:
(1)   The MSEL pin settings are in the AS or AP configuration scheme.
(2)   Bit definitions are the same as previous state register 1, except all fields reflect the current state when a reconfiguration source caused the Cyclone III device to leave the application configuration before the previous application configuration.

If a capture is done inappropriately, for example capturing a previous state before the system has entered remote update application configuration for the first time, a value will be output from the shift register to indicate that capture was incorrectly called.

Remote System Upgrade State Machine

The remote system upgrade control and update registers have identical bit definitions, but serve different roles (refer to Table 12–2). While both registers can only be updated when the device is loaded with a factory configuration image, the update register writes are controlled by the user logic, and the control register writes are controlled by the remote system upgrade state machine.

In factory configurations, the user logic should send the option bits (`Cd_early` and `Osc_int`), the configuration address, and watchdog timer settings for the next application configuration bit to the update register. When the logic array configuration reset (`RU_nCONFIG`) goes high, the remote system upgrade state machine updates the control register with the contents of the update register and initiates system reconfiguration from the new application page.

In the event of an error or reconfiguration trigger condition, the remote system upgrade state machine directs the system to load a factory or application configuration (based on mode and error condition) by setting the control register accordingly. Table 12–9 lists the contents of the control register after such an event occurs for all possible error or trigger conditions.

The remote system upgrade status register is updated by the dedicated error monitoring circuitry after an error condition but before the factory configuration is loaded.

Table 12–9. Control Register Contents After an Error or Reconfiguration Trigger Condition

Reconfiguration Error/Trigger	Control Register Setting In Remote Update
nCONFIGU reset	All bits are 0
nSTATUS error	All bits are 0
CORE triggered reconfiguration	Update register
CRC error	All bits are 0
Wd time out	All bits are 0

Read operations during factory configuration access the contents of the update register. This feature is used by the user logic to verify that the configuration address and watchdog timer settings were written correctly. Read operations in application configurations access the contents of the control register. This information is used by the user logic in the application configuration.

User Watchdog Timer

The user watchdog timer prevents a faulty application configuration from stalling the device indefinitely. The system uses the timer to detect functional errors after an application configuration is successfully loaded into the Cyclone III device.

The user watchdog timer is a counter that counts down from the initial value loaded into the remote system upgrade control register by the factory configuration. The counter is 29 bits wide and has a maximum count value of 2^{29}. When specifying the user watchdog timer value, specify only the most significant 12 bits. The granularity of the timer setting is 2^{17} cycles. The cycle time is based on the frequency of the 10-MHz internal oscillator. Table 12–10 specifies the operating range of the 10-MHz internal oscillator.

Table 12–10. 10-MHz Internal Oscillator Specifications *Note (1)*			
Minimum	**Typical**	**Maximum**	**Units**
5	6.5	10	MHz

Note to Table 12–10:
(1)   These values are preliminary.

The user watchdog timer begins counting once the application configuration enters device user mode. This timer must be periodically reloaded or reset by the application configuration before the timer expires by asserting RU_nRSTIMER. If the application configuration does not reload the user watchdog timer before the count expires, a time-out signal is generated by the remote system upgrade dedicated circuitry. The timeout signal tells the remote system upgrade circuitry to set the user watchdog timer status bit (Wd) in the remote system upgrade status register and reconfigures the device by loading the factory configuration.

The user watchdog timer is not enabled during the configuration cycle of the device. Errors during configuration are detected by the CRC engine. Also, the timer is disabled for factory configurations. Functional errors should not exist in the factory configuration since it is stored and validated during production and is never updated remotely.

☞   The user watchdog timer is disabled in factory configurations and during the configuration cycle of the application configuration. It is enabled after the application configuration enters user mode.

Interface Signals between Remote System Upgrade Circuitry and Cyclone III Device Logic Array

The dedicated remote system upgrade circuitry drives (or receives) seven signals to (or from) the Cyclone III device logic array. The device logic array uses these signals to read and write the remote system upgrade

control, status, and update registers using the remote system upgrade shift register. Table 12–11 lists each of these seven signals and describes their functionality.

Except for `RU_nRSTIMER` and `RU_CAPTnUPDT`, the logic array signals are enabled for remote update mode and for both factory and application configurations. `RU_nRSTIMER` is only valid for application configurations in remote update mode, since factory configurations have the user watchdog timer disabled. When `RU_CAPTnUPDT` is low, the device can write to the update register only for factory configurations in remote update mode, since this is the only case where the update register is written to by the user logic. When the `RU_nCONFIG` signal goes high, the contents of the update register are written into the control register for controlling the next configuration cycle.

Table 12–11. Interface Signals Between Remote System Upgrade Circuitry and Cyclone III Device Logic Array (Part 1 of 2)		
Signal Name	**Signal Direction**	**Description**
`RU_nRSTIMER`	Input to remote system upgrade block (driven by device logic array)	Request from the application configuration to reset the user watchdog timer with its initial count. A falling edge of this signal triggers a reset of the user watchdog timer.
`RU_nCONFIG`	Input to remote system upgrade block (driven by device logic array)	When driven low, this signal triggers the device to reconfigure. If asserted by the factory configuration in remote update mode, the application configuration specified in the remote update control register is loaded. If requested by the application configuration in remote update mode, the factory configuration is loaded.
`RU_CLK`	Input to remote system upgrade block (driven by device logic array)	Clocks the remote system upgrade shift register and update register so that the contents of the status, control, and update registers can be read, and so that the contents of the update register can be loaded. The shift register latches data on the rising edge of this clock signal.

Table 12–11. Interface Signals Between Remote System Upgrade Circuitry and Cyclone III Device Logic Array   (Part 2 of 2)

Signal Name	Signal Direction	Description
RU_SHIFTnLD	Input to remote system upgrade block (driven by device logic array)	This pin determines if the shift register contents are shifted over during the next clock edge or loaded in/out. When this signal is driven high (1'b1), the remote system upgrade shift register shifts data left on each rising edge of RU_CLK. When RU_SHIFTnLD is driven low (1'b0) and RU_CAPTnUPDT is driven low (1'b0), the remote system upgrade update register is updated with the contents of the shift register on the rising edge of RU_CLK. When RU_SHIFTnLD is driven low (1'b0) and RU_CAPTnUPDT is driven high (1'b1), the remote system upgrade shift register captures the status register and either the control or update register (depending on whether the current configuration is application or factory, respectively) on the rising edge of RU_CLK.
RU_CAPTnUPDT	Input to remote system upgrade block (driven by device logic array)	This pin determines if the contents of the shift register are captured or updated on the next clock edge. When the RU_SHIFTnLD signal is driven high (1'b1), this input signal has no function. When RU_SHIFTnLD is driven low (1'b0) and RU_CAPTnUPDT is driven high (1'b1), the remote system upgrade shift register captures the status register and either the control or update register (depending on whether the current configuration is application or factory, respectively) on the rising edge of RU_CLK. When RU_SHIFTnLD is driven low (1'b0) and RU_CAPTnUPDT is driven low (1'b0), the remote system upgrade update register is updated with the contents of the shift register on the rising edge of RU_CLK.
RU_DIN	Input to remote system upgrade block (driven by device logic array)	Data to be written to the remote system upgrade shift register on the rising edge of RU_CLK. To load data into the shift register, RU_SHIFTnLD must be asserted.
RU_DOUT	Output from remote system upgrade block (driven to device logic array)	Output data from the remote system upgrade shift register to be read by logic array logic. New data arrives on each rising edge of RU_CLK.

Quartus II Software Support

Implementation in your design requires a remote system upgrade interface between the Cyclone III device logic array and remote system upgrade circuitry. You also need to generate configuration files for production and remote programming of the system configuration memory. The Quartus II software provides these features.

The two implementation options, `altremote_update` megafunction and remote system upgrade atom, are for the interface between the remote system upgrade circuitry and the device logic array interface. Using the megafunction block instead of creating your own logic saves design time and offers more efficient logic synthesis and device implementation.

altremote_update Megafunction

The `altremote_update` megafunction provides a memory-like interface to the remote system upgrade circuitry and handles the shift register read/write protocol in Cyclone III device logic. This implementation is suitable for designs that implement the factory configuration functions using a Nios II processor in the device.

For more information on the `altremote_update` megafunction for Cyclone III devices, please contact Altera Technical Support from the Altera® web site at **www.altera.com/mysupport**.

Remote System Upgrade Atom

The remote system upgrade atom is a WYSIWYG atom or primitive that can be instantiated in your design. The primitive is used to access the remote system upgrade shift register, logic array reset, and watchdog timer reset signals. The ports on this primitive are the same as those listed in Table 12–11. This implementation is suitable for designs that implement the factory configuration functions using state machines (without a processor).

Conclusion

Cyclone III devices offer remote system upgrade capability, where you can upgrade a system in real-time through any network. Remote system upgrade helps to deliver feature enhancements and bug fixes without costly recalls, reduces time to market, and extends product life cycles. The dedicated remote system upgrade circuitry in Cyclone III devices provides error detection, recovery, and status information to ensure reliable reconfiguration.

Document Revision History

Table 12–12 shows the revision history for this document.

Table 12–12. Document Revision History		
Date and Document Version	**Changes Made**	**Summary of Changes**
March 2007 v1.0	Initial Release	N/A

CIII51013.1.0

Introduction

In critical applications used in the fields of avionics, telecommications, system control, medical, and military applications, it is important to be able to:

■ Confirm the accuracy of the configuration data stored in an FPGA device
■ Alert the system to an occurrence of a configuration error

Dedicated circuitry built into Cyclone® III devices consists of a cyclic redundancy check (CRC) error detection feature that can optionally check for a single event upset (SEU) continuously and automatically.

This section describes how to:

■ Activate and use the error detection CRC feature in user mode
■ Recover from configuration errors caused by CRC errors

☞ For Cyclone III devices, use of the error detection CRC feature is provided in the Quartus® II software, starting with version 6.1.

Using CRC error detection for the Cyclone III family does not impact fitting or performance.

Information about SEU is located in the Products page on the Altera® web site (**www.altera.com**).

Error Detection Fundamentals

Error detection determines if the data received through an input device has been corrupted during transmission. In validating the data, the transmitter uses a function to calculate a checksum value for the data and appends the checksum to the original data frame. The receiver uses the same calculation methodology to generate a checksum for the received data frame and compares the received checksum to the transmitted checksum. If the two checksum values are equal, the received data frame is correct and no data corruption occurred during transmission or storage.

The error detection CRC feature in Cyclone III devices puts theory into practice. In user mode, a Cyclone III device's error detection CRC feature ensures the integrity of the configuration data.

There are two CRC error checks:

- One always during configuration
- A second optional CRC error check runs in the background in user mode

For more information, refer to "Configuration Error Detection" on page 13–2 and "User Mode Error Detection" on page 13–2.

Configuration Error Detection

In configuration mode, a frame-based CRC is stored within the configuration data and contains the CRC value for each data frame.

During configuration, the FPGA calculates the CRC value based on the frame of data that is received and compares it against the frame CRC value in the data stream. Configuration continues until either the device detects an error or all the values are calculated.

For Cyclone III devices, the CRC is computed by the Quartus II software and downloaded into the device as part of the configuration bit stream. These devices store the CRC in the 32-bit storage register at the end of the configuration mode.

User Mode Error Detection

Soft errors are changes in a configuration random-access memory (CRAM) bit state due to an ionizing particle. All Cyclone series devices have built-in error detection circuitry to detect data corruption by soft errors in the CRAM cells.

This error detection capability continuously computes the CRC of the configured CRAM bits based on the contents of the device and compares it with the pre-calculated CRC value obtained at the end of the configuration. If the CRCs match, there is no error in the current configuration CRAM bits. The process of error detection continues until the device is reset (by setting nCONFIG to low).

The Cyclone III device error detection feature does not check memory blocks and I/O buffers. These device memory blocks support parity bits that are used to check the contents of memory blocks for any error. The I/O buffers are not verified during error detection because these bits use flip-flops as storage elements that are more resistant to soft errors. Similar flip-flops are used to store the pre-calculated CRC and other error detection circuitry option bits.

The error detection circuitry in Cyclone III devices uses a 32-bit CRC IEEE 802 standard and 32-bit polynomial as the CRC generator. Therefore, a single 32-bit CRC calculation is performed by the device. If a soft error does not occur, the resulting 32-bit signature value is 0x000000, which

results in a `0` on the output signal `CRC_ERROR`. If a soft error occurs within the device, the resulting signature value is non-zero and the `CRC_ERROR` output signal is `1`.

You can inject a soft error by changing the 32-bit CRC storage register in the CRC circuitry. After verifying the failure induced, you can restore the 32-bit CRC value to the correct CRC value using the same instruction and inserting the correct value. Be sure to read out the correct value first before updating it with a known bad value.

Cyclone III devices, when in user mode, support the `CHANGE_EDREG` Joint Test Action Group (JTAG) instruction, which allows you to write to the 32-bit storage register. You can use Jam files (**.jam**) to automate the testing and verification process. This is a powerful design feature that enables you to dynamically verify the CRC functionality in-system without having to reconfigure the device. You can then switch to use the CRC circuit to check for real errors induced by an SEU. You can only execute the `CHANGE_EDREG` JTAG instruction when the device is in user mode.

Table 13–1. CHANGE_EDREG JTAG Instruction

JTAG Instruction	Instruction Code	Description
CHANGE_EDREG	00 0001 0101	This instruction connects the 32-bit CRC storage register between `TDI` and `TDO`. Any precomputed CRC is loaded into the CRC storage register to test the operation of the error detection CRC circuitry at the `CRC_ERROR` pin.

☞ After the test completes, Altera recommends that you reconfigure the device.

Automated Single Event Upset Detection

Cyclone III devices offer on-chip circuitry for automated checking of SEU detection. Applications that require the device to operate error-free at high elevations or in close proximity to earth's North or South Pole require periodic checks to ensure continued data integrity. The error detection cyclic redundancy code feature controlled by the **Device & Pin Options** dialog box in the Quartus II software uses a 32-bit CRC circuit to ensure data reliability and is one of the best options for mitigating SEU.

You can implement the error detection CRC feature with existing circuitry in Cyclone III devices, eliminating the need for external logic. The CRC is computed by the device during configuration and checked against an automatically computed CRC during normal operation. The `CRC_ERROR`

pin reports a soft error when configuration CRAM data is corrupted, and you have to decide whether to reconfigure the FPGA by strobing the nCONFIG pin low or ignore the error.

Error Detection Pin Description

A specific error detection pin, CRC_ERROR, is required to monitor the results of the error detection circuitry during user mode.

CRC_ERROR Pin

Table 13–2 describes the CRC_ERROR pin.

Table 13–2. CRC_ERROR Pin Description

Pin Name	Pin Type	Description
CRC_ERROR	I/O, output	This is an active high signal that indicates that the error detection circuit has detected errors in the configuration CRAM bits. This pin is optional and is used when the error detection CRC circuit is enabled. When the error detection CRC circuit is disabled, it is a user I/O pin. The CRC error output, when using the WYSIWYG function, is a dedicated path to the CRC_ERROR pin. The CRC_ERROR pin does not support open-drain or inversion.

The CRC_ERROR pin information for Cyclone III devices is reported in the Device Pin-Outs on the **Literature** page of the Altera web site (**www.altera.com**).

Error Detection Block

You can enable the Cyclone III device error detection block in the Quartus II software (refer to "Software Support" on page 13–8). This block contains the logic necessary to calculate the 32-bit CRC signature for the configuration CRAM bits in the device.

The CRC circuit continues running even if an error occurs. When a soft error occurs, the device sets the CRC_ERROR pin high. There are two types of CRC detection to check the configuration bits:

■ CRAM error checking ability (32-bit CRC) during user mode, for use by the CRC_ERROR pin.

☞ There is only one 32-bit CRC value and this 32-bit CRC value covers all of the CRAM data.

■ 16-bit CRC embedded in every configuration data frame.

During configuration, after a frame of data has loaded into the device, the pre-computed CRC is shifted into the CRC circuitry. Simultaneously, the CRC value for the data frame shifted-in is calculated. If the pre-computed CRC and calculated CRC values do not match, `nSTATUS` is set low. Every data frame has a 16-bit CRC, and therefore, there are many 16-bit CRC values for the whole configuration bit stream. Every device has a different length of the configuration data frame.

This section focuses on the first type, the 32-bit CRC when the device is in user mode.

Error Detection Registers

There are two sets of 32-bit registers in the error detection circuitry that store the computed CRC signature and precalculated CRC value. A non-zero value on the signature register causes the `CRC_ERROR` pin to set high. Figure 13–1 shows the block diagram of the error detection block and the two related 32-bit registers: the signature register and the storage register.

Figure 13–1. Error Detection Block Diagram
Table 13–3 defines the registers shown in Figure 13–1.

Table 13–3. Error Detection Registers

Register	Function
32-bit signature register	This register contains the CRC signature. The signature register contains the result of the user mode calculated CRC value compared against the pre-calculated CRC value. If no errors are detected, the signature register is all zeros. A non-zero signature register indicates an error in the configuration CRAM contents. The CRC_ERROR signal is derived from the contents of this register.
32-bit storage register	This register is loaded with the 32-bit pre-computed CRC signature at the end of the configuration stage. The signature is then loaded into the 32-bit CRC circuit (called the Compute & Compare CRC block, as shown in Figure 13–1) during user mode to calculate the CRC error. This register forms a 32-bit scan chain during execution of the CHANGE_EDREG JTAG instruction. The CHANGE_EDREG JTAG instruction can change the content of the storage register. Therefore, the functionality of the error detection CRC circuitry is checked in-system by executing the instruction to inject an error during the operation. The operation of the device is not halted when issuing the CHANGE_EDREG instruction.

Error Detection Timing

When the error detection CRC feature is enabled through the Quartus II software, the device automatically activates the CRC process upon entering user mode, after configuration and initialization is complete.

The CRC_ERROR pin is driven low until the error detection circuitry has detected a corrupted bit in the previous CRC calculation. Once the pin goes high, it remains high during the next CRC calculation. This pin does not log the previous CRC calculation. If the new CRC calculation does not contain any corrupted bits, the CRC_ERROR pin is driven low. The error detection runs until the device is reset.

The error detection circuitry runs off an internal configuration oscillator with a divisor that sets the maximum frequency. Table 13–4 shows the minimum and maximum error detection frequencies.

Table 13–4. Minimum and Maximum Error Detection Frequencies

Device Type	Error Detection Frequency	Maximum Error Detection Frequency	Minimum Error Detection Frequency	Valid Divisors (2^n)
Cyclone III	80 MHz/2^n	80 MHz	312.5 kHz	0, 1, 2, 3, 4, 5, 6, 7, 8

You can set a lower clock frequency by specifying a division factor in the Quartus II software (refer to "Software Support" on page 13–8). The divisor is a power of two (2), where *n* is between 0 and 8. The divisor ranges from 1 through 256. See the following equation:

$$\text{Error detection frequency} = \frac{80MHz}{2^n}$$

CRC calculation time depends on the device and the error detection clock frequency. Table 13–5 shows the estimated time for each CRC calculation with minimum and maximum clock frequencies for Cyclone III devices.

Table 13–5. CRC Calculation Time

Device	Minimum Time (ms) *(1)*	Maximum Time (s) *(2)*
EP3C5	5	2.29
EP3C10	5	2.29
EP3C16	7	3.17
EP3C25	9	4.51
EP3C40	15	7.48
EP3C55	23	11.77
EP3C80	31	15.81
EP3C120	45	22.67

Notes to Table 13–5:
(1) The minimum time corresponds to the maximum error detection clock frequency and may vary with different processes, voltages, and temperatures.
(2) The maximum time corresponds to the minimum error detection clock frequency and may vary with different processes, voltages, and temperatures.

Software Support

Starting with version 6.1, Quartus II supports the error detection CRC feature. Enabling this feature generates the CRC_ERROR output to the optional dual purpose CRC_ERROR pin.

The error detection CRC feature is controlled by the **Device & Pin Options** dialog box in the Quartus II software.

Enable the error detection feature using CRC by performing the following steps:

1. Open the Quartus II software and load a project using a Stratix or Cyclone series device.

2. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.

3. In the Category list, select **Device**. The **Device** page appears.

4. Click **Device & Pin Options**, as shown in Figure 13–2.

5. In the **Device & Pin Options** dialog box, click the **Error Detection CRC** tab.

6. Turn on **Enable error detection CRC**.

7. In the **Divide error check frequency by** box, enter a valid divisor as documented in Table 13–4.

☞ The divisor value divides down the frequency of the configuration oscillator output clock that measures the CRC circuitry.

8. Click **OK**.

Figure 13–2. Enabling the Error Detection CRC Feature in the Quartus II Software
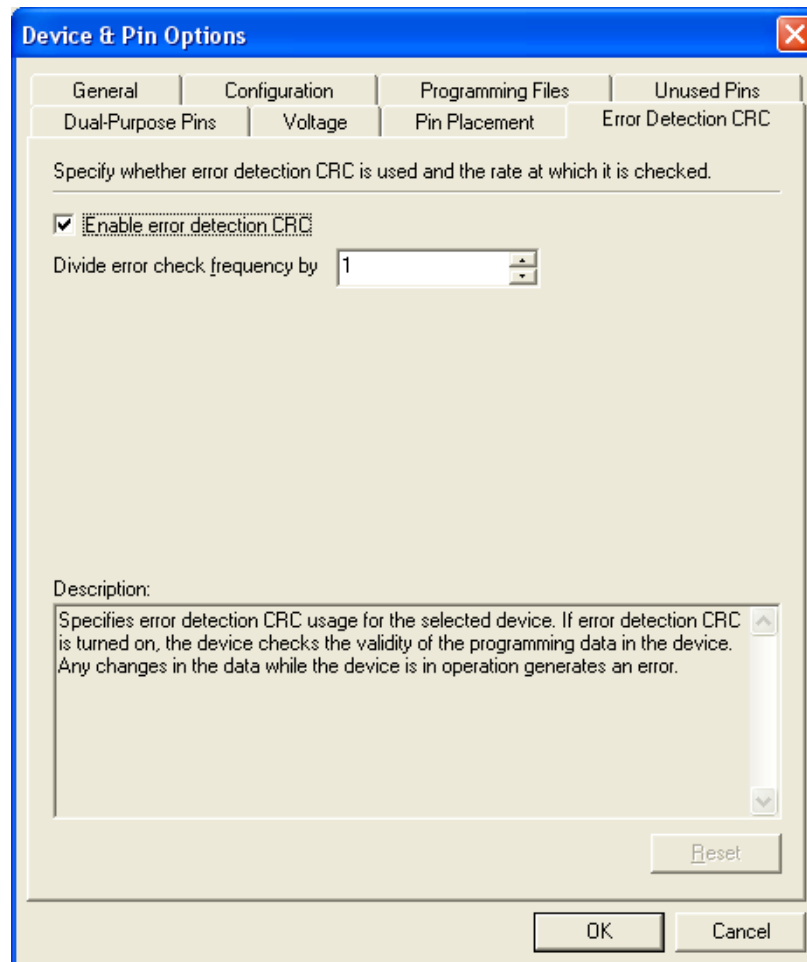

Recovering from CRC Errors

The system that the Altera FPGA resides in must control device reconfiguration. After detecting an error on the `CRC_ERROR` pin, strobing the `nCONFIG` low directs the system to perform the reconfiguration at a time when it is safe for the system to reconfigure the FPGA.

When the data bit is rewritten with the correct value by reconfiguring the device, the device functions correctly.

While soft errors are uncommon in Altera devices, certain high-reliability applications may require a design to account for these errors.

Conclusion

The purpose of the error detection CRC feature is to detect a flip in any of the configuration CRAM bits in Cyclone III devices due to a soft error. By using the error detection circuitry, you can continuously verify the integrity of the configuration CRAM bits.

Document Revision History

Table 13–6 shows the revision history for this document.

March 2007 v1.0	Initial Release	N/A

Introduction

As PCBs become more complex, the need for thorough testing becomes increasingly important. Advances in surface-mount packaging and PCB manufacturing have resulted in smaller boards, making traditional test methods (such as external test probes and "bed-of-nails" test fixtures) harder to implement. As a result, cost savings from PCB space reductions increase the cost for traditional testing methods.

In the 1980s, the JTAG developed a specification for boundary-scan testing that was later standardized as the IEEE Std. 1149.1 specification. This boundary-scan test (BST) architecture offers the ability to efficiently test components on PCBs with tight lead spacing.

BST architecture tests pin connections without using physical test probes and captures functional data while a device is operating normally. Boundary-scan cells in a device can force signals onto pins or capture data from pin or logic array signals. Forced test data is serially shifted into the boundary-scan cells. Captured data is serially shifted out and externally compared to expected results. Figure 14–1 illustrates the concept of BST.

Figure 14–1. IEEE Std. 1149.1 Boundary-Scan Testing
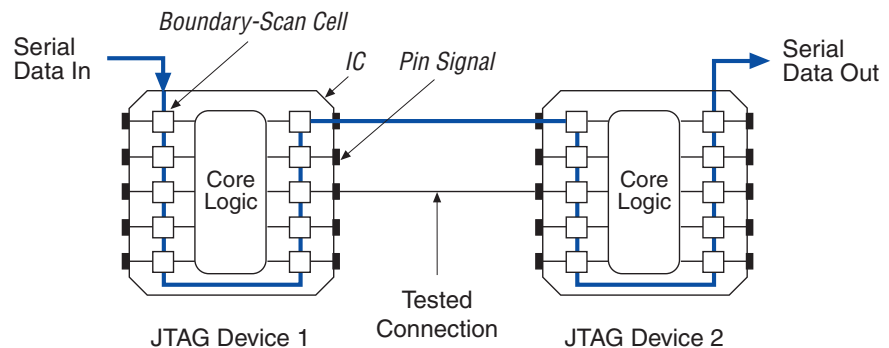

This chapter discusses how to use the IEEE Std. 1149.1 BST circuitry in Cyclone® III devices, including:

■ IEEE Std. 1149.1 BST architecture
■ IEEE Std. 1149.1 boundary-scan register
■ IEEE Std. 1149.1 BST operation control
■ I/O voltage support in JTAG chain
■ Using IEEE Std. 1149.1 BST circuitry

■   BST for configured devices
■   Disabling IEEE Std. 1149.1 BST circuitry
■   Guidelines for IEEE Std. 1149.1 boundary-scan testing
■   Boundary-scan description language (BSDL) support

In addition to BST, you can use the IEEE Std. 1149.1 controller for Cyclone III device in-circuit reconfiguration (ICR). However, this chapter only discusses the BST feature of the IEEE Std. 1149.1 circuitry.

☞   For information on configuring Cyclone III devices via the IEEE Std. 1149.1 circuitry, refer to the *Configuring Cyclone III Devices* chapter in the *Cyclone III Device Handbook*.

IEEE Std. 1149.1 BST Architecture

A Cyclone III device operating in IEEE Std. 1149.1 BST mode uses four required pins, TDI, TDO, TMS and TCK. The TCK pin has an internal weak pull-down resistor, while the TDI and TMS pins have weak internal pull-up resistors. The TDO output pin and all the JTAG input pins are powered by the 2.5-V/3.0-V V_{CCIO} supply. All user I/O pins are tri-stated during JTAG configuration.

☞   For recommendations on how to connect a JTAG chain with multiple voltages across the devices in the chain, refer to "I/O Voltage Support in JTAG Chain" on Pg. 19.

Table 14–1 summarizes the functions of each of these pins.

Table 14–1. IEEE Std. 1149.1 Pin Descriptions		
Pin	**Description**	**Function**
TDI	Test data input	Serial input pin for instructions as well as test and programming data. A signal applied to TDI is expected to change state at the falling edge of TCK. Data is shifted in on the rising edge of TCK.
TDO	Test data output	Serial data output pin for instructions as well as test and programming data. Data is shifted out on the falling edge of TCK. The pin is tri-stated if data is not being shifted out of the device.
TMS	Test mode select	Input pin that provides the control signal to determine the transitions of the Test Access Port (TAP) controller state machine. Transitions within the state machine occur at the rising edge of TCK. Therefore, TMS must be set up before the rising edge of TCK. TMS is evaluated on the rising edge of TCK. During non-JTAG operation, TMS is recommended to be driven high.
TCK	Test clock input	The clock input to the BST circuitry. Some operations occur at the rising edge, while others occur at the falling edge.

The IEEE Std. 1149.1 BST circuitry requires the following registers:

■ The instruction register determines the action to be performed and the data register to be accessed.
■ The bypass register is a 1-bit-long data register that provides a minimum-length serial path between TDI and TDO.
■ The boundary-scan register is a shift register composed of all the boundary-scan cells of the device.

Figure 14–2 shows a functional model of the IEEE Std. 1149.1 circuitry.

Figure 14–2. IEEE Std. 1149.1 Circuitry
Notes to Figure 14–2:
(1) For register lengths, see the device data sheet in the Configuring Cyclone III Devices chapter of the Cyclone III Device Handbook.

IEEE Std. 1149.1 boundary-scan testing is controlled by a test access port (TAP) controller. For more information on the TAP controller, refer to the "IEEE Std. 1149.1 BST Operation Control" section. The `TMS` and `TCK` pins operate the TAP controller, and the `TDI` and `TDO` pins provide the serial path for the data registers. The `TDI` pin also provides data to the instruction register, which then generates control logic for the data registers.

IEEE Std. 1149.1 Boundary-Scan Register

The boundary-scan register is a large serial shift register that uses the `TDI` pin as an input and the `TDO` pin as an output. The boundary-scan register consists of 3-bit peripheral elements that are associated with Cyclone III I/O pins. You can use the boundary-scan register to test external pin connections or to capture internal data.

For more information on the Cyclone III device family's boundary-scan register lengths, refer to the *Configuring Cyclone III Devices* chapter of the *Cyclone III Device Handbook*.

Figure 14–3 shows how test data is serially shifted around the periphery of the IEEE Std. 1149.1 device.

Figure 14–3. Boundary-Scan Register

Each peripheral element is either an I/O pin, dedicated input pin, or dedicated configuration pin.
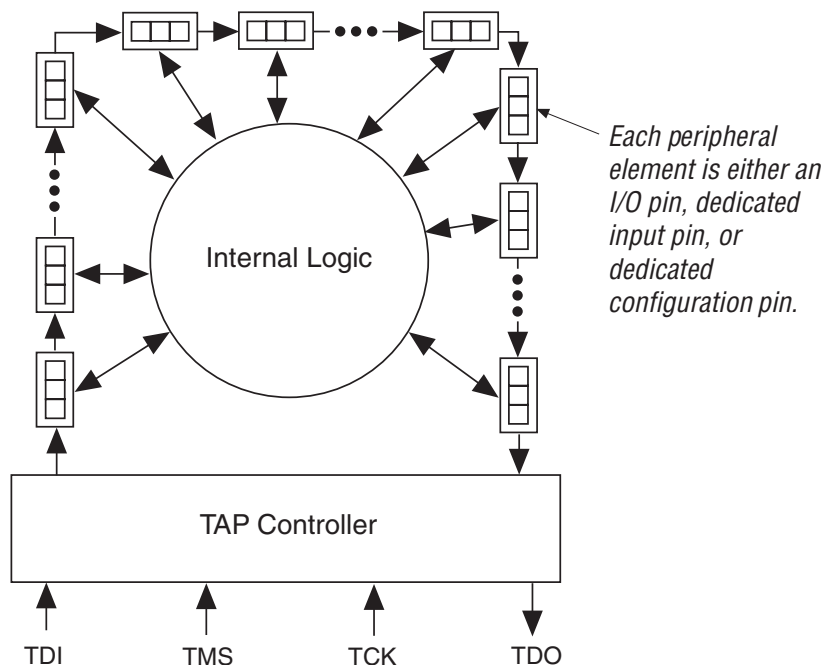

Table 14–2 shows the boundary-scan register length for Cyclone III devices.

Table 14–2. Cyclone III Boundary-Scan Register Length

Device	Boundary-Scan Register Length
EP3C5	603
EP3C10	603
EP3C16	1080
EP3C25	732
EP3C40	1632
EP3C55	1164
EP3C80	1314
EP3C120	1620

Boundary-Scan Cells of a Cyclone III Device I/O Pin

The Cyclone III device 3-bit boundary-scan cell (BSC) consists of a set of capture registers and a set of update registers. The capture registers can connect to internal device data via the OUTJ, OEJ, and PIN_IN signals, while the update registers connect to external data through the PIN_OUT, and PIN_OE signals. The global control signals for the IEEE Std. 1149.1 BST registers (such as shift, clock, and update) are generated internally by the TAP controller. The MODE signal is generated by a decode of the instruction register. The HIGHZ signal is high when executing the HIGHZ instruction. The data signal path for the boundary-scan register runs from the SDI signal to the SDO signal. The scan register begins at the TDI pin and ends at the TDO pin of the device.

Figure 14–4 shows the Cyclone III device's user I/O boundary-scan cell.

Figure 14–4. Cyclone III Device's User I/O BSC with IEEE Std. 1149.1 BST Circuitry
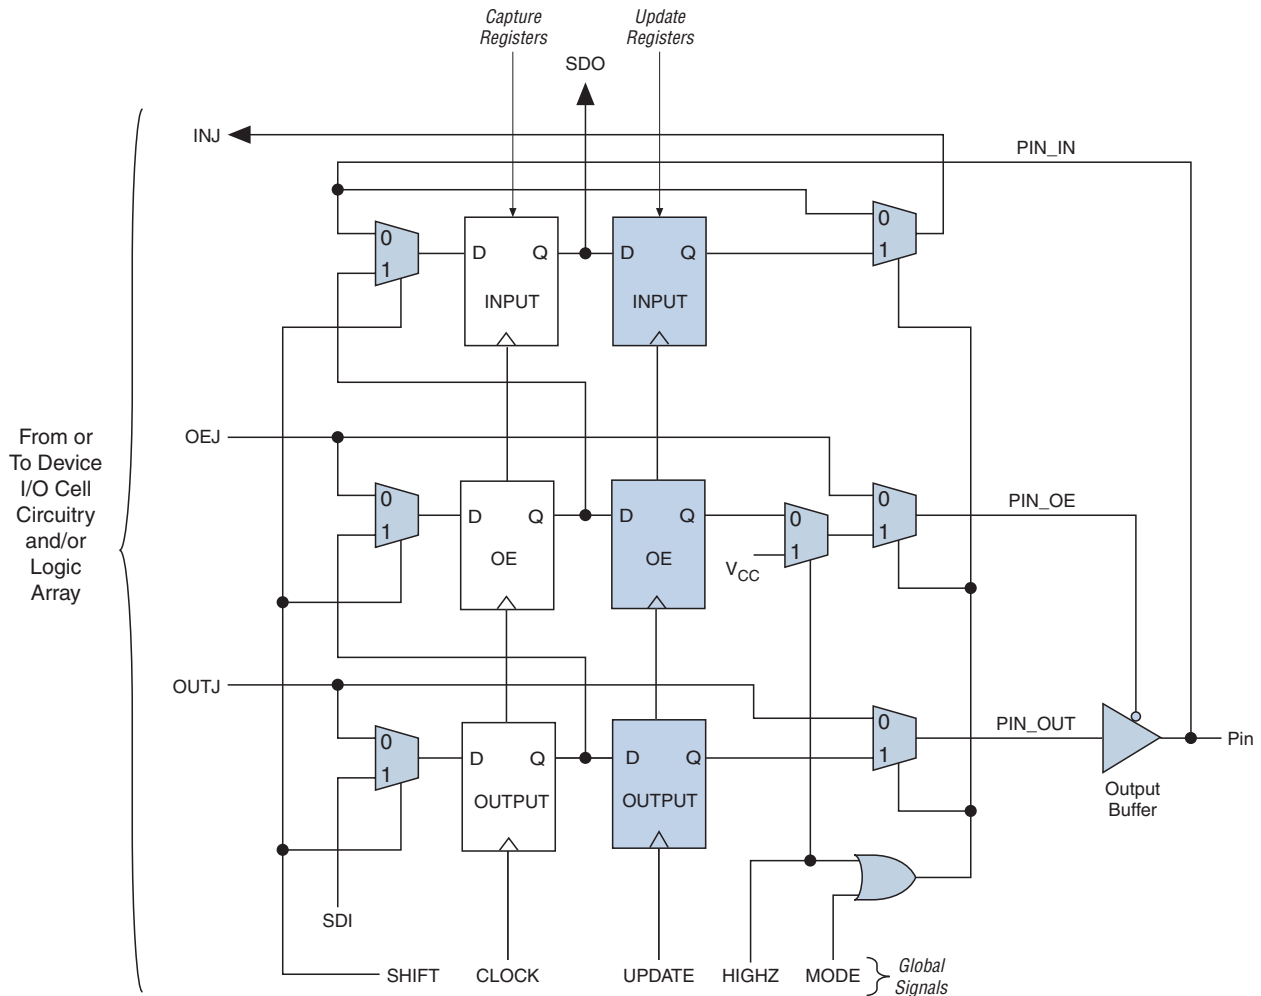

Table 14–3 describes the capture and update register capabilities of all boundary-scan cells within Cyclone III devices.

Table 14–3. Cyclone III Device Boundary Scan Cell Descriptions Note (1)							
	Captures			Drives			
Pin Type	Output Capture Register	OE Capture Register	Input Capture Register	Output Update Register	OE Update Register	Input Update Register	Comments
User I/O pins	OUTJ	OEJ	PIN_IN	PIN_OUT	PIN_OE	INJ	
Dedicated clock input	0	1	PIN_IN	N.C. (2)	N.C. (2)	N.C. (2)	PIN_IN drives to clock network or logic array
Dedicated input (3)	0	1	PIN_IN	N.C. (2)	N.C. (2)	N.C. (2)	PIN_IN drives to control logic
Dedicated bidirectional (open drain) (4)	0	OEJ	PIN_IN	N.C. (2)	N.C. (2)	N.C. (2)	PIN_IN drives to configuration control
Dedicated output	OUTJ	0	0	N.C. (2)	N.C. (2)	N.C. (2)	OUTJ drives to output buffer

Notes to Table 14–3:

(1)   TDI, TDO, TMS, TCK, all V_{CC} and GND pin types do not have BSCs.
(2)   No Connect (N.C.).
(3)   This includes pins nCONFIG, MSEL0, MSEL1, MSEL2, MSEL3, and nCE.
(4)   This includes pins CONF_DONE and nSTATUS.

IEEE Std. 1149.1 BST Operation Control

Cyclone III devices support the IEEE Std. 1149.1 (JTAG) instructions shown in Table 14–4.

Table 14–4. Cyclone III JTAG Instructions		
JTAG Instruction	Instruction Code	Description
SAMPLE/PRELOAD	00 0000 0101	Allows a snapshot of signals at the device pins to be captured and examined during normal device operation, and permits an initial data pattern to be output at the device pins. Also used by the SignalTap II embedded logic analyzer.
EXTEST (1)	00 0000 1111	Allows the external circuitry and board-level interconnects to be tested by forcing a test pattern at the output pins and capturing test results at the input pins.

Table 14–4. Cyclone III JTAG Instructions

JTAG Instruction	Instruction Code	Description
BYPASS	11 1111 1111	Places the 1-bit bypass register between the `TDI` and `TDO` pins, which allows the BST data to pass synchronously through selected devices to adjacent devices during normal device operation.
USERCODE	00 0000 0111	Selects the 32-bit `USERCODE` register and places it between the `TDI` and `TDO` pins, allowing the `USERCODE` to be serially shifted out of `TDO`.
IDCODE	00 0000 0110	Selects the `IDCODE` register and places it between `TDI` and `TDO`, allowing the `IDCODE` to be serially shifted out of `TDO`.
HIGHZ	00 0000 1011	Places the 1-bit bypass register between the `TDI` and `TDO` pins, which allows the `BST` data to pass synchronously through selected devices to adjacent devices during normal device operation, while tri-stating all of the I/O pins.
CLAMP	00 0000 1010	Places the 1-bit bypass register between the `TDI` and `TDO` pins, which allows the `BST` data to pass synchronously through selected devices to adjacent devices during normal device operation while holding I/O pins to a state defined by the data in the boundary-scan register.
ICR instructions		Used when configuring a Cyclone III device via the JTAG port with a USB Blaster™ ByteBlaster™ II, MasterBlaster™ or ByteBlasterMV™ download cable, or when using a Jam File, or JBC File via an embedded processor.
PULSE_NCONFIG	00 0000 0001	Emulates pulsing the `nCONFIG` pin low to trigger reconfiguration even though the physical pin is unaffected.
CONFIG_IO *(2)*	00 0000 1101	Allows I/O reconfiguration through JTAG ports using the `IOCSR` for JTAG testing. Can be executed after or during configurations. `nSTATUS` pin must go high before you can issue the `CONFIG_IO` instruction.
ACTIVE_DISENGAGE *(2)*	10 1101 0000	Places the active configuration mode controllers into idle state prior to CONFIG_IO to configure the IOCSR or perform board level testing.
ACTIVE_ENGAGE *(2)*	10 1011 0000	This instruction may need to be used in AS and AP configuration schemes to re-engage the active controller.
APFC_BOOT_ADDR *(2)*	10 0111 0000	Places the 22-bit active boot address register between the `TDI` and `TDO` pins, allowing a new active boot address to be serially shifted into `TDI` and into the active parallel (AP) flash controller. In remote system upgrade, the `APFC_BOOT_ADDR` instruction sets the boot address for the factory configuration.

Table 14–4. Cyclone III JTAG Instructions

JTAG Instruction	Instruction Code	Description
SignalTap II instructions		Monitors internal device operation with the SignalTap II embedded logic analyzer.

Notes to Table 14–4:
(1) Bus hold and weak pull-up resistor features override the high-impedance state of HIGHZ, CLAMP, and EXTEST.
(2) For more information on how to use CONFIG_IO, ACTIVE_DISENGAGE, ACTIVE_ENGAGE and APFC_BOOT_ADDR instructions for Cyclone III devices, refer to the *Configuring Cyclone III Devices* chapter of the *Cyclone III Device Handbook*.

The IEEE Std. 1149.1 TAP controller, a 16-state state machine clocked on the rising edge of TCK, uses the TMS pin to control IEEE Std. 1149.1 operation in the device. Figure 14–5 shows the TAP controller state machine.

Figure 14–5. IEEE Std. 1149.1 TAP Controller State Machine
When the TAP controller is in the TEST_LOGIC/RESET state, the BST circuitry is disabled, the device is in normal operation, and the instruction register is initialized with IDCODE as the initial instruction. At device power-up, the TAP controller starts in this TEST_LOGIC/RESET state. In addition, forcing the TAP controller to the TEST_LOGIC/RESET state is done by holding TMS high for five TCK clock cycles. Once in the TEST_LOGIC/RESET state, the TAP controller remains in this state as long as TMS is held high (while TCK is clocked). Figure 14–6 shows the timing requirements for the IEEE Std. 1149.1 signals.

Figure 14–6. IEEE Std. 1149.1 Timing Waveforms (1)
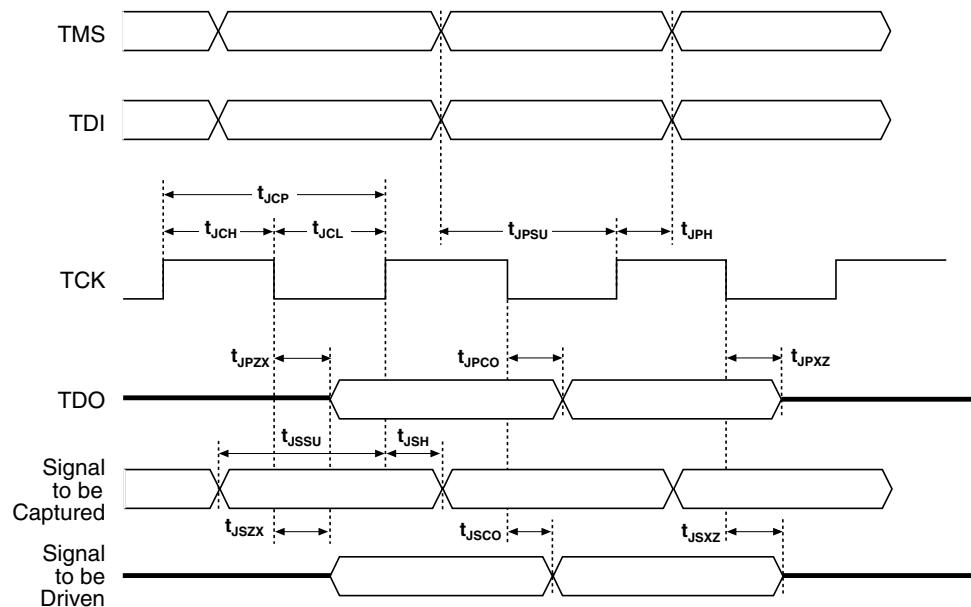

Notes to Figure 6:
(1)   For JTAG timing parameters, please refer to the *DC andSwitching Characteristics* chapter in the *Cyclone III Device Handbook.*

To start IEEE Std. 1149.1 operation, select an instruction mode by advancing the TAP controller to the shift instruction register (SHIFT_IR) state and shift in the appropriate instruction code on the TDI pin. The waveform diagram in Figure 14–7 represents the entry of the instruction code into the instruction register. Figure 14–7 shows the values of TCK, TMS, TDI, TDO, and the states of the TAP controller. From the RESET state, TMS is clocked with the pattern 01100 to advance the TAP controller to SHIFT_IR.

Figure 14–7. Selecting the Instruction Mode
The TDO pin is tri-stated in all states except in the SHIFT_IR and SHIFT_DR states. The TDO pin is activated at the first falling edge of TCK after entering either of the shift states and is tri-stated at the first falling edge of TCK after leaving either of the shift states.

When the SHIFT_IR state is activated, TDO is no longer tri-stated, and the initial state of the instruction register is shifted out on the falling edge of TCK. The first 10 bits shifted out from the instruction register are 1010101010. TDO continues to shift out the contents of the instruction register as long as the SHIFT_IR state is active. The TAP controller remains in the SHIFT_IR state as long as TMS remains low.

During the SHIFT_IR state, an instruction code is entered by shifting data on the TDI pin on the rising edge of TCK. The last bit of the instruction code is clocked at the same time that the next state, EXIT1_IR, is activated. Set TMS to high to activate the EXIT1_IR state. Once in the EXIT1_IR state, TDO becomes tri-stated again. After an instruction code is entered correctly, the TAP controller advances to serially shift test data in one of three modes. The three serial shift test data instruction modes are:

- SAMPLE/PRELOAD Instruction Mode
- EXTEST Instruction Mode
- BYPASS Instruction Mode

These three modes will be discussed in greater detail in the following three sections.

SAMPLE/PRELOAD Instruction Mode

The SAMPLE/PRELOAD instruction mode allows you to take a snapshot of device data without interrupting normal device operation. However, this instruction is most often used to preload the test data into the update registers prior to loading the EXTEST instruction. Figure 14–8 shows the capture, shift, and update phases of the SAMPLE/PRELOAD mode.

Figure 14–8. IEEE Std. 1149.1 BST SAMPLE/PRELOAD Mode
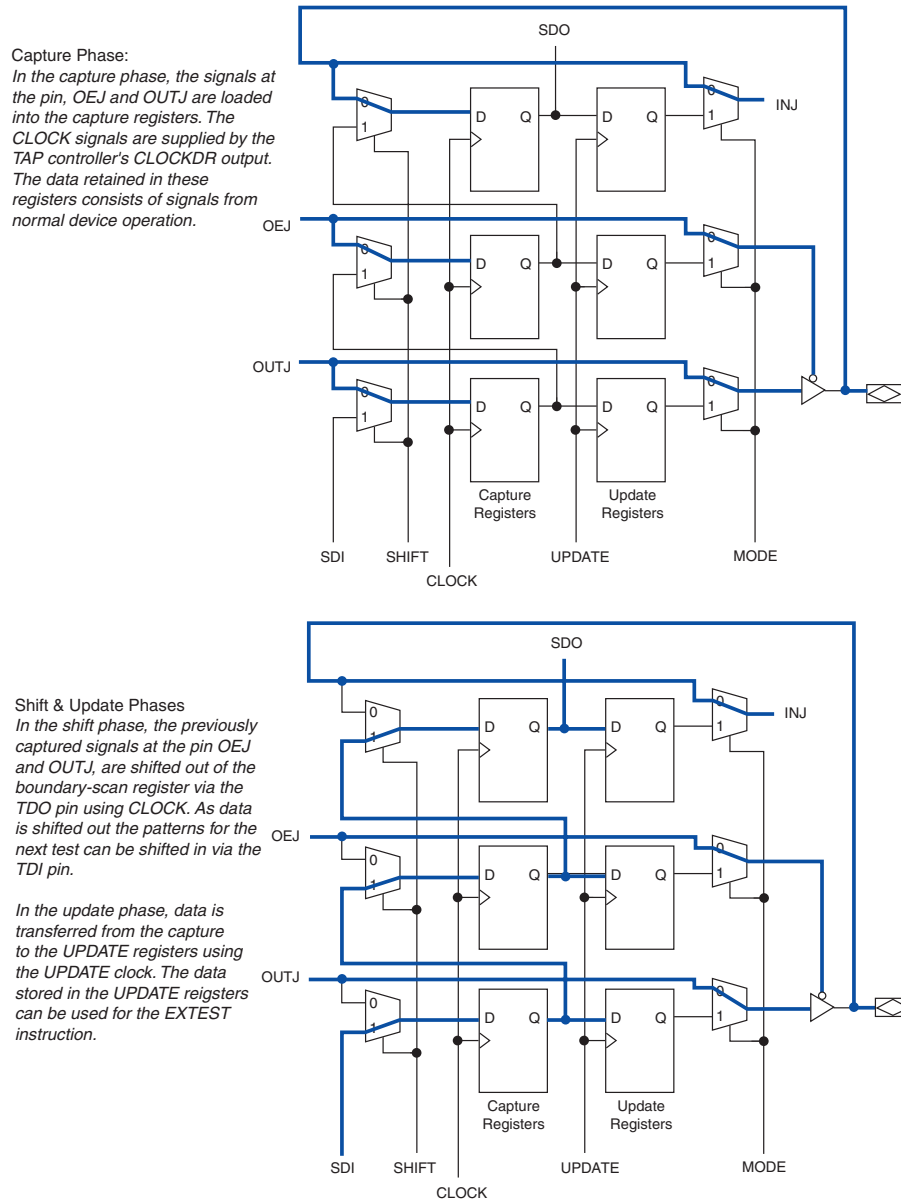

During the capture phase, multiplexers preceding the capture registers select the active device data signals. This data is then clocked into the capture registers. The multiplexers at the outputs of the update registers also select active device data to prevent functional interruptions to the device. During the shift phase, the boundary-scan shift register is formed by clocking data through capture registers around the device periphery and then out of the TDO pin. The device can simultaneously shift new test data into TDI and replace the contents of the capture registers. During the update phase, data in the capture registers is transferred to the update registers. This data can then be used in the EXTEST instruction mode. Refer to the "EXTEST Instruction Mode" section for more information.

Figure 14–9 shows the SAMPLE/PRELOAD waveforms. The SAMPLE/PRELOAD instruction code is shifted in through the TDI pin. The TAP controller advances to the CAPTURE_DR state and then to the SHIFT_DR state, where it remains if TMS is held low. The data that was present in the capture registers after the capture phase is shifted out of the TDO pin. New test data shifted into the TDI pin appears at the TDO pin after being clocked through the entire boundary-scan register. If TMS is held high on two consecutive TCK clock cycles, the TAP controller advances to the UPDATE_DR state for the update phase.

Figure 14–9. SAMPLE/PRELOAD Shift Data Register Waveforms
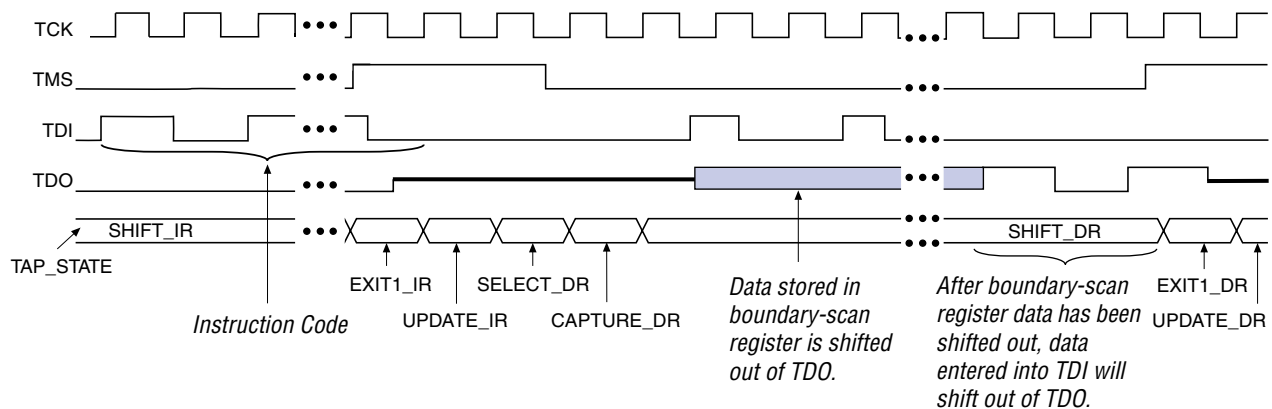

EXTEST Instruction Mode

The EXTEST instruction mode is used primarily to check external pin connections between devices. Unlike the SAMPLE/PRELOAD mode, EXTEST allows test data to be forced onto the pin signals. By forcing known logic high and low levels on output pins, opens and shorts can be detected at pins of any device in the scan chain.

Figure 14–10 shows the capture, shift, and update phases of the EXTEST mode.

Figure 14–10. IEEE Std. 1149.1 BST EXTEST Mode

Capture Phase
In the capture phase, the signals at the pin, OEJ and OUTJ, are loaded into the capture registers. The CLOCK signals are supplied by the TAP controller's CLOCKDR output. Previously retained data in the update registers drive the PIN_OUT, INJ and allows the I/O pin to tri-state or drive a signal out.

A "1" in the OEJ update register tri-states the output buffer.
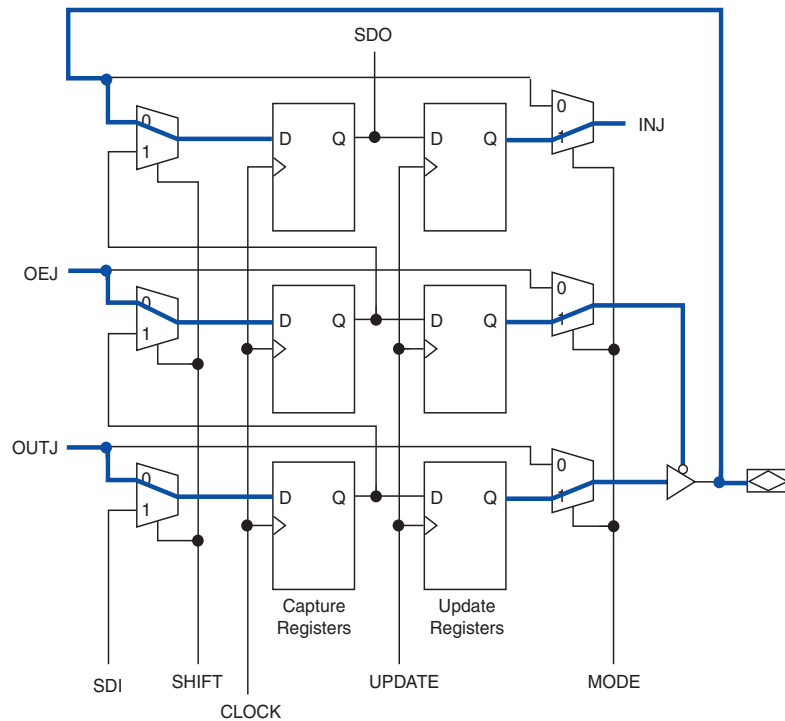

Shift & Update Phases
In the shift phase, the previously captured signals at the pin, OEJ and OUTJ, are shifted out of the boundary-scan register via the TDO pin using CLOCK. As data is shifted out, the patterns for the next test can be shifted in via the TDI pin.

In the update phase, data is transferred from the capture registers to the update registers using the UPDATE clock. The update registers then drive the PIN_IN, INU, and allow the I/O pin to tri-state or drive a signal out.
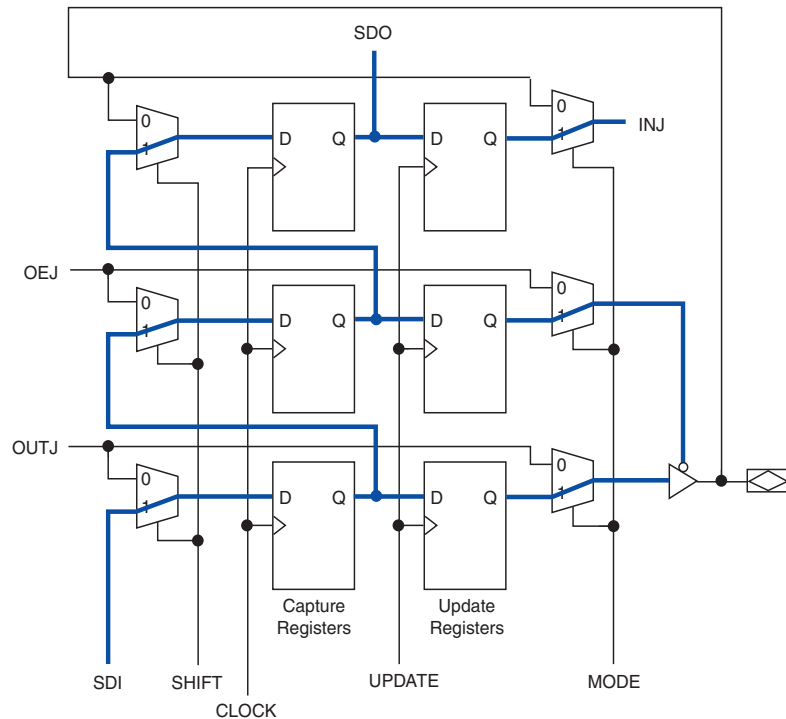

EXTEST selects data differently than SAMPLE/PRELOAD. EXTEST chooses data from the update registers as the source of the output and output enable signals. Once the EXTEST instruction code is entered, the multiplexers select the update register data. Thus, data stored in these registers from a previous EXTEST or SAMPLE/PRELOAD test cycle can be forced onto the pin signals. In the capture phase, the results of this test data are stored in the capture registers and then shifted out of TDO during the shift phase. New test data can then be stored in the update registers during the update phase.

The EXTEST waveform diagram in Figure 14–11 resembles the SAMPLE/PRELOAD waveform diagram, except for the instruction code. The data shifted out of TDO consists of the data that was present in the capture registers after the capture phase. New test data shifted into the TDI pin appears at the TDO pin after being clocked through the entire boundary-scan register.

Figure 14–11. EXTEST Shift Data Register Waveforms
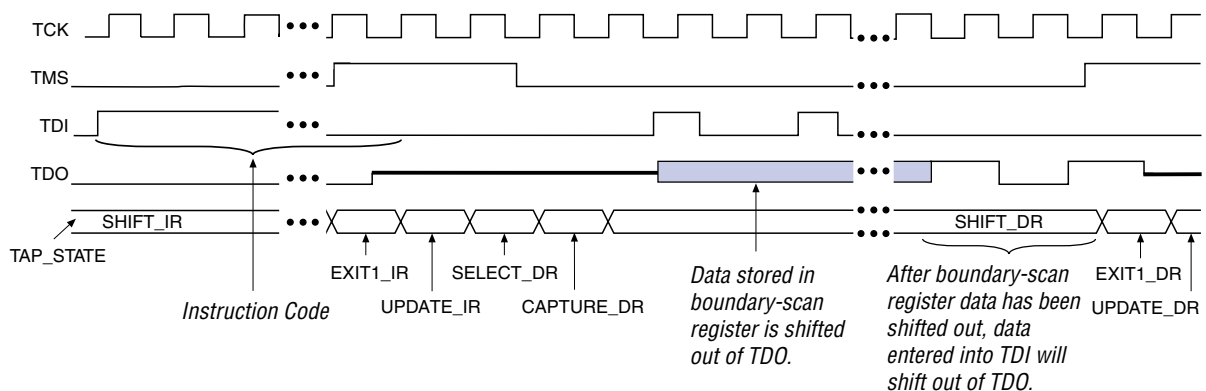

BYPASS Instruction Mode

The BYPASS mode is activated when an instruction code of all ones is loaded in the instruction register. This mode allows the boundary scan data to pass the selected device synchronously to adjacent devices when no test operation of the device is needed at the board level. The waveforms in Figure 14–12 show how scan data passes through a device once the TAP controller is in the SHIFT_DR state. In this state, data signals are clocked into the bypass register from TDI on the rising edge of TCK and out of TDO on the falling edge of the same clock pulse.

Figure 14–12. BYPASS Shift Data Register Waveforms
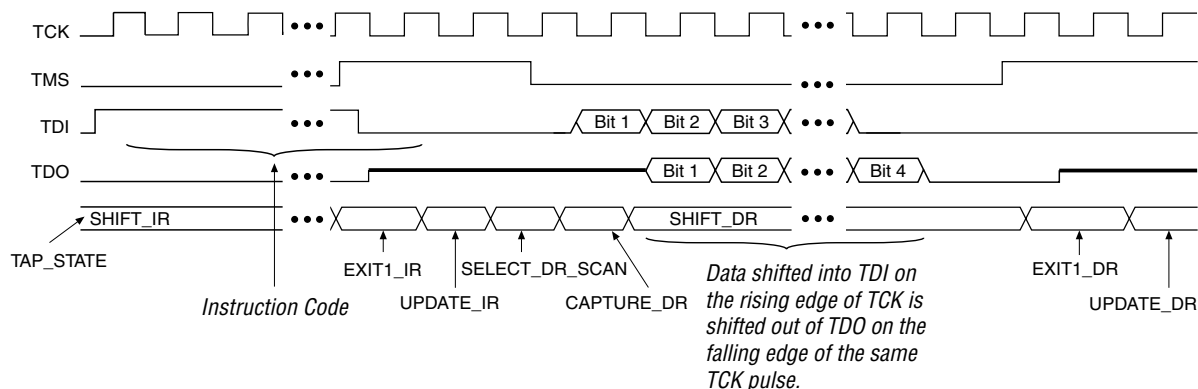

IDCODE Instruction Mode

The IDCODE instruction mode is used to identify the devices in an IEEE Std. 1149.1 chain. When IDCODE is selected, the device identification register is loaded with the 32-bit vendor-defined identification code. The device ID register is connected between the TDI and TDO ports, and the device IDCODE is shifted out.

Table 14–5 shows the IDCODE information for Cyclone III devices.

Table 14–5. 32-Bit Cyclone III Device IDCODE

Device	IDCODE (32 Bits) *(1)*			
	Version (4 Bits)	Part Number (16 Bits)	Manufacturer Identity (11 Bits)	LSB (1 Bit) *(2)*
EP3C5	0000	0010 0000 1111 0001	000 0110 1110	1
EP3C10	0000	0010 0000 1111 0001	000 0110 1110	1
EP3C16	0000	0010 0000 1111 0010	000 0110 1110	1
EP3C25	0000	0010 0000 1111 0011	000 0110 1110	1
EP3C40	0000	0010 0000 1111 0100	000 0110 1110	1
EP3C55	0000	0010 0000 1111 0101	000 0110 1110	1
EP3C80	0000	0010 0000 1111 0110	000 0110 1110	1

Table 14–5. 32-Bit Cyclone III Device IDCODE				
Device	**IDCODE (32 Bits)** *(1)*			
	Version (4 Bits)	**Part Number (16 Bits)**	**Manufacturer Identity (11 Bits)**	**LSB (1 Bit)** *(2)*
EP3C120	0000	0010 0000 1111 0111	000 0110 1110	1

Notes to Table 14–5:
(1) The most significant bit (MSB) is on the left.
(2) The IDCODE's least significant bit (LSB) is always 1.

USERCODE Instruction Mode

The USERCODE instruction mode is used to examine the UES within the devices along an IEEE Std. 1149.1 chain. When this instruction is selected, the device identification register is connected between the TDI and TDO ports. The user-defined UES is shifted into the device ID register in parallel from the 32-bit USERCODE register. The UES is then shifted out through the device ID register.

☞   The UES value is not user defined until after the device is configured. This is because the value is stored in the POF file and only loaded to the device during configuration. Before configuration, the UES value is set to the default value.

CLAMP Instruction Mode

The CLAMP instruction mode is used to allow the state of the signals driven from the pins to be determined from the boundary-scan register while the bypass register is selected as the serial path between the TDI and TDO ports. The state of all signals driven from the pins are completely defined by the data held in the boundary-scan register.

☞   If you are testing after configuring the device, the programmable weak pull-up resistor or the bus hold feature overrides the CLAMP value (the value stored in the update register of the boundary-scan cell) at the pin.

HIGHZ Instruction Mode

The HIGHZ instruction mode sets all of the user I/O pins to an inactive drive state. These pins are tri-stated until a new JTAG instruction is executed. When this instruction is loaded into the instruction register, the bypass register is connected between the TDI and TDO ports.

☞ If you are testing after configuring the device, the programmable weak pull-up resistor or the bus hold feature overrides the HIGHZ value at the pin.

CONFIG_IO Instruction Mode

The CONFIG_IO instruction allows you to perform I/O reconfiguration through JTAG ports using the I/O configuration shift register (IOCSR). IOCSR is a chain of I/O element (IOE) registers, which contains configuration bits to control the IOE characteristics. Thus, you can perform I/O reconfiguration by shifting new configuration data into the IOCSR. CONFIG_IO instruction needs to be used together with ACTIVE_DISENGAGE instruction to interrupt active configuration. CONFIG_IO also drives the nSTATUS pin low and releases it when the CONFIG_IO instruction is no longer active.

☞ The nCONFIG pin must not be low and nSTATUS pin must go high before you can issue the CONFIG_IO instruction.

I/O Voltage Support in JTAG Chain

A JTAG chain can contain several different devices. However, you should be cautious if the chain contains devices that have different V_{CCIO} levels. The output voltage level of the TDO pin must meet the specifications of the TDI pin it drives. For Cyclone III devices, the TDO pin is powered by the V_{CCIO} power supply. Since the V_{CCIO} supply is 3.3 V, the TDO pin drives out 3.3 V.

Devices can interface with each other although they might have different V_{CCIO} levels. For example, a device with a 3.3-V TDO pin can drive to a device with a 5.0-V TDI pin because 3.3 V meets the minimum TTL-level V_{IH} for the 5.0-V TDI pin. JTAG pins on Cyclone III devices can support 2.5-V or 3.3-V input levels.

☞ For multiple devices in a JTAG chain with 3.0-V/ 3.3-V I/O standard, you need to connect a 25 Ω series resistor on a TDO pin driving a TDI pin.

👣 For more information on MultiVolt™ I/O support, see the *Cyclone III Device I/O Feature* chapter of the *Cyclone III Device Handbook*.

You can also interface the TDI and TDO lines of the devices that have different V_{CCIO} levels by inserting a level shifter between the devices. If possible, the JTAG chain should be built such that a device with a higher V_{CCIO} level drives to a device with an equal or lower V_{CCIO} level. This way, a level shifter may be required only to shift the TDO level to a level acceptable to the JTAG tester. Figure 14–13 shows the JTAG chain of mixed voltages and how a level shifter is inserted in the chain.

Figure 14–13. JTAG Chain of Mixed Voltages
Using IEEE Std. 1149.1 BST Circuitry

Cyclone III devices have dedicated JTAG pins and the IEEE Std. 1149.1 BST circuitry is enabled upon device power-up. Not only can you perform BST on Cyclone III FPGAs before and after, but also during configuration. Cyclone III FPGAs support the BYPASS, IDCODE and SAMPLE instructions during configuration without interrupting configuration. To send all other JTAG instructions, you must interrupt configuration using the CONFIG_IO instruction except for active configuration schemes where ACTIVE_DISENGAGE instruction is used instead.

The CONFIG_IO instruction allows you to configure I/O buffers via the JTAG port, and when issued, interrupts configuration. This instruction allows you to perform board-level testing prior to configuring the Cyclone III FPGA or you can wait for the configuration device to complete configuration. Once configuration is interrupted and JTAG BST is complete, you must reconfigure the part via JTAG (PULSE_NCONFIG instruction) or by pulsing nCONFIG low.

☞ When you perform JTAG boundary-scan testing before configuration, the nCONFIG pin must be held low.

When you design a board for JTAG configuration of Cyclone III devices, you need to consider the connections for the dedicated configuration pins.

For more information on using the IEEE Std.1149.1 circuitry for device configuration, refer to the *Configuring Cyclone III Devices* chapter of the *Cyclone III Device Handbook*.

BST for Configured Devices

For a configured device, the input buffers are turned off by default for I/O pins that are set as output only in the design file. Nevertheless, executing the SAMPLE instruction will turn on the input buffers for the output pins. You can set the Quartus® II software to always enable the input buffers on a configured device so it behaves the same as an unconfigured device for boundary-scan testing, allowing sample function on output pins in the design. This aspect can cause a slight increase in standby current because the unused input buffer is always on. In the Quartus II software, do the following:

1. Choose **Settings** (Assignments menu).

2. Click **Assembler**.

3. Turn on **Always Enable Input Buffers**.

4. If you use the default setting with input disabled, you need to convert the default BSDL file to the design-specific BSDL file using the BSDL Customizer script. For more information regarding BSDL files, refer to the "Boundary-Scan Description Language (BSDL) Support" section on page 21.

Disabling IEEE Std. 1149.1 BST Circuitry

The IEEE Std. 1149.1 BST circuitry for Cyclone III devices is enabled upon device power-up. Because the IEEE Std. 1149.1 BST circuitry is used for BST or in-circuit reconfiguration, you must enable the circuitry only at specific times as mentioned in, "Using IEEE Std. 1149.1 BST Circuitry"

☞ If you are not using the IEEE Std. 1149.1 circuitry in Cyclone III, then you should permanently disable the circuitry to ensure that you do not inadvertently enable when it is not required.

Table 14–6 shows the pin connections necessary for disabling the IEEE Std. 1149.1 circuitry in Cyclone III devices.

Table 14–6. Disabling IEEE Std. 1149.1 Circuitry	
JTAG Pins *(1)*	**Connection for Disabling**
TMS	VCC
TCK	GND
TDI	VCC
TDO	Leave open

Note to Table 14–6:
(1)   There is no software option to disable JTAG in Cyclone III devices. The JTAG pins are dedicated.

Guidelines for IEEE Std. 1149.1 Boundary-Scan Testing

Use the following guidelines when performing boundary-scan testing with IEEE Std. 1149.1 devices:

■   If the 10 bit checkerboard pattern (1010101010) does not shift out of the instruction register via the TDO pin during the first clock cycle of the SHIFT_IR state, the TAP controller did not reach the proper state. To solve this problem, try one of the following procedures:

   ●   Verify that the TAP controller has reached the SHIFT_IR state correctly. To advance the TAP controller to the SHIFT_IR state, return to the RESET state and send the code 01100 to the TMS pin.
   ●   Check the connections to the V_{CC}, GND, JTAG, and dedicated configuration pins on the device.

■   Perform a SAMPLE/PRELOAD test cycle prior to the first EXTEST test cycle to ensure that known data is present at the device pins when you enter the EXTEST mode. If the OEJ update register contains a 0, the data in the OUTJ update register is driven out. The state must be known and correct to avoid contention with other devices in the system.

■   Do not perform EXTEST testing during ICR. This instruction is supported before or after ICR, but not during ICR. Use the CONFIG_IO instruction to interrupt configuration and then perform testing, or wait for configuration to complete.

■   If performing testing before configuration, hold nCONFIG pin low.

For more information on boundary scan testing, contact mySupport at altera.com.

Boundary-Scan Description Language (BSDL) Support

BSDL, a subset of VHDL, provides a syntax that allows you to describe the features of an IEEE Std. 1149.1 BST-capable device that can be tested. Test software development systems then use the BSDL files for test generation, analysis, and failure diagnostics.

For more information on BSDL files for IEEE Std. 1149.1-compliant Cyclone III devices and the BSDLCustomizer script, visit the Altera web site at **www.altera.com**.

Conclusion

The IEEE Std. 1149.1 BST circuitry available in Cyclone III devices provides a cost-effective and efficient way to test systems that contain devices with tight lead spacing. Circuit boards with Altera and other IEEE Std. 1149.1-compliant devices can use the EXTEST, SAMPLE/PRELOAD, and BYPASS modes to create serial patterns that internally test the pin connections between devices and check device operation.

Section IV. Packaging Information

This section includes the following chapter:

■ Chapter 15, Package Information for Cyclone III Devices

Revision History

Refer to each chapter for its own specific revision history. For information on when each chapter was updated, refer to the Chapter Revision Dates section, which appears in the complete handbook.

15. Package Information for Cyclone III Devices

Introduction

This chapter provides package information for Altera® Cyclone® III devices, including:

- Device and package cross-reference
- Thermal resistance values
- Package outlines

Table 15–1 shows Cyclone III device package options.

Table 15–1. Cyclone III Device Package Options (Part 1 of 2)		
Device	**Package** *(2)*	**Pins**
EP3C5	Plastic Enhanced Quad Flat Pack (EQFP) – Wire Bond	144 *(1)*
	FineLine Ball-Grid Array (FBGA) – Option 2 – Wire Bond	256

	Ultra FineLine Ball-Grid Array (UBGA) – Wire Bond	484
	FineLine Ball-Grid Array (FBGA) – Option 2 – Wire Bond	780

Table 15–1. Cyclone III Device Package Options (Part 2 of 2)		
Device	**Package** *(2)*	**Pins**
EP3C55	FineLine Ball-Grid Array (FBGA) – Option 3 – Wire Bond	484
	Ultra FineLine Ball-Grid Array (UBGA) – Wire Bond	484
	FineLine Ball-Grid Array (FBGA) – Option 2 – Wire Bond	780
EP3C80	FineLine Ball-Grid Array (FBGA) – Option 3 – Wire Bond	484
	Ultra FineLine Ball-Grid Array (UBGA) - Wire Bond	484
	FineLine Ball-Grid Array (FBGA) – Option 2 – Wire Bond	780
EP3C120	FineLine Ball-Grid Array (FBGA) – Option 3 – Wire Bond	484
	FineLine Ball-Grid Array (FBGA) – Option 2 – Wire Bond	780

Notes to Table 15–1:
(1) The E144 package has an exposed pad at the bottom of the package. This exposed pad is a ground pad that must be connected to the ground plane on your PCB. This exposed pad is used for electrical connectivity and not for thermal purposes.
(2) The package type entries with "Option #" refer to instances where multiple package options exist for a given package type and pin count. The Option number identifies the specific type used by the corresponding device density.

Thermal Resistance

For thermal resistance specifications for Cyclone III devices, refer to the *Cyclone Series Device Thermal Resistance Data Sheet*.

Package Outlines

Cyclone III device package outlines can be downloaded from the *Device Packaging Specifications* web page.

Typographic Conventions

This document uses the typographic conventions shown below.

Visual Cue	Meaning
Bold Type with Initial Capital Letters	Command names, dialog box titles, checkbox options, and dialog box options are shown in bold, initial capital letters. Example: **Save As** dialog box.
bold type	External timing parameters, directory names, project names, disk drive names, filenames, filename extensions, and software utility names are shown in bold type. Examples: f_{MAX}, **\qdesigns** directory, **d:** drive, **chiptrip.gdf** file.
Italic Type with Initial Capital Letters	Document titles are shown in italic type with initial capital letters. Example: *AN 75: High-Speed Board Design.*

Visual Cue	Meaning
Italic type	Internal timing parameters and variables are shown in italic type. Examples: t_{PIA}, $n + 1$. Variable names are enclosed in angle brackets (< >) and shown in italic type. Example: *<file name>*, *<project name>***.pof** file.
Initial Capital Letters	Keyboard keys and menu names are shown with initial capital letters. Examples: Delete key, the Options menu.
"Subheading Title"	References to sections within a document and titles of on-line help topics are shown in quotation marks. Example: "Typographic Conventions."
`Courier type`	Signal and port names are shown in lowercase Courier type. Examples: `data1`, `tdi`, `input`. Active-low signals are denoted by suffix `n`, e.g., `resetn`. Anything that must be typed exactly as it appears is shown in Courier type. For example: `c:\qdesigns\tutorial\chiptrip.gdf`. Also, sections of an actual file, such as a Report File, references to parts of files (e.g., the AHDL keyword `SUBDESIGN`), as well as logic function names (e.g., `TRI`) are shown in Courier.
1., 2., 3., and a., b., c., etc.	Numbered steps are used in a list of items when the sequence of the items is important, such as the steps listed in a procedure.
■ ● •	Bullets are used in a list of items when the sequence of the items is not important.
✓	The checkmark indicates a procedure that consists of one step only.
☞	The hand points to information that requires special attention.
⚠ CAUTION	The caution indicates required information that needs special consideration and understanding and should be read prior to starting or continuing with the procedure or process.
⚠	The warning indicates information that should be read prior to starting or continuing the procedure or processes.
↵	The angled arrow indicates you should press the Enter key.
👣	The feet direct you to more information on a particular topic.

Section I. Cyclone III Device Datasheet

This section includes the following chapter:

■ Chapter 1, Cyclone III Device Datasheet: DC & Switching Characteristics

Altera Corporation- Preliminary

1. Cyclone III Device Datasheet: DC & Switching Characteristics

Electrical Characteristics

Operating Conditions

When Cyclone® III devices are implemented in a system, they are rated according to a set of defined parameters. To maintain the highest possible performance and reliability of Cyclone III devices, system designers must consider the operating requirements within this document. Cyclone III devices are offered in both commercial and industrial grades. Commercial devices are offered in -6 (fastest), -7, -8 speed grades.

Absolute Maximum Ratings

Absolute maximum ratings define the maximum operating conditions for Cyclone III devices. The values are based on experiments conducted with the device and theoretical modeling of breakdown and damage mechanisms. The functional operation of the device is not implied at these conditions. Conditions beyond those listed in Table 1–1 may cause permanent damage to the device. Additionally, device operation at the absolute maximum ratings for extended periods of time may have adverse effects on the device. All parameters representing voltages are measured with respect to ground.

Table 1–1. Cyclone III Device Absolute Maximum Ratings (1)

Symbol	Parameter	Min	Max	Unit
V_{CCINT}	Supply voltage for internal logic and input buffers	-0.5	1.8	V
V_{CCIO}	Supply voltage for output buffers	-0.5	3.9	V
V_{CCA}	Supply (analog) voltage for PLL regulator	-0.5	3.75	V
V_{CCD_PLL}	Supply (digital) voltage for PLL	-0.5	1.8	V
V_I	DC input voltage	-0.5	3.95	V
I_{OUT}	DC output current, per pin	-25	40	µA
T_{STG}	Storage temperature	-65	150	°C
T_J	Operating junction temperature	-40	125	°C

Note to Table 1–1:
(1) Supply voltage specifications apply to voltage readings taken at the device pins, not at the power supply.

Maximum Allowed Overshoot/Undershoot Voltage

During transitions, input signals may overshoot to the voltage shown in Table 1–2 and undershoot to -2.0 V for input currents less than 100 μA and for periods shorter than 20 ns.

Table 1–2 lists the maximum allowed input overshoot voltage and the duration of the overshoot voltage as a percentage over the lifetime of the device. The maximum allowed overshoot duration is specified as percentage of high-time over the lifetime of the device.

A DC signal is equivalent to 100% duty cycle. For example, a signal that overshoots to 4.2 V can only be at 4.2 V for 10.74% over the lifetime of the device; for device lifetime of 10 years, this amounts to 10.74/10ths of a year.

Table 1–2. Maximum Allowed Overshoot During Transitions				
Symbol	**Parameter**	**Condition**	**Overshoot Duration as % of High Time**	**Unit**
Vi	DC Input Voltage	V_I=3.95V	100	%
		V_I=4.0V	95.67	%
		V_I=4.05V	55.24	%
		V_I=4.10V	31.97	%
		V_I=4.15V	18.52	%
		V_I=4.20V	10.74	%
		V_I=4.25V	6.23	%
		V_I=4.30V	3.62	%
		V_I=4.35V	2.1	%
		V_I=4.40V	1.22	%
		V_I=4.45V	0.71	%
		V_I=4.50V	0.41	%
		V_I=4.60V	0.14	%
		V_I=4.70V	0.047	%

Recommended Operating Conditions

This section lists the functional operation limits for AC and DC parameters for Cyclone III devices. The steady-state voltage and current values expected from Cyclone III devices are provided in the Table 1–3. All supplies must be strictly monotonic without plateaus.

Symbol	Parameter	Conditions	Min	Typ	Max	Unit
V_{CCINT}	Supply voltage for internal logic and input buffers		1.15	1.2	1.25	V
V_{CCIO}	Supply voltage for output buffers, 3.3-V operation		3.15	3.3	3.45	V
	Supply voltage for output buffers, 3.0-V operation		2.85	3	3.15	V
	Supply voltage for output buffers, 2.5-V operation		2.375	2.5	2.625	V
	Supply voltage for output buffers, 1.8-V operation		1.71	1.8	1.89	V
	Supply voltage for output buffers, 1.5-V operation		1.425	1.5	1.575	V
	Supply voltage for output buffers, 1.2-V operation		1.14	1.2	1.26	V
V_{CCA}	Supply (analog) voltage for PLL regulator		2.375	2.5	2.625	V
V_{CCD_PLL}	Supply (digital) voltage for PLL		1.15	1.2	1.25	V
V_I	Input voltage		-0.5		3.6	V
V_O	Output voltage		0		V_{CCIO}	V
T_J	Operating junction temperature	For commercial use	0		85	°C
		For industrial use	-40		100	°C
tRAMP	Power supply ramptime	Standard POR (1)	50 us		50 ms	-
		Fast POR (2)	50 us		3 ms	-

Table 1–3. Recommended Operating Conditions (3), (4)

Notes to Table 1–3:

(1) POR time for Standard POR will range between 50 ms - 200 ms. All supplies must be up and stable within 50 ms.
(2) POR time for Fast POR will range between 3 - 9 ms. All supplies must be up and stable within 3 ms.
(3) V_{CCIO} for all I/O banks should be powered up during device operation. All V_{CCA} pins must be powered to 2.5 V (even when PLLs are not used), and must be powered-up and powered-down at the same time.
(4) V_{CCD_PLL} must always be connected to V_{CCINT} through a decoupling capacitor and ferrite bead.

DC Characteristics

This section lists the I/O leakage currents, pin capacitance, on chip termination tolerance and and bus hold specifications for Cyclone III devices.

Supply Current

Standby current is the current the device draws after the device is configured with no inputs/outputs toggling and no activity in the device. Since these currents vary largely with resources used, use the Excel based Early Power Estimator to get supply current estimates for your design. Table 1–4 lists I/O pin leakage current for Cyclone III.

Table 1–4. Cyclone III I/O Pin Leakage Current (1), (2)

Symbol	Parameter	Conditions	Min	Typ	Max	Unit
I_I	Input Pin Leakage Current	$V_I = V_{CCIOMAX}$ to 0 V	-10		10	μA
I_{OZ}	Tri-stated I/O Pin Leakage Current	$V_O = V_{CCIOMAX}$ to 0 V	-10		10	μA

Notes to Table 1–4

(1) This value is specified for normal device operation. The value may vary during power-up. This applies for all V_{CCIO} settings (3.3, 3.0, 2.5, 1.8, 1.5 and 1.2 V).

(2) 10 μA I/O leakage current limit is applicable when the internal clamping diode is off. A higher current can be the observed when the diode is on.

Bus Hold

Bus hold retains the last valid logic state after the source driving it either enters the high impedance state or is removed. Each I/O pin has an option to enable bus hold in user mode. Bus hold is always disabled in configuration mode. Table 1–5 lists bus hold specifications for Cyclone III. Also listed are the input pin capacitances and on-chip termination tolerance specifications.

Table 1–5. Cyclone III Bus Hold Parameter (1)

Parameter	Condition	V_{CCIO} (V)												Unit
		1.2		1.5		1.8		2.5		3.0		3.3		
		Min	Max	Min	Max	Min	Max	Min	Max	Min	Max	Min	Max	
Bus-hold low, sustaining current	$V_{IN} > V_{IL}$ (maximum)	8		12		30		50		70		70		μA
Bus-hold high, sustaining current	$V_{IN} < V_{IL}$ (minimum)	-8		-12		-30		-50		-70		-70		μA
Bus-hold low, overdrive current	$0\ V < V_{IN} < V_{CCIO}$		125		175		200		300		500		500	μA
Bus-hold high, overdrive current	$0\ V < V_{IN} < V_{CCIO}$		-125		-175		-200		-300		-500		-500	μA
Bus-hold trip point		0.3	0.9	0.375	1.125	0.68	1.07	0.7	1.7	0.8	2	0.8	2	V

Note to Table 1–5:

(1)   The bus-hold trip points are based on calculated input voltages from the JEDEC standard.

On-Chip Termination (OCT) Specifications

Table 1–6 lists variation of uncalibrated OCT across process, temperature and voltage

Table 1–6. Uncalibrated On-Chip Series Termination Specifications						Preliminary
Symbol	V_{CCIO} (V)	Resistance Tolerance				Unit
		Commercial		Industrial		
		Min	Max	Min	Max	
Series Termination without calibration	3.0	-30	+30	(1)	(1)	%
	2.5	-30	+30	(1)	(1)	%
	1.8	-30	+30	(1)	(1)	%
	1.5	-30	+30	(1)	(1)	%
	1.2	-40	+40	(1)	(1)	%

Note to Table 1–6:
(1) Pending silicon characterization

OCT calibration is automatically performed at power up for OCT enabled I/Os.

Table 1–7 lists the OCT calibration accuracy at power up.

Table 1–7. On-Chip Series Termination Power-up Calibration Specifications				Preliminary
Symbol	V_{CCIO} (V)	Calibration Accuracy		Unit
		Commercial Max	Industrial Max	
Series Termination with power-up calibration	3.0	±10%	(1)	%
	2.5	±10%	(1)	%
	1.8	±10%	(1)	%
	1.5	±10%	(1)	%
	1.2	±10%	(1)	%

Note to Table 1–7:
(1) Pending silicon characterization

Table 1–8 lists the percentage change of the OCT resistance with voltage and temperature. Use Table 1–8 and Equation 1–1 to determine OCT variation after power-up calibration.

Table 1–8. On-Chip Termination Variation After Power-up Calibration		
Nominal Voltage	**dR/dT (%ΔOhm/°C)**	**dR/dmV (%ΔOhm/mV)**
3.0	0.262	-0.026
2.5	0.234	-0.039
1.8	0.219	-0.086
1.5	0.199	-0.136
1.2	0.161	-0.288

Note to Table 1–8:
(1)   This table is needed to calculate the final OCT resistance with the variation of temperature and voltage.

Equation 1–1. *(1)*, *(2)*, *(3)*, *(4)*, *(5)*, *(6)*, *(7)*, *(8)*, *(9)*, *(10)*, *(11)*, *(12)*

$\Delta R_V = (V_2 - V_1) \times 1000 \times dR/dmV$ ----- (1)

$\Delta R_T = (T_2 - T_1) \times dR/dT$ ----- (2)

For $\Delta R_x < 0$; $MF_x = 1/ (|\Delta R_x| /100 + 1)$ ----- (3)

For $\Delta R_x > 0$; $MF_x = \Delta R_x/100 + 1$ ----- (4)

$MF = MF_V \times MF_T$ ----- (5)

$R_{final} = R_{initial} \times MF$ ----- (6)

Notes to Equation 1–1:
(1) ΔR_V is variation of resistance with voltage.
(2) ΔR_T is variation of resistance with temperature.
(3)   dR/dT is the percentage change of resistance with temperature.
(4)   dR/dmV is the percentage change of resistance with voltage.
(5) V_2 is final voltage.
(6) V_1 is the initial voltage.
(7) T_2 is the final temperature.
(8) T_1 is the initial temperature.
(9)   MF is multiplication factor.
(10) R_{final} is final resistance.
(11) $R_{initial}$ is initial resistance.
(12)   Subscript x refers to both $_V$ and $_T$.

For example, to calculate the change of 50 Ω I/O impedance from 25° C at 3.0 V to 85° C at 3.15 V,

$\Delta R_V = (3.15 - 3) \times 1000 \times -0.026 = -3.83$
$\Delta R_T = (85 - 25) \times 0.262 = 15.72$

Since ΔR_V is negative,

$MF_V = 1 / (3.83/100 + 1) = 0.963$

Since ΔR_T is positive,

$MF_T = 15.72/100 + 1 = 1.157$

$MF = 0.963 \times 1.157 = 1.114$

$R_{final} = 50 \times 1.114 = \underline{55.71}\ \Omega$

Pin Capacitance

Table 1–9 shows the Cyclone III device family pin capacitance.

Table 1–9. Cyclone III Device Pin Capacitance (1)				*Preliminary*
Symbol	**Parameter**	**Typical - QFP**	**Typical - FBGA**	**Unit**
C_{IOTB}	Input capacitance on top/bottom I/O pins	7	6	pF
C_{IOLR}	Input capacitance on left/right I/O pins	6	5	pF
C_{LVDSLR}	Input capacitance on left/right I/O pins with Dedicated LVDS output	7	6	pF
C_{VREFLR}	Input capacitance on left/right I/O pins with V_{REF}	21	21	pF
C_{VREFTB}	Input capacitance on top/bottom I/O pins with V_{REF}	21	21	pF
C_{CLKTB}	Input capacitance on top/bottom dedicated clock input pins	7	6	pF
C_{CLKLR}	Input capacitance on left/right dedicated clock input pins	6	5	pF

Note to Table 1–9:
(1) Pending silicon characterization.

Internal Weak Pull-up and Weak Pull-down Resistor

Table 1–10 lists the weak pull-up and pull-down resistor values for Cyclone III devices.

Table 1–10. Cyclone III Internal Weak Pull-Up / Weak Pull-Down Resistor (1)						
Symbol	**Parameter**	**Conditions**	**Min**	**Typ**	**Max**	**Unit**
R_{CONF_PU} *(2)*	Value of I/O pin pull-up resistor before and during configuration	V_I = 0 V, V_{CCIO} = 3.3 V +/-5% *(3), (4)*	7	25	41	KΩ
		V_I = 0 V, V_{CCIO} = 3.0 V +/-5% *(3), (4)*	7	28	47	KΩ
		V_I = 0 V, V_{CCIO} = 2.5 V +/-5% *(3), (4)*	8	35	61	KΩ
		V_I = 0 V, V_{CCIO} = 1.8 V +/-5% *(3), (4)*	10	57	108	KΩ
		V_I = 0 V, V_{CCIO} = 1.5 V +/-5% *(3), (4)*	13	82	163	KΩ
		V_I = 0 V, V_{CCIO} = 1.2 V +/-5% *(3), (4)*	19	143	351	KΩ

Table 1–10. Cyclone III Internal Weak Pull-Up / Weak Pull-Down Resistor (1)

Symbol	Parameter	Conditions	Min	Typ	Max	Unit
R_{CONF_PD} (2)	Value of I/O pin pull-down resistor before and during configuration	$V_I = 0$ V, $V_{CCIO} = 3.3$ V +/-5% (3), (4)	6	19	30	KΩ
		$V_I = 0$ V, $V_{CCIO} = 3.0$ V +/-5% (3), (4)	6	22	36	KΩ
		$V_I = 0$ V, $V_{CCIO} = 2.5$ V +/-5% (3), (4)	6	25	43	KΩ
		$V_I = 0$ V, $V_{CCIO} = 1.8$ V +/-5% (3), (4)	7	35	71	KΩ
		$V_I = 0$ V, $V_{CCIO} = 1.5$ V +/-5% (3), (4)	8	50	90	KΩ

Notes to Table 1–10:

(1) All I/O pins have an option to enable weak pull-up except configuration, test and JTAG pin. Weak pull-down feature is only available for JTAG TCK.

(2) R_{CONF} values are based on characterization. $R_{CONF} = V_{CCIO}/I_{RCON}F$. R_{CONF} values may be different if V_I value is not 0 V. V_I refers to the input voltage at the I/O pin.

(3) Pin pull-up resistance values may be lower if an external source drives the pin higher than V_{CCIO}.

(4) Minimum condition at -40° C and high V_{CC}, typical condition at 25° C and nominal V_{CC} and maximum condition at 125° C and low V_{CC} for R_{CONF} values.

Hot Socketing

Table 1–11 lists the hot-socketing specifications for Cyclone III devices.

Table 1–11. Cyclone III Hot Socketing Specifications

Symbol	Parameter	Maximum
$I_{IOPIN(DC)}$	DC current per I/O pin	300 µA
$I_{IOPIN(AC)}$	AC current per I/O pin	8 µA (1)

Note to Table 1–11:

(1) The I/O ramp rate is 10 ns or more. For ramp rates faster than 10 ns, $|IIOPIN| = C\, dv/dt$, where C is I/O pin capacitance and dv/dt is the slew rate.

I/O Standard Specifications

The following tables list input voltage sensitivities (V_{IH} and V_{IL}), and output voltage (V_{OH} and V_{OL}), and current drive characteristics (I_{OH} and I_{OL}) for various I/O standards supported by Cyclone III devices. Table 1–12 to Table 1–17 show the Cyclone III device family I/O standard specifications. See "Single-ended Voltage referenced I/O Standard" in

"Glossary" for voltage referenced receiver input waveform and explanation of terms used in Table 1–12. V_{OL} and V_{OH} values are valid at the corresponding I_{OL} and I_{OH}, respectively.

Table 1–12. Single-Ended I/O Standard Specifications (1)										
I/O Standard	**V_{CCIO}(V)**			**V_{IL}(V)**		**V_{IH}(V)**		**V_{OL}(V)**	**V_{OH}(V)**	**I_{OL}**	**I_{OH}**
	Min	**Typ**	**Max**	**Min**	**Max**	**Min**	**Max**	**Max**	**Min**	**(µA)**	**(µA)**
3.3-V LVTTL (2)	3.15	3.3	3.45		0.8	1.7	3.6	0.45	2.4	4	-4
3.3-V LVCMOS (2)	3.15	3.3	3.45		0.8	1.7	3.6	0.2	V_{CCIO} - 0.2	2	-2
3.0-V LVTTL (2)	2.85	3.0	3.15	-0.3	0.8	1.7	V_{CCIO} + 0.3	0.45	2.4	4	-4
3.0-V LVCMOS (2)	2.85	3.0	3.15	-0.3	0.8	1.7	V_{CCIO} + 0.3	0.2	V_{CCIO} - 0.2	0.1	-0.1
2.5-V LVTTL and LVCMOS (2)	2.375	2.5	2.625	-0.3	0.7	1.7	V_{CCIO} + 0.3	0.2	2.1	0.1	-0.1
								0.4	2.0	1	-1
								0.7	1.7	2	-2
1.8-V LVTTL and LVCMOS	1.71	1.8	1.89	-0.3	0.35 * V_{CCIO}	0.65 * V_{CCIO}	2.25	0.45	V_{CCIO} -0.45	2	-2
1.5-V LVCMOS	1.425	1.5	1.575	-0.3	0.35 * V_{CCIO}	0.65 * V_{CCIO}	V_{CCIO} + 0.3	0.25 * V_{CCIO}	0.75 * V_{CCIO}	2	-2
1.2-V LVCMOS	1.14	1.2	1.26	-0.3	0.35 * V_{CCIO}	0.65 * V_{CCIO}	V_{CCIO} + 0.3	0.25 * V_{CCIO}	0.75 * V_{CCIO}	2	-2
PCI and PCI-X	2.85	3.0	3.15		0.3 * V_{CCIO}	0.5 * V_{CCIO}	V_{CCIO} + 0.3	0.1 * V_{CCIO}	0.9 * V_{CCIO}	1.5	-0.5

Notes to Table 1–12:

(1)   AC load CL = 10 pF.

(2)   For more detail of interfacing Cyclone III devices with 3.3/3.0/2.5-V LVTTL/LVCMOS I/O standards, please refer to Application Note, AN447.

See "Glossary" for explanation of terms used in Table 1–13.

Table 1–13. Single-Ended SSTL and HSTL I/O Reference Voltage Specifications

I/O Standard	V_{CCIO}(V)			V_{REF}(V)			V_{TT}(V) (3)		
	Min	Typ	Max	Min	Typ	Max	Min	Typ	Max
SSTL-2 Class I, II	2.375	2.5	2.625	1.19	1.25	1.31	V_{REF} - 0.04	V_{REF}	V_{REF} + 0.04
SSTL-18 Class I, II	1.7	1.8	1.9	0.833	0.9	0.969	V_{REF} - 0.04	V_{REF}	V_{REF} + 0.04
HSTL-18 Class I, II	1.71	1.8	1.89	0.85	0.9	0.95	0.85	0.9	0.95
HSTL-15 Class I, II	1.425	1.5	1.575	0.71	0.75	0.79	0.71	0.75	0.79
HSTL-12 Class I, II	1.14	1.2	1.26	0.48 * V_{CCIO} (1)	0.5 * V_{CCIO} (1)	0.52 * V_{CCIO} (1)		0.5 * V_{CCIO}	
				0.47 * V_{CCIO} (2)	0.5 * V_{CCIO} (2)	0.53 * V_{CCIO} (2)			

Notes to Table 1–13:
(1) Value shown refers to DC input reference voltage, $V_{REF(DC)}$.
(2) Value shown refers to AC input reference voltage, $V_{REF(AC)}$.
(3) V_{TT} of transmitting device must track V_{REF} of the receiving device.

.

Table 1–14. Single-Ended SSTL and HSTL I/O Standards Signal Specifications   (Part 1 of 2)

I/O Standard	$V_{IL(DC)}$(V)		$V_{IH(DC)}$(V)		$V_{IL(AC)}$(V)		$V_{IH(AC)}$(V)		V_{OL}(V)	V_{OH}(V)	I_{OL} (μA)	I_{OH} (μA)

							0.5	500 Mbps ≤D_{MAX} ≤ 700Mbps	1.85						
							1	D_{MAX} > 700Mbps	1.6						
mini-LVDS (Row I/Os) (3)	2.375	2.5	2.625							300		600	1.0	1.2	1.4
mini-LVDS (Column I/Os) (3)	2.375	2.5	2.625							300		600	1.0	1.2	1.4
RSDS (Row I/Os) (3)	2.375	2.5	2.625							100	200	600	0.5	1.2	1.5
RSDS (Column I/Os) (3)	2.375	2.5	2.625							100	200	600	0.5	1.2	1.5
PPDS (Row I/Os) (3)	2.375	2.5	2.625							100	200	600	0.5	1.2	1.4
PPDS (Column I/Os) (3)	2.375	2.5	2.625							100	200	600	0.5	1.2	1.4

Notes to Table 1–17:

(1) R_L range : 90 ≤R_L ≤110 ohm.

(2) LVPECL input standard is only supported at clock input. Output standard is not supported.

(3) Mini-LVDS, RDSD and PPDS standards are only supported at output pins of Cyclone III.

Power Consumption

Altera® offers two ways to estimate power for a design: the Excel-based Early Power Estimator and the Quartus® II **PowerPlay Power Analyzer** feature.

The interactive Excel-based Early Power Estimator is typically used prior to designing the device in order to get a magnitude estimate of the device power. The Quartus II **PowerPlay Power Analyzer** provides better quality estimates based on the specifics of the design after place-and-route is complete. The **PowerPlay Power Analyzer** can apply a combination of user-entered, simulation-derived, and estimated signal activities which, combined with detailed circuit models, can yield very accurate power estimates.

For more information on power estimation tools, refer to the *Early Power Estimator User Guide* and the *PowerPlay Power Analysis* chapters in the *Quartus II Handboo*k.

Switching Characteristics

This section provides performance characteristics of the Cyclone III core and periphery blocks for commercial grade devices.

These characteristics can be designated as Preliminary and Final. Each designation is defined below.

Preliminary	Final
Preliminary characteristics are created using simulation results, process data, and other known parameters.	Final numbers are based on actual silicon characterization and testing. These numbers reflect the actual performance of the device under worst-case silicon process, voltage and junction temperature conditions.

The upper-right hand corner of a table shows the designation as '*Preliminary*' or '*Final*'.

Core Performance Specifications

Clock Tree Specifications

Table 1–18 lists the clock tree specifications for Cyclone III.

Table 1–18. Cyclone III Clock Tree Performance				Preliminary
Device	**Performance**			**Unit**
	-6 Speed Grade	**-7 Speed Grade**	**-8 Speed Grade**	
EP3C5	500	*(2)*	*(2)*	MHz
EP3C10	500	*(2)*	*(2)*	MHz
EP3C16	500	*(2)*	*(2)*	MHz
EP3C25	500	*(2)*	*(2)*	MHz
EP3C40	500	*(2)*	*(2)*	MHz
EP3C55	500	*(2)*	*(2)*	MHz
EP3C80	500	*(2)*	*(2)*	MHz
EP3C120	*(1)*	437.5	*(2)*	MHz

Notes to Table 1–18:
(1)   EP3C120 offered in -7 and -8 speed grades only.
(2)   Pending silicon characterization.

PLL Specifications

Table 1–19 describes the Cyclone III PLL specifications when operating in both the commercial junction temperature range (0° C to 85° C) and the industrial junction temperature range(-40° C to 100° C). For more information on PLL Block, see "PLL Block" in "Glossary".

Table 1–19. Cyclone III PLL Specifications *(5)* (Part 1 of 2)					Preliminary
Symbol	**Parameter**	**Min**	**Typ**	**Max**	**Unit**
f_{IN} *(1)*	Input clock frequency (-6 speed grade)	5		*(4)*	MHz
	Input clock frequency (-7 speed grade)	5		*(4)*	MHz
	Input clock frequency (-8 speed grade)	5		*(4)*	MHz
f_{INPFD}	PFD input frequency (-6 speed grade)	5		325	MHz
	PFD input frequency (-7 speed grade)	5		325	MHz
	PFD input frequency (-8 speed grade)	5		325	MHz
f_{INDUTY}	Input clock duty cycle	40		60	%

Symbol	Parameter	Min	Typ	Max	Unit
Table 1–19. Cyclone III PLL Specifications (5) (Part 2 of 2)					**Preliminary**
$f_{EINDUTY}$	External feedback clock input duty cycle				%
$t_{INJITTER}$	Input clock period jitter		100		ps
f_{OUT_EXT} (external clock output) *(1)*	PLL output frequency (-6 speed grade)	5		*(4)*	MHz
	PLL output frequency (-7 speed grade)	5		*(4)*	MHz
	PLL output frequency (-8 speed grade)	5		*(4)*	MHz
f_{OUT} (to global clock)	PLL output frequency (-6 speed grade)	5		472.5	MHz
	PLL output frequency (-7 speed grade)	5		450	MHz
	PLL output frequency (-8 speed grade)	5		402.5	MHz
$t_{OUTDUTY}$	Duty cycle for external clock output (when set to 50%)	45		55	%
t_{LOCK}	Time required to lock from end of device configuration			100 *(2)*	us
t_{DLOCK}	Time required to lock dynamically (after switchover or reconfiguring any non-post-scale counters/delays)			100 *(2)*	ms
$t_{OUTJITTER\_DEDCLK}$	Dedicated clock output period jitter			300	ps
$t_{OUTJITTER\_IO}$	Regular I/O period jitter			*(4)*	ps
t_{PLL_PSERR}	Accuracy of PLL phase shift			±60	ps
f_{VCO}	PLL internal VCO operating range	600		1300	MHz
t_{ARESET}	Minimum pulse width on areset signal.	10			ns
$t_{CONFIGPLL}$	Time required to reconfigure scan chains for PLLs		3.5 *(3)*		SCANCLK cycles
$f_{SCANCLK}$	scanclk frequency			100	MHz

Notes to Table 1–19:
(1) This parameter is limited in Quartus II software by the I/O maximum frequency. The maximum I/O frequency is different for each I/O standard.
(2) For extended temperature devices, the maximum lock time is 500 us.
(3) With 100 MHz scanclk frequency.
(4) Pending silicon characterization.
(5) V_{CCD_PLL} should always be connected to V_{CCINT} through decoupling capacitor and ferrite bead.

Embedded Multiplier Specifications

Table 1–20 describes the Cyclone III embedded multiplier specifications.

Table 1–20. Cyclone III Embedded Multiplier Specifications					Preliminary
Mode	**Resources Used**	**Performance**			**Unit**
	Number of Multipliers	**-6 Speed Grade**	**-7 Speed Grade**	**-8 Speed Grade**	
9x9-bit multiplier	1	260	223	180	MHz
18x18-bit multiplier	1	260	223	180	MHz

Memory Block Specifications

Table 1–21 describes the Cyclone III M9K Memory block specifications.

Table 1–21. Cyclone III Memory Block Performance Specifications (1)				Preliminary	
Memory	**Mode**	**Resources Used**		**Performance**	
		LEs	**M9K Memory**	**-6 Speed Grade**	**Unit**
M9K Block	FIFO 256x36	47	1	260	MHz
	Single-port 256x36	0	1	260	MHz
	Simple dual-port 256x36 CLK	0	1	260	MHz
	True dual port 512x18 single CLK	0	1	260	MHz

Note to Table 1–21:

(1) Values for device speed grade -7 and -8 will be available after characterization.

Configuration and JTAG Specifications

Table 1–22 lists the Cyclone III Configuration Mode Specifications.

Table 1–22. Cyclone III Configuration Mode Specifications		Preliminary
Programming Mode	**DCLK F_{max}**	**Unit**
Passive Serial (PS)	133	MHz
Fast Passive Parallel (FPP)	133	MHz

Table 1–23 lists the Cyclone III Active Configuration Mode Specifications.

Table 1–23. Cyclone III Active Configuration Mode Specifications		Preliminary
Programming Mode	**DCLK Range**	**Unit**
Active Parallel (AP)	20 - 40	MHz
Active Serial (AS)	20 - 40	MHz

Table 1–24 shows the JTAG timing parameters and values for Cyclone III. For more information, see "JTAG Waveform" at "Glossary".

Table 1–24. Cyclone III JTAG Timing Parameters				Preliminary
Symbol	**Parameter**	**Min**	**Max**	**Unit**
t_{JCP}	TCK clock period	40		ns
t_{JCH}	TCK clock high time	20		ns
t_{JCL}	TCK clock low time	20		ns
t_{JPSU_TDI}	JTAG port setup time for TDI [1]	1		ns
t_{JPSU_TMS}	JTAG port setup time for TMS [1]	3		ns
t_{JPH}	JTAG port hold time	10		ns
t_{JPCO}	JTAG port clock to output [1]		15	ns
t_{JPZX}	JTAG port high impedance to valid output [1]		15	ns
t_{JPXZ}	JTAG port valid output to high impedance [1]		15	ns
t_{JSSU}	Capture register setup time [1]	5		ns
t_{JSH}	Capture register hold time	10		ns
t_{JSCO}	Update register clock to output		25	ns
t_{JSZX}	Update register high impedance to valid output		25	ns
t_{JSXZ}	Update register valid output to high impedance		25	ns

Note to Table 1–24:

(1) The specification is shown for 3.3 V, 3.0 V and 2.5 V LVTTL/LVCMOS operation of JTAG pins. For 1.8- V LVTTL/LVCMOS and 1.5- V LVCMOS, the JTAG port/capture register clock setup time is 3 ns and port clock to output time is 15 ns.

Periphery Performance

High-Speed I/O Specification

Table 1–25 to Table 1–34 show the high-speed I/O timing for Cyclone III devices. See "Glossary" for definitions of high-speed timing specifications.

Symbol	**Modes**	**-6 Speed Grade**			**Unit**
		Min	**Typ**	**Max**	
f_{HSCLK} (input clock frequency)	x10	10		180	MHz
	x8	10		180	MHz
	x7	10		180	MHz
	x4	10		180	MHz
	x2	10		180	MHz
	x1	10		360	MHz
Device operation in Mbps	x10	100		360	Mbps
	x8	80		360	Mbps
	x7	70		360	Mbps
	x4	40		360	Mbps
	x2	20		360	Mbps
	x1	10		360	Mbps
t_{DUTY}		*(1)*		*(1)*	%
TCCS				*(1)*	ns
Output jitter (peak to peak)				*(1)*	ps
t_{RISE}	20–80%		*(1)*		ps
t_{FALL}	80–20%		*(1)*		ps
t_{LOCK}				*(1)*	ms

Table 1–25. Dedicated RSDS Transmitter Timing Specification (2), (3)

Notes to Table 1–25:

(1)   Pending silicon characterization.
(2)   Values for device speed grade -7 and -8 will be available after characterization.
(3)   Dedicated RSDS is only supported at output pin of Row I/O (Bank 1, 2, 5 and 6).

Table 1–26. Single-Resistor RSDS Transmitter Timing Specification (2), (3)

Symbol	Modes	-6 Speed Grade			Unit
		Min	Typ	Max	
f_{HSCLK} (input clock frequency)	x10	10		85	MHz
	x8	10		85	MHz
	x7	10		85	MHz
	x4	10		85	MHz
	x2	10		85	MHz
	x1	10		85	MHz
Device operation in Mbps	x10	100		*(1)*	Mbps
	x8	80		*(1)*	Mbps
	x7	70		*(1)*	Mbps
	x4	40		*(1)*	Mbps
	x2	20		*(1)*	Mbps
	x1	10		*(1)*	Mbps
t_{DUTY}		*(1)*		*(1)*	%
TCCS				*(1)*	ps
Output jitter (peak to peak)				*(1)*	ps
t_{RISE}	20–80%		*(1)*		ps
t_{FALL}	80–20%		*(1)*		ps
t_{LOCK}				*(1)*	ms

Notes to Table 1–26:
(1) Pending silicon characterization.
(2) Values for device speed grade -7 and -8 will be available after characterization.
(3) Single-resistor RSDS is only supported at output pin of Column I/O (Bank 3, 4, 7 and 8).

Table 1–27. Three-Resistor RSDS Transmitter Timing Specification (2), (3) (Part 1 of 2)

Symbol	Modes	-6 Speed Grade			Unit
		Min	Typ	Max	
f_{HSCLK} (input clock frequency)	x10	10		155.5	MHz
	x8	10		155.5	MHz
	x7	10		155.5	MHz
	x4	10		155.5	MHz
	x2	10		155.5	MHz
	x1	10		155.5	MHz

Table 1–27. Three-Resistor RSDS Transmitter Timing Specification *(2)*, *(3)* **(Part 2 of 2)**

Symbol	Modes	-6 Speed Grade			Unit
		Min	Typ	Max	
Device operation in Mbps	x10	100		*(1)*	Mbps
	x8	80		*(1)*	Mbps
	x7	70		*(1)*	Mbps
	x4	40		*(1)*	Mbps
	x2	20		*(1)*	Mbps
	x1	10		*(1)*	Mbps
t_{DUTY}		*(1)*		*(1)*	%
TCCS				*(1)*	ps
Output jitter (peak to peak)				*(1)*	ps
t_{RISE}	20–80%		*(1)*		ps
t_{FALL}	80–20%		*(1)*		ps
t_{LOCK}				*(1)*	ms

Notes to Table 1–27:
(1) Pending silicon characterization.
(2) Values for device speed grade -7 and -8 will be available after characterization.
(3) Three-resistor RSDS is only supported at output pin of Column I/O (Bank 3, 4, 7 and 8).

Table 1–28. Dedicated PPDS Transmitter Timing Specification *(2)*, *(3)* **(Part 1 of 2)**

Symbol	Modes	-6 Speed Grade			Unit
		Min	Typ	Max	
f_{HSCLK} (input clock frequency)	x10	10		*(1)*	MHz
	x8	10		*(1)*	MHz
	x7	10		*(1)*	MHz
	x4	10		*(1)*	MHz

t_{FALL}	80–20%		*(1)*		ps
t_{LOCK}				*(1)*	ms

Notes to Table 1–30:
(1) Pending silicon characterization.
(2) Values for device speed grade -7 and -8 will be available after characterization.
(3) Dedicated mini-LVDS is only supported at output pin of Row I/O (Bank 1, 2, 5 and 6).

Table 1–31. Three-Resistor mini-LVDS Transmitter Timing Specification (2), (3)

Symbol	Modes	-6 Speed Grade			Unit
		Min	**Typ**	**Max**	
f_{HSCLK} (input clock frequency)	x10	10		155.5	MHz
	x8	10		155.5	MHz
	x7	10		155.5	MHz
	x4	10		155.5	MHz
	x2	10		155.5	MHz
	x1	10		155.5	MHz
Device operation in Mbps	x10	100		*(1)*	Mbps
	x8	80		*(1)*	Mbps
	x7	70		*(1)*	Mbps
	x4	40		*(1)*	Mbps
	x2	20		*(1)*	Mbps
	x1	10		*(1)*	Mbps
t_{DUTY}		*(1)*		*(1)*	%
TCCS				*(1)*	ps
Output jitter (peak to peak)				*(1)*	ps
t_{RISE}	20–80%		*(1)*		ps
t_{FALL}	80–20%		*(1)*		ps
t_{LOCK}				*(1)*	ms

Notes to Table 1–31:

(1) Pending silicon characterization.
(2) Values for device speed grade -7 and -8 will be available after characterization.
(3) Three-resistor mini-LVDS is only supported at output pin of Column I/O (Bank 3, 4, 7 and 8).

Table 1–32. Dedicated LVDS Transmitter Timing Specification (2), (5) **(Part 1 of 2)**

Symbol	Modes	-6 Speed Grade				Unit
		Min	**Typ**	**Max** *(3)*	**Max** *(4)*	
f_{HSCLK} (input clock frequency)	x10	10		420	*(1)*	MHz
	x8	10		420	*(1)*	MHz
	x7	10		420	*(1)*	MHz
	x4	10		420	*(1)*	MHz
	x2	10		420	*(1)*	MHz
	x1	10		420	*(1)*	MHz

Table 1–32. Dedicated LVDS Transmitter Timing Specification (2), (5) (Part 2 of 2)		-6 Speed Grade				
Symbol	**Modes**	**Min**	**Typ**	**Max** (3)	**Max** (4)	**Unit**
HSIODR	x10	100		840	(1)	Mbps
	x8	80		840	(1)	Mbps
	x7	70		840	(1)	Mbps
	x4	40		840	(1)	Mbps
	x2	20		840	(1)	Mbps
	x1	10		420	(1)	Mbps
t$_{DUTY}$		(1)		(1)	(1)	%
TCCS				248		ps
Output jitter (peak to peak)				(1)		ps
t$_{RISE}$	20–80%	(1)	(1)	(1)	(1)	ps
t$_{FALL}$	80–20%	(1)	(1)	(1)	(1)	ps
t$_{LOCK}$				(1)		ms

Notes to Table 1–32:

(1) Pending silicon characterization.

(2) Values for device speed grade -7 and -8 will be available after characterization.

(3) The maximum data rate that complies with duty cycle distortion of 45–55%.

(4) The maximum data rate when taking duty cycle in absolute ps into consideration that may not comply with 45–55% duty cycle distortion. If the downstream receiver can handle duty cycle distortion beyond the 45–55% range, you may use the higher data rate values from this column. You can calculate the duty cycle distortion as a percentage using the absolute ps value. For example, for a data rate of 640 Mbps (UI = 1625 ps) and a tDUTY of 250 ps, the duty cycle distortion is tDUTY/(UI*2) *100% = 250 ps/(1625 *2) * 100% = 7.7%, which gives you a duty cycle distortion of 42.3-57.7%.

(5) Dedicated LVDS transmitter is only supported at output pin of Row I/O (Bank 1, 2, 5 and 6).

Table 1–33. Three-Resistor LVDS Transmitter Timing Specification (2), (5)						
Symbol	**Modes**	**-6 Speed Grade**				**Unit**
		Min	**Typ**	**Max** *(3)*	**Max** *(4)*	
f$_{HSCLK}$ (input clock frequency)	x10	10		320	320	MHz
	x8	10		320	320	MHz
	x7	10		320	320	MHz
	x4	10		320	320	MHz
	x2	10		320	320	MHz
	x1	10		402.5	402.5	MHz
HSIODR	x10	*(1)*		*(1)*	*(1)*	Mbps
	x8	*(1)*		*(1)*	*(1)*	Mbps
	x7	*(1)*		*(1)*	*(1)*	Mbps
	x4	*(1)*		*(1)*	*(1)*	Mbps
	x2	*(1)*		*(1)*	*(1)*	Mbps
	x1	*(1)*		*(1)*	*(1)*	Mbps
t$_{DUTY}$		*(1)*		*(1)*	*(1)*	%
TCCS				*(1)*	*(1)*	ps
Output jitter (peak to peak)				*(1)*	*(1)*	ps
t$_{RISE}$	20–80%	*(1)*	*(1)*	*(1)*	*(1)*	ps
t$_{FALL}$	80–20%	*(1)*	*(1)*	*(1)*	*(1)*	ps
t$_{LOCK}$				*(1)*		ms

Notes to Table 1–33:

(1) Pending silicon characterization.
(2) Values for device speed grade -7 and -8 will be available after characterization.
(3) The maximum data rate that complies with duty cycle distortion of 45–55%.
(4) The maximum data rate when taking duty cycle in absolute ps into consideration that may not comply with 45–55% duty cycle distortion. If the downstream receiver can handle duty cycle distortion beyond the 45–55% range, you may use the higher data rate values from this column. You can calculate the duty cycle distortion as a percentage using the absolute ps value. For example, for a data rate of 640 Mbps (UI = 1625 ps) and a t$_{DUTY}$ of 250 ps, the duty cycle distortion is t$_{DUTY}$/(UI*2) *100% = 250 ps/(1625 *2) * 100% = 7.7%, which gives you a duty cycle distortion of 42.3 - 57.7%.
(5) Three-resistor LVDS is only supported at output pin of Column I/O (Bank 3, 4, 7 and 8).

Table 1–34. Dedicated LVDS Receiver Timing Specification (2), (3)					
Symbol	**Modes**	**-6 Speed Grade**			**Unit**
		Min	**Typ**	**Max**	
f$_{HSCLK}$ (input clock frequency)	x10	10		437.5	MHz
	x8	10		437.5	MHz
	x7	10		437.5	MHz
	x4	10		437.5	MHz
	x2	10		437.5	MHz
	x1	10		437.5	MHz
HSIODR	x10	100		875	Mbps
	x8	80		875	Mbps
	x7	70		875	Mbps
	x4	40		875	Mbps
	x2	20		875	Mbps
	x1	10		437.5	Mbps
SW				400	ps
Input jitter tolerance				(1)	ps
t$_{LOCK}$				(1)	ps

Notes to Table 1–34:
(1) Pending silicon characterization.
(2) Values for device speed grade -7 and -8 will be available after characterization.
(3) Dedicated LVDS Receiver is supported at all banks.

External Memory Interface Specifications

Cyclone III devices support external memory interfaces up to 200 MHz. Cyclone III external memory interfaces are auto-calibrating and easy to implement. Table 1–35 to Table 1–38 list the External Memory Interface Specifications for the Cyclone III device family.

Use the following tables for memory interface timing analysis..

Table 1–35. Cyclone III Maximum Clock Rate Support for External Memory Interfaces (1) (5)							
		Commercial					
Memory Standard	**I/O Standard**	**-6 Speed Grade (MHz)**		**-7 Speed Grade (MHz)**		**-8 Speed Grade (MHz)**	
		Column I/Os	Row I/Os	Column I/Os	Row I/Os	Column I/Os	Row I/Os
DDR2 SDRAM (2)	SSTL-18 class I	200	167	167	150	167	133
	SSTL-18 class II	133	125	125	(3)	(3)	(3)
DDR SDRAM (2)	SSTL-2 class I	167	150	150	133	133	125
	SSTL-2 class II	133	125	125	100	100	(3)
QDRII SRAM (4)	1.8-V HSTL class I	167	150	150	133	133	125
	1.8V HSTL class II	100	(3)	(3)	(3)	(3)	(3)

Notes to Table 1–35:
(1)   These numbers are preliminary until characterization is final.
(2)   The values apply for interfaces with both modules and components.
(3)   Support will be evaluated after characterization.
(4)   QDRII SRAM also supports the 1.5-V HSTL I/O standard. However, Altera recommends using the 1.8-V HSTL I/O standard for maximum performance because of the higher I/O Current Strength.
(5)   Column I/Os refer to Top and Bottom I/Os. Row I/Os refer to Right and Left I/Os.

Table 1–36. FPGA Sampling Window (SW) Requirement - Read Side (1)													Preliminary
Memory Standards	**–6 Speed Grade**				**–7 Speed Grade**				**–8 Speed Grade**				**Units**
	Column I/Os		Row I/Os		Column I/Os		Row I/Os		Column I/Os		Row I/Os

DCD Specifications

Table 1–39 lists the worst case duty cycle distortion for Cyclone III devices. Detailed information on duty cycle distortion will be published after characterization.

Table 1–39. Duty Cycle Distortion on Cyclone III I/O Pins (1) (2)							
Symbol	**-6 Speed Grade**		**-7 Speed Grade**		**-8 Speed Grade**		**Unit**
	Min	**Max**	**Min**	**Max**	**Min**	**Max**	
Output Duty Cycle	45	55	45	55	40	60	%

Notes to Table 1–39:
(1)   Preliminary DCD specification applies to clock outputs from PLLs, global clock tree and IOE driving dedicated and general purpose I/O pins.
(2)   Detailed DCD specification pending silicon characterization.

I/O Timing

Timing Model

The DirectDrive™ technology and MultiTrack™ interconnect ensure predictable performance, accurate simulation, and accurate timing analysis across all Cyclone III device densities and speed grades. This section describes and specifies the performance of I/Os and internal timing.

All specifications are representative of worst-case supply voltage and junction temperature conditions.

☞ The timing numbers listed in the tables of this section are extracted from the Quartus II software version 7.0 Build 31.

Preliminary, Correlated & Final Timing

Timing models can have either preliminary, correlated, or final status. The Quartus II software issues an informational message during the design compilation if the timing models are preliminary. Table 1–40 shows the status of the Cyclone III device timing models.

Preliminary status means the timing model is subject to change. Initially, timing numbers are created using simulation results, process data, and other known parameters. These tests are used to make the preliminary numbers as close to the actual timing parameters as possible.

Correlated numbers are based on actual device operation and testing. These numbers reflect the actual performance of the device under worst-case voltage and junction temperature conditions.

Final timing numbers are based on complete correlation to actual devices and addressing any minor deviations from the correlated timing model. When the timing models are final, all or most of the Cyclone III family devices have been completely characterized and no further changes to the timing model are expected.

Table 1–40. Cyclone III Device Timing Model Status			
Device	**Preliminary**	**Correlated**	**Final**
EP3C5	*(1)*		
EP3C10	✓		
EP3C16	✓		
EP3C25	✓		
EP3C40	✓

Device	**Preliminary**	**Correlated**	**Final**
EP3C55	✓		
EP3C80	✓		
EP3C120	✓		

Note to Table 1–40:
(1)   Device EP3C5 information is not available at current version Quartus II.

I/O Timing Measurement Methodology

Altera characterizes timing delays at the worst-case process, minimum voltage, and maximum temperature for input register setup time (t_{SU}) and hold time (t_H). The Quartus II software uses the following equations to calculate t_{SU} and t_H timing for Cyclone III devices input signals:

$$t_{SU} = \text{ + data delay from input pin to input register}$$
$$\text{+ micro setup time of the input register}$$
$$\text{– clock delay from input pin to input register}$$

$$t_H = \text{ – data delay from input pin to input register}$$
$$\text{+ micro hold time of the input register}$$
$$\text{+ clock delay from input pin to input register}$$

Figure 1–1 shows the setup and hold timing diagram for input registers.

Figure 1–1. Input Register Setup & Hold Timing Diagram
For output timing, different I/O standards require different baseline loading techniques for reporting timing delays. Altera characterizes timing delays with the required termination for each I/O standard and with 0 pF (except for PCI and PCI-X which use 10 pF) loading and the timing is specified up to the output pin of the FPGA device. The Quartus II software calculates the I/O timing for each I/O standard with a default baseline loading as specified by the I/O standards.

The following measurements are made during device characterization. Altera measures clock-to-output delays (t_{CO}) at worst-case process, minimum voltage, and maximum temperature (PVT) for default loading conditions shown in Table 1–41. Use the following equations to calculate clock pin to output pin timing for Cyclone III devices.

t_{CO} from clock pin to I/O pin = delay from clock pad to I/O output register + IOE output register clock-to-output delay + delay from output register to output pin

Figure 1–2. Output Register Clock to Output Timing Diagram
Simulation using IBIS models is required to determine the delays on the PCB traces in addition to the output pin delay timing reported by the Quartus II software and the timing model in the device handbook.

1. Simulate the output driver of choice into the generalized test setup, using values from Table 1–41.

2. Record the time to V_{MEAS}.

3. Simulate the output driver of choice into the actual PCB trace and load, using the appropriate IBIS model or capacitance value to represent the load.

4. Record the time to V_{MEAS}.

5. Compare the results of steps 2 and 4. The increase or decrease in delay should be added to or subtracted from the I/O Standard Output Adder delays to yield the actual worst-case propagation delay (clock-to-output) of the PCB trace.

The Quartus II software reports the timing with the conditions shown in Table 1–41 using the above equation. Figure 1–3 shows the model of the circuit that is represented by the output timing of the Quartus II software.

Figure 1–3. Output Delay Timing Reporting Setup Modeled by Quartus II (1), (2)
Notes to Figure 1–3:
(1) Output pin timing is reported at the output pin of the FPGA device. Additional delays for loading and board trace delay need to be accounted for with IBIS model simulations.
(2) V_{CCINT} is 1.10 V unless otherwise specified.

Figure 1–4 and Figure 1–5 show the I/O interface with single and multiple external output resistors.

Figure 1–4. I/O Interface with Single External Output Resistor
Figure 1–5. I/O Interface with Three External Output Resistor Network
Table 1–41. Output Timing Measurement Methodology for Output Pins *(1)*, *(2)*, *(4)*, *(5)* (Part 1 of 2)								Preliminary
I/O Standard	**Loading and Termination**							**Measurement Point**

RSDS_E_3R	120 (6)		100	170 (6)	2.375		0	1.1875

Notes to Table 1–41:
(1)   Input measurement point at internal node is 0.5 x V_{CCINT}.
(2)   Output measuring point for V_{MEAS} at buffer output is 0.5 x V_{CCIO}.
(3)   Input stimulus edge rate is 0 to V_{CC} in 0.2 ns (internal signal) from the driver preceding the I/O buffer.
(4)   Less than 50-mV ripple on V_{CCIO}. V_{CCINT}=1.10 V with less than 30-mV ripple.
(5)   The interface has to use external termination RT. The termination voltage V_{TT} may either be supplied by an independent power supply or created through a Thevenin equivalent circuit.
(6)   Pending silicon characterization.

I/O Default Capacitive Loading

See Table 1–42 for default capacitive loading of different I/O standards.

Maximum Input & Output Clock Toggle Rate

The maximum clock toggle rate is defined as the maximum frequency achievable for a clock type signal at an I/O pin. The I/O pin can be a regular I/O pin or a dedicated clock I/O pin.

The maximum clock toggle rate is different from the maximum data bit rate. If the maximum clock toggle rate on a regular I/O pin is 300 MHz, the maximum data bit rate for dual data rate (DDR) could be potentially as high as 600 Mbps on the same I/O pin.

Table 1–43 specifies the maximum input clock toggle rates. Table 1–44 specifies the maximum output clock toggle rates at 0 pF load. Table 1–45 specifies the derating factors for the output clock toggle rate for a non 0 pF load.

To calculate the output toggle rate for a non 0 pF load, use this formula:

The toggle rate for a non 0 pF load

= 1000 / (1000/ toggle rate at 0 pF load + derating factor * load value in pF /1000)

For example, the output toggle rate at 0 pF load for SSTL-18 Class II 16 μA I/O standard is 260 MHz on a -6 device clock output pin. The derating factor is 26 ps/pF. For a 10 pF load the toggle rate is calculated as:

1000 / (1000/260 + 26 x 10 /1000) = 243 (MHz)

Table 1–43 through Table 1–45 show the I/O toggle rates for Cyclone III devices.

Table 1–43. Maximum Input Clock Toggle Rate on Cyclone III Devices (Part 1 of 3)									Preliminary

	OCT_50_OHMS	290	240	200	290	240	200	290	240	200
1.2-V LVTTL/LVCMOS	OCT_25_OHMS	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)
	OCT_50_OHMS	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)

Notes to Table 1–44:
(1)   Current version of Quartus II does not have the information for the standard.
(2)   The 1.2 V (12 mA) and 1.2 V_HSTL_CLASS_I / II (12 mA and 14 mA respectively) are only supported on column I/O pins.
(3)   Output differential standard is only supported on PLLCLKOUT pin.
(4)   Dedicated differential standards are supported at row I/O pins.
(5)   Differential standards with external resistor network are supported at column I/O pins.
(6)   Output dedicated LVDS is only supported on row I/O pins. Input dedicated LVDS is supported at all I/O pins.

Notes to Table 1–45:

(1)   Current version of Quartus II does not have the information for the standard.
(2)   The 1.2 V (12 mA) and 1.2 V_HSTL_CLASS_I / II (12 mA and 14 mA respectively) are only supported on column I/O pins.
(3)   Output differential standard is only supported on PLLCLKOUT pin.
(4)   Dedicated differential standards are supported at row I/O pins.
(5)   Differential standards with external resistor network are supported at column I/O pins.
(6)   Output dedicated LVDS is only supported on row I/O pins. Input dedicated LVDS is supported at all I/O pins.
(7)   Indicate the lowest value of derating factor.

IOE Programmable Delay

Table 1–46 and Table 1–47 show IOE programmable delay for Cyclone III devices.

Table 1–46. Cyclone III IOE Programmable Delay on Column Pins (1), (2)										
Parameter	**Paths Affected**	**Number of Settings**	**Fast Corner (3)**		**-6 Speed Grade**		**-7 Speed Grade**		**-8 Speed Grade**		**Unit**
			Min Offset	**Max Offset**	**Min Offset**	**Max Offset**	**Min Offset**	**Max Offset**	**Min Offset**	**Max Offset**	
Input Delay from Pin to Internal Cells	Pad -> I/O dataout to core	7	0	2344	0	3827	0	4088	0	4349	ps
Input Delay from Pin to Input Register	Pad -> I/O input register	8	0	2788	0	4555	0	4748	0	4940	ps
Delay from Output Register to Output Pin	I/O output register -> Pad	2	0	318	0	563	0	617	0	670	ps

Notes to Table 1–46:
(1)   The incremental values for the settings are generally linear. For exact values of each setting, please use the latest version of Quartus III software.
(2)   The minimum and maximum offset timing numbers are in reference to setting "0" as available in the Quartus II software.
(3)   The fast corner timing parameter is for commercial devices.

Table 1–47. Cyclone III IOE Programmable Delay on Row Pins (1), (2)										
Parameter	**Paths Affected**	**Number of Settings**	**Fast Corner (3)**		**-6 Speed Grade**		**-7 Speed Grade**		**-8 Speed Grade**		**Unit**
			Min Offset	**Max Offset**	**Min Offset**	**Max Offset**	**Min Offset**	**Max Offset**	**Min Offset**	**Max Offset**	
Input Delay from Pin to Internal Cells	Pad -> I/O dataout to core	7	0	2352	0	3776	0	4033	0	4290	ps
Input Delay from Pin to Input Register	Pad -> I/O input register	8	0	2802	0	4482	0	4671	0	4859	ps
Delay from Output Register to Output Pin	I/O output register -> Pad	2	0	324	0	572	0	626	0	682	ps

Notes to Table 1–47:

(1) The incremental values for the settings are generally linear. For exact values of each setting, please use the latest version of Quartus II software.

(2) The minimum and maximum offset timing numbers are in reference to setting "0" as available in the Quartus II software.

(3) The fast corner timing parameter is for commercial devices.

Typical Design Performance

User I/O Pin Timing Parameters

Table 1–48 to Table 1–89 show user I/O pin timing for Cyclone III devices. I/O buffer t_{SU}, t_H and t_{CO} are reported for the cases when clock is driven by global clock and a PLL. Device EP3C5 is not available for the current version of Quartus II.

The 12 μA programmable current strength for 1.2 V and 1.2-V HSTL Class I I/O standard is not supported at row I/Os. The 1.2-V HSTL Class II standard is only supported at column I/Os. PCI and PCI-X do not support programmable current strength.

For more information about programmable current strength, please refer to the *Cyclone III Device I/O Features* chapter of the *Cyclone III Handbook*.

Dedicated LVDS, mini-LVDS, PPDS, and RSDS I/O standards are supported at row I/Os. External resistor networks are required if the differential standards are used as output pins at column banks. LVDS I/O standard is supported at both input and output pins. PPDS, RDSD, and mini-LVDS standards are only supported at output pins.

For more information about the differential I/O interface, please refer to *High-Speed Differential Interfaces in Cyclone III Devices* of the *Cyclone III Handbook*.

EP3C10 I/O Timing Parameters

Table 1–48 through Table 1–52 show the maximum I/O timing parameters for EP3C10 devices.

Table 1–48. EP3C10 Column I/O Pin Input Timing Parameters for Single-Ended I/O Standards (Part 1 of 3)						
I/O Standard	**Clock**	**Parameter**	**Specification**			**Units**

tpllcin		0.944	1.195	1.272	1.390	ns
tpllcout		0.973	1.248	1.333	1.460	ns

EP3C80 Clock Timing Parameters

Table 1–100 through Table 1–101 show the maximum clock timing parameters for EP3C80 devices.

Table 1–100. EP3C80 Column Pin Global Clock Timing Parameters						
Parameter	Fast Model		-6	-7	-8	Units
	Industrial	Commercial				
tcin		1.950	2.831	3.112	3.418	ns
tcout		1.979	2.884	3.173	3.488	ns
tpllcin		1.038	1.324	1.421	1.559	ns
tpllcout		1.067	1.377	1.482	1.629	ns

Table 1–101. EP3C80 Row Pin Global Clock Timing Parameters

Parameter	Fast Model		-6	-7	-8	Units
	Industrial	Commercial				
tcin		1.892	2.736	2.993	3.296	ns
tcout		1.921	2.789	3.054	3.366	ns
tpllcin		0.980	1.229	1.302	1.437	ns
tpllcout		1.009	1.282	1.363	1.507	ns

EP3C120 Clock Timing Parameters

Table 1–102 through Table 1–103 show the maximum clock timing parameters for EP3C120 devices. EP3C120 devices are offered in -7 and -8 speed grades only.

Table 1–102. EP3C120 Column Pin Global Clock Timing Parameters

Parameter	Fast Model		-7	-8	Units
	Industrial	Commercial			
tcin		2.104	3.369	3.706	ns

Glossary

Table 1–104 shows the glossary for this chapter.

Table 1–104. Glossary

Letter	Term	Definitions
A	—	—
B	—	—
C	—	—
D	—	—
E	—	—
F	f_{HSCLK}	HIGH-SPEED I/O Block: High-speed receiver/transmitter input and output clock frequency.
G	GCLK	Input pin directly to Global Clock network.
	GCLK PLL	Input pin to Global Clock network through PLL.
H	HSIODR	HIGH-SPEED I/O Block: Maximum/minimum LVDS data transfer rate (HSIODR = 1/TUI).
I	Input Waveforms for the SSTL Differential I/O Standard	
J	JTAG Waveform	
K	—	—
L	—	—
M	—	—

Letter	**Term**	**Definitions**
N	—	—
O	—	—
P	PLL Block	The following block diagram highlights the PLL Specification parameters.

Q	—	—
R	R_L	Receiver differential input discrete resistor (external to Cyclone III device).
	RSKM (Receiver input skew margin)	HIGH-SPEED I/O Block: The total margin left after accounting for the sampling window and TCCS. RSKM = (TUI - SW - TCCS) / 2.
S	Single-ended Voltage referenced I/O Standard	The JEDEC standard for SSTI and HSTL I/O standards defines both the AC and DC input signal values. The AC values indicate the voltage levels at which the receiver must meet its timing specifications. The DC values indicate the voltage levels at which the final logic state of the receiver is unambiguously defined. Once the receiver input has crossed the AC value, the receiver will change to the new logic state. The new logic state will then be maintained as long as the input stays beyond the DC threshold. This approach is intended to provide predictable receiver timing in the presence of input waveform *ringing*.
	SW (Sampling Window)	HIGH-SPEED I/O Block: The period of time during which the data must be valid in order to capture it correctly. The setup and hold times determine the ideal strobe position within the sampling window.

Table 1–104. Glossary

Table 1–104. Glossary		
Letter	**Term**	**Definitions**
T	t_C	High-speed receiver/transmitter input and output clock period.
	TCCS (Channel-to-channel-skew)	HIGH-SPEED I/O Block: The timing difference between the fastest and slowest output edges, including t_{CO} variation and clock skew. The clock is included in the TCCS measurement.
	tcin	Delay from clock pad to I/O input register.
	t_{CO}	Delay from clock pad to I/O output.
	tcout	Delay from clock pad to I/O output register.
	t_{DUTY}	HIGH-SPEED I/O Block: Duty cycle on high-speed transmitter output clock.
	t_{FALL}	Signal High-to-low transition time (80-20%).
	t_H	Input register hold time.
	Timing Unit Interval (TUI)	HIGH-SPEED I/O block: The timing budget allowed for skew, propagation delays, and data sampling window. (TUI = 1/(Receiver Input Clock Frequency Multiplication Factor) = t_C/w).
	$t_{INJITTER}$	Period jitter on PLL clock input.
	$t_{OUTJITTER\_DEDCLK}$	Period jitter on dedicated clock output driven by a PLL.
	$t_{OUTJITTER\_IO}$	Period jitter on general purpose I/O driven by a PLL.
	tpllcin	Delay from PLL inclk pad to I/O input register.
	tpllcout	Delay from PLL inclk pad to I/O output register.
	Transmitter Output Waveform	Transmitter Output Waveforms for the LVDS, mini-LVDS, PPDS and RSDS Differential I/O Standard **Single-Ended Waveform** Positive Channel (p) = V_{OH} V_{OD} Negative Channel (n) = V_{OL} V_{OS} Ground **Differential Waveform (Mathematical Function of Positive & Negative Channel)** V_{OD} 0 V V_{OD} p − n (1)
	t_{RISE}	Signal Low-to-high transition time (20-80%).
	tSU	Input register setup time.
U	—	—

Table 1–104. Glossary		
Letter	**Term**	**Definitions**
V	$V_{CM(DC)}$	DC Common Mode Input Voltage.
	$V_{DIF(AC)}$	AC differential Input Voltage: The minimum AC input differential voltage required for switching.
	$V_{DIF(DC)}$	DC differential Input Voltage: The minimum DC input differential voltage required for switching.
	V_{ICM}	Input Common Mode Voltage: The common mode of the differential signal at the receiver.
	V_{ID}	Input differential Voltage Swing: The difference in voltage between the positive and complementary conductors of a differential transmission at the receiver.
	V_{IH}	Voltage Input High: The minimum positive voltage applied to the input which will be accepted by the device as a logic high.
	$V_{IH(AC)}$	High-level AC input voltage.
	$V_{IH(DC)}$	High-level DC input voltage.
	V_{IL}	Voltage Input Low: The maximum positive voltage applied to the input which will be accepted by the device as a logic low.
	$V_{IL\ (AC)}$	Low-level AC input voltage.
	$V_{IL\ (DC)}$	Low-level DC input voltage.
	V_{IN}	DC input voltage.
	V_{OCM}	Output Common Mode Voltage: The common mode of the differential signal at the transmitter.
	V_{OD}	Output differential Voltage Swing: The difference in voltage between the positive and complementary conductors of a differential transmission at the transmitter. $V_{OD} = V_{OH} - V_{OL}$.
	V_{OH}	Voltage Output High: The maximum positive voltage from an output which the device considers will be accepted as the minimum positive high level.
	V_{OL}	Voltage Output Low: The maximum positive voltage from an output which the device considers will be accepted as the maximum positive low level.
	V_{OS}	Output offset voltage: $V_{OS} = (V_{OH} + V_{OL}) / 2$.
	$V_{OX\ (AC)}$	AC differential Output cross point voltage: The voltage at which the differential output signals must cross.
	V_{REF}	Reference voltage for SSTL, HSTL I/O Standards.
	$V_{REF\ (AC)}$	AC input reference voltage for SSTL, HSTL I/O Standards. $V_{REF(AC)} = V_{REF(DC)}$ + noise, The peak-to-peak AC noise on V_{REF} should not exceed 2% of $V_{REF(DC)}$.
	$V_{REF\ (DC)}$	DC input reference voltage for SSTL, HSTL I/O Standards.
	$V_{SWING\ (AC)}$	AC differential Input Voltage: AC Input differential voltage required for switching. See Input Waveforms for the SSTL Differential I/O Standard.
	$V_{SWING\ (DC)}$	DC differential Input Voltage: DC Input differential voltage required for switching. See Input Waveforms for the SSTL Differential I/O Standard.

Table 1–104. Glossary

Letter	Term	Definitions
V	V_{TH}	Differential input threshold.
	V_{TT}	Termination voltage for SSTL, HSTL I/O Standards.
	$V_{X\ (AC)}$	AC differential Input cross point Voltage: The voltage at which the differential input signals must cross.
