GENERAL DESCRIPTION

The AMD family of subscriber line interface circuit (SLIC) products provide the telephone interface functions required throughout the worldwide market. AMD SLIC devices address all major telephony markets including central office (CO), private branch exchange (PBX), digital loop carrier (DLC), fiber-in-the-loop (FITL), radio-in-the-loop (RITL), hybrid fiber coax (HFC), and video telephony applications.

The AMD SLIC devices offer support of BORSHT (battery feed, overvoltage protection, ringing, supervision, hybrid, and test) functions with features including current limiting, on-hook transmission, polarity reversal, Tip Open, and loop-current detection. These features allow reduction of linecard cost by minimizing component count, conserving board space, and supporting automated manufacturing.

The AMD SLIC devices provide the two- to four-wire hybrid function, DC-loop feed, and two-wire supervision. Two-wire termination is programmed by a scaled impedance network. Transhybrid balance can be achieved with an external balance circuit or simply programmed using a companion AMD codec device, the Am79C02/03/031 DSLAC™ device, the Am79Q02/021/03 Programmable Quad SLAC (QSLAC™) device, or the Am79Q5457/4457 Nonprogrammable QSLAC device.

The Am79R79 Ringing SLIC device is a bipolar monolithic SLIC that offers on-chip ringing. Now designers can achieve significant cost reductions at the system level for short-loop applications by integrating the ringing function on chip. Examples of such applications

would be ISDN terminal adaptors, fiber-in-the-loop, radio-in-the-loop, hybrid fiber/coax and video telephony (home-side) boxes. The Am79R79 Ringing SLIC can provide sufficient voltage to meet the stringent LSSGR five-ringer equivalent specification. Using a CMOS-compatible input waveform and wave shaping R-C network, the Am79R79 Ringing SLIC can provide trapezoidal wave ringing to meet various design requirements.

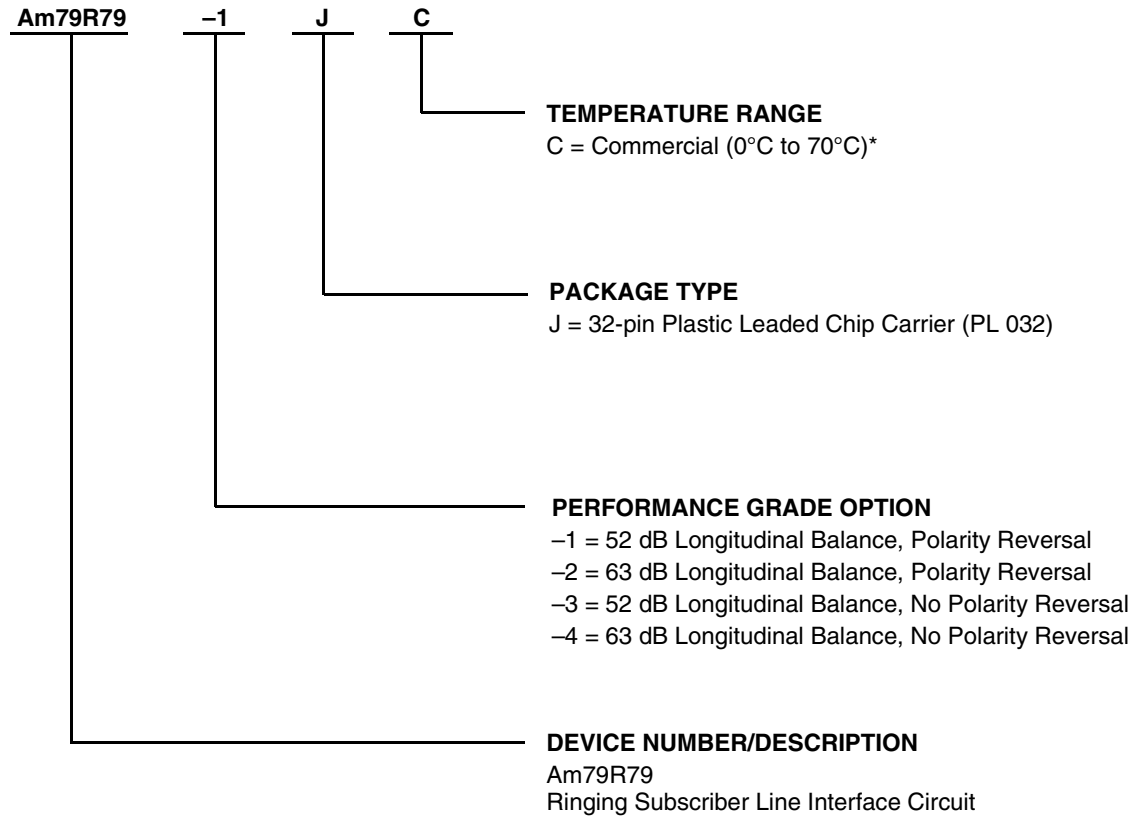

In order to further enhance the suitability of this device in short-loop, distributed switching applications, AMD has maximized power savings by incorporating battery switching on chip. The Am79R79 Ringing SLIC device switches between two battery supplies such that in the off-hook (active) state, a low battery is used to save power. In order to meet the Open Circuit voltage requirements of fax machines and maintenance termination units (MTU), the SLIC automatically switches to a higher voltage in the on-hook (standby) state.

Like all of the AMD SLIC devices, the Am79R79 Ringing SLIC device supports on-hook transmission, ring-trip detection, programmable loop-detect threshold, and is available with on-chip polarity reversal. The Am79R79 Ringing SLIC device is a programmable constant-current feed device with two on-chip relay drivers to operate external relays. Several performance grades are available to meet both CCITT and LSSGR requirements, including various longitudinal balance options. This unique device is available in the proven AMD 75 V bipolar process in the 32-pin PLCC package.

Notes:

- Unless otherwise noted, test conditions are $BAT1 = -75\text{ V}$, $BAT2 = -24\text{ V}$, $V_{CC} = +5\text{ V}$, $V_{NEG} = -5\text{ V}$, $R_L = 600\ \Omega$, $R_{DC1} = 80\text{ k}\Omega$, $R_{DC2} = 20\text{ k}\Omega$, $R_D = 75\text{ k}\Omega$, no fuse resistors, $C_{HP} = 0.018\ \mu\text{F}$, $C_{DC} = 1.2\ \mu\text{F}$, $D_1 = D_2 = 1N400x$, two-wire AC input impedance (ZSL) is a $600\ \Omega$ resistance synthesized by the programming network shown below. $R_{SGL} = \text{open}$, $R_{SGH} = \text{open}$, $R_{DCR} = 2\text{ k}\Omega$, $R_{RT1} = 430\text{ k}\Omega$, $R_{RT2} = 12\text{ k}\Omega$, $C_{RT} = 1.5\ \mu\text{F}$, $R_{SLEW} = 100\text{ k}\Omega$, $C_{SLEW} = 0.33\ \mu\text{F}$.

- Overload level is defined when $THD = 1\%$.
 - Overload level is defined when $THD = 1.5\%$.
- Balance return signal is the signal generated at V_{TX} by V_{RX} . This specification assumes that the two-wire AC load impedance matches the programmed impedance.
- Not tested in production. This parameter is guaranteed by characterization or correlation to other tests.
- This parameter is tested at 1 kHz in production. Performance at other frequencies is guaranteed by characterization.
- Group delay can be greatly reduced by using a Z_T network such as that shown in Note 1 above. The network reduces the group delay to less than $2\ \mu\text{s}$ and increases 2WRL. The effect of group delay on linecard performance may also be compensated for by synthesizing complex impedance with the QSLAC or DSLAC device.
- 70 Vpk provides 50 Vrms with a crest factor of 1.25 to a load of $1400\ \Omega$ with $2 \cdot R_f = 100$, and $R_{line} = 70\ \Omega$ ($1570\ \Omega$).
- Open Circuit V_{AB} can be modified using RSGH.
- R_D must be greater than $56\text{ k}\Omega$. Refer to Table 2 for typical value of R_{LTH} .
- Lower power is achieved by switching into low-battery state in standby. Standby loop current is returned to V_{BAT1} regardless of the battery selected.

- ** For correct ground-start operation using Tip Open, V_{BAT1} on-hook battery must be used.

Table 2. User-Programmable Components

$Z_T = 500(Z_{2WIN} - 2R_F)$	Z_T is connected between the VTX and RSN pins. The fuse resistors are R_F , and Z_{2WIN} is the desired 2-wire AC input impedance. When computing Z_T , the internal current amplifier pole and any external stray capacitance between VTX and RSN must be taken into account.
$Z_{RX} = \frac{Z_L}{G_{42L}} \cdot \frac{1000 \cdot Z_T}{Z_T + 500(Z_L + 2R_F)}$	Z_{RX} is connected from V_{RX} to R_{SN} . Z_T is defined above, and G_{42L} is the desired receive gain.
$R_{DC1} + R_{DC2} = \frac{2500}{I_{LOOP}}$ $R_{DCR1} + R_{DCR2} = \frac{3000}{I_{ringlim}}$ $C_{DC} = 19 \text{ ms} \cdot \frac{R_{DC1} + R_{DC2}}{R_{DC1}R_{DC2}}$ $C_{DCR} = \frac{R_{DCR1} + R_{DCR2}}{R_{DCR1}R_{DCR2}} \cdot 150 \text{ } \mu\text{s}$	<p>R_{DC1}, R_{DC2}, and C_{DC} form the network connected to the RDC pin. I_{LOOP} is the desired loop current in the constant-current region.</p> <p>R_{DCR1}, R_{DCR2}, and C_{DCR} form the network connected to the RDCR pin. See Applications Circuit for these components.</p> <p>C_{DCR} sets the ringing time constant, which can be between 15 μs and 150 μs.</p>
$R_D = R_{LTH} \cdot 12.67$ for high battery state	R_D is the resistor connected from the RD pin to GND and R_{LTH} is the loop-resistance threshold between on-hook and off-hook detection. R_D should be greater than 56 k Ω to guarantee detection occurs in the Standby state. Choose the value of R_D for high battery state; then use the equation for R_{LTH} to find where the threshold is for low battery.
Loop-Threshold Detect Equations	
$R_{LTH} = \frac{R_D}{12.67}$ for high battery	This is the same equation as for R_D above, except solved for R_{LTH} .
$R_{LTH} = \frac{R_D}{11.37}$ for low battery	For low battery, the detect threshold is slightly higher, which avoids oscillating between states.
$R_{LTH} = \frac{ V_{BAT1} - 10}{915} \cdot R_D - 400 - 2R_F$	$R_{LTH \text{ standby}} < R_{LTH \text{ active}} < V_{BAT1} < R_{LTH \text{ active}} < V_{BAT2}$, which guarantees no unstable states under all operating conditions. This equation shows at what resistance the standby threshold is; it is actually a current threshold rather than a resistance threshold, which is shown by the Vbat dependency.

DC FEED CHARACTERISTICS

 Anti-sat region: $V_{ASHH} = \frac{1000 \cdot (70 \cdot 10^3 + R_{SGH})}{1934 \cdot 10^3 + (31.75 \cdot R_{SGH})}$; where R_{SGH} = resistor to GND, B2EN = logic High.

$$V_{ASHH} = \frac{1000 \cdot (R_{SGH} + 2.75 \cdot 10^3)}{1934 \cdot 10^3 + (31.75 \cdot R_{SGH})}$$
; where R_{SGH} = resistor to V_{CC} , B2EN = logic High. R_{SGH} to V_{CC} must be greater than 100 k Ω .

5. $V_{APPH} = 4.17 + V_{ASH}$
 $I_{LOOPH} = \frac{V_{APPH}}{\frac{(R_{DC1} + R_{DC2})}{600} + 2R_F + R_{LOOP}}$

RING-TRIP COMPONENTS

$$R_{RT2} = 12 \text{ k}\Omega$$

$$C_{RT} = 1.5 \text{ }\mu\text{F}$$

$$R_{RT1} = 320 \cdot CF \cdot \frac{V_{BAT1}}{V_{bat} - 5 - (24 \text{ }\mu\text{A} \cdot 320 \cdot CF \cdot (R_{LRT} + 150 + 2R_F))} \cdot (R_{LRT} + 150 + 2R_F)$$

where R_{LRT} = Loop-detection threshold resistance for ring trip and CF = Crest factor of ringing signal (≈ 1.25)

R_{SLEW} , C_{SLEW}

Ring waveform rise time $\approx 0.214 \cdot (R_{SLEW} \cdot C_{SLEW}) \approx tr$.

For a 1.25 crest factor @ 20 Hz, $tr \approx 10 \text{ mS}$.

$\therefore (R_{SLEW} = 150 \text{ k}\Omega, C_{SLEW} = 0.33 \text{ }\mu\text{F})$

C_{SLEW} should be changed if a different crest factor is desired.
