SIEMENS

C16x-Family of   **C167CR-16RM**
High-Performance CMOS 16-Bit Microcontrollers

Advance Information
C167CR-16RM   16-Bit Microcontroller

- High Performance 16-bit CPU with 4-Stage Pipeline
- 100 ns Instruction Cycle Time at 20 MHz CPU Clock
- 500 ns Multiplication (16 $\times$ 16 bit), 1 μs Division (32 / 16 bit)
- Enhanced Boolean Bit Manipulation Facilities
- Additional Instructions to Support HLL and Operating Systems
- Register-Based Design with Multiple Variable Register Banks
- Single-Cycle Context Switching Support
- Clock Generation via on-chip PLL or via direct clock input
- Up to 16 MBytes Linear Address Space for Code and Data
- 2 KBytes On-Chip Internal RAM (IRAM)
- 2 KBytes On-Chip Extension RAM (XRAM)
- 128 KBytes On-Chip ROM
- Programmable External Bus Characteristics for Different Address Ranges
- 8-Bit or 16-Bit External Data Bus
- Multiplexed or Demultiplexed External Address/Data Buses
- Five Programmable Chip-Select Signals
- Hold- and Hold-Acknowledge Bus Arbitration Support
- 1024 Bytes On-Chip Special Function Register Area
- Idle and Power Down Modes
- 8-Channel Interrupt-Driven Single-Cycle Data Transfer Facilities via Peripheral Event Controller (PEC)
- 16-Priority-Level Interrupt System with 56 Sources, Sample-Rate down to 50 ns
- 16-Channel 10-bit A/D Converter with 9.7μs Conversion Time
- Two 16-Channel Capture/Compare Units
- 4-Channel PWM Unit
- Two Multi-Functional General Purpose Timer Units with 5 Timers
- Two Serial Channels (Synchronous/Asynchronous and High-Speed-Synchronous)
- On-Chip CAN Interface with 15 Message Objects (Full-CAN/Basic-CAN)
- Programmable Watchdog Timer
- Up to 111 General Purpose I/O Lines, partly with Selectable Input Thresholds and Hysteresis
- Supported by a Wealth of Development Tools like C-Compilers, Macro-Assembler Packages, Emulators, Evaluation Boards, HLL-Debuggers, Simulators, Logic Analyzer Disassemblers, Programming Boards
- On-Chip Bootstrap Loader
- 144-Pin MQFP Package (EIAJ)

This document describes the **SAB-C167CR-16RM** and the **SAK-C167CR-16RM**. For simplicity all versions are referred to by the term **C167CR-16RM** throughout this document.

SIEMENS

Introduction

The C167CR-16RM is a new derivative of the Siemens C16x Family of full featured single-chip CMOS microcontrollers. It combines high CPU performance (up to 10 million instructions per second) with high peripheral functionality and enhanced IO-capabilities. It also provides on-chip ROM, on-chip high-speed RAM and clock generation via PLL.

Pin Definitions and Functions

| Symbol	Pin Number	Input (I) Output (O)	Function
P6.0 – P6.7	1 - 8	I/O	Port 6 is an 8-bit bidirectional I/O port. It is bit-wise programmable for input or output via direction bits. For a pin configured as input, the output driver is put into high-impedance state. Port 6 outputs can be configured as push/ pull or open drain drivers.
			The following Port 6 pins also serve for alternate functions:
	1	O	P6.0 $\overline{CS0}$ Chip Select 0 Output
	...	...	... ...
	5	O	P6.4 $\overline{CS4}$ Chip Select 4 Output
	6	I	P6.5 $\overline{HOLD}$ External Master Hold Request Input
	7	O	P6.6 $\overline{HLDA}$ Hold Acknowledge Output
	8	O	P6.7 $\overline{BREQ}$ Bus Request Output
P8.0 – P8.7	9 - 16	I/O	Port 8 is an 8-bit bidirectional I/O port. It is bit-wise programmable for input or output via direction bits. For a pin configured as input, the output driver is put into high-impedance state. Port 8 outputs can be configured as push/ pull or open drain drivers. The input threshold of Port 8 is selectable (TTL or special).
			The following Port 8 pins also serve for alternate functions:
	9	I/O	P8.0 CC16IO CAPCOM2: CC16 Cap.-In/Comp.Out
	...	...	... ...
	16	I/O	P8.7 CC23IO CAPCOM2: CC23 Cap.-In/Comp.Out
P7.0 – P7.7	19 - 26	I/O	Port 7 is an 8-bit bidirectional I/O port. It is bit-wise programmable for input or output via direction bits. For a pin configured as input, the output driver is put into high-impedance state. Port 7 outputs can be configured as push/ pull or open drain drivers. The input threshold of Port 7 is selectable (TTL or special).
			The following Port 7 pins also serve for alternate functions:
	19	O	P7.0 POUT0 PWM Channel 0 Output
	...	...	... ...
	22	O	P7.3 POUT3 PWM Channel 3 Output

Pin Definitions and Functions (cont'd)

Symbol	Pin Number	Input (I) Output (O)	Function
P3.0 – P3.13, P3.15	65 – 70, 73 – 80, 81	I/O I/O I/O	Port 3 is a 15-bit (P3.14 is missing) bidirectional I/O port. It is bit-wise programmable for input or output via direction bits. For a pin configured as input, the output driver is put into high-impedance state. Port 3 outputs can be configured as push/pull or open drain drivers. The input threshold of Port 3 is selectable (TTL or special). The following Port 3 pins also serve for alternate functions:
	65	I	P3.0　　T0IN　　CAPCOM Timer T0 Count Input
	66	O	P3.1　　T6OUT　GPT2 Timer T6 Toggle Latch Output
	67	I	P3.2　　CAPIN　 GPT2 Register CAPREL Capture Input
	68	O	P3.3　　T3OUT　GPT1 Timer T3 Toggle Latch Output
	69	I	P3.4　　T3EUD　GPT1 Timer T3 Ext.Up/Down Ctrl.Input
	70	I	P3.5　　T4IN　　GPT1 Timer T4 Input for Count/Gate/Reload/Capture
	73	I	P3.6　　T3IN　　GPT1 Timer T3 Count/Gate Input
	74	I	P3.7　　T2IN　　GPT1 Timer T2 Input for Count/Gate/Reload/Capture
	75	I/O	P3.8　　MRST　 SSC Master-Rec./Slave-Transmit I/O
	76	I/O	P3.9　　MTSR　 SSC Master-Transmit/Slave-Rec. O/I
	77	O	P3.10　T×D0　 ASC0 Clock/Data Output (Asyn./Syn.)
	78	I/O	P3.11　R×D0　 ASC0 Data Input (Asyn.) or I/O (Syn.)
	79	O O	P3.12　$\overline{BHE}$　 Ext. Memory High Byte Enable Signal, 　　　 $\overline{WRH}$　 Ext. Memory High Byte Write Strobe
	80	I/O	P3.13　SCLK　 SSC Master Clock Outp./Slave Cl. Inp.
	81	O	P3.15　CLKOUT System Clock Output (=CPU Clock)
P4.0 – P4.7	85 - 92	I/O	Port 4 is an 8-bit bidirectional I/O port. It is bit-wise programmable for input or output via direction bits. For a pin configured as input, the output driver is put into high-impedance state. In case of an external bus configuration, Port 4 can be used to output the segment address lines:
	85	O	P4.0　　A16　　Least Significant Segment Addr. Line
	...	...	...　　　 ...　　　 ...
	89	O	P4.4　　A20　　Segment Address Line
	90	O I	P4.5　　A21　　Segment Address Line, 　　　 CAN_RxD CAN Receive Data Input
	91	O O	P4.6　　A22　　Segment Address Line, 　　　 CAN_TxD CAN Transmit Data Output
	92	O	P4.7　　A23　　Most Significant Segment Addr. Line
$\overline{RD}$	95	O	External Memory Read Strobe. $\overline{RD}$ is activated for every external instruction or data read access.

Pin Definitions and Functions (cont'd)

Symbol	Pin Number	Input (I) Output (O)	Function
$\overline{WR}$/ $\overline{WRL}$	96	O	External Memory Write Strobe. In $\overline{WR}$-mode this pin is activated for every external data write access. In $\overline{WRL}$-mode this pin is activated for low byte data write accesses on a 16-bit bus, and for every data write access on an 8-bit bus. See WRCFG in register SYSCON for mode selection.
$\overline{READY}$	97	I	Ready Input. When the Ready function is enabled, a high level at this pin during an external memory access will force the insertion of memory cycle time waitstates until the pin returns to a low level.
ALE	98	O	Address Latch Enable Output. Can be used for latching the address into external memory or an address latch in the multiplexed bus modes.
$\overline{EA}$	99	I	External Access Enable pin. A low level at this pin during and after Reset forces the C167CR-16RM to begin instruction execution out of external memory. A high level forces execution out of the internal ROM. ROMless versions must have this pin tied to '0'.
PORT0: P0L.0 – P0L.7, P0H.0 - P0H.7	100 – 107 108, 111-117	I/O	PORT0 consists of the two 8-bit bidirectional I/O ports P0L and P0H. It is bit-wise programmable for input or output via direction bits. For a pin configured as input, the output driver is put into high-impedance state. In case of an external bus configuration, PORT0 serves as the address (A) and address/data (AD) bus in multiplexed bus modes and as the data (D) bus in demultiplexed bus modes. **Demultiplexed bus modes:** Data Path Width: 8-bit 16-bit; P0L.0 – P0L.7: D0 – D7 D0 - D7; P0H.0 – P0H.7: I/O D8 - D15; **Multiplexed bus modes:** Data Path Width: 8-bit 16-bit; P0L.0 – P0L.7: AD0 – AD7 AD0 - AD7; P0H.0 – P0H.7: A8 - A15 AD8 - AD15

7 Semiconductor Group

Pin Definitions and Functions (cont'd)

Symbol	Pin Number	Input (I) Output (O)	Function
PORT1: P1L.0 – P1L.7, P1H.0 - P1H.7	118 – 125 128 – 135	I/O	PORT1 consists of the two 8-bit bidirectional I/O ports P1L and P1H. It is bit-wise programmable for input or output via direction bits. For a pin configured as input, the output driver is put into high-impedance state. PORT1 is used as the 16-bit address bus (A) in demultiplexed bus modes and also after switching from a demultiplexed bus mode to a multiplexed bus mode. The following PORT1 pins also serve for alternate functions:
	132	I	P1H.4 CC24IO CAPCOM2: CC24 Capture Input
	133	I	P1H.5 CC25IO CAPCOM2: CC25 Capture Input
	134	I	P1H.6 CC26IO CAPCOM2: CC26 Capture Input
	135	I	P1H.7 CC27IO CAPCOM2: CC27 Capture Input
XTAL1 XTAL2	138 137	I O	XTAL1: Input to the oscillator amplifier and input to the internal clock generator XTAL2: Output of the oscillator amplifier circuit. To clock the device from an external source, drive XTAL1, while leaving XTAL2 unconnected. Minimum and maximum high/low and rise/fall times specified in the AC Characteristics must be observed.
$\overline{\text{RSTIN}}$	140	I	Reset Input with Schmitt-Trigger characteristics. A low level at this pin for a specified duration while the oscillator is running resets the C167CR-16RM. An internal pullup resistor permits power-on reset using only a capacitor connected to V_{SS}.
$\overline{\text{RSTOUT}}$	141	O	Internal Reset Indication Output. This pin is set to a low level when the part is executing either a hardware-, a software- or a watchdog timer reset. $\overline{\text{RSTOUT}}$ remains low until the EINIT (end of initialization) instruction is executed.
$\overline{\text{NMI}}$	142	I	Non-Maskable Interrupt Input. A high to low transition at this pin causes the CPU to vector to the NMI trap routine. When the PWRDN (power down) instruction is executed, the $\overline{\text{NMI}}$ pin must be low in order to force the C167CR-16RM to go into power down mode. If $\overline{\text{NMI}}$ is high, when PWRDN is executed, the part will continue to run in normal mode. If not used, pin $\overline{\text{NMI}}$ should be pulled high externally.
V_{AREF}	37	-	Reference voltage for the A/D converter.
V_{AGND}	38	-	Reference ground for the A/D converter.
V_{PP}	84	-	Flash programming voltage. This pin accepts the programming voltage for flash versions of the C167CR-16RM. **Note:** This pin is not connected (**NC**) on non-flash versions.

Pin Definitions and Functions (cont'd)

Symbol	Pin Number	Input (I) Output (O)	Function
V_{CC}	17, 46, 56, 72, 82, 93, 109, 126, 136, 144	-	Digital Supply Voltage: + 5 V during normal operation and idle mode. $\geq$ 2.5 V during power down mode.
V_{SS}	18, 45, 55, 71, 83, 94, 110, 127, 139, 143	-	Digital Ground.

Functional Description

The architecture of the C167CR-16RM combines advantages of both RISC and CISC processors and of advanced peripheral subsystems in a very well-balanced way. The following block diagram gives an overview of the different on-chip components and of the advanced, high bandwidth internal bus structure of the C167CR-16RM.

Note: All time specifications refer to a CPU clock of 20 MHz
(see definition in the AC Characteristics section).

Figure 3
Block Diagram

Memory Organization

The memory space of the C167CR-16RM is configured in a Von Neumann architecture which means that code memory, data memory, registers and I/O ports are organized within the same linear address space which includes 16 MBytes. The entire memory space can be accessed bytewise or wordwise. Particular portions of the on-chip memory have additionally been made directly bitaddressable.

The C167CR-16RM contains 128 KBytes of on-chip mask-programmable ROM for code or constant data. The lower 32 KBytes of the on-chip ROM can be mapped either to segment 0 or segment 1.

2 KBytes of on-chip Internal RAM are provided as a storage for user defined variables, for the system stack, general purpose register banks and even for code. A register bank can consist of up to 16 wordwide (R0 to R15) and/or bytewide (RL0, RH0, …, RL7, RH7) so-called General Purpose Registers (GPRs).

1024 bytes (2 * 512 bytes) of the address space are reserved for the Special Function Register areas (SFR space and ESFR space). SFRs are wordwide registers which are used for controlling and monitoring functions of the different on-chip units. Unused SFR addresses are reserved for future members of the C16x family.

2 KBytes of on-chip Extension RAM (XRAM) are provided to store user data, user stacks or code. The XRAM is accessed like external memory and therefore cannot be used for the system stack or for register banks and is not bitadressable. The XRAM allows 16-bit accesses with maximum speed.

In order to meet the needs of designs where more memory is required than is provided on chip, up to 16 MBytes of external RAM and/or ROM can be connected to the microcontroller.

SIEMENS

External Bus Controller

All of the external memory accesses are performed by a particular on-chip External Bus Controller (EBC). It can be programmed either to Single Chip Mode when no external memory is required, or to one of four different external memory access modes, which are as follows:

– 16-/18-/20-/24-bit Addresses, 16-bit Data, Demultiplexed

– 16-/18-/20-/24-bit Addresses, 16-bit Data, Multiplexed

– 16-/18-/20-/24-bit Addresses,   8-bit Data, Multiplexed

– 16-/18-/20-/24-bit Addresses,   8-bit Data, Demultiplexed

In the demultiplexed bus modes, addresses are output on PORT1 and data is input/output on PORT0 or P0L, respectively. In the multiplexed bus modes both addresses and data use PORT0 for input/output.

Important timing characteristics of the external bus interface (Memory Cycle Time, Memory Tri-State Time, Length of ALE and Read Write Delay) have been made programmable to allow the user the adaption of a wide range of different types of memories and external peripherals.
In addition, up to 4 independent address windows may be defined (via register pairs ADDRSELx / BUSCONx) which allow to access different resources with different bus characteristics. These address windows are arranged hierarchically where BUSCON4 overrides BUSCON3 and BUSCON2 overrides BUSCON1. All accesses to locations not covered by these 4 address windows are controlled by BUSCON0.
Up to 5 external $\overline{\text{CS}}$ signals (4 windows plus default) can be generated in order to save external glue logic. Access to very slow memories is supported via a particular 'Ready' function.

A $\overline{\text{HOLD}}$/$\overline{\text{HLDA}}$ protocol is available for bus arbitration and allows to share external resources with other bus masters. The bus arbitration is enabled by setting bit HLDEN in register SYSCON. After setting HLDEN once, pins P6.7...P6.5 ($\overline{\text{BREQ}}$, $\overline{\text{HLDA}}$, $\overline{\text{HOLD}}$) are automatically controlled by the EBC. In Master Mode (default after reset) the $\overline{\text{HLDA}}$ pin is an output. By setting bit DP6.7 to '1' the Slave Mode is selected where pin $\overline{\text{HLDA}}$ is switched to input. This allows to directly connect the slave controller to another master controller without glue logic.

For applications which require less than 16 MBytes of external memory space, this address space can be restricted to 1 MByte, 256 KByte or to 64 KByte. In this case Port 4 outputs four, two or no address lines at all. It outputs all 8 address lines, if an address space of 16 MBytes is used.

Note: When the on-chip CAN Module is to be used the segment address output on Port 4 must be limited to 4 bits (ie. A19...A16) in order to enable the alternate function of the CAN interface pins.

SIEMENS

Central Processing Unit (CPU)

The main core of the CPU consists of a 4-stage instruction pipeline, a 16-bit arithmetic and logic unit (ALU) and dedicated SFRs. Additional hardware has been spent for a separate multiply and divide unit, a bit-mask generator and a barrel shifter.

Based on these hardware provisions, most of the C167CR-16RM's instructions can be executed in just one machine cycle which requires 100 ns at 20-MHz CPU clock. For example, shift and rotate instructions are always processed during one machine cycle independent of the number of bits to be shifted. All multiple-cycle instructions have been optimized so that they can be executed very fast as well: branches in 2 cycles, a 16 × 16 bit multiplication in 5 cycles and a 32-/16 bit division in 10 cycles. Another pipeline optimization, the so-called 'Jump Cache', allows reducing the execution time of repeatedly performed jumps in a loop from 2 cycles to 1 cycle.

Figure 4
CPU Block Diagram

Semiconductor Group

The CPU disposes of an actual register context consisting of up to 16 wordwide GPRs which are physically allocated within the on-chip RAM area. A Context Pointer (CP) register determines the base address of the active register bank to be accessed by the CPU at a time. The number of register banks is only restricted by the available internal RAM space. For easy parameter passing, a register bank may overlap others.

A system stack of up to 2048 bytes is provided as a storage for temporary data. The system stack is allocated in the on-chip RAM area, and it is accessed by the CPU via the stack pointer (SP) register. Two separate SFRs, STKOV and STKUN, are implicitly compared against the stack pointer value upon each stack access for the detection of a stack overflow or underflow.

The high performance offered by the hardware implementation of the CPU can efficiently be utilized by a programmer via the highly efficient C167CR-16RM instruction set which includes the following instruction classes:

– Arithmetic Instructions
– Logical Instructions
– Boolean Bit Manipulation Instructions
– Compare and Loop Control Instructions
– Shift and Rotate Instructions
– Prioritize Instruction
– Data Movement Instructions
– System Stack Instructions
– Jump and Call Instructions
– Return Instructions
– System Control Instructions
– Miscellaneous Instructions

The basic instruction length is either 2 or 4 bytes. Possible operand types are bits, bytes and words. A variety of direct, indirect or immediate addressing modes are provided to specify the required operands.

Interrupt System

With an interrupt response time within a range from just 250 ns to 600 ns (in case of internal program execution), the C167CR-16RM is capable of reacting very fast to the occurence of non-deterministic events.

The architecture of the C167CR-16RM supports several mechanisms for fast and flexible response to service requests that can be generated from various sources internal or external to the microcontroller. Any of these interrupt requests can be programmed to being serviced by the Interrupt Controller or by the Peripheral Event Controller (PEC).

In contrast to a standard interrupt service where the current program execution is suspended and a branch to the interrupt vector table is performed, just one cycle is 'stolen' from the current CPU activity to perform a PEC service. A PEC service implies a single byte or word data transfer between any two memory locations with an additional increment of either the PEC source or the destination pointer. An individual PEC transfer counter is implicity decremented for each PEC service except when performing in the continuous transfer mode. When this counter reaches zero, a standard interrupt is performed to the corresponding source related vector location. PEC services are very well suited, for example, for supporting the transmission or reception of blocks of data. The C167CR-16RM has 8 PEC channels each of which offers such fast interrupt-driven data transfer capabilities.

A separate control register which contains an interrupt request flag, an interrupt enable flag and an interrupt priority bitfield exists for each of the possible interrupt sources. Via its related register, each source can be programmed to one of sixteen interrupt priority levels. Once having been accepted by the CPU, an interrupt service can only be interrupted by a higher prioritized service request. For the standard interrupt processing, each of the possible interrupt sources has a dedicated vector location.

Fast external interrupt inputs are provided to service external interrupts with high precision requirements. These fast interrupt inputs feature programmable edge detection (rising edge, falling edge or both edges).

Software interrupts are supported by means of the 'TRAP' instruction in combination with an individual trap (interrupt) number.

The following table shows all of the possible C167CR-16RM interrupt sources and the corresponding hardware-related interrupt flags, vectors, vector locations and trap (interrupt) numbers:

Note: Three nodes in the table (X-Peripheral nodes) are prepared to accept interrupt requests from integrated X-Bus peripherals. Nodes, where no X-Peripherals are connected, may be used to generate software controlled interrupt requests by setting the respective XPnIR bit.

Source of Interrupt or PEC Service Request	Request Flag	Enable Flag	Interrupt Vector	Vector Location	Trap Number
CAPCOM Register 0	CC0IR	CC0IE	CC0INT	$00'0040_H$	10_H

SIEMENS

The C167CR-16RM also provides an excellent mechanism to identify and to process exceptions or error conditions that arise during run-time, so-called 'Hardware Traps'. Hardware traps cause immediate non-maskable system reaction which is similar to a standard interrupt service (branching to a dedicated vector table location). The occurence of a hardware trap is additionally signified by an individual bit in the trap flag register (TFR). Except when another higher prioritized trap service is in progress, a hardware trap will interrupt any actual program execution. In turn, hardware trap services can normally not be interrupted by standard or PEC interrupts.

The following table shows all of the possible exceptions or error conditions that can arise during run-time:

Exception Condition	Trap Flag	Trap Vector	Vector Location	Trap Number	Trap Priority
Reset Functions:					
Hardware Reset		RESET	$00'0000_H$	00_H	III
Software Reset		RESET	$00'0000_H$	00_H	III
Watchdog Timer Overflow		RESET	$00'0000_H$	00_H	III
Class A Hardware Traps:					
Non-Maskable Interrupt	NMI	NMITRAP	$00'0008_H$	02_H	II
Stack Overflow	STKOF	STOTRAP	$00'0010_H$	04_H	II
Stack Underflow	STKUF	STUTRAP	$00'0018_H$	06_H	II
Class B Hardware Traps:					
Undefined Opcode	UNDOPC	BTRAP	$00'0028_H$	$0A_H$	I
Protected Instruction Fault	PRTFLT	BTRAP	$00'0028_H$	$0A_H$	I

Software Traps					
TRAP Instruction			Any $[00'0000_H -$ $00'01FC_H]$ in steps of 4_H	Any $[00_H - 7F_H]$	Current CPU Priority

SIEMENS

Capture/Compare (CAPCOM) Units

The CAPCOM units support generation and control of timing sequences on up to 32 channels with a maximum resolution of 400 ns (at 20-MHz system clock). The CAPCOM units are typically used to handle high speed I/O tasks such as pulse and waveform generation, pulse width modulation (PMW), Digital to Analog (D/A) conversion, software timing, or time recording relative to external events.

Four 16-bit timers (T0/T1, T7/T8) with reload registers provide two independent time bases for the capture/compare register array.

The input clock for the timers is programmable to several prescaled values of the internal system clock, or may be derived from an overflow/underflow of timer T6 in module GPT2. This provides a wide range of variation for the timer period and resolution and allows precise adjustments to the application specific requirements. In addition, external count inputs for CAPCOM timers T0 and T7 allow event scheduling for the capture/compare registers relative to external events.

Both of the two capture/compare register arrays contain 16 dual purpose capture/compare registers, each of which may be individually allocated to either CAPCOM timer T0 or T1 (T7 or T8, respectively), and programmed for capture or compare function. Each register has one port pin associated with it which serves as an input pin for triggering the capture function, or as an output pin (except for CC24...CC27) to indicate the occurence of a compare event.

When a capture/compare register has been selected for capture mode, the current contents of the allocated timer will be latched ('capture'd) into the capture/compare register in response to an external event at the port pin which is associated with this register. In addition, a specific interrupt request for this capture/compare register is generated. Either a positive, a negative, or both a positive and a negative external signal transition at the pin can be selected as the triggering event. The contents of all registers which have been selected for one of the five compare modes are continuously compared with the contents of the allocated timers. When a match occurs between the timer value and the value in a capture/compare register, specific actions will be taken based on the selected compare mode.

| Compare Modes	Function
Mode 0	Interrupt-only compare mode; several compare interrupts per timer period are possible
Mode 1	Pin toggles on each compare match; several compare events per timer period are possible
Mode 2	Interrupt-only compare mode; only one compare interrupt per timer period is generated
Mode 3	Pin set '1' on match; pin reset '0' on compare time overflow; only one compare event per timer period is generated
Double Register Mode	Two registers operate on one pin; pin toggles on each compare match; several compare events per timer period are possible.

SIEMENS

PWM Module

The Pulse Width Modulation Module can generate up to four PWM output signals using edge-aligned or center-aligned PWM. In addition the PWM module can generate PWM burst signals and single shot outputs. The frequency range of the PWM signals covers 4.8 Hz to 1 MHz (referred to a CPU clock of 20 MHz), depending on the resolution of the PWM output signal. The level of the output signals is selectable and the PWM module can generate interrupt requests.

General Purpose Timer (GPT) Unit

The GPT unit represents a very flexible multifunctional timer/counter structure which may be used for many different time related tasks such as event timing and counting, pulse width and duty cycle measurements, pulse generation, or pulse multiplication.

The GPT unit incorporates five 16-bit timers which are organized in two separate modules, GPT1 and GPT2. Each timer in each module may operate independently in a number of different modes, or may be concatenated with another timer of the same module.

Each of the three timers T2, T3, T4 of **module GPT1** can be configured individually for one of four basic modes of operation, which are Timer, Gated Timer, Counter, and Incremental Interface Mode. In Timer Mode, the input clock for a timer is derived from the CPU clock, divided by a programmable prescaler, while Counter Mode allows a timer to be clocked in reference to external events.
Pulse width or duty cycle measurement is supported in Gated Timer Mode, where the operation of a timer is controlled by the 'gate' level on an external input pin. For these purposes, each timer has one associated port pin (TxIN) which serves as gate or clock input. The maximum resolution of the timers in module GPT1 is 400 ns (@ 20-MHz CPU clock).

The count direction (up/down) for each timer is programmable by software or may additionally be altered dynamically by an external signal on a port pin (TxEUD) to facilitate eg. position tracking.

In Incremental Interface Mode the GPT1 timers (T2, T3, T4) can be directly connected to the incremental position sensor signals A and B via their respective inputs TxIN and TxEUD. Direction and count signals are internally derived from these two input signals, so the contents of the respective timer Tx corresponds to the sensor position. The third position sensor signal TOP0 can be connected to an interrupt input.

Timers T3 and T4 have output toggle latches (TxOTL) which change their state on each timer over-flow/underflow. The state of these latches may be output on port pins (TxOUT) eg. for time out monitoring of external hardware components, or may be used internally to clock timers T2 and T4 for measuring long time periods with high resolution.

In addition to their basic operating modes, timers T2 and T4 may be configured as reload or capture registers for timer T3. When used as capture or reload registers, timers T2 and T4 are stopped. The contents of timer T3 is captured into T2 or T4 in response to a signal at their associated input pins (TxIN). Timer T3 is reloaded with the contents of T2 or T4 triggered either by an external signal or by a selectable state transition of its toggle latch T3OTL. When both T2 and T4 are configured to alternately reload T3 on opposite state transitions of T3OTL with the low and high times of a PWM signal, this signal can be constantly generated without software intervention.

With its maximum resolution of 200 ns (@ 20 MHz), the **GPT2 module** provides precise event control and time measurement. It includes two timers (T5, T6) and a capture/reload register

(CAPREL). Both timers can be clocked with an input clock which is derived from the CPU clock via a programmable prescaler or with external signals. The count direction (up/down) for each timer is programmable by software or may additionally be altered dynamically by an external signal on a port pin (TxEUD). Concatenation of the timers is supported via the output toggle latch (T6OTL) of timer T6, which changes its state on each timer overflow/underflow.

The state of this latch may be used to clock timer T5, and/or it may be output on a port pin (T6OUT). The overflows/underflows of timer T6 can additionally be used to clock the CAPCOM timers T0 or T1, and to cause a reload from the CAPREL register. The CAPREL register may capture the contents of timer T5 based on an external signal transition on the corresponding port pin (CAPIN), and timer T5 may optionally be cleared after the capture procedure. This allows absolute time differences to be measured or pulse multiplication to be performed without software overhead.

The capture trigger (timer T5 to CAPREL) may also be generated upon transitions of GPT1 timer T3's inputs T3IN and/or T3EUD. This is especially advantageous when T3 operates in Incremental Interface Mode.

Block Diagram of GPT1

Figure 7
Block Diagram of GPT2

Watchdog Timer

The Watchdog Timer represents one of the fail-safe mechanisms which have been implemented to prevent the controller from malfunctioning for longer periods of time.

The Watchdog Timer is always enabled after a reset of the chip, and can only be disabled in the time interval until the EINIT (end of initialization) instruction has been executed. Thus, the chip's start-up procedure is always monitored. The software has to be designed to service the Watchdog Timer before it overflows. If, due to hardware or software related failures, the software fails to do so, the Watchdog Timer overflows and generates an internal hardware reset and pulls the $\overline{\text{RSTOUT}}$ pin low in order to allow external hardware components to be reset.

The Watchdog Timer is a 16-bit timer, clocked with the system clock divided either by 2 or by 128. The high byte of the Watchdog Timer register can be set to a prespecified reload value (stored in WDTREL) in order to allow further variation of the monitored time interval. Each time it is serviced by the application software, the high byte of the Watchdog Timer is reloaded. Thus, time intervals between 25 μs and 420 ms can be monitored (@ 20 MHz). The default Watchdog Timer interval after reset is 6.55 ms (@ 20 MHz).

A/D Converter

For analog signal measurement, a 10-bit A/D converter with 16 multiplexed input channels and a sample and hold circuit has been integrated on-chip. It uses the method of successive approximation. The sample time (for loading the capacitors) and the conversion time is programmable and can so be adjusted to the external circuitry.

Overrun error detection/protection is provided for the conversion result register (ADDAT): either an interrupt request will be generated when the result of a previous conversion has not been read from the result register at the time the next conversion is complete, or the next conversion is suspended in such a case until the previous result has been read.

For applications which require less than 16 analog input channels, the remaining channel inputs can be used as digital input port pins.

The A/D converter of the C167CR-16RM supports four different conversion modes. In the standard Single Channel conversion mode, the analog level on a specified channel is sampled once and converted to a digital result. In the Single Channel Continuous mode, the analog level on a specified channel is repeatedly sampled and converted without software intervention. In the Auto Scan mode, the analog levels on a prespecified number of channels are sequentially sampled and converted. In the Auto Scan Continuous mode, the number of prespecified channels is repeatedly sampled and converted. In addition, the conversion of a specific channel can be inserted (injected) into a running sequence without disturbing this sequence. This is called Channel Injection Mode.

The Peripheral Event Controller (PEC) may be used to automatically store the conversion results into a table in memory for later evaluation, without requiring the overhead of entering and exiting interrupt routines for each data transfer.

After each reset and also during normal operation the ADC automatically performs calibration cycles. This automatic self-calibration constantly adjusts the converter to changing operating conditions (eg. temperature) and compensates process variations.

These calibration cycles are part of the conversion cycle, so they do not affect the normal operation of the A/D converter.

Serial Channels

Serial communication with other microcontrollers, processors, terminals or external peripheral components is provided by two serial interfaces with different functionality, an Asynchronous/ Synchronous Serial Channel (**ASC0**) and a High-Speed Synchronous Serial Channel (**SSC**).

The ASC0 is upward compatible with the serial ports of the Siemens 8-bit microcontroller families and supports full-duplex asynchronous communication at up to 625 KBaud and half-duplex synchronous communication at up to 2.5 MBaud @ 20 MHz CPU clock.
A dedicated baud rate generator allows to set up all standard baud rates without oscillator tuning. For transmission, reception and error handling 4 separate interrupt vectors are provided. In asynchronous mode, 8- or 9-bit data frames are transmitted or received, preceded by a start bit and terminated by one or two stop bits. For multiprocessor communication, a mechanism to distinguish address from data bytes has been included (8-bit data plus wake up bit mode).
In synchronous mode, the ASC0 transmits or receives bytes (8 bits) synchronously to a shift clock which is generated by the ASC0. The ASC0 always shifts the LSB first. A loop back option is available for testing purposes.
A number of optional hardware error detection capabilities has been included to increase the reliability of data transfers. A parity bit can automatically be generated on transmission or be checked on reception. Framing error detection allows to recognize data frames with missing stop bits. An overrun error will be generated, if the last character received has not been read out of the receive buffer register at the time the reception of a new character is complete.

The SSC supports full-duplex synchronous communication at up to 5 Mbaud @ 20 MHz CPU clock. It may be configured so it interfaces with serially linked peripheral components. A dedicated baud rate generator allows to set up all standard baud rates without oscillator tuning. For transmission, reception and error handling 3 separate interrupt vectors are provided.
The SSC transmits or receives characters of 2...16 bits length synchronously to a shift clock which can be generated by the SSC (master mode) or by an external master (slave mode). The SSC can start shifting with the LSB or with the MSB and allows the selection of shifting and latching clock edges as well as the clock polarity.
A number of optional hardware error detection capabilities has been included to increase the reliability of data transfers. Transmit and receive error supervise the correct handling of the data buffer. Phase and baudrate error detect incorrect serial data.

CAN-Module

The integrated CAN-Module handles the completely autonomous transmission and reception of CAN frames in accordance with the CAN specification V2.0 part B (active), ie. the on-chip CAN-Module can receive and transmit standard frames with 11-bit identifiers as well as extended frames with 29-bit identifiers.

The module provides Full CAN functionality on up to 15 message objects. Message object 15 may be configured for Basic CAN functionality. Both modes provide separate masks for acceptance filtering which allows to accept a number of identifiers in Full CAN mode and also allows to disregard a number of identifiers in Basic CAN mode. All message objects can be updated independent from the other objects and are equipped for the maximum message length of 8 bytes.

The bit timing is derived from the XCLK and is programmable up to a data rate of 1 MBaud. The CAN-Module uses two pins of Port 4 to interface to a bus transceiver.

Note: When the CAN interface is to be used the segment address output on Port 4 must be limited to 4 bits, ie. A19...A16. This is necessary to enable the alternate function of the CAN interface pins.

Parallel Ports

The C167CR-16RM provides up to 111 I/O lines which are organized into eight input/output ports and one input port. All port lines are bit-addressable, and all input/output lines are individually (bit-wise) programmable as inputs or outputs via direction registers. The I/O ports are true bidirectional ports which are switched to high impedance state when configured as inputs. The output drivers of five   I/O ports can be configured (pin by pin) for push/pull operation or open-drain operation via control registers. During the internal reset, all port pins are configured as inputs.

The input threshold of Port 2, Port 3, Port 7 and Port 8 is selectable (TTL or CMOS like), where the special CMOS like input threshold reduces noise sensitivity due to the input hysteresis. The input threshold may be selected individually for each byte of the respective ports.

All port lines have programmable alternate input or output functions associated with them.
PORT0 and PORT1 may be used as address and data lines when accessing external memory, while Port 4 outputs the additional segment address bits A23/19/17...A16 in systems where segmentation is enabled to access more than 64 KBytes of memory.

Port 2, Port 8 and Port 7 are associated with the capture inputs or compare outputs of the CAPCOM units and/or with the outputs of the PWM module.
Port 6 provides optional bus arbitration signals ($\overline{\text{BREQ}}$, $\overline{\text{HLDA}}$, $\overline{\text{HOLD}}$) and chip select signals.
Port 3 includes alternate functions of timers, serial interfaces, the optional bus control signal $\overline{\text{BHE}}$ and the system clock output (CLKOUT).
Port 5 is used for the analog input channels to the A/D converter or timer control signals.

All port lines that are not used for these alternate functions may be used as general purpose IO lines.

Instruction Set Summary

The table below lists the instructions of the C167CR-16RM in a condensed way.
The various addressing modes that can be used with a specific instruction, the operation of the instructions, parameters for conditional execution of instructions, and the opcodes for each instruction can be found in the **"C16x Family Instruction Set Manual"**.

This document also provides a detailed description of each instruction.

Instruction Set Summary

Mnemonic	Description	Bytes
ADD(B)	Add word (byte) operands	2 / 4
ADDC(B)	Add word (byte) operands with Carry	2 / 4
SUB(B)	Subtract word (byte) operands	2 / 4
SUBC(B)	Subtract word (byte) operands with Carry	2 / 4
MUL(U)	(Un)Signed multiply direct GPR by direct GPR (16-16-bit)	2
DIV(U)	(Un)Signed divide register MDL by direct GPR (16-/16-bit)	2
DIVL(U)	(Un)Signed long divide reg. MD by direct GPR (32-/16-bit)	2
CPL(B)	Complement direct word (byte) GPR	2
NEG(B)	Negate direct word (byte) GPR	2
AND(B)	Bitwise AND, (word/byte operands)	2 / 4
OR(B)	Bitwise OR, (word/byte operands)	2 / 4
XOR(B)	Bitwise XOR, (word/byte operands)	2 / 4
BCLR	Clear direct bit	2
BSET	Set direct bit	2
BMOV(N)	Move (negated) direct bit to direct bit	4
BAND, BOR, BXOR	AND/OR/XOR direct bit with direct bit	4
BCMP	Compare direct bit to direct bit	4
BFLDH/L	Bitwise modify masked high/low byte of bit-addressable direct word memory with immediate data	4
CMP(B)	Compare word (byte) operands	2 / 4
CMPD1/2	Compare word data to GPR and decrement GPR by 1/2	2 / 4
CMPI1/2	Compare word data to GPR and increment GPR by 1/2	2 / 4
PRIOR	Determine number of shift cycles to normalize direct word GPR and store result in direct word GPR	2
SHL / SHR	Shift left/right direct word GPR	2
ROL / ROR	Rotate left/right direct word GPR	2
ASHR	Arithmetic (sign bit) shift right direct word GPR	2

Instruction Set Summary (cont'd)

Mnemonic	Description	Bytes
MOV(B)	Move word (byte) data	2 / 4
MOVBS	Move byte operand to word operand with sign extension	2 / 4
MOVBZ	Move byte operand to word operand. with zero extension	2 / 4
JMPA, JMPI, JMPR	Jump absolute/indirect/relative if condition is met	4
JMPS	Jump absolute to a code segment	4
J(N)B	Jump relative if direct bit is (not) set	4
JBC	Jump relative and clear bit if direct bit is set	4
JNBS	Jump relative and set bit if direct bit is not set	4
CALLA, CALLI, CALLR	Call absolute/indirect/relative subroutine if condition is met	4
CALLS	Call absolute subroutine in any code segment	4
PCALL	Push direct word register onto system stack and call absolute subroutine	4
TRAP	Call interrupt service routine via immediate trap number	2
PUSH, POP	Push/pop direct word register onto/from system stack	2
SCXT	Push direct word register onto system stack und update register with word operand	4
RET	Return from intra-segment subroutine	2
RETS	Return from inter-segment subroutine	2
RETP	Return from intra-segment subroutine and pop direct word register from system stack	2
RETI	Return from interrupt service subroutine	2
SRST	Software Reset	4
IDLE	Enter Idle Mode	4
PWRDN	Enter Power Down Mode (supposes $\overline{\text{NMI}}$-pin being low)	4
SRVWDT	Service Watchdog Timer	4
DISWDT	Disable Watchdog Timer	4
EINIT	Signify End-of-Initialization on RSTOUT-pin	4
ATOMIC	Begin ATOMIC sequence	2
EXTR	Begin EXTended Register sequence	2
EXTP(R)	Begin EXTended Page (and Register) sequence	2 / 4
EXTS(R)	Begin EXTended Segment (and Register) sequence	2 / 4
NOP	Null operation	2

Special Function Registers Overview

The following table lists all SFRs which are implemented in the C167CR-16RM in alphabetical order.

Bit-addressable SFRs are marked with the letter "**b**" in column "Name". SFRs within the **Extended SFR-Space** (ESFRs) are marked with the letter "**E**" in column "Physical Address".

An SFR can be specified via its individual mnemonic name. Depending on the selected addressing mode, an SFR can be accessed via its physical address (using the Data Page Pointers), or via its short 8-bit address (without using the Data Page Pointers).

Special Function Registers Overview

Name		Physical Address	8-Bit Address	Description	Reset Value
ADCIC	b	FF98$_H$	CC$_H$	A/D Converter End of Conversion Interrupt Control Register	0000$_H$
ADCON	b	FFA0$_H$	D0$_H$	A/D Converter Control Register	0000$_H$
ADDAT		FEA0$_H$	50$_H$	A/D Converter Result Register	0000$_H$
ADDAT2		F0A0$_H$ E	50$_H$	A/D Converter 2 Result Register	0000$_H$
ADDRSEL1		FE18$_H$	0C$_H$	Address Select Register 1	0000$_H$

[1] The system configuration is selected during reset.

[2] Bit WDTR indicates a watchdog timer triggered reset.

Note: The Interrupt Control Registers XPnIC are prepared to control interrupt requests from integrated X-Bus peripherals. Nodes, where no X-Peripherals are connected, may be used to generate software controlled interrupt requests by setting the respective XPnIR bit.

SIEMENS

Absolute Maximum Ratings

Ambient temperature under bias (T_A):
SAB-C167CR-16RM ....0 to +70 °C
SAF-C167CR-16RM ....−40 to +85 °C
SAK-C167CR-16RM ....−40 to +125 °C
Storage temperature (T_{ST}) .... − 65 to +150 °C
Voltage on V_{CC} pins with respect to ground (V_{SS}) .... −0.5 to +6.5 V
Voltage on any pin with respect to ground (V_{SS}) ....−0.5 to V_{CC} +0.5 V
Input current on any pin during overload condition .... −10 to +10 mA
Absolute sum of all input currents during overload condition ....|100 mA|
Power dissipation .... 1.5 W

Note: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. During overload conditions ($V_{IN} > V_{CC}$ or $V_{IN} < V_{SS}$) the voltage on pins with respect to ground (V_{SS}) must not exceed the values defined by the Absolute Maximum Ratings.

Parameter Interpretation

The parameters listed in the following partly represent the characteristics of the C167CR-16RM and partly its demands on the system. To aid in interpreting the parameters right, when evaluating them for a design, they are marked in column "Symbol":

CC (**C**ontroller **C**haracteristics):
The logic of the C167CR-16RM will provide signals with the respective timing characteristics.

SR (**S**ystem **R**equirement):
The external system must provide signals with the respective timing characteristics to the C167CR-16RM.

DC Characteristics

V_{CC} = 5 V $\pm$ 10 %; V_{SS} = 0 V; f_{CPU} = 20 MHz
T_A = 0 to +70 °C   for SAB-C167CR-16RM
T_A = -40 to +85 °C   for SAF-C167CR-16RM
T_A = -40 to +125 °C   for SAK-C167CR-16RM

Parameter	Symbol		Limit Values		Unit	Test Condition
			min.	max.		
Input low voltage (TTL)	V_{IL}	SR	– 0.5	$0.2\,V_{CC}$ – 0.1	V	–

Power-down mode supply current	I_{PD}	–	100	µA	$V_{CC} = 5.5\ V$ [7]

Notes

[1] This specification is not valid for outputs which are switched to open drain mode. In this case the respective output will float and the voltage results from the external circuitry.

[2] The maximum current may be drawn while the respective signal line remains inactive.

[3] The minimum current must be drawn in order to drive the respective signal line active.

[4] This specification is only valid during Reset, or during Hold- or Adapt-mode. Port 6 pins are only affected, if they are used for $\overline{CS}$ output and the open drain function is not enabled.

[5] Not 100% tested, guaranteed by design characterization.

[6] The supply current is a function of the operating frequency. This dependency is illustrated in the figure below. These parameters are tested at V_{CCmax} and 20 MHz CPU clock with all outputs disconnected and all inputs at V_{IL} or V_{IH}.

[7] This parameter is tested including leakage currents. All inputs (including pins configured as inputs) at 0 V to 0.1 V or at V_{CC} – 0.1 V to V_{CC}, V_{REF} = 0 V, all outputs (including pins configured as outputs) disconnected.

[8] Overload conditions occur if the standard operatings conditions are exceeded, ie. the voltage on any pin exceeds the specified range (ie. $V_{OV} > V_{CC}+0.5V$ or $V_{OV} < V_{SS}-0.5V$). The absolute sum of input overload currents on all port pins may not exceed **50 mA**. The supply voltage must remain within the specified limits.

V_{CC} = 5 V $\pm$ 10 %; V_{SS} = 0 V
T_A = 0 to +70 °C   for SAB-C167CR-16RM
T_A = -40 to +85 °C   for SAF-C167CR-16RM
T_A = -40 to +125 °C   for SAK-C167CR-16RM
4.0 V $\leq V_{AREF} \leq V_{CC}$+0.1 V ; V_{SS}-0.1 V $\leq V_{AGND} \leq V_{SS}$+0.2 V

Parameter	Symbol	Limit Values		Unit	Test Condition
		min.	max.		
Analog input voltage range	V_{AIN} SR	V_{AGND}	V_{AREF}	V	1)
Sample time	t_S CC	–	2 t_{SC}		2) 4)
Conversion time	t_C CC	–	14 t_{CC} + t_S + 4TCL		3) 4)
Total unadjusted error	TUE CC	–	$\pm$ 2	LSB	5)
Internal resistance of reference voltage source	R_{AREF} SR	–	t_{CC} / 165 - 0.25	kΩ	t_{CC} in [ns] 6) 7)
Internal resistance of analog source	R_{ASRC} SR	–	t_S / 330 - 0.25	kΩ	t_S in [ns] 2) 7)
ADC input capacitance	C_{AIN} CC	–	33	pF	7)

Sample time and conversion time of the C167CR-16RM's ADC are programmable. The table below should be used to calculate the above timings.

ADCON.15|14 (ADCTC)	Conversion clock t_{CC}	ADCON.13|12 (ADSTC)	Sample clock t_{SC}
00	TCL * 24	00	t_{CC}
01	Reserved, do not use	01	t_{CC} * 2
10	TCL * 96	10	t_{CC} * 4
11	TCL * 48	11	t_{CC} * 8

Notes

1) V_{AIN} may exceed V_{AGND} or V_{AREF} up to the absolute maximum ratings. However, the conversion result in these cases will be X000$_H$ or X3FF$_H$, respectively.

2) During the sample time the input capacitance C_I can be charged/discharged by the external source. The internal resistance of the analog source must allow the capacitance to reach its final voltage level within t_S. After the end of the sample time t_S, changes of the analog input voltage have no effect on the conversion result. Values for the sample clock t_{SC} depend on programming and can be taken from the table above.

3) This parameter includes the sample time t_S, the time for determining the digital result and the time to load the result register with the conversion result.
Values for the conversion clock t_{CC} depend on programming and can be taken from the table above.

4) This parameter depends on the ADC control logic. It is not a real maximum value, but rather a fixum.

5) TUE is tested at V_{AREF}=5.0V, V_{AGND}=0V, V_{CC}=4.9V. It is guaranteed by design characterization for all other voltages within the defined voltage range.
The specified TUE is guaranteed only if an overload condition (see I_{OV} specification) occurs on maximum 2 not selected analog input pins and the absolute sum of input overload currents on all analog input pins does not exceed 10 mA.
During the reset calibration sequence the maximum TUE may be ±4 LSB.

6) During the conversion the ADC's capacitance must be repeatedly charged or discharged. The internal resistance of the reference voltage source must allow the capacitance to reach its respective voltage level within t_{CC}. The maximum internal resistance results from the programmed conversion timing.

7) Not 100% tested, guaranteed by design characterization.

Testing Waveforms
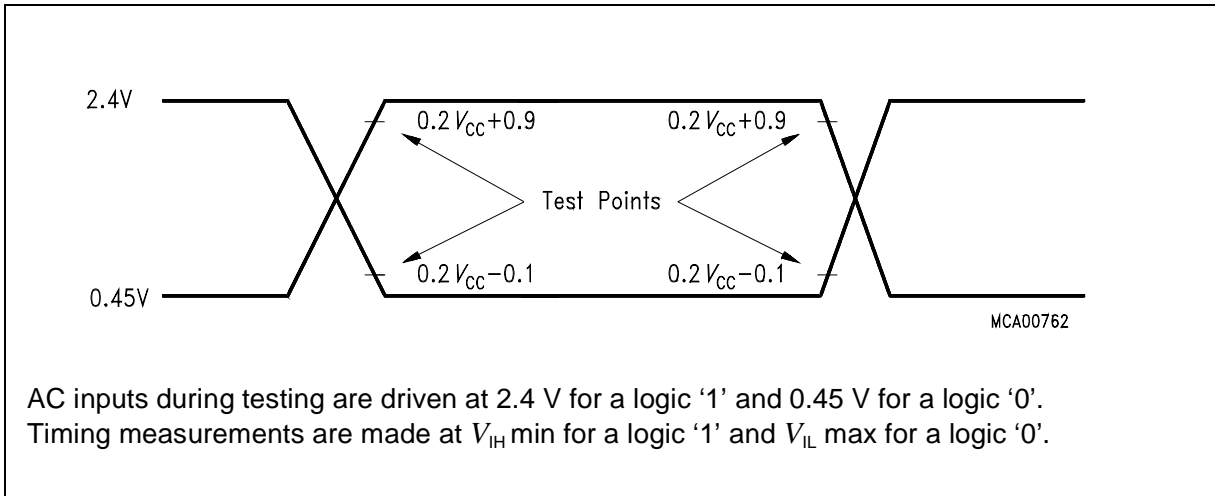

AC inputs during testing are driven at 2.4 V for a logic '1' and 0.45 V for a logic '0'.
Timing measurements are made at V_{IH} min for a logic '1' and V_{IL} max for a logic '0'.

Figure 9
Input Output Waveforms
For timing purposes a port pin is no longer floating when a 100 mV change from load voltage occurs, but begins to float when a 100 mV change from the loaded V_{OH}/V_{OL} level occurs (I_{OH}/I_{OL} = 20 mA).

Figure 10
Float Waveforms

Semiconductor Group

AC Characteristics
Definition of Internal Timing

The internal operation of the C167CR-16RM is controlled by the internal CPU clock f_{CPU}. Both edges of the CPU clock can trigger internal (eg. pipeline) or external (eg. bus cycles) operations.

The specification of the external timing (AC Characteristics) therefore depends on the time between two consecutive edges of the CPU clock, called "TCL" (see figure below).
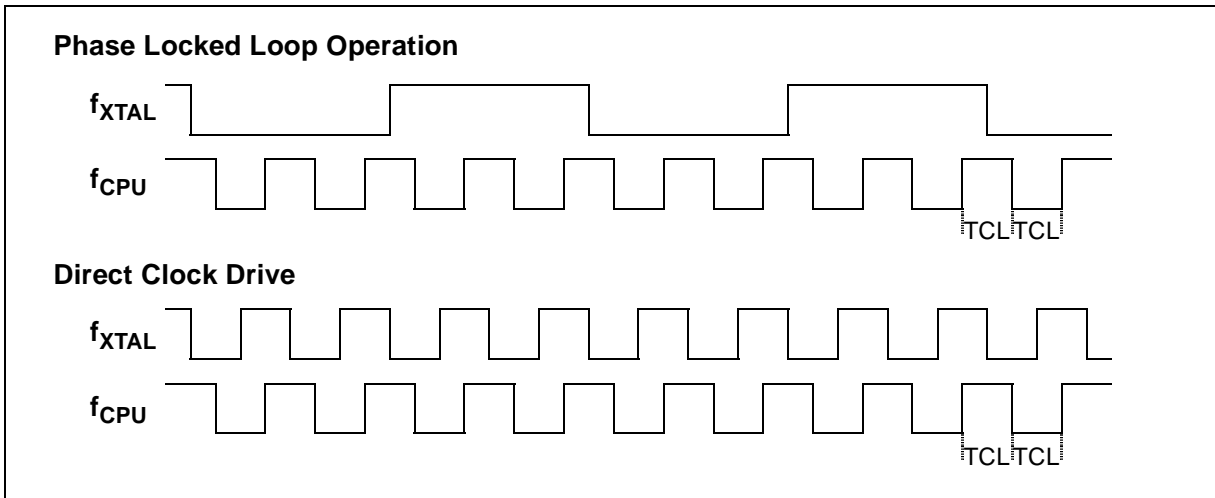

Figure 11
Generation Mechanisms for the CPU Clock

The CPU clock signal can be generated via different mechanisms. The duration of TCLs and their variation (and also the derived external timing) depends on the used mechanism to generate f_{CPU}. This influence must be regarded when calculating the timings for the C167CR-16RM.

Direct Drive

When pin P0.15 (P0H.7) is low ('0') during reset the on-chip phase locked loop is disabled and the CPU clock is directly driven from the internal oscillator with the input clock signal.
The frequency of f_{CPU} directly follows the frequency of f_{XTAL} so the high and low time of f_{CPU} (ie. the duration of an individual TCL) is defined by the duty cycle of the input clock f_{XTAL}.

The timings listed below that refer to TCLs therefore must be calculated using the minimum TCL that is possible under the respective circumstances. This minimum value can be calculated via the following formula:

$$TCL_{min} = 1/f_{XTAL} * DC_{min} \qquad (DC = \text{duty cycle})$$

For two consecutive TCLs the deviation caused by the duty cycle of f_{XTAL} is compensated so the duration of 2TCL is always $1/f_{XTAL}$. The minimum value TCL_{min} therefore has to be used only once for timings that require an odd number of TCLs (1,3,...). Timings that require an even number of TCLs (2,4,...) may use the formula $2TCL = 1/f_{XTAL}$.

Note: The address float timings in Multiplexed bus mode (t_{11} and t_{45}) use the maximum duration of TCL ($TCL_{max} = 1/f_{XTAL} * DC_{max}$) instead of TCL_{min}.

Phase Locked Loop

When pin P0.15 (P0H.7) is high ('1') during reset the on-chip phase locked loop is enabled and provides the CPU clock. The PLL multiplies the input frequency by 4 (ie. $f_{CPU} = f_{XTAL} * 4$). With every fourth transition of f_{XTAL} the PLL circuit synchronizes the CPU clock to the input clock. This synchronization is done smoothely, ie. the CPU clock frequency does not change abruptly.

Due to this adaptation to the input clock the frequency of f_{CPU} is constantly adjusted so it is locked to f_{XTAL}. The slight variation causes a jitter of f_{CPU} which also effects the duration of individual TCLs.

The timings listed in the AC Characteristics that refer to TCLs therefore must be calculated using the minimum TCL that is possible under the respective circumstances.

The actual minimum value for TCL depends on the jitter of the PLL. As the PLL is constantly adjusting its output frequency so it corresponds to the applied input frequency (crystal or oscillator) the relative deviation for periods of more than one TCL is lower than for one single TCL (see formula and figure below).

For a period of N * TCL the minimum value is computed using the corresponding deviation D_N:

$$TCL_{min} = TCL_{NOM} * (1 - D_N / 100) \qquad D_N = \pm(4 - N/15) \, [\%],$$

where N = number of consecutive TCLs and $1 \leq N \leq 40$.

So for a period of 3 TCLs (ie. $N = 3$): $D_3 = 4 - 3/15 = 3.8\%$,
and $TCL_{min} = TCL_{NOM} * (1 - 3.8 / 100) = TCL_{NOM} * 0.962$ (24.1 nsec @ f_{CPU} = 20 MHz).

This is especially important for bus cycles using waitstates and eg. for the operation of timers, serial interfaces, etc. For all slower operations and longer periods (eg. pulse train generation or measurement, lower baudrates, etc.) the deviation caused by the PLL jitter is neglectible.

CLKOUT high time	t_{30}	CC	20	–	TCL – 5	–	ns
CLKOUT low time	t_{31}	CC	15	–	TCL – 10	–	ns
CLKOUT rise time	t_{32}	CC	–	5	–	5	ns
CLKOUT fall time	t_{33}	CC	–	5	–	5	ns
CLKOUT rising edge to ALE falling edge	t_{34}	CC	$0 + t_A$	$10 + t_A$	$0 + t_A$	$10 + t_A$	ns
Synchronous READY setup time to CLKOUT	t_{35}	SR	15	–	15	–	ns
Synchronous READY hold time after CLKOUT	t_{36}	SR	0	–	0	–	ns
Asynchronous READY low time	t_{37}	SR	65	–	2TCL + 15	–	ns
Asynchronous READY setup time [1]	t_{58}	SR	15	–	15	–	ns
Asynchronous READY hold time [1]	t_{59}	SR	0	–	0	–	ns
Async. READY hold time after RD, WR high (Demultiplexed Bus) [2]	t_{60}	SR	0	$0 + 2t_A + t_C + t_F$ [2]	0	TCL - 25 $+ 2t_A + t_C + t_F$ [2]	ns

Notes

[1]   These timings are given for test purposes only, in order to assure recognition at a specific clock edge.

[2]   Demultiplexed bus is the worst case. For multiplexed bus 2TCL are to be added to the maximum values. This adds even more time for deactivating READY.
The $2t_A$ and t_C refer to the next following bus cycle, t_F refers to the current bus cycle.
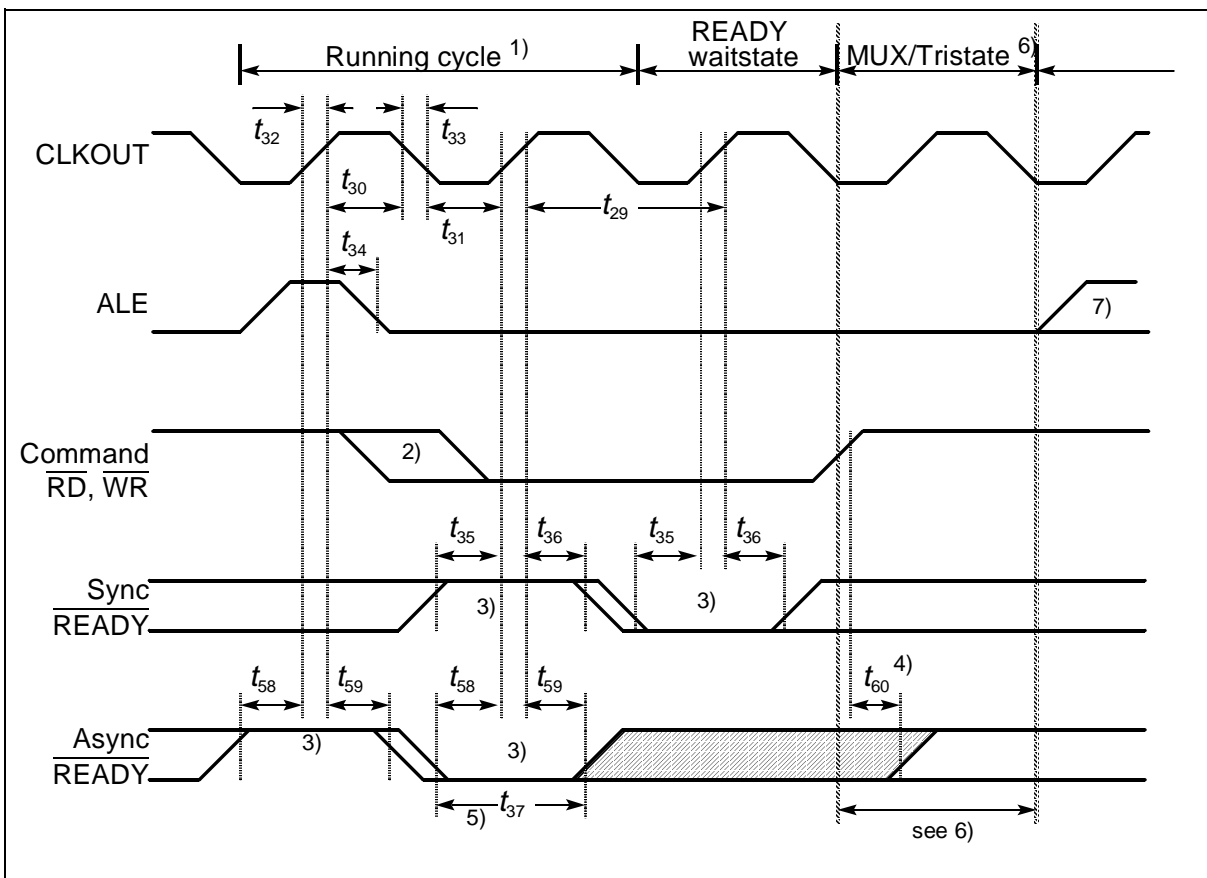

Figure 16
CLKOUT and $\overline{\text{READY}}$

Notes

1) Cycle as programmed, including MCTC waitstates (Example shows 0 MCTC WS).

2) The leading edge of the respective command depends on RW-delay.

3) $\overline{\text{READY}}$ sampled HIGH at this sampling point generates a READY controlled waitstate,
   READY sampled LOW at this sampling point terminates the currently running bus cycle.

4) $\overline{\text{READY}}$ may be deactivated in response to the trailing (rising) edge of the corresponding command ($\overline{\text{RD}}$ or $\overline{\text{WR}}$).

5) If the Asynchronous $\overline{\text{READY}}$ signal does not fulfill the indicated setup and hold times with respect to CLKOUT (eg. because CLKOUT is not enabled), it must fulfill t_{37} in order to be safely synchronized. This is guaranteed, if $\overline{\text{READY}}$ is removed in reponse to the command (see Note 4)).

6) Multiplexed bus modes have a MUX waitstate added after a bus cycle, and an additional MTTC waitstate may be inserted here.
   For a multiplexed bus with MTTC waitstate this delay is 2 CLKOUT cycles, for a demultiplexed bus without MTTC waitstate this delay is zero.

7) The next external bus cycle may start here.

Other signals drive	t_{67}	CC	-5	25	-5	25	ns

SIEMENS

Figure 17
**External Bus Arbitration, Releasing the Bus**

Notes

[1] The C167CR-16RM will complete the currently running bus cycle before granting bus access.

[2] This is the first possibility for $\overline{BREQ}$ to get active.

[3] The $\overline{CS}$ outputs will be resistive high (pullup) after t_{64}.

Figure 18
**External Bus Arbitration, (Regaining the Bus)**

Notes

[1] This is the last chance for $\overline{BREQ}$ to trigger the indicated regain-sequence.
Even if $\overline{BREQ}$ is activated earlier, the regain-sequence is initiated by $\overline{HOLD}$ going high.
Please note that $\overline{HOLD}$ may also be deactivated without the C167CR-16RM requesting the bus.

[2] The next C167CR-16RM driven bus cycle may start here.

Package Outline

Plastic Package, P-MQFP-144-1 (SMD)
(Plastic Metric Quad Flat Package)

1) Does not include plastic or metal protrusions of 0.25max per side
