## Electroluminescent Lamp Driver Low Power Applications

■ 2.2V-5.0V Battery Operation
■ 50nA Maximum Standby Current
■ High Voltage Output $160 \mathrm{~V}_{\mathrm{pp}}$ typical

- Internal Oscillator

## APPLICATIONS

- PDAs
- Cellular Phones
- Remote Controls
- Hand Held Computers

## DESCRIPTION

The SP4423 is a high voltage output DC-AC converter that can operate from a $2.2 \mathrm{~V}-6.0 \mathrm{~V}$ power supply. The SP4423 is capable of supplying up to $200 \mathrm{~V}_{\text {pp }}$ signals, making it ideal for driving electroluminescent lamps. The device features 10 nA (typical) standby current, for use in low power portable products. An inductor is used to generate the high voltage, and an external capacitor is used to select the oscillator frequency. The SP4423 is offered in an 8 -pin narrow SOIC and 8 -pin $\mu$ SOIC packages. For delivery in die form, please consult the factory.

## Block Diagram

ABSOLUTE MAXIMUM RATINGS
These are stress ratings only and functional operation of the device at these ratings or any other above those indicated in the operation sections of the specifications below is not implied. Exposure to absolute maximum rating conditions for extended periods of time may affect reliability.
$V_{D D}$.........................................................................................................7.0V
Input Voltages/Currents
HON (pin1) ......................................... 0.5 V to $\left(\mathrm{V}_{\mathrm{DD}}+0.5 \mathrm{~V}\right)$
COIL (pin3).............................................................. 60 mA
Lamp Outputs.................................................................................. $230 \mathrm{~V}_{\mathrm{PP}}$
Storage Temperature.................................................... $65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$

## SPECIFICATIONS

Power Dissipation Per Package
8-pin NSOIC (derate $6.14 \mathrm{~mW}{ }^{\circ} \mathrm{C}$ above $+70^{\circ} \mathrm{C}$ ) $\qquad$ .500 mW 8 -pin $\mu$ SOIC (derate $4.85 \mathrm{~mW}{ }^{\circ} \mathrm{C}$ above $+70^{\circ} \mathrm{C}$ ).................. 390 mW

## NOTES:

1. Dimensions are in Microns unless otherwise noted.
2. Bonding pads are $125 \times 125$ typical
3. Outside dimensions are maximum, including scribe area.
4. Die thickness is 10 mils $+/-1$.
5. Pad center coordinates are relative to die center.
6. Die size $1447 \times 1346$ ( $57 \times 53 \mathrm{mils}$ ).

PIN DESCRIPTION

Pin 1 - HON- Enable for driver operation, high $=$ active; low $=$ inactive.

Pin $2-\mathrm{V}_{\mathrm{ss}}$ - Power supply common, connect to ground.

Pin 3 - Coil- Coil input, connect coil from $V_{D D}$ to pin 3.

Pin 4 - Lamp- Lamp driver output2, connect to EL lamp.

Pin 5 - Lamp- Lamp driver output1, connect to EL lamp.

Pin $6-V_{D D}-$ Power supply for driver, connect to system $\mathrm{V}_{\mathrm{DD}}^{\mathrm{DD}}$.

Pin 7 - Cap1- Capacitor input 1 , connect to $\mathrm{C}_{\text {OSC }}$.
Pin 8 - Cap2- Capacitor input 2 , connect to $\mathrm{C}_{\text {osc }}$.

## THEORY OF OPERATION

The SP4423 is made up of three basic circuit elements, an oscillator, coil, and switched H -bridge network. The oscillator provides the device with an on-chip clock source used to control the charge and discharge phases for the coil and lamp. An external capacitor connected between pins 7 and 8 allows the user to vary the oscillator frequency from 32 kHz to 400 kHz . The graphs on page 6 show the relationship between $\mathrm{C}_{\text {osc }}$ and lamp output voltage. In general, increasing the $\mathrm{C}_{\text {osc }}$ capacitor will increase the lamp output voltage and decrease the lamp frequency.

The suggested oscillator frequency is 64 kHz ( $\mathrm{C}_{\text {osc }}=150 \mathrm{pF}$ ). The oscillator output is internally divided to create two internal control signals, $\mathrm{f}_{\text {CoII }}$ and $\mathrm{f}_{\text {LAMP }}$. The oscillator output is internally divided down by 8 flip flops; a 64 kHz signal will be divided into 8 frequencies; $32,16,8,4$, $2,1,0.5$, and 0.25 Hz . The 3rd flip flop output $(8 \mathrm{kHz})$ is used to drive the coil (see Figure 2 on page 9) and the 8th flip flop output ( 250 Hz ) is used to drive the lamp. Although the oscillator frequency can be varied to optimize the lamp output, the ratio of $\mathrm{f}_{\text {COIL }} / \mathrm{f}_{\text {LAMP }}$ will always equal 32 .

## SP4423 Schematic

The on-chip oscillator of the SP4423 can be overdriven with an external clock source by removing the $\mathrm{C}_{\mathrm{OSC}}$ capacitor and connecting a clock source to pin 8 (Cap 2). The clock should have a $50 \%$ duty cycle and range from $V_{D D}-1 \mathrm{~V}$ to ground. An external clock signal may be desirable in order to synchronize any parasitic switching noise with the system clock. The maximum external clock frequencies that can be supplied is 400 kHz .

The coil is an external component connected from $\mathrm{V}_{\text {battery }}$ to pin 3 of the $\mathbf{S P 4 4 2 3}$. Energy is stored in the coil according to the equation $\mathrm{E}_{\mathrm{L}}=1 / 2 \mathrm{LI}^{2}$, where I is the peak current flowing in the inductor. The current in the inductor is time dependent and is set by the "ON" time of the coil switch: $\mathrm{I}=\left(\mathrm{V}_{\mathrm{L}} / \mathrm{L}\right) \mathrm{t}_{\mathrm{oN}}$, where $\mathrm{V}_{\mathrm{L}}$ is the voltage across the inductor. At the moment the switch closes, the current in the inductor is zero and the entire supply voltage (minus the $\mathrm{V}_{\mathrm{SAT}}$ of the switch) is across the inductor. The current in the inductor will then ramp up at a linear rate. As the current in the inductor builds up, the voltage across the inductor will decrease due to the resistance of the coil and the "ON" resistance of the switch: $\mathrm{V}_{\mathrm{L}}=\mathrm{V}_{\text {battery }}{ }^{-}$ $\mathrm{IR}_{\mathrm{L}}-\mathrm{V}_{\mathrm{SAT}}$. Since the voltage across the inductor is decreasing, the current ramp-rate also decreases which reduces the current in the coil at the end of $\mathrm{t}_{\mathrm{ON}}$ the energy stored in the inductor per coil cycle and therefore the light output. The other important issue is that maximum current (saturation current) in the coil is set by the design and manufacturer of the coil. If the parameters of the application such as $\mathrm{V}_{\text {battery }}$, L , RL or $\mathrm{t}_{\text {ON }}$ cause the current in the coil to increase beyond its rated $\mathrm{I}_{\mathrm{SAT}}$, excessive heat will be generated and the power efficiency will decrease with no additional light output. The Sipex SP4423 is final tested using a $20 \mathrm{mH} / 70 \Omega$ coil from CTC. For suggested coil sources see page 10.

The supply $\mathrm{V}_{\mathrm{DD}}$ can range from 2.2 to 6.0 V . It is not necessary that $\mathrm{Vdd}=\mathrm{V}_{\text {bAttery }} . \mathrm{V}_{\text {battery }}$ should not exceed max coil current specification. The majority of the current goes through the coil and is typically much greater than $\mathrm{I}_{\mathrm{DD}}$.

The $\mathrm{f}_{\text {coil }}$ signal controls a switch that connects the end of the coil at pin 3 to ground or to open circuit. The $\mathrm{f}_{\text {coil }}$ signal is a $75 \%$ duty cycle signal, switching at $1 / 8$ the oscillator frequency. For a 64 kHz oscillator $\mathrm{f}_{\text {coil }}$ is 8 kHz . During the time when the $\mathrm{f}_{\text {coll }}$ signal is high, the coil is
connected from $V_{\text {battery }}$ to ground and a charged magnetic field is created in the coil. During the low part of $\mathrm{f}_{\text {coil }}$, the ground connection is switched open, the field collapses and the energy in the inductor is forced to flow toward the high voltage H -bridge switches. $\mathrm{f}_{\text {coil }}$ will send 16 of these charge pulses to the lamp, each pulse increases the voltage drop across the lamp in discrete steps. As the voltage potential approaches its maximum, the steps become shorter (see Figure 1 on page 9).

The H-bridge consists of two SCR structures that act as high voltage switches. These two switches control the polarity of how the lamp is charged. The SCR switches are controlled by the $f_{\text {LAMP }}$ signal which is the oscillator frequency divided by 256 . For a 64 kHz oscillator, $\mathrm{f}_{\text {LAMP }}=250 \mathrm{~Hz}$.

When the energy from the coil is released, a high voltage spike is created triggering the SCR switches. The direction of current flow is determined by which SCR is enabled. One full cycle of the H -bridge will create 16 voltage steps from ground to 80 V (typical) on pins 4 and 5 which are 180 degrees out of phase with each other (see Figure 3 on page 9). A differential representation of the outputs is shown in Figure 4 on page 9. To minimize AC interference it is advisable to use a decoupling filter capacitor between $\mathrm{V}_{\mathrm{DD}}$ and ground.

## Electroluminescent Technology

## What is electroluminescence?

An EL lamp is basically a strip of plastic that is coated with a phosphorous material which emits light (fluoresces) when a high voltage ( $>40 \mathrm{~V}$ ) which was first applied across it, is removed or reversed. Long periods of DC voltages applied to the material tend to breakdown the material and reduce its lifetime. With these considerations in mind, the ideal signal to drive an EL lamp is a high voltage sine wave. Traditional approaches to achieving this type of waveform included discrete circuits incorporating a transformer, transistors, and several resistors and capacitors. This approach is large and bulky, and cannot be implemented in most hand held equipment. Sipex now offers low power single chip driver circuits specifically designed to drive small to medium sized electroluminescent panels. All that is required is one external inductor and capacitor.

Electroluminescent backlighting is ideal when used with LCD displays, keypads, or other backlit readouts. Its main use is to illuminate displays in dim to dark conditions for momentary periods of time. EL lamps typically consume less than LEDs or incandescent bulbs making them ideal for battery powered products. Also, EL lamps are able to evenly light an area without creating "hot spots" in the display.

The amount of light emitted is a function of the voltage applied to the lamp, the frequency at which it is applied, the lamp material used and its size. There are many variables which can be optimized for specific applications. Sipex supplies characterization charts to aid the designer in selecting the optimum circuit configuration (see page 6).

## Typical SP4423 Application Circuit

Typical SP4423 Test Circuit

The following performance curves are intended to give the designer a relative scale from which to optimize specific applications. Absolute measurements may vary depending upon the brand of components chosen.
