IMP706P/R/S/T/J, IMP708R/S/T/J

POWER MANAGEMENT

3/3.3/4.0V µP Supervisor Circuits

- Low supply current
- Watchdog timer
- Brownout detection

The IMP706P/R/S/T/J and IMP708R/S/T/J CMOS supervisor circuits monitor power-supply and battery voltage level, and μ P/ μ C operation. A reset is generated when the supply drops below 2.63V (IMP706P/R, IMP708R), 2.93V (IMP706S, IMP708S), 3.08V (IMP706T, IMP708T) or 4.00 (IMP706J, IMP708J).

The family offers several functional options. Each device generates a reset signal during power-up, power-down and during brownout conditions.

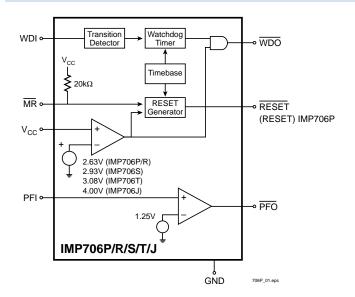

In addition, the IMP706P/R/S/T/J feature a 1.6 second watchdog timer. The watchdog timer output will trigger a reset if connected to $\overline{\text{MR}}$. Unlike competitive devices, floating the WDI input pin disables the watchdog timer.

The IMP708R/S/T/J have both active-HIGH and active-LOW reset outputs but no watchdog function. The IMP706P has the same pin-out and functions as the IMP706R but has an active-HIGH reset output.

A versatile power-fail circuit, useful in checking battery levels and non-5V supplies, has a 1.25V threshold. All devices have a manual reset input.

All devices are available in 8-pin DIP, SO and the compact MicroSO packages. The MicroSO package requires 50% less PC board area than the conventional SO package.

Block Diagrams

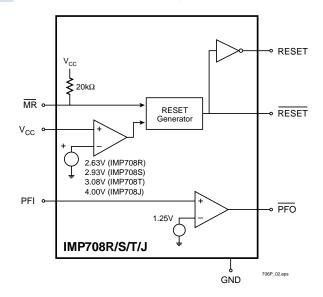

Key Features

- Lower power, pin compatible replacements for Maxim MAX706P/R/S/T, MAX708R/S/T
 - 30% lower supply current:140µA vs. 200µA
- Precision power supply monitor
 - 2.63V threshold (IMP706P/R, IMP708R)
 - 2.93V threshold (IMP706S, IMP708S)
 - 3.08V threshold (IMP706T, IMP708T)
 - New 4.00V threshold (IMP706J, IMP708J)
- ◆ Debounced manual reset input
- ♦ Auxiliary voltage monitor comparator
 - 1.25V threshold
 - Battery monitor/auxiliary supply monitor
- ♦ Watchdog timer (IMP706P/R/S/T/J)
 - Watchdog can be disabled by floating WDI
- ◆ 200ms reset time delay
- **♦** Three reset signal options
 - Active HIGH: IMP706P
 - Active LOW: IMP706R/S/T/J
 - Active HIGH & LOW outputs: IMP708R/S/T/J
- ◆ DIP, SO and MicroSO packages
- ◆ Guaranteed RESET assertion to V_{CC} = 1.1V

Applications

- Computers and controllers
- CTI applications
- Embedded controllers
- Battery operated systems
- Intelligent instruments
- Wireless communication systems
- ◆ PDAs and handheld equipment

Pin Descriptions

	Pin Number		Pin Number				
IMP7	706P	IMP706R/S/T/J		IMP708R/S/T/J			
DIP/SO	MicroSO	DIP/SO	MicroSO		MicroSO	Name	Function
1	3	1	3	1	3	MR	Manual reset input. The active LOW input triggers a reset pulse. It is pulled HIGH by a $20 k\Omega$ pull-up resistor. It is compatible with TTL/CMOS signals when $V_{CC} = 5V$. It can be shorted to ground through a mechanical switch. Leave floating or connect to V_{CC} if the function is not used.
2	4	2	4	2	4	Vcc	Monitored power supply input.
3	5	3	5	3	5	GND	Ground
4	6	4	6	4	6	PFI	Power-fail input voltage monitor. With PFI less than 1.25V, PFO goes LOW. Connect PFI to ground when not used.
5	7	5	7	5	7	PFO	Power-fail output. The output is active LOW and sinks current when PFI is less than 1.25V. If not used, leave the pin unconnected.
6	8	6	8	_	_	WDI	Watchdog input. WDI controls the internal watchdog timer. A HIGH or LOW signal for 1.6 sec at WDI allows the internal timer to run-out, setting WDO low. A rising or falling edge must occur at WDI within 1.6 seconds or WDO goes LOW. The watchdog function is disabled by floating WDI. The internal watchdog timer clears when: RESET is asserted; WDI is three-stated; or WDI sees a rising or falling edge.
_	_	_	_	6	8	NC	Not connected.
_	_	7	1	7	1	RESET	Active-LOW reset output. Pulses LOW for 200ms when triggered, and stays LOW whenever V_{CC} is below the reset threshold. RESET remains LOW for 200ms after V_{CC} rises above the RESET threshold or \overline{MR} goes from HIGH to LOW. A watchdog timeout will not trigger RESET unless WDO is connected to MR.
8	2	8	2	_	_	WDO	Watchdog output. WDO goes LOW when the 1.6 second internal watchdog timer times-out and does not go HIGH until a transition occurs at WDI. In addition, when V _{CC} falls below the reset threshold, WDO goes LOW. Unlike RESET, WDO does not have a minimum pulse width and as soon as V _{CC} exceeds the reset threshold, WDO becomes HIGH with no delay.
7	1	_	_	8	2	RESET	Active-HIGH reset output. RESET is the inverse of RESET.

Detail Descriptions

RESET/RESET Operation

The RESET/ \overline{RESET} signals are designed to start or return a $\mu P/\mu C$ to a known state.

With V_{CC} above 1.2V, RESET and \overline{RESET} are guaranteed to be asserted. During a power-up sequence, the reset outputs remain asserted until the supply rises above the threshold level. The resets are deasserted approximately 200ms after crossing the threshold.

In a brownout situation where V_{CC} falls below the threshold level, the reset outputs are asserted. If a brownout occurs during an already initiated reset period, the reset period will extend for an additional reset period of 200ms.

The IMP708 devices have dual reset outputs, one active LOW and one active HIGH. The IMP706P has a single active HIGH reset and the IMP706/R/S/T/J devices have an active LOW reset output.

IMP Part	RESET Polarity	Threshold	Watchdog Timer
IMP706P	HIGH	2.63V	Yes
IMP706R	LOW	2.63V	Yes
IMP706S	LOW	2.93V	Yes
IMP706T	LOW	3.08V	Yes
IMP706J	LOW	4.00V	Yes
IMP708R	Both: HIGH & LOW	2.63V	No
IMP708S	Both: HIGH & LOW	2.93V	No
IMP708T	Both: HIGH & LOW	3.08V	No
IMP708J	Both: HIGH & LOW	4.00V	No

Manual Reset (MR)

The active-LOW manual reset input is pulled high by an internal $20k\Omega$ pull-up resistor and can be driven low by CMOS/TTL logic or a mechanical switch to ground. An external debounce circuit is unnecessary since the 140ms minimum reset time will debounce mechanical pushbutton switches. The minimum \overline{MR} input pulse

width is 0.5 μs with a 3V V_{CC} input and 0.15 μs with a 5V V_{CC} input. If not used, tie \overline{MR} to V_{CC} or leave floating.

By connecting the watchdog output (\overline{WDO}) and \overline{MR} , a watchdog timeout forces a RESET to be generated.

Watchdog Timer

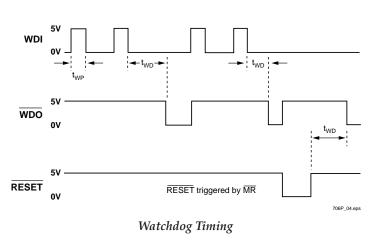

A watchdog timer available on the IMP706P/R/S/T/J monitors $\mu P/\mu C$ activity. If activity is not detected within 1.6 seconds on the Watchdog Input (WDI), the internal timer puts the Watchdog Output (WDO) into a LOW state. WDO will remain LOW until activity is detected at WDI.

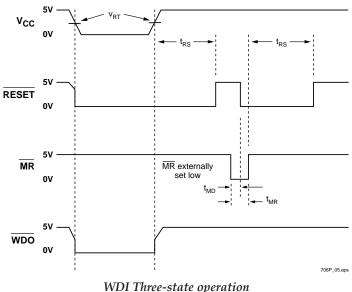

The watchdog function is disabled, meaning it is cleared and not counting, if WDI is floated or connected to a three-stated circuit. The watchdog timer is also disabled if RESET is asserted. When RESET becomes inactive and the WDI input sees a high or low transition as short as 100ns ($V_{\rm CC}=2.7V$)/50ns ($V_{\rm CC}=4.5V$), the watchdog timer will begin a 1.6 second countdown. Additional transitions at WDI will reset the watchdog timer and initiate a new countdown sequence.

WDO will also become LOW and remain so, whenever the supply voltage, V_{CC} , falls below the device threshold level. \overline{WDO} goes HIGH as soon as V_{CC} transitions above the threshold. There is no minimum pulse width for \overline{WDO} as there is for the RESET outputs. If WDI is floated, \overline{WDO} essentially acts as a low supply voltage output indicator.

Power-failure detection with auxiliary comparator

All devices have an auxiliary comparator with 1.25V trip point. The output, \overline{PFO} , is active LOW and the noninverting input is PFI. This comparator can be used as a supply voltage monitor with an external resistor voltage divider. As the monitored voltage level falls, PFI is reduced causing the \overline{PFO} output to go LOW. Normally \overline{PFO} interrupts the processor so the system can be shut down in a controlled manner.

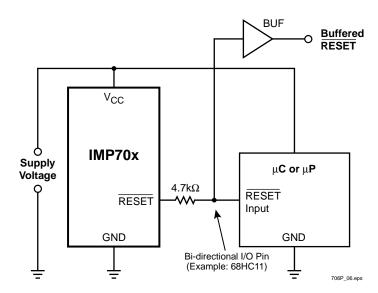

Bi-directional Reset Pin Interfacing

The IMP706/8 can interface with $\mu P/\mu C$ bi-directional reset pins by connecting a $4.7k\Omega$ resistor in series with the RESET output and the $\mu P/\mu C$ bi-directional reset pin.

Application Information

Ensuring That RESET is Valid Down to $V_{CC} = 0V$

When V_{CC} falls below 1.2V, the IMP706R/S/T/J and IMP708R/S/T/J RESET reset outputs no longer pull down; it becomes indeterminate. To avoid the possibility that stray charges could build up and force RESET to the wrong state, a pull-down resistor should be connected to the RESET pin, thus draining such charges to ground. The resistor value is not critical. A $100 \mathrm{k}\Omega$ resistor will pull RESET to ground without loading it.

Monitoring Voltages Other Than V_{CC}

The IMP706/708 can monitor voltages other than V_{CC} using the Power Fail circuitry. If a resistive divider is connected from the voltage to be monitored to the PFI input, the \overline{PFO} (output) will go LOW if the divider voltage goes below its 1.25V reference. Should hysteresis be desired, connect a resistor (equal to approximately 10 times the sum of the two resistors in the divider) between the PFI and \overline{PFO} pins. A capacitor between PFI and GND will reduce circuit sensitivity to input high frequency noise. If it is desired to assert a reset in addition to the \overline{PFO} flag, this may be achieved by connecting the \overline{PFO} output to \overline{MR} .
