## FEATURES

Complete quad, 16-bit digital-to-analog converter (DAC) Programmable output range: $\pm 10 \mathrm{~V}, \pm 10.2564 \mathrm{~V}$, or $\pm 10.5263 \mathrm{~V}$
$\pm 1$ LSB maximum INL error, $\pm 1$ LSB maximum DNL error
Low noise: $60 \mathrm{nV} / \sqrt{\mathrm{Hz}}$
Settling time: $10 \mu \mathrm{~s}$ maximum
Integrated reference buffers
Internal reference: $10 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$ maximum
On-chip die temperature sensor
Output control during power-up/brownout
Programmable short-circuit protection
Simultaneous updating via $\overline{\text { LDAC }}$
Asynchronous CLR to zero code
Digital offset and gain adjust
Logic output control pins
DSP-/microcontroller-compatible serial interface
Temperature range: $-\mathbf{4 0}{ }^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
iCMOS process technology

## APPLICATIONS

## Industrial automation

Open-loop/closed-loop servo control
Process control
Data acquisition systems
Automatic test equipment
Automotive test and measurement
High accuracy instrumentation

## GENERAL DESCRIPTION

The AD5764R is a quad, 16 -bit, serial input, bipolar voltage output DAC that operates from supply voltages of $\pm 11.4 \mathrm{~V}$ to $\pm 16.5 \mathrm{~V}$. Nominal full-scale output range is $\pm 10 \mathrm{~V}$. The AD5764R provides integrated output amplifiers, reference buffers, and proprietary power-up/power-down control circuitry. The part also features a digital I/O port, programmed via the serial interface, and an analog temperature sensor. The part incorporates digital offset and gain adjust registers per channel.
The AD5764R is a high performance converter that provides guaranteed monotonicity, integral nonlinearity (INL) of $\pm 1$ LSB, low noise, and $10 \mu$ s settling time. The AD5764R includes an on-chip 5 V reference with a reference temperature coefficient of $10 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$ maximum. During power-up when the supply voltages are changing, VOUTx is clamped to 0 V via a low impedance path.

The AD5764R is based on the $i$ CMOS $^{\circledR}$ technology platform, which is designed for analog systems designers within industrial/ instrumentation equipment OEMs who need high performance ICs at higher voltage levels. $i$ CMOS enables the development of analog ICs capable of 30 V and operation at $\pm 15 \mathrm{~V}$ supplies, while allowing reductions in power consumption and package size, coupled with increased ac and dc performance.
The AD5764R uses a serial interface that operates at clock rates of up to 30 MHz and is compatible with DSP and microcontroller interface standards. Double buffering allows the simultaneous updating of all DACs. The input coding is programmable to either twos complement or offset binary formats. The asynchronous clear function clears all data registers to either bipolar zero or zero scale, depending on the coding used. The AD5764R is ideal for both closed-loop servo control and open-loop control applications. The AD5764R is available in a 32 -lead TQFP and offers guaranteed specifications over the $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ industrial temperature range (see Figure 1 for the functional block diagram).

[^2]
## TIMING CHARACTERISTICS

$\mathrm{AV}_{\mathrm{DD}}=11.4 \mathrm{~V}$ to $16.5 \mathrm{~V}, \mathrm{AV}_{\mathrm{SS}}=-11.4 \mathrm{~V}$ to $-16.5 \mathrm{~V}, \mathrm{AGND}=\mathrm{DGND}=\mathrm{REFGND}=\mathrm{PGND}=0 \mathrm{~V} ; \mathrm{REFAB}=\mathrm{REFCD}=5 \mathrm{~V}$ external; $D V_{\mathrm{CC}}=2.7 \mathrm{~V}$ to $5.25 \mathrm{~V}, \mathrm{R}_{\mathrm{LOAD}}=10 \mathrm{k} \Omega, \mathrm{C}_{\mathrm{L}}=200 \mathrm{pF}$. All specifications $\mathrm{T}_{\text {MIN }}$ to $\mathrm{T}_{\mathrm{MAX}}$, unless otherwise noted.

Table 3.

| Parameter ${ }^{1,2,3}$ | Limit at $\mathrm{T}_{\text {MIN, }} \mathbf{T}_{\text {MAX }}$ | Unit | Description |
| :---: | :---: | :---: | :---: |
| $\mathrm{t}_{1}$ | 33 | ns min | SCLK cycle time |
| $\mathrm{t}_{2}$ | 13 | ns min | SCLK high time |
| $\mathrm{t}_{3}$ | 13 | ns min | SCLK low time |
| $\mathrm{t}_{4}$ | 13 | ns min | $\overline{\text { SYNC }}$ falling edge to SCLK falling edge setup time |
| $\mathrm{t}_{5}{ }^{4}$ | 13 | ns min | $24^{\text {th }}$ SCLK falling edge to $\overline{\text { SYNC }}$ rising edge |
| t6 | 90 | ns min | Minimum $\overline{\text { SYNC }}$ high time |
| $\mathrm{t}_{7}$ | 2 | ns min | Data setup time |
| $\mathrm{t}_{8}$ | 5 | ns min | Data hold time |
| $\mathrm{t}_{9}$ | 1.7 | $\mu \mathrm{s}$ min | $\overline{\text { SYNC }}$ rising edge to $\overline{L D A C}$ falling edge (all DACs updated) |
|  | 480 | ns min | $\overline{\text { SYNC }}$ rising edge to $\overline{L D A C}$ falling edge (single DAC updated) |
| $\mathrm{t}_{10}$ | 10 | ns min | $\overline{\text { LDAC }}$ pulse width low |
| $\mathrm{t}_{11}$ | 500 | ns max | $\overline{\text { LDAC }}$ falling edge to DAC output response time |
| $\mathrm{t}_{12}$ | 10 | $\mu \mathrm{s}$ max | DAC output settling time |
| $\mathrm{t}_{13}$ | 10 | ns min | $\overline{\mathrm{CLR}}$ pulse width low |
| $\mathrm{t}_{14}$ | 2 | $\mu \mathrm{s}$ max | $\overline{\mathrm{CLR}}$ pulse activation time |
| $t_{15}{ }^{5,6}$ | 25 | ns max | SCLK rising edge to SDO valid |
| $\mathrm{t}_{16}$ | 13 | $n \mathrm{~ns}$ min | $\overline{\text { SYNC }}$ rising edge to SCLK falling edge |
| $\mathrm{t}_{17}$ | 2 | $\mu \mathrm{s}$ max | $\overline{\text { SYNC }}$ rising edge to DAC output response time (LDAC $=0$ ) |
| $\mathrm{t}_{18}$ | 170 | ns min | $\overline{\text { LDAC }}$ falling edge to $\overline{S Y N C}$ rising edge |

## ABSOLUTE MAXIMUM RATINGS

$\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$, unless otherwise noted. Transient currents of up to 100 mA do not cause SCR latch-up.

Table 4.

| Parameter | Rating |
| :---: | :---: |
| $\mathrm{AV}_{\text {DD }}$ to AGND, DGND | -0.3 V to +17 V |
| AV ${ }_{\text {ss }}$ to AGND, DGND | +0.3 V to -17 V |
| DV $\mathrm{cc}^{\text {to }}$ DGND | -0.3 V to +7V |
| Digital Inputs to DGND | $-0.3 \mathrm{~V} \text { to }(\mathrm{DV} \mathrm{cc}+0.3 \mathrm{~V}) \text { or }+7 \mathrm{~V} \text {, }$ <br> whichever is less |
| Digital Outputs to DGND | -0.3 V to $\mathrm{DV}_{\mathrm{cc}}+0.3 \mathrm{~V}$ |
| REFAB, REFCD to AGND, PGND | -0.3 V to $\mathrm{AV}_{\mathrm{DD}}+0.3 \mathrm{~V}$ |
| REFOUT to AGND | $\mathrm{AV}_{\text {SS }}$ to $A V_{\text {DD }}$ |
| TEMP | $A V_{S S}$ to $A V_{\text {dD }}$ |
| VOUTx to AGND | $\mathrm{AV}_{\text {Ss }}$ to $\mathrm{AV}_{\text {DD }}$ |
| AGND to DGND | -0.3 V to +0.3 V |
| Operating Temperature Range Industrial | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Junction Temperature (T, max) | $150^{\circ} \mathrm{C}$ |
| Lead Temperature (Soldering) | JEDEC industry standard J-STD-020 |

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## THERMAL RESISTANCE

$\theta_{\mathrm{JA}}$ is specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages.

Table 5. Thermal Resistance

| Package Type | $\boldsymbol{\theta}_{\mathrm{JA}}$ | $\boldsymbol{\theta}_{\mathbf{\prime c}}$ | Unit |
| :--- | :--- | :--- | :--- |
| 32-Lead TQFP | 65 | 12 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

## ESD CAUTION

|  | ESD (electrostatic discharge) sensitive device. <br> Charged devices and circuit boards can discharge <br> without detection. Although this product features <br> patented or proprietary protection circuitry, damage <br> may occur on devices subjected to high energy ESD. <br> Therefore, proper ESD precautions should be taken to <br> avoid performance degradation or loss of functionality. |
| :--- | :--- |

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Table 6. Pin Function Descriptions

| Pin No. | Mnemonic | Description |
| :---: | :---: | :---: |
| 1 | $\overline{\text { SYNC }}$ | Active Low Input. This is the frame synchronization signal for the serial interface. While $\overline{\text { SYNC }}$ is low, data is transferred in on the falling edge of SCLK. |
| 2 | SCLK | Serial Clock Input. Data is clocked into the input shift register on the falling edge of SCLK. This operates at clock speeds of up to 30 MHz . |
| 3 | SDIN | Serial Data Input. Data must be valid on the falling edge of SCLK. |
| 4 | SDO | Serial Data Output. This pin is used to clock data from the serial register in daisy-chain or readback mode. |
| 5 | $\overline{\mathrm{CLR}}$ | Negative Edge Triggered Input. ${ }^{1}$ Asserting this pin sets the data registers to 0x0000. |
| 6 | $\overline{\text { LDAC }}$ | Load DAC. This logic input is used to update the data registers and, consequently, the analog outputs. When tied permanently low, the addressed data register is updated on the rising edge of $\overline{\text { SYNC. If }} \overline{\mathrm{LDAC}}$ is held high during the write cycle, the DAC input register is updated but the output update is held off until the falling edge of $\overline{\overline{L D A C}}$. In this mode, all analog outputs can be updated simultaneously on the falling edge of $\overline{\overline{L D A C}}$. The $\overline{\mathrm{LDAC}}$ pin must not be left unconnected. |
| 7,8 | D0, D1 | Digital I/O Port. D0 and D1 form a digital I/O port. The user can set up these pins as inputs or outputs that are configurable and readable over the serial interface. When configured as inputs, these pins have weak internal pull-ups to DVcc. When programmed as outputs, D0 and D1 are referenced by DV $c c$ and DGND. |
| 9 | $\overline{\text { RSTOUT }}$ | Reset Logic Output. This is the output from the on-chip voltage monitor used in the reset circuit. If desired, it can be used to control other system components. |
| 10 | $\overline{\text { RSTIN }}$ | Reset Logic Input. This input allows external access to the internal reset logic. Applying a Logic 0 to this input clamps the DAC outputs to 0 V. In normal operation, $\overline{\mathrm{RSTIN}}$ should be tied to Logic 1. Register values remain unchanged. |
| 11 | DGND | Digital Ground Pin. |
| 12 | DV ${ }_{\text {cc }}$ | Digital Supply Pin. Voltage ranges from 2.7 V to 5.25 V. |
| 13,31 | AV ${ }_{\text {DD }}$ | Positive Analog Supply Pins. Voltage ranges from 11.4V to 16.5 V. |
| 14 | PGND | Ground Reference Point for Analog Circuitry. |
| 15,30 | $\mathrm{AV}_{\text {ss }}$ | Negative Analog Supply Pins. Voltage ranges from -11.4 V to -16.5 V. |
| 16 | ISCC | This pin is used in association with an optional external resistor to AGND to program the short-circuit current of the output amplifiers. Refer to the Design Features section for more information. |
| 17 | AGNDD | Ground Reference Pin for DAC D Output Amplifier. |
| 18 | VOUTD | Analog Output Voltage of DAC D. Buffered output with a nominal full-scale output range of $\pm 10 \mathrm{~V}$. The output amplifier is capable of directly driving a $10 \mathrm{k} \Omega, 200 \mathrm{pF}$ load. |
| 19 | VOUTC | Analog Output Voltage of DAC C. Buffered output with a nominal full-scale output range of $\pm 10 \mathrm{~V}$. The output amplifier is capable of directly driving a $10 \mathrm{k} \Omega, 200 \mathrm{pF}$ load. |
| 20 | AGNDC | Ground Reference Pin for DAC C Output Amplifier. |
| 21 | AGNDB | Ground Reference Pin for DAC B Output Amplifier. |

| Pin No. | Mnemonic | Description |
| :---: | :---: | :---: |
| 22 | VOUTB | Analog Output Voltage of DAC B. Buffered output with a nominal full-scale output range of $\pm 10 \mathrm{~V}$. The output amplifier is capable of directly driving a $10 \mathrm{k} \Omega, 200 \mathrm{pF}$ load. |
| 23 | VOUTA | Analog Output Voltage of DAC A. Buffered output with a nominal full-scale output range of $\pm 10 \mathrm{~V}$. The output amplifier is capable of directly driving a $10 \mathrm{k} \Omega, 200 \mathrm{pF}$ load. |
| 24 | AGNDA | Ground Reference Pin for DAC A Output Amplifier. |
| 25 | REFAB | External Reference Voltage Input for Channel A and Channel B . The reference input range is 1 V to 7 V , and it programs the full-scale output voltage. $\mathrm{V}_{\text {REFIN }}=5 \mathrm{~V}$ for specified performance. |
| 26 | REFCD | External Reference Voltage Input for Channel C and Channel D . The reference input range is 1 V to 7 V , and it programs the full-scale output voltage. $\mathrm{V}_{\text {REFIN }}=5 \mathrm{~V}$ for specified performance. |
| 27 | REFOUT | Reference Output. This is the reference output from the internal voltage reference. The internal reference is $5 \mathrm{~V} \pm$ 3 mV at $25^{\circ} \mathrm{C}$, with a reference temperature coefficient of $10 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$. |
| 28 | REFGND | Reference Ground Return for the Reference Generator and Buffers. |
| 29 | TEMP | This pin provides an output voltage proportional to temperature. The output voltage is 1.47 V typical at $25^{\circ} \mathrm{C}$ die temperature; variation with temperature is $5 \mathrm{mV} /{ }^{\circ} \mathrm{C}$. |
| 32 | BIN/ $/ \overline{\text { SCOMP }}$ | This pin determines the DAC coding. This pin should be hardwired to either DV ${ }_{c C}$ or DGND. When hardwired to $D V_{c c}$, input coding is offset binary (see Table 7). When hardwired to DGND, input coding is twos complement (see Table 8). |

${ }^{1}$ Internal pull-up device on this logic input. Therefore, it can be left floating; and it defaults to a logic high condition.

## TERMINOLOGY

## Relative Accuracy or Integral Nonlinearity (INL)

For the DAC, a measure of the maximum deviation, in LSBs, from a straight line passing through the endpoints of the DAC transfer function.

## Differential Nonlinearity (DNL)

The difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of $\pm 1$ LSB maximum ensures monotonicity. This DAC is guaranteed monotonic.

## Monotonicity

A DAC is monotonic if the output either increases or remains constant for increasing digital input code. The AD5744R is monotonic over its full operating temperature range.

## Bipolar Zero Error

The deviation of the analog output from the ideal half-scale output of 0 V when the DAC register is loaded with 0 x 8000 (offset binary coding) or 0x0000 (twos complement coding). Figure 22 shows a plot of bipolar zero error vs. temperature.

## Bipolar Zero Temperature Coefficient

The measure of the change in the bipolar zero error with a change in temperature. It is expressed as parts per million of full-scale range per degree Celsius (ppm FSR $/{ }^{\circ} \mathrm{C}$ ).

## Full-Scale Error

The measure of the output error when full-scale code is loaded to the data register. Ideally, the output voltage should be $2 \times$ $V_{\text {refin }}-1$ LSB. Full-scale error is expressed as a percentage of full-scale range (\% FSR).

## Negative Full-Scale Error/Zero-Scale Error

The error in the DAC output voltage when 0x0000 (offset binary coding) or $0 \times 8000$ (twos complement coding) is loaded to the data register. Ideally, the output voltage should be $-2 \times V_{\text {refin }}$. Figure 21 shows a plot of zero-scale error vs. temperature.

## Output Voltage Settling Time

The amount of time it takes for the output to settle to a specified level for a full-scale input change.

## Slew Rate

A limitation in the rate of change of the output voltage. The output slewing speed of a voltage-output DAC is usually limited by the slew rate of the amplifier used at its output. Slew rate is measured from $10 \%$ to $90 \%$ of the output signal and is given in volts per microsecond ( $\mathrm{V} / \mu \mathrm{s}$ ).

## Gain Error

A measure of the span error of the DAC. It is the deviation in slope of the DAC transfer characteristic from the ideal, expressed as a percentage of the full-scale range (\% FSR). Figure 23 shows a plot of gain error vs. temperature.

## Total Unadjusted Error (TUE)

A measure of the output error, considering all the various errors. Figure 19 shows a plot of total unadjusted error vs. reference voltage.

## Zero-Scale Error Temperature Coefficient

A measure of the change in zero-scale error with a change in temperature. It is expressed as parts per million of full-scale range per degree Celsius (ppm FSR/ ${ }^{\circ} \mathrm{C}$ ).

## Gain Error Temperature Coefficient

A measure of the change in gain error with changes in temperature. It is expressed as parts per million of full-scale range per degree Celsius (ppm FSR/ ${ }^{\circ} \mathrm{C}$ ).

## Digital-to-Analog Glitch Energy

The impulse injected into the analog output when the input code in the data register changes state. It is normally specified as the area of the glitch in nanovolt-seconds ( $\mathrm{nV}-\mathrm{sec}$ ) and is measured when the digital input code is changed by 1 LSB at the major carry transition ( 0 x 7 FFF to 0 x 8000 ), as seen in Figure 28.

## Digital Feedthrough

A measure of the impulse injected into the analog output of the DAC from the digital inputs of the DAC, but measured when the DAC output is not updated. It is specified in nanovolt-seconds ( $\mathrm{nV}-\mathrm{sec}$ ) and measured with a full-scale code change on the data bus, that is, from all 0 s to all 1 s , and vice versa.

## Power Supply Sensitivity

Indicates how the output of the DAC is affected by changes in the power supply voltage.

## DC Crosstalk

The dc change in the output level of one DAC in response to a change in the output of another DAC. It is measured with a fullscale output change on one DAC while monitoring another DAC, and is expressed in least significant bits (LSBs).
DAC-to-DAC Crosstalk
The glitch impulse transferred to the output of one DAC due to a digital code change and subsequent output change of another DAC. This includes both digital and analog crosstalk. It is measured by loading one of the DACs with a full-scale code change (from all 0 s to all 1 s , and vice versa) with $\overline{\mathrm{LDAC}}$ low and monitoring the output of another DAC. The energy of the glitch is expressed in nanovolt-seconds ( nV -sec).

## Channel-to-Channel Isolation

The ratio of the amplitude of the signal at the output of one DAC to a sine wave on the reference input of another DAC. It is measured in decibels (dB).

## Reference Temperature Coefficient

A measure of the change in the reference output voltage with a change in temperature. It is expressed in parts per million per degree Celsius ( $\mathrm{ppm} /{ }^{\circ} \mathrm{C}$ ).

Digital Crosstalk
A measure of the impulse injected into the analog output of one DAC from the digital inputs of another DAC but is measured when the DAC output is not updated. It is specified in nanovoltseconds ( nV -sec) and measured with a full-scale code change on the data bus; that is, from all 0 s to all 1 s , and vice versa.

## Thermal Hysteresis

The change of reference output voltage after the device is cycled through temperatures from $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ and back to $-40^{\circ} \mathrm{C}$. This is a typical value from a sample of parts put through such a cycle.

## THEORY OF OPERATION

The AD5764R is a quad, 16 -bit, serial input, bipolar voltage output DAC that operates from supply voltages of $\pm 11.4 \mathrm{~V}$ to $\pm 16.5 \mathrm{~V}$ and has a buffered output voltage of up to $\pm 10.5263 \mathrm{~V}$. Data is written to the AD5764R in a 24 -bit word format via a 3-wire serial interface. The AD5764R also offers an SDO pin that is available for daisy chaining or readback.
The AD5764R incorporates a power-on reset circuit that ensures that the data registers are loaded with $0 x 0000$ at power-up. The AD5764R features a digital I/O port that can be programmed via the serial interface, an analog die temperature sensor, on-chip $10 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$ voltage reference, on-chip reference buffers, and per channel digital gain and offset registers.

## DAC ARCHITECTURE

The DAC architecture of the AD5764R consists of a 16-bit, current mode, segmented R-2R DAC. The simplified circuit diagram for the DAC section is shown in Figure 39.

Figure 39. DAC Ladder Structure
The four MSBs of the 16-bit data-word are decoded to drive 15 switches, E1 to E15. Each of these switches connects one of the 15 matched resistors to either AGNDx or Iout. The remaining 12 bits of the data-word drive Switch S0 to Switch S11 of the 12-bit R-2R ladder network.

## REFERENCE BUFFERS

The AD5764R can operate with either an external or an internal reference. The reference inputs (REFAB and REFCD) have an input range of up to 7 V . This input voltage is then used to provide a buffered positive and negative reference for the DAC cores. The positive reference is given by

$$
+V_{\text {REF }}=2 \times V_{\text {REFIN }}
$$

The negative reference to the DAC cores is given by

$$
-V_{R E F}=-2 \times V_{\text {REFIN }}
$$

These positive and negative reference voltages (along with the gain register values) define the output ranges of the DACs.

## SERIAL INTERFACE

The AD5764R is controlled over a versatile 3-wire serial interface that operates at clock rates of up to 30 MHz and is compatible with SPI, QSPI ${ }^{\mathrm{mw}}$, MICROWIRE ${ }^{\mathrm{mm}}$, and DSP standards.

## Input Shift Register

The input shift register is 24 bits wide. Data is loaded into the device, MSB first, as a 24 -bit word under the control of a serial clock input, SCLK. The input register consists of a read/write bit, a reserved bit that must be set to 0 , three register select bits, three DAC address bits, and 16 data bits, as shown in Table 9. The timing diagram for this operation is shown in Figure 2.

Upon power-up, the data registers are loaded with zero code ( $0 \times 0000$ ) and the outputs are clamped to 0 V via a low impedance path. The outputs can be updated with the zero code value by asserting either $\overline{\mathrm{LDAC}}$ or $\overline{\mathrm{CLR}}$. The corresponding output voltage depends on the state of the BIN $/ \overline{2 s C O M P}$ pin. If the BIN $/ \overline{2 s C O M P}$ pin is tied to DGND, the data coding is twos complement and the outputs update to 0 V . If the $\mathrm{BIN} / 2 \mathrm{sCOMP}$ pin is tied to DV CC, the data coding is offset binary and the outputs update to negative full scale. To have the outputs power up with zero code loaded to the outputs, hold the $\overline{\mathrm{CLR}}$ pin low during power-up.

## Standalone Operation

The serial interface works with both a continuous and noncontinuous serial clock. A continuous SCLK source can be used only if $\overline{S Y N C}$ is held low for the correct number of clock cycles. In gated clock mode, a burst clock containing the exact number of clock cycles must be used, and SYNC must be taken high after the final clock to latch the data. The first falling edge of SYNC starts the write cycle. Exactly 24 falling clock edges must be applied to SCLK before $\overline{\text { SYNC }}$ is brought high again. If $\overline{\text { SYNC }}$ is brought high before the $24^{\text {th }}$ falling SCLK edge, then the data written is invalid. If more than 24 falling SCLK edges are applied before $\overline{\text { SYNC }}$ is brought high, the input data is also invalid. The input register addressed is updated on the rising edge of $\overline{S Y N C}$. For another serial transfer to take place, $\overline{\text { SYNC }}$ must be brought low again. After the end of the serial data transfer, data is automatically transferred from the input shift register to the addressed register.

When the data has been transferred into the chosen register of the addressed DAC, all data registers and outputs can be updated by taking $\overline{\text { LDAC }}$ low.

*ADDITIONAL PINS OMITTED FOR CLARITY.
Figure 40. Daisy-Chaining the AD5764R

## Daisy-Chain Operation

For systems that contain several devices, the SDO pin can be used to daisy-chain several devices together. This daisy-chain mode can be useful in system diagnostics and in reducing the number of serial interface lines. The first falling edge of $\overline{\text { SYNC }}$ starts the write cycle. The SCLK is continuously applied to the input shift register when $\overline{\text { SYNC }}$ is low. If more than 24 clock pulses are applied, the data ripples out of the input shift register and appears on the SDO line. This data is clocked out on the rising edge of SCLK and is valid on the falling edge. By connecting the SDO of the first device to the SDIN input of the next device in the chain, a multidevice interface is constructed.
Each device in the system requires 24 clock pulses. Therefore, the total number of clock cycles must equal $24 n$, where $n$ is the total number of AD5764R devices in the chain. When the serial transfer to all devices is complete, $\overline{\text { SYNC }}$ is taken high. This latches the input data in each device in the daisy chain and prevents any further data from being clocked into the input shift register. The serial clock can be a continuous or a gated clock.

A continuous SCLK source can be used only if $\overline{\text { SYNC }}$ is held low for the correct number of clock cycles. In gated clock mode, a burst clock containing the exact number of clock cycles must be used, and $\overline{\text { SYNC }}$ must be taken high after the final clock to latch the data.

## Readback Operation

Before a readback operation is initiated, the SDO pin must be enabled by writing to the function register and clearing the SDO disable bit; this bit is cleared by default. Readback mode is invoked by setting the $R / \bar{W}$ bit to 1 in the serial input register write. With $\mathrm{R} / \overline{\mathrm{W}}$ set to 1, Bit A2 to Bit A0, in association with Bit REG2 to Bit REG0, select the register to be read. The remaining data bits in the write sequence are don't care. During the next SPI write, the data appearing on the SDO output contains the data from the previously addressed register. For a read of a single register, the NOP command can be used in clocking out the data from the selected register on SDO. The readback diagram in Figure 4 shows the readback sequence. For example, to read back the fine gain register of Channel A, implement the following sequence:

1. Write 0 xA 0 XXXX to the input shift register. This write configures the AD5764R for read mode with the fine gain register of Channel A selected. Note that all the data bits, DB15 to DB0, are don't care.
2. Follow with a second write: an NOP condition, $0 \times 00 \mathrm{XXXX}$. During this write, the data from the fine gain register is clocked out on the SDO line; that is, data clocked out contains the data from the fine gain register in Bit DB5 to Bit DB0.

## SIMULTANEOUS UPDATING VIA $\overline{\text { LDAC }}$

Depending on the status of both $\overline{\text { SYNC }}$ and $\overline{\text { LDAC }}$, and after data has been transferred into the input register of the DACs, there are two ways to update the data registers and DAC outputs.

## Individual DAC Updating

In individual DAC updating mode, $\overline{\mathrm{LDAC}}$ is held low while data is being clocked into the input shift register. The addressed DAC output is updated on the rising edge of $\overline{S Y N C}$.

## Simultaneous Updating of All DACs

In simultaneous updating of all DACs mode, $\overline{\text { LDAC }}$ is held high while data is being clocked into the input shift register. All DAC outputs are updated by taking $\overline{\text { LDAC }}$ low any time after $\overline{\text { SYNC }}$ has been taken high. The update then occurs on the falling edge of $\overline{\text { LDAC }}$.

See Figure 41 for a simplified block diagram of the DAC load circuitry.

Figure 41. Simplified Serial Interface of Input Loading Circuitry for One DAC Channel

## TRANSFER FUNCTION

Table 7 and Table 8 show the ideal input code to output voltage relationship for offset binary data coding and twos complement data coding, respectively.

The output voltage expression for the AD5764R is given by

$$
V_{\text {OUT }}=-2 \times V_{\text {REFIN }}+4 \times V_{\text {REFIN }}\left[\frac{D}{65,536}\right]
$$

where:
$D$ is the decimal equivalent of the code loaded to the DAC. $V_{\text {REFIN }}$ is the reference voltage applied at the REFAB and REFCD pins.

## ASYNCHRONOUS CLEAR ( $\overline{\mathbf{C L R}})$

$\overline{\mathrm{CLR}}$ is a negative edge triggered clear that allows the outputs to be cleared to either 0 V (twos complement coding) or negative full scale (offset binary coding). It is necessary to maintain $\overline{\text { CLR }}$ low for a minimum amount of time for the operation to complete (see Figure 2). When the $\overline{\mathrm{CLR}}$ signal is returned high, the output remains at the cleared value until a new value is programmed. If $\overline{\mathrm{CLR}}$ is at 0 V at power-on, all DAC outputs are updated with the clear value. A clear can also be initiated through software by writing the command of 0 x 04 XXXX .

## FUNCTION REGISTER

The function register is addressed by setting the three REG bits to 000 . The values written to the address bits and the data bits determine the function addressed. The functions available via the function register are outlined in Table 11 and Table 12.

Table 11. Function Register Options

| REG2 | REG1 | REGO | A2 | A1 | A0 | DB15 to DB6 | DB5 | DB4 | DB3 | DB2 | DB1 | DB0 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 0 | 0 | 0 | NOP, data = don't care |  |  |  |  |  |  |
| 0 | 0 | 0 | 0 | 0 | 1 | Don't care | Local ground offset adjust | D1 direction | D1 value | D0 direction | D0 value | SDO disable |
| 0 | 0 | 0 | 1 | 0 | 0 | Clear, data = don't care |  |  |  |  |  |  |
| 0 | 0 | 0 | 1 | 0 | 1 | Load, data = don't care |  |  |  |  |  |  |

Table 12. Explanation of Function Register Options

| Option | Description |
| :--- | :--- |
| NOP | No operation instruction used in readback operations. |
| Local Ground | Set by the user to enable the local ground offset adjust function. Cleared by the user to disable the local ground offset |
| Offset Adjust | adjust function (default). See the Design Features section for more information. |
| D0, D1 | Set by the user to enable the D0 and D1 pins as outputs. Cleared by the user to enable the D0 and D1 pins as inputs (default). |
| Direction | See the Design Features section for more information. |
| D0, D1 Value | I/O port status bits. Logic values written to these locations determine the logic outputs on the D0 and D1 pins when <br> configured as outputs. These bits indicate the status of the D0 and D1 pins when the I/O port is active as an input. When <br> enabled as inputs, these bits are don't cares during a write operation. |
|  | Set by the user to disable the SDO output. Cleared by the user to enable the SDO output (default). <br> SDO Disable <br> Clear |
| Load | Addressing this function resets the DAC outputs to 0 V in twos complement mode and negative full scale in binary mode. <br> Addressing this function updates the DAC registers and consequently the analog outputs. |

## DATA REGISTER

The data register is addressed by setting the three REG bits to 010 . The DAC address bits select the DAC channel with which the data transfer takes place (see Table 10). The data bits are positioned in DB15 to DB0, as shown in Table 13.

Table 13. Programming the Data Register

| REG2 | REG1 | REG0 | A2 | A1 | A0 | DB15 to DB0 |
| :--- | :--- | :--- | :--- | :--- | :--- | :---: |
| 0 | 1 | 0 | DAC address |  | 16-bit DAC data |  |

## COARSE GAIN REGISTER

The coarse gain register is addressed by setting the three REG bits to 011 . The DAC address bits select the DAC channel with which the data transfer takes place (see Table 10). The coarse gain register is a 2 -bit register that allows the user to select the output range of each DAC, as shown in Table 15.

Table 14. Programming the Coarse Gain Register

| REG2 | REG1 | REG0 | A2 | A1 | A0 | DB15 to DB2 | DB1 | DB0 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 1 | 1 | DAC address | Don't care | CG1 | CG0 |  |  |

Table 15. Output Range Selection

| Output Range | CG1 | CG0 |
| :--- | :--- | :--- |
| $\pm 10 \mathrm{~V}$ (Default) | 0 | 0 |
| $\pm 10.2564 \mathrm{~V}$ | 0 | 1 |
| $\pm 10.5263 \mathrm{~V}$ | 1 | 0 |

## FINE GAIN REGISTER

The fine gain register is addressed by setting the three REG bits to 100 . The DAC address bits select the DAC channel with which the data transfer takes place (see Table 10). The AD5764R fine gain register is a 6-bit register that allows the user to adjust the gain of each DAC channel by -32 LSBs to +31 LSBs in 1 LSB steps, as shown in Table 16 and Table 17. The adjustment is made to both the positive full-scale points and the negative full-scale points simultaneously, with each point adjusted by one-half of one step. The fine gain register coding is twos complement.

Table 16. Programming the Fine Gain Register

| REG2 | REG1 | REG0 | A2 | A1 | A0 | DB15 to DB6 | DB5 | DB4 | DB3 | DB2 | DB1 | DB0 |
| :--- | :--- | :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| -31 LSBs | 1 | 0 | 0 | 0 | 0 | 1 |
| -32 LSBs | 1 | 0 | 0 | 0 | 0 | 0 |

## OFFSET REGISTER

The offset register is addressed by setting the three REG bits to 101 . The DAC address bits select the DAC channel with which the data transfer takes place (see Table 10). The AD5764R offset register is an 8-bit register that allows the user to adjust the offset of each channel by -16 LSBs to +15.875 LSBs in steps of one-eighth LSB, as shown in Table 18 and Table 19. The offset register coding is twos complement.

Table 18. Programming the Offset Register

## OFFSET AND GAIN ADJUSTMENT WORKED EXAMPLE

Using the information provided in the Offset Register section, the following worked examples demonstrate how the AD5764R functions can be used to eliminate both offset and gain errors. Because the AD5764R is factory calibrated, offset and gain errors should be negligible. However, errors can be introduced by the system within which the AD5764R is operating. For example, a voltage reference value that is not equal to 5 V introduces a gain error. An output range of $\pm 10 \mathrm{~V}$ and twos complement data coding are assumed.

## Removing Offset Error

The AD5764R can eliminate an offset error in the range of -4.88 mV to +4.84 mV with a step size of one-eighth of a 16-bit LSB.

1. Calculate the step size of the offset adjustment, using the following equation:

Offset Adjust Step Size $=\frac{20}{2^{16} \times 8}=38.14 \mu \mathrm{~V}$
2. Measure the offset error by programming 0x0000 to the data register and measuring the resulting output voltage. For this example, the measured value is $614 \mu \mathrm{~V}$.
3. Determine how many offset adjustment steps this value represents, using the following equation:
Number of Steps $=\frac{\text { Measured Offset Value }}{\text { Offset Step Size }}=\frac{614 \mu \mathrm{~V}}{38.14 \mu \mathrm{~V}}=16$ Steps The offset error measured is positive; therefore, a negative adjustment of 16 steps is required. The offset register is eight bits wide, and the coding is twos complement.

The required offset register value can be calculated as follows:

1. Convert the adjustment value to binary: 00010000 .
2. Convert this binary value to a negative twos complement number by inverting all bits and adding 1: 11110000 .
3. Program this value, 11110000 , to the offset register.

Note that this twos complement conversion is not necessary in the case of a positive offset adjustment. The value to be programmed to the offset register is simply the binary representation of the adjustment value.

## Removing Gain Error

The AD5764R can eliminate a gain error at negative full-scale output in the range of -9.77 mV to +9.46 mV with a step size of one-half of a 16-bit LSB.

1. Calculate the step size of the gain adjustment, using the following equation:

Gain Adjust Step Size $=\frac{20}{2^{16} \times 2}=152.59 \mu \mathrm{~V}$
2. Measure the gain error by programming $0 \times 8000$ to the data register and measuring the resulting output voltage. The gain error is the difference between this value and -10 V . For this example, the gain error is -1.2 mV .
3. Determine how many gain adjustment steps this value represents, using the following equation:

$$
\text { Number of Steps }=\frac{\text { Measured GainValue }}{\text { Gain Step Size }}=\frac{1.2 \mathrm{mV}}{152.59 \mu \mathrm{~V}}=8 \text { Steps }
$$

The gain error measured is negative (in terms of magnitude). Therefore, a positive adjustment of eight steps is required. The gain register is six bits wide, and the coding is twos complement. The required gain register value can be determined as follows:

1. Convert the adjustment value to binary: 001000 .
2. Program this binary number to the gain register.

## DESIGN FEATURES

## ANALOG OUTPUT CONTROL

In many industrial process control applications, it is vital that the output voltage be controlled during power-up and during brownout conditions. When the supply voltages are changing, the VOUTx pins are clamped to 0 V via a low impedance path. To prevent the output amp from being shorted to 0 V during this time, Transmission Gate G1 is also opened (see Figure 42).

Figure 42. Analog Output Control Circuitry
These conditions are maintained until the power supplies stabilize and a valid word is written to the data register. G2 then opens, and G1 closes. Both transmission gates are also externally controllable by using the reset in ( $\overline{\text { RSTIN }}$ ) control input. For example, if $\overline{\text { RSTIN }}$ is driven from a battery supervisor chip, the RSTIN input is driven low to open G1 and close G2 on power-off or during a brownout. Conversely, the on-chip voltage detector output (RSTOUT) is also available to the user to control other parts of the system. The basic transmission gate functionality is shown in Figure 42.

## DIGITAL OFFSET AND GAIN CONTROL

The AD5764R incorporates a digital offset adjust function with a $\pm 16$ LSB adjust range and 0.125 LSB resolution. The gain register allows the user to adjust the AD5764R full-scale output range. The full-scale output can be programmed to achieve full-scale ranges of $\pm 10 \mathrm{~V}, \pm 10.25 \mathrm{~V}$, and $\pm 10.5 \mathrm{~V}$. A fine gain trim is also available.

## PROGRAMMABLE SHORT-CIRCUIT PROTECTION

The short-circuit current ( $\mathrm{I}_{\mathrm{sc}}$ ) of the output amplifiers can be programmed by inserting an external resistor between the ISCC pin and the PGND pin. The programmable range for the current is $500 \mu \mathrm{~A}$ to 10 mA , corresponding to a resistor range of $120 \mathrm{k} \Omega$ to $6 \mathrm{k} \Omega$. The resistor value is calculated as follows:

$$
\mathrm{R} \approx \frac{60}{I_{S C}}
$$

If the ISCC pin is left unconnected, the short circuit current limit defaults to 5 mA . It should be noted that limiting the short-circuit current to a small value can affect the slew rate of the output when driving into a capacitive load. Therefore, the value of the short-circuit current that is programmed should take into account the size of the capacitive load being driven.

## DIGITAL I/O PORT

The AD5764R contains a 2-bit digital I/O port (D1 and D0). These bits can be configured independently as inputs or outputs and can be driven or have their values read back via the serial interface. The I/O port signals are referenced to $\mathrm{DV}_{\mathrm{CC}}$ and DGND . When configured as outputs, they can be used as control signals to multiplexers or can be used to control calibration circuitry elsewhere in the system. When configured as inputs, the logic signals from limit switches, for example, can be applied to D0 and D1 and can be read back using the digital interface.

## DIE TEMPERATURE SENSOR

The on-chip die temperature sensor provides a voltage output that is linearly proportional to the Celsius temperature scale. Its nominal output voltage is 1.47 V at $+25^{\circ} \mathrm{C}$ die temperature, varying at $5 \mathrm{mV} /{ }^{\circ} \mathrm{C}$, giving a typical output range of 1.175 V to 1.9 V over the full temperature range. Its low output impedance, and linear output simplify interfacing to temperature control circuitry and analog-to-digital converters (ADCs). The temperature sensor is provided as more of a convenience than as a precise feature; it is intended for indicating a die temperature change for recalibration purposes.

## LOCAL GROUND OFFSET ADJUST

The AD5764R incorporates a local ground offset adjust feature that, when enabled in the function register, adjusts the DAC outputs for voltage differences between the individual DAC ground pins and the REFGND pin, ensuring that the DAC output voltages are always referenced to the local DAC ground pin. For example, if the AGNDA pin is at +5 mV with respect to the REFGND pin, and VOUTA is measured with respect to AGNDA, a -5 mV error results, enabling the local ground offset adjust feature to adjust VOUTA by +5 mV , thereby eliminating the error.

## APPLICATIONS INFORMATION <br> TYPICAL OPERATING CIRCUIT

Figure 43 shows the typical operating circuit for the AD5764R. The only external components needed for this precision 16-bit DAC are decoupling capacitors on the supply pins and reference inputs, and an optional short-circuit current setting resistor. Because the AD5764R incorporates a voltage reference and reference buffers, it eliminates the need for an external bipolar reference and associated buffers, resulting in an overall savings in both cost and board space.

In Figure 43, AVDD is connected to +15 V , and AVSS is connected to -15 V , but $A V_{\mathrm{DD}}$ and $A V_{\mathrm{ss}}$ can operate with supplies from $\pm 11.4 \mathrm{~V}$ to $\pm 16.5 \mathrm{~V}$. In Figure 43 , AGNDx is connected to REFGND.

## Precision Voltage Reference Selection

To achieve the optimum performance from the AD5764R over its full operating temperature range, an external voltage reference must be used. Care must be taken in the selection of a precision voltage reference. The AD5764R has two reference inputs, REFAB and REFCD. The voltages applied to the reference inputs are used to provide a buffered positive and negative reference for the DAC cores. Therefore, any error in the voltage reference is reflected in the outputs of the device.

There are four possible sources of error to consider when choosing a voltage reference for high accuracy applications: initial accuracy, temperature coefficient of the output voltage, long term drift, and output voltage noise.

Initial accuracy error on the output voltage of an external reference could lead to a full-scale error in the DAC. Therefore, to minimize these errors, a reference with low initial accuracy error specification is preferred. Choosing a reference with an output trim adjustment, such as the ADR425, allows a system designer to trim system errors out by setting the reference voltage to a voltage other than the nominal. The trim adjustment can also be used at temperature to trim out any error.
Long-term drift is a measure of how much the reference output voltage drifts over time. A reference with a tight long-term drift specification ensures that the overall solution remains relatively stable over its entire lifetime.
The temperature coefficient of a reference output voltage affects INL, DNL, and TUE. A reference with a tight temperature coefficient specification should be chosen to reduce the dependence of the DAC output voltage on ambient conditions.
In high accuracy applications, which have a relatively low noise budget, reference output voltage noise must be considered. It is important to choose a reference with as low an output noise voltage as practical for the system resolution that is required. Precision voltage references, such as the ADR435 (XFET ${ }^{\circledR}$ design), produce low output noise in the 0.1 Hz to 10 Hz region. However, as the circuit bandwidth increases, filtering the output of the reference may be required to minimize the output noise.

Table 20. Some Precision References Recommended for Use with the AD5764R

| Part No. | Initial Accuracy <br> $(\mathbf{m V}$ Maximum) | Long-Term Drift <br> (ppm Typical) | Temperature Drift <br> (ppm/ ${ }^{\circ}$ C Maximum) | $\mathbf{0 . 1 ~ H z ~ t o ~ 1 0 ~ H z ~ N o i s e ~}$ <br> ( $\boldsymbol{\mu}$ V p-p Typical) |
| :--- | :--- | :--- | :--- | :--- |
| ADR435 | $\pm 6$ | 30 | 3 | 3.5 |
| ADR425 | $\pm 6$ | 50 | 3 | 3.4 |
| ADR02 | $\pm 5$ | 50 | 3 | 10 |
| ADR395 | $\pm 6$ | 50 | 25 | 5 |
| AD586 | $\pm 2.5$ | 15 | 10 | 4 |

## LAYOUT GUIDELINES

In any circuit where accuracy is important, careful consideration of the power supply and ground return layout helps to ensure the rated performance. Design the PCB on which the AD5764R is mounted such that the analog and digital sections are separated and confined to certain areas of the board. If the AD5764R is in a system where multiple devices require an AGNDx-to-DGND connection, establish the connection at one point only. Establish the star ground point as close as possible to the device. The AD5764R should have ample supply bypassing of $10 \mu \mathrm{~F}$ in parallel with $0.1 \mu \mathrm{~F}$ on each supply located as close to the package as possible, ideally right up against the device. The $10 \mu \mathrm{~F}$ capacitors are of the tantalum bead type. The $0.1 \mu \mathrm{~F}$ capacitor should have low effective series resistance (ESR) and low effective series inductance (ESI), such as the common ceramic types that provide a low impedance path to ground at high frequencies to handle transient currents due to internal logic switching.
The power supply lines of the AD5764R should use as large a trace as possible to provide low impedance paths and reduce the effects of glitches on the power supply line. Shield fast-switching signals, such as clocks, with digital ground to avoid radiating noise to other parts of the board; they should never be run near the reference inputs. A ground line routed between the SDIN and SCLK lines helps reduce cross talk between them. (A ground line is not required on a multilayer board because it has a separate ground plane; however, it is helpful to separate the lines.) It is essential to minimize noise on the reference inputs because it couples through to the DAC output. Avoid crossover of digital and analog signals. Run traces on opposite sides of the board at right
angles to each other to reduce the effects of feedthrough on the board. A microstrip technique is recommended but not always possible with a double-sided board. In this technique, the component side of the board is dedicated to the ground plane, and the signal traces are placed on the solder side.

## GALVANICALLY ISOLATED INTERFACE

In many process control applications, it is necessary to provide an isolation barrier between the controller and the unit being controlled to protect and isolate the controlling circuitry from any hazardous common-mode voltages that may occur. Isocouplers provide voltage isolation in excess of 2.5 kV . The serial loading structure of the AD5764R makes it ideal for isolated interfaces because the number of interface lines is kept to a minimum. Figure 44 shows a 4 -channel isolated interface to the AD5764R using an ADuM1400 iCoupler ${ }^{\ominus}$ product. For more information on iCoupler products, refer to www.analog.com.

## MICROPROCESSOR INTERFACING

Microprocessor interfacing to the AD5764R is accomplished via a serial bus that uses standard protocol that is compatible with microcontrollers and DSP processors. The communication channel is a 3-wire (minimum) interface consisting of a clock signal, a data signal, and a synchronization signal. The AD5764R requires a 24 -bit data-word with data valid on the falling edge of SCLK.

For all the interfaces, a DAC output update can be performed automatically when all the data is clocked in, or it can be done under the control of LDAC. The contents of the DAC register can be read using the readback function.

*ADDITIONAL PINS OMITTED FOR CLARITY.

## EVALUATION BOARD

The AD5764R comes with a full evaluation board to help designers evaluate the high performance of the part with a minimum of effort. All that is required to run the evaluation board is a power supply and a PC. The AD5764R evaluation kit includes a populated, tested AD5764R PCB. The evaluation board interfaces to
the USB interface of the PC. Software that allows easy programming of the AD5764R is available with the evaluation board. The software runs on any PC that has Microsoft ${ }^{\circ}$ Windows ${ }^{\text {® }}$ 2000/XP installed.
