

VERSATILE TELEPHONE TRANSMISSION CIRCUITS WITH DIALLER INTERFACE

GENERAL DESCRIPTION

The TEA1060 and TEA1061 are bipolar integrated circuits performing all speech, and line interface functions required in fully electronic telephone sets. The circuits internally perform electronic switching between dialling and speech.

Features

- Voltage regulator with adjustable static resistance
- Provides supply for external circuitry
- Symmetrical low-impedance inputs for dynamic and magnetic microphones (TEA1060)
- Symmetrical high-impedance inputs for piezoelectric microphone (TEA1061)
- Asymmetrical high-impedance input for electret microphone (TEA1061)
- DTMF signal input with confidence tone
- Mute input for pulse or DTMF dialling
- Power down input for pulse dial or register recall
- Receiving amplifier for magnetic, dynamic or piezoelectric earpieces
- Large amplification setting range on microphone and earpiece amplifiers
- Line loss compensation facility, line current dependent (microphone and earpiece amplifiers)
- Gain control adaptable to exchange supply
- DC line voltage adjustment facility

16	REG	voltage regulator decoupling
17	AGC	automatic gain control input
18	SLPE	slope (DC resistance) adjustment

FUNCTIONAL DESCRIPTION

Supply: VCC, LN, SLPE, REG and STAB

The circuit and its peripheral circuits are usually supplied from the telephone line. The circuit develops its own supply voltage at VCC and regulates its voltage drop. The supply voltage VCC may also be used to supply external peripheral circuits, e.g. dialling and control circuits.

The supply has to be decoupled by connecting a smoothing capacitor between VCC and VEE; the internal voltage regulator has to be decoupled by a capacitor from REG to VEE. An internal current stabilizer is set by a resistor of 3.6 kΩ between STAB and VEE.

The DC current flowing into the set is determined by the exchange supply voltage (V_{exch}), the feeding bridge resistance (R_{exch}), the DC resistance of the subscriber line (R_{line}) and the DC voltage on the subscriber set (see Fig.4).

If the line current (I_{line}) exceeds the current $I_{CC} + 0.5$ mA required by the circuit itself (I_{CC} ca. 1 mA), plus the current I_p required by the peripheral circuits connected to VCC, then the voltage regulator diverts the excess current via LN.

The voltage regulator adjusts the average voltage on LN to:

$$V_{LN} = V_{ref} + I_{SLPE} \times R_9 = V_{ref} + (I_{line} - I_{CC} - 0.5 \times 10^{-3} \text{ A} - I_p) \times R_9.$$

V_{ref} being an internally generated temperature compensated reference voltage of 4.2 V and R_9 being an external resistor connected between SLPE and VEE. The preferred value of R_9 is 20 Ω. Changing R_9 will have influence on microphone gain, DTMF gain, gain control characteristics, side tone and maximum output swing on LN.

Under normal conditions $I_{SLPE} \gg I_{CC} + 0.5$ mA + I_p . The static behaviour of the circuit then equals a 4.2 V voltage regulator diode with an internal resistance R_9 . In the audio frequency range the dynamic impedance equals R_9 . The internal reference voltage can be adjusted by means of an external resistor R_{VA} . This resistor connected between pins 1 and 16 (LN and REG) will decrease the internal reference voltage. R_{VA} connected between pins 16 and 18 (REG and SLPE) will increase the internal reference voltage.

Supply: V_{CC} , LN, SLPE, REG and STAB (continued)

The current I_p available from V_{CC} for supplying peripheral circuits depends on external components and on the line current. Fig.5 shows this current for $V_{CC} > 2.2$ V and for $V_{CC} > 3$ V, of which 3 V is the minimum supply voltage for most CMOS circuits including a diode voltage drop for an enable diode. If MUTE is LOW the available current is further reduced when the receiving amplifier is driven.

Microphone inputs MIC+ and MIC– and gain adjustment connections GAS1 and GAS2

The TEA1060 and TEA1061 have symmetrical microphone inputs.

The TEA1060 is intended for low-sensitivity low-impedance dynamic or magnetic microphones. Its input impedance is $8.2\text{ k}\Omega$ ($2 \times 4.1\text{ k}\Omega$) and its voltage amplification is typ. 52 dB.

The TEA1061 is intended for a piezoelectric microphone or an electret microphone with built-in FET source follower. Its input impedance is $40.8\text{ k}\Omega$ ($2 \times 20.4\text{ k}\Omega$) and its voltage amplification is typ. 38 dB.

The arrangements with the microphone types mentioned are shown in Fig.6.

The gain of the microphone amplifier in both types can be adjusted over a range of + and -8 dB to suit the sensitivity of the transducer used. The gain is proportional to external resistor R7 connected between GAS1 and GAS2.

An external capacitor (C6) of 100 pF between GAS1 and SLPE is required to ensure stability. A larger value may be chosen to obtain a first-order low-pass filter. The cut-off frequency corresponds with the time constant $R7 \times C6$.

Mute input MUTE

A HIGH level at MUTE enables the DTMF input and inhibits the microphone inputs and the receiving amplifier, a LOW level or an open circuit does the reverse. Switching the mute input will cause negligible clicks at the telephone outputs and on the line.

Dual-tone multi-frequency input DTMF

When the DTMF input is enabled, dialling tones may be sent onto the line. The voltage gain from DTMF to LN is typ. 25.5 dB and varies with R7 in the same way as the gain of the microphone amplifier. The signalling tones can be heard in the earpiece at a low level (confidence tone).

Receiving amplifier: IR, QR+, QR– and GAR

The receiving amplifier has one input IR and two complementary outputs, a non-inverting output QR+ and an inverting output QR–. These outputs may be used for single-ended or for differential drive, depending on the sensitivity and type of earpiece used (see Fig.7). The gain from IR to QR+ is typ. 25 dB. This will be sufficient for low-impedance magnetic or dynamic earpieces; these are suited for single-ended drive. By using both outputs (differential drive) the gain is increased by 6 dB and differential drive becomes possible.

This feature can be used in case the earpiece impedance exceeds $450\ \Omega$ (high-impedance dynamic, magnetic or piezoelectric earpieces).

The output voltage of the receiving amplifier is specified for continuous-wave drive. The maximum output voltage will be higher under speech conditions, where the ratio of peak and RMS value is higher.

The gain of the receiving amplifier can be adjusted over a range of + and -8 dB to suit the sensitivity of the transducer used. The gain is proportional to external resistor R4 connected from GAR to QR+.

Two external capacitors $C4 = 100\text{ pF}$ and $C7 = 10 \times C4 = 1\text{ nF}$ are necessary to ensure stability. A larger value of C4 may be chosen to obtain a first-order low-pass filter. The "cut-off" frequency corresponds with the time constant $R4 \times C4$.

Automatic gain control input AGC

Automatic line loss compensation will be obtained by connecting a resistor R6 from AGC to V_{EE} . This automatic gain control varies the gain of the microphone amplifier and the receiving amplifier in accordance with the DC line current. The control range is 6 dB. This corresponds with a line length of 5 km for a 0.5 mm diameter copper twisted-pair cable with a DC resistance of 176 Ω /km and an average attenuation of 1.2 dB/km.

Resistor R6 should be chosen in accordance with the exchange supply voltage and its feeding bridge resistance (see Fig.8 and Table 1). Different values of R6 give the same ratio of line currents for begin and end of the control range. If automatic line loss compensation is not required AGC may be left open. The amplifiers then all give their maximum gain as specified.

Power-down input PD

During pulse dialling or register recall (timed loop break) the telephone line is interrupted, as a consequence it provides no supply for the transmission circuit and the peripherals connected to V_{CC} . These gaps have to be bridged by the charge in the smoothing capacitor C1. The requirements on this capacitor are relaxed by applying a HIGH level to the PD input during the time of the loop break, which reduces the supply current from typ. 1 mA to typ. 55 μ A.

A HIGH level at PD further disconnects the capacitor at REG, with the effect that the voltage stabilizer will have no switch-on delay after line interruptions. This results in no contribution of the IC to the current waveform during pulse dialling or register recall.

When this facility is not required PD may be left open.

Side-tone suppression

Suppression of the transmitted signal in the earpiece is obtained by the antiside-tone network consisting of R1// Z_{line} , R2, R3, R8 and Z_{bal} (see Fig.11). Maximum compensation is obtained when the following conditions are fulfilled:

$$\begin{aligned} \text{a) } R9.R2 &= R1 \{ R3 + (R8//Z_{bal}) \} \\ \text{b) } |Z_{bal}/(Z_{bal} + R8)| &= |Z_{line}/(Z_{line} + R1)| \end{aligned}$$

If fixed values are chosen for R1, R2, R3 and R9, then condition a) will always be fulfilled provided that $|R8//Z_{bal}| \ll R3$.

To obtain optimum side-tone-suppression, condition (b) has to be fulfilled resulting in:

$$Z_{bal} = (R8/R1)Z_{line} = k.Z_{line}$$

where k is a scale factor; $k = (R8/R1)$

Scale factor k (value of R8) must be chosen to meet the following criteria:

- compatibility with a standard capacitor from the E6 or E12 range for Z_{bal}
- $|Z_{bal}/R8| \ll R3$
- $|Z_{bal} + R8| \gg R9$

In practice Z_{line} varies strongly with line length and cable type; consequently an average value has to be chosen for Z_{bal} . The suppression further depends on the accuracy with which Z_{bal} equals the average line impedance.

The anti-side-tone network as used in the standard application (Fig.11) attenuates the signal from the line with 32 dB. The attenuation is nearly flat over the audio-frequency range.

Instead of the above described special bridge, the conventional Wheatstone bridge configuration can be used as an alternative anti-side tone circuit. Both bridges can be used with either a resistive set impedance or with a complex set impedance.

RATINGS

Limiting values in accordance with the Absolute Maximum System (IEC 134)

parameter	conditions	symbol	min.	max.	unit
Positive continuous line voltage		V_{LN}	—	12	V
Repetitive line voltage during switch-on or line interruption		V_{LN}	—	13.2	V
Repetitive peak line voltage for a 1 ms pulse per 5 s	$R_{10} = 13 \Omega$; $R_9 = 20 \Omega$; (see Fig.11)	V_{LN}	—	28	V
Line current TEA1060 (1)	$R_9 = 20 \Omega$	I_{line}	—	140	mA
Line current TEA1061 (1)	$R_9 = 20 \Omega$	I_{line}	—	140	mA
Voltage on all other pins		V_i	—	$V_{CC} + 0.7$	V
		$-V_i$	—	0.7	V
Total power dissipation (2)		P_{tot}	—	769	mW
Storage temperature range		T_{stg}	-40	+125	°C
Operating ambient temperature range		T_{amb}	-25	+75	°C
Junction temperature		T_j	—	+125	°C

1. Mostly dependent on the maximum required T_{amb} and the voltage between LN and SLPE (see Fig.3).
2. Calculated for the maximum ambient temperature specified $T_{amb} = 75 \text{ }^\circ\text{C}$ and a maximum junction temperature of $125 \text{ }^\circ\text{C}$.

THERMAL RESISTANCE

From junction to ambient in free air
