

16-bit MCU with 512 Kbyte Flash memory and 36 Kbyte RAM

Features

- High performance 16-bit CPU with DSP functions
 - 31.25 ns instruction cycle time at 64 MHz max CPU clock
 - Multiply/accumulate unit (MAC) 16 x 16-bit multiplication, 40-bit accumulator
 - Enhanced boolean bit manipulations
 - Single-cycle context switching support
- Memory organization
 - 512 Kbyte on-chip Flash memory single voltage with erase/program controller (full performance, 32-bit fetch)
 - 100K erasing/programming cycles.
 - Up to 16 Mbyte linear address space for code and data (5 Mbytes with CAN or I²C)
 - 2 Kbyte on-chip internal RAM (IRAM)
 - 34 Kbyte on-chip extension RAM (XRAM)
 - Programmable external bus configuration & characteristics for different address ranges
 - 5 programmable chip-select signals
 - Hold-acknowledge bus arbitration support
- Interrupt
 - 8-channel peripheral event controller for single cycle interrupt driven data transfer
 - 16-priority-level interrupt system with 56 sources, sampling rate down to 15.6 ns
- Timers
 - 2 multifunctional general purpose timer units with 5 timers
- Two 16-channel capture / compare units
- 4-channel PWM unit + 4-channel XPWM

- A/D Converter
 - 24-channel 10-bit
 - 3 µs Minimum conversion time
- Serial channels
 - 2 synch. / asynch. serial channels
 - 2 high-speed synchronous channels
 - I²C standard interface
- 2 CAN 2.0B interfaces operating on 1 or 2 CAN busses (64 or 2x32 messages, C-CAN version)
- Fail-safe protection
 - Programmable watchdog timer
 - Oscillator watchdog
- On-chip bootstrap loader
- Clock generation
 - On-chip PLL and 4 to 12 MHz oscillator
 - Direct or prescaled clock input
- Real-time clock and 32 kHz on-chip oscillator
- Up to 111 general purpose I/O lines
 - Individually programmable as input, output or special function
 - Programmable threshold (hysteresis)
- Idle, power down and stand-by modes
- Single voltage supply: 5 V ±10%.

Table 1. Device summary

Part Number	Package	Max CPU frequency	Flash	Xflash	RAM	Temperature range (°C)

1 Introduction

The ST10F273Z4 device is a derivative of the STMicroelectronics ST10 family of 16-bit single-chip CMOS microcontrollers.

The ST10F273Z4 combines high CPU performance (up to 32 million instructions per second) with high peripheral functionality and enhanced I/O-capabilities. It also provides on-chip high-speed single voltage Flash memory, on-chip high-speed RAM, and clock generation via PLL.

ST10F273Z4 is processed in 0.18mm CMOS technology. The MCU core and the logic is supplied with a 5 V to 1.8 V on-chip voltage regulator. The part is supplied with a single 5 V supply and I/Os work at 5 V.

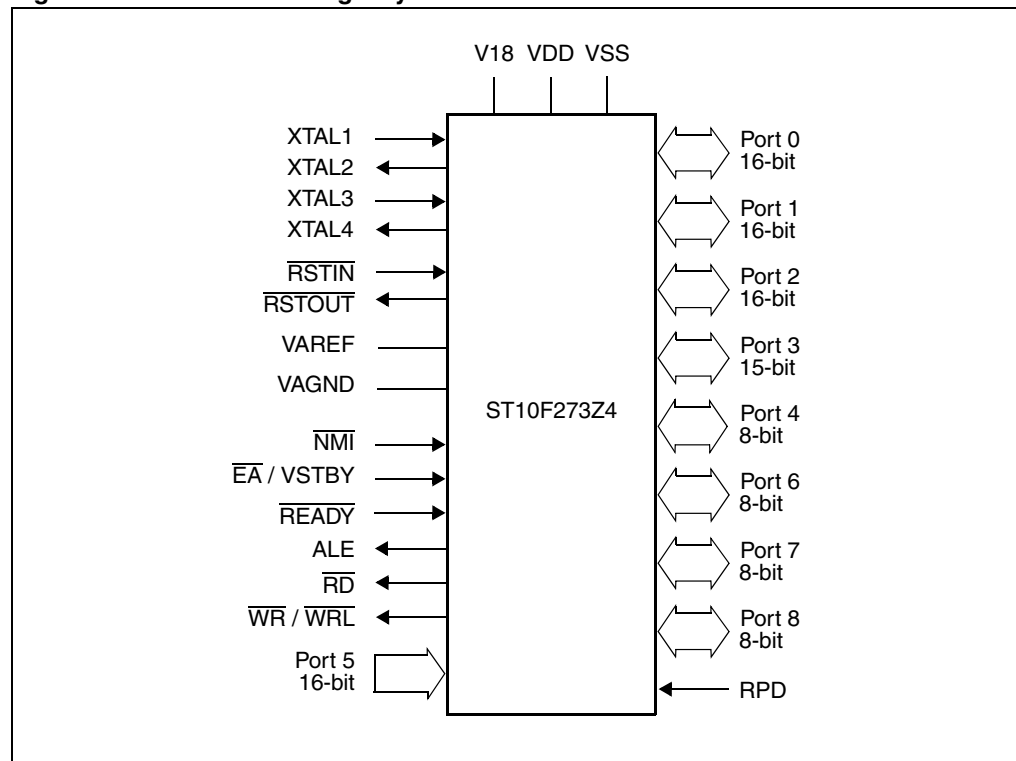

The device is upward compatible with the ST10F269 device, with the following set of differences:

- Flash control interface is now based on STMicroelectronics third generation of stand-alone Flash memories (M29F400 series), with an embedded Program/Erase Controller. This completely frees up the CPU during programming or erasing the Flash.
- Only one supply pin (ex DC1 in ST10F269, renamed into V18) on the QFP144 package is used for decoupling the internally generated 1.8V core logic supply. Do not connect this pin to 5.0 V external supply. Instead, this pin should be connected to a decoupling capacitor (ceramic type, typical value 10nF, maximum value 100nF).
- The AC and DC parameters are modified due to a difference in the maximum CPU frequency.
- A new V_{DD} pin replaces DC2 of ST10F269.
- $\bar{E}A$ pin assumes a new alternate functionality: it is also used to provide a dedicated power supply (see VSTBY) to maintain biased a portion of the XRAM (16 Kbytes) when the main Power Supply of the device (V_{DD} and consequently the internally generated V18) is turned off for low power mode, allowing data retention. VSTBY voltage shall be in the range 4.5 to 5.5 volts and a dedicated embedded low power voltage regulator is in charge to provide the 1.8 V for the RAM, the low-voltage section of the 32 kHz oscillator and the Real-Time Clock module when not disabled. It is allowed to exceed the upper limit up to 6 V for a very short period of time during the global life of the device and exceed the lower limit down to 4 V when RTC and 32 kHz on-chip oscillator are not used.
- A second SSC mapped on the XBUS is added (SSC of ST10F269 becomes here SSC0, while the new one is referred as XSSC or simply SSC1). Note that some restrictions and functional differences due to the XBUS peculiarities are present between the classic SSC and the new XSSC.
- A second ASC mapped on the XBUS is added (ASC0 of ST10F269 remains ASC0, while the new one is referred as XASC or simply as ASC1). Note that some restrictions and functional differences due to the XBUS peculiarities are present between the classic ASC and the new XASC.
- A second PWM mapped on the XBUS is added (PWM of ST10F269 becomes here PWM0, while the new one is referred as XPWM or simply as PWM1). Note that some

restrictions and functional differences due to the XBUS peculiarities are present between the classic PWM and the new XPWM.

- An I2C interface on the XBUS is added (see X-I2C or simply I2C interface).
- CLKOUT function can output either the CPU clock (like in ST10F269) or a software programmable prescaled value of the CPU clock.
- On-chip RAM memory and FLASH size have been increased.
- PLL multiplication factors have been adapted to new frequency range.
- A/D Converter is not fully compatible versus ST10F269 (timing and programming model). Formula for the conversion time is still valid, while the sampling phase programming model is different.
Besides, additional 8 channels are available on P1L pins as alternate function: The accuracy reachable with these extra channels is reduced with respect to the standard Port5 channels.
- External Memory bus is affected by limitations on maximum speed and maximum capacitance load: ST10F273Z4 is not able to address an external memory at 64 MHz with 0 wait states.
- XPERCON register bit mapping modified according to new peripherals implementation (not fully compatible with ST10F269).
- Bondout chip for emulation (ST10R201) cannot achieve more than 50MHz at room temperature (so no real-time emulation possible at maximum speed).
- Input section characteristics are different. The threshold programmability is extended to all port pins (additional XPICON register); it is possible to select standard TTL (with up to 400mV of hysteresis) and standard CMOS (with up to 750mV of hysteresis).
- Output transition is not programmable.
- CAN module is enhanced: ST10F273Z4 implements two C-CAN modules, so the programming model is slightly different. Besides, the possibility to map in parallel the two CAN modules is added (on P4.5/P4.6).
- On-chip main oscillator input frequency range has been reshaped, reducing it from 1 to 25 MHz down to 4 to 12 MHz. This is a low power oscillator amplifier, that allows a power consumption reduction when Real-Time Clock is running in Power down mode, using as reference the on-chip main oscillator clock. When this on-chip amplifier is used as reference for Real-Time Clock module, the Power-down consumption is dominated by the consumption of the oscillator amplifier itself.
- A second on-chip oscillator amplifier circuit (32 kHz) is implemented for low power modes: it can be used to provide the reference to the Real-Time Clock counter (either in Power down or Stand-by mode). Pin XTAL3 and XTAL4 replace a couple of V_{DD}/V_{SS} pins of ST10F269.

2 Pin data

Figure 2. Pin configuration (top view)

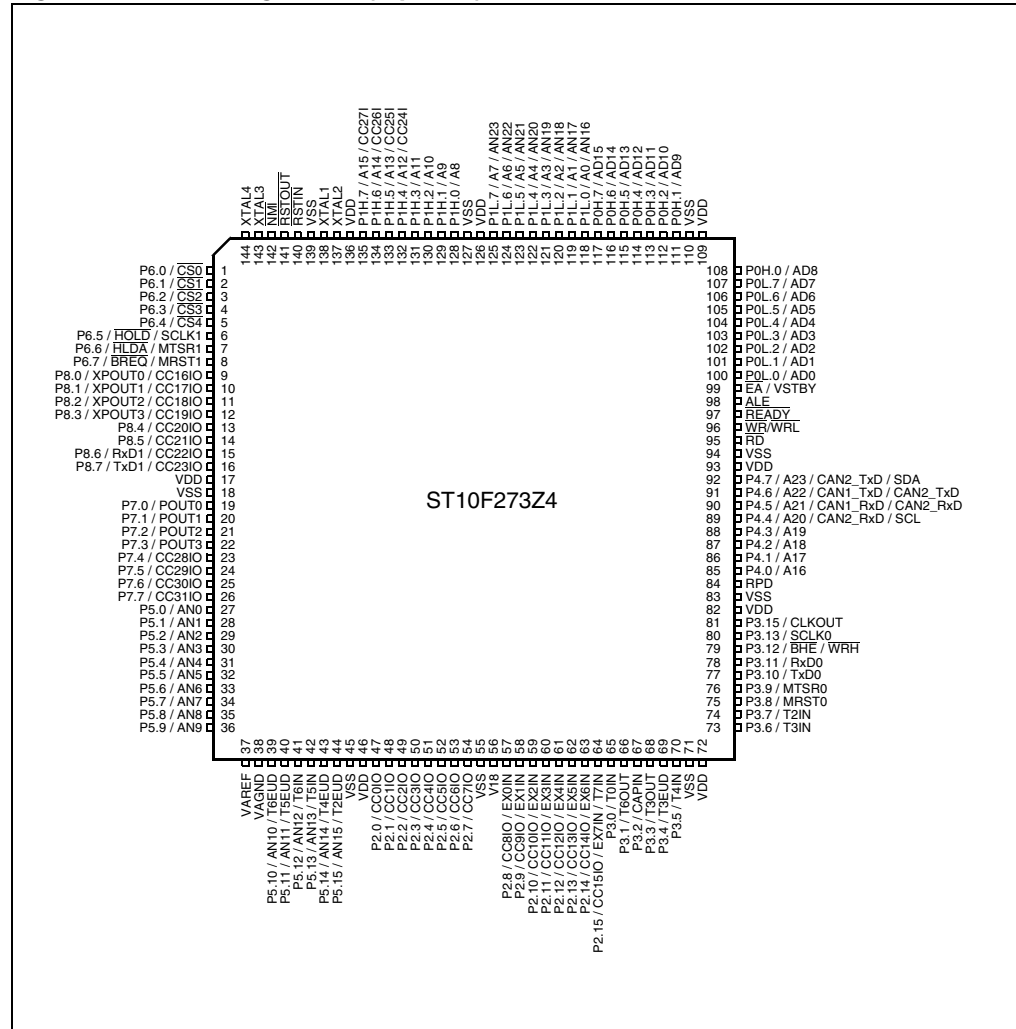

Table 2. Pin description

Symbol	Pin	Type	Function		
P6.0 - P6.7	1 - 8	I/O	8-bit bidirectional I/O port, bit-wise programmable for input or output via direction bit. Programming an I/O pin as input forces the corresponding output driver to high impedance state. Port 6 outputs can be configured as push-pull or open drain drivers. The input threshold of Port 6 is selectable (TTL or CMOS). The following Port 6 pins have alternate functions:		
	1	O	P6.0	$\overline{CS0}$	Chip select 0 output

	5	O	P6.4	$\overline{CS4}$	Chip select 4 output
	6	I	P6.5	\overline{HOLD}	External master hold request input
		I/O		SCLK1	SSC1: master clock output / slave clock input
	7	O	P6.6	\overline{HLDA}	Hold acknowledge output
		I/O		MTSR1	SSC1: master-transmitter / slave-receiver O/I
P8.0 - P8.7	8	O	P6.7	\overline{BREQ}	Bus request output
		I/O		MRST1	SSC1: master-receiver / slave-transmitter I/O
	9-16	I/O	8-bit bidirectional I/O port, bit-wise programmable for input or output via direction bit. Programming an I/O pin as input forces the corresponding output driver to high impedance state. Port 8 outputs can be configured as push-pull or open drain drivers. The input threshold of Port 8 is selectable (TTL or CMOS). The following Port 8 pins have alternate functions:		
	9	I/O	P8.0	CC16IO	CAPCOM2: CC16 capture input / compare output
		O		XPWM0	PWM1: channel 0 output

	12	I/O	P8.3	CC19IO	CAPCOM2: CC19 capture input / compare output
		O		XPWM0	PWM1: channel 3 output
	13	I/O	P8.4	CC20IO	CAPCOM2: CC20 capture input / compare output
	14	I/O	P8.5	CC21IO	CAPCOM2: CC21 capture input / compare output
	15	I/O	P8.6	CC22IO	CAPCOM2: CC22 capture input / compare output
		I/O		RxD1	ASC1: Data input (Asynchronous) or I/O (Synchronous)
	16	I/O	P8.7	CC23IO	CAPCOM2: CC23 capture input / compare output
		O		TxD1	ASC1: Clock / Data output (Asynchronous/Synchronous)

Table 2. Pin description (continued)

Symbol	Pin	Type	Function		
P7.0 - P7.7	19-26	I/O	8-bit bidirectional I/O port, bit-wise programmable for input or output via direction bit. Programming an I/O pin as input forces the corresponding output driver to high impedance state. Port 7 outputs can be configured as push-pull or open drain drivers. The input threshold of Port 7 is selectable (TTL or CMOS). The following Port 7 pins have alternate functions:		
	19	O	P7.0	POUT0	PWM0: channel 0 output

	22	O	P7.3	POUT3	PWM0: channel 3 output
	23	I/O	P7.4	CC28IO	CAPCOM2: CC28 capture input / compare output

P5.0 - P5.9 P5.10 - P5.15	27-36 39-44	I	16-bit input-only port with Schmitt-Trigger characteristics. The pins of Port 5 can be the analog input channels (up to 16) for the A/D converter, where P5.x equals ANx (Analog input channel x), or they are timer inputs. The input threshold of Port 5 is selectable (TTL or CMOS). The following Port 5 pins have alternate functions:		
	39	I	P5.10	T6EUD	GPT2: timer T6 external up/down control input
	40	I	P5.11	T5EUD	GPT2: timer T5 external up/down control input
	41	I	P5.12	T6IN	GPT2: timer T6 count input
	42	I	P5.13	T5IN	GPT2: timer T5 count input
	43	I	P5.14	T4EUD	GPT1: timer T4 external up/down control input
P2.0 - P2.7 P2.8 - P2.15	47-54 57-64	I/O	16-bit bidirectional I/O port, bit-wise programmable for input or output via direction bit. Programming an I/O pin as input forces the corresponding output driver to high impedance state. Port 2 outputs can be configured as push-pull or open drain drivers. The input threshold of Port 2 is selectable (TTL or CMOS). The following Port 2 pins have alternate functions:		
	47	I/O	P2.0	CC0IO	CAPCOM: CC0 capture input/compare output

	54	I/O	P2.7	CC7IO	CAPCOM: CC7 capture input/compare output
	57	I/O	P2.8	CC8IO	CAPCOM: CC8 capture input/compare output
		I		EX0IN	Fast external interrupt 0 input

	64	I/O	P2.15	CC15IO	CAPCOM: CC15 capture input/compare output
		I		EX7IN	Fast external interrupt 7 input
		I		T7IN	CAPCOM2: timer T7 count input

Table 2. Pin description (continued)

	70	I	P3.5	T4IN	GPT1; timer T4 input for count/gate/reload/capture
	73	I	P3.6	T3IN	GPT1: timer T3 count/gate input
	74	I	P3.7	T2IN	GPT1: timer T2 input for count/gate/reload / capture
	75	I/O	P3.8	MRST0	SSC0: master-receiver/slave-transmitter I/O
	76	I/O	P3.9	MTSR0	SSC0: master-transmitter/slave-receiver O/I
	77	O	P3.10	TxD0	ASC0: clock / data output (asynchronous/synchronous)
	78	I/O	P3.11	RxD0	ASC0: data input (asynchronous) or I/O (synchronous)
	79	O	P3.12	$\overline{\text{BHE}}$	External memory high byte enable signal
				$\overline{\text{WRH}}$	External memory high byte write strobe
	80	I/O	P3.13	SCLK0	SSC0: master clock output / slave clock input
	81	O	P3.15	CLKOUT	System clock output (programmable divider on CPU clock)

Table 2. Pin description (continued)

Symbol	Pin	Type	Function		
P4.0 –P4.7	85-92	I/O	Port 4 is an 8-bit bidirectional I/O port. It is bit-wise programmable for input or output via direction bit. Programming an I/O pin as input forces the corresponding output driver to high impedance state. The input threshold is selectable (TTL or CMOS). Port 4.4, 4.5, 4.6 and 4.7 outputs can be configured as push-pull or open drain drivers. In case of an external bus configuration, Port 4 can be used to output the segment address lines:		
	85	O	P4.0	A16	Segment address line
	86	O	P4.1	A17	Segment address line
	87	O	P4.2	A18	Segment address line
	88	O	P4.3	A19	Segment address line
	89	O	P4.4	A20	Segment address line
		I		CAN2_RxD	CAN2: receive data input
		I/O		SCL	I ² C Interface: serial clock
	90	O	P4.5	A21	Segment address line
		I		CAN1_RxD	CAN1: receive data input
		I		CAN2_RxD	CAN2: receive data input
	91	O	P4.6	A22	Segment address line
		O		CAN1_TxD	CAN1: transmit data output
		O		CAN2_TxD	CAN2: transmit data output
	92	O	P4.7	A23	Most significant segment address line
		O		CAN2_TxD	CAN2: transmit data output
		I/O		SDA	I ² C Interface: serial data
\overline{RD}	95	O	External memory read strobe. \overline{RD} is activated for every external instruction or data read access.		
$\overline{WR}/\overline{WRL}$	96	O	External memory write strobe. In \overline{WR} -mode this pin is activated for every external data write access. In \overline{WRL} mode this pin is activated for low byte data write accesses on a 16-bit bus, and for every data write access on an 8-bit bus. See WRCFG in the SYSCON register for mode selection.		
READY/ \overline{READY}	97	I	Ready input. The active level is programmable. When the ready function is enabled, the selected inactive level at this pin, during an external memory access, will force the insertion of waitstate cycles until the pin returns to the selected active level.		
ALE	98	O	Address latch enable output. In case of use of external addressing or of multiplexed mode, this signal is the latch command of the address lines.		

Table 2. Pin description (continued)

Symbol	Pin	Type	Function																				
$\overline{\text{EA}} / \text{V}_{\text{STBY}}$	99	I	External access enable pin. A low level applied to this pin during and after Reset forces the ST10F273Z4 to start the program from the external memory space. A high level forces ST10F273Z4 to start in the internal memory space. This pin is also used (when Stand-by mode is entered, that is ST10F273Z4 under reset and main V_{DD} turned off) to bias the 32 kHz oscillator amplifier circuit and to provide a reference voltage for the low-power embedded voltage regulator which generates the internal 1.8V supply for the RTC module (when not disabled) and to retain data inside the Stand-by portion of the XRAM (16Kbyte). It can range from 4.5 to 5.5V (6V for a reduced amount of time during the device life, 4.0V when RTC and 32 kHz on-chip oscillator amplifier are turned off). In running mode, this pin can be tied low during reset without affecting 32 kHz oscillator, RTC and XRAM activities, since the presence of a stable V_{DD} guarantees the proper biasing of all those modules.																				
P0L.0 -P0L.7, P0H.0 P0H.1 - P0H.7	100-107, 108, 111-117	I/O	Two 8-bit bidirectional I/O ports P0L and P0H, bit-wise programmable for input or output via direction bit. Programming an I/O pin as input forces the corresponding output driver to high impedance state. The input threshold of Port 0 is selectable (TTL or CMOS). In case of an external bus configuration, PORT0 serves as the address (A) and as the address / data (AD) bus in multiplexed bus modes and as the data (D) bus in demultiplexed bus modes. Demultiplexed bus modes <table><tr><td>Data path width</td><td>8-bit</td><td>16-bit</td></tr><tr><td>P0L.0 – P0L.7:</td><td>D0 – D7</td><td>D0 - D7</td></tr><tr><td>P0H.0 – P0H.7:</td><td>I/O</td><td>D8 - D15</td></tr></table> Multiplexed bus modes <table><tr><td>Data path width</td><td>8-bit</td><td>16-bit</td></tr><tr><td>P0L.0 – P0L.7:</td><td>AD0 – AD7</td><td>AD0 - AD7</td></tr><tr><td>P0H.0 – P0H.7:</td><td>A8 – A15</td><td>AD8 - AD15</td></tr></table>			Data path width	8-bit	16-bit	P0L.0 – P0L.7:	D0 – D7	D0 - D7	P0H.0 – P0H.7:	I/O	D8 - D15	Data path width	8-bit	16-bit	P0L.0 – P0L.7:	AD0 – AD7	AD0 - AD7	P0H.0 – P0H.7:	A8 – A15	AD8 - AD15
Data path width	8-bit	16-bit																					
P0L.0 – P0L.7:	D0 – D7	D0 - D7																					
P0H.0 – P0H.7:	I/O	D8 - D15																					
Data path width	8-bit	16-bit																					
P0L.0 – P0L.7:	AD0 – AD7	AD0 - AD7																					
P0H.0 – P0H.7:	A8 – A15	AD8 - AD15																					
P1L.0 - P1L.7 P1H.0 - P1H.7	118-125 128-135	I/O	Two 8-bit bidirectional I/O ports P1L and P1H, bit-wise programmable for input or output via direction bit. Programming an I/O pin as input forces the corresponding output driver to high impedance state. PORT1 is used as the 16-bit address bus (A) in demultiplexed bus modes: if at least BUSCONx is configured such the demultiplexed mode is selected, the pins of PORT1 are not available for general purpose I/O function. The input threshold of Port 1 is selectable (TTL or CMOS). The pins of P1L also serve as the additional (up to 8) analog input channels for the A/D converter, where P1L.x equals ANY (Analog input channel y, where $y = x + 16$). This additional function have higher priority on demultiplexed bus function. The following PORT1 pins have alternate functions:																				
	132	I	P1H.4	CC24IO	CAPCOM2: CC24 capture input																		
	133	I	P1H.5	CC25IO	CAPCOM2: CC25 capture input																		
	134	I	P1H.6	CC26IO	CAPCOM2: CC26 capture input																		
	135	I	P1H.7	CC27IO	CAPCOM2: CC27 capture input																		

Table 2. Pin description (continued)

Symbol	Pin	Type	Function	
XTAL1	138	I	XTAL1	Main oscillator amplifier circuit and/or external clock input.
XTAL2	137	O	XTAL2	Main oscillator amplifier circuit output.
			To clock the device from an external source, drive XTAL1 while leaving XTAL2 unconnected. Minimum and maximum high / low and rise / fall times specified in the AC Characteristics must be observed.	
XTAL3	143	I	XTAL3	32 kHz oscillator amplifier circuit input
XTAL4	144	O	XTAL4	32 kHz oscillator amplifier circuit output
			When 32 kHz oscillator amplifier is not used, to avoid spurious consumption, XTAL3 shall be tied to ground while XTAL4 shall be left open. Besides, bit OFF32 in RTCCON register shall be set. 32 kHz oscillator can only be driven by an external crystal, and not by a different clock source.	
$\overline{\text{RSTIN}}$	140	I	Reset Input with CMOS Schmitt-Trigger characteristics. A low level at this pin for a specified duration while the oscillator is running resets the ST10F273Z4. An internal pull-up resistor permits power-on reset using only a capacitor connected to V_{SS} . In bidirectional reset mode (enabled by setting bit BDRSTEN in SYSCON register), the $\overline{\text{RSTIN}}$ line is pulled low for the duration of the internal reset sequence.	
$\overline{\text{RSTOUT}}$	141	O	Internal Reset Indication Output. This pin is driven to a low level during hardware, software or watchdog timer reset. $\overline{\text{RSTOUT}}$ remains low until the EINIT (end of initialization) instruction is executed.	
$\overline{\text{NMI}}$	142	I	Non-Maskable Interrupt Input. A high to low transition at this pin causes the CPU to vector to the NMI trap routine. If bit PWDCFG = '0' in SYSCON register, when the PWRDN (power down) instruction is executed, the $\overline{\text{NMI}}$ pin must be low in order to force the ST10F273Z4 to go into power down mode. If $\overline{\text{NMI}}$ is high and PWDCFG = '0', when PWRDN is executed, the part will continue to run in normal mode. If not used, pin $\overline{\text{NMI}}$ should be pulled high externally.	
V_{AREF}	37	-	A/D converter reference voltage and analog supply	
V_{AGND}	38	-	A/D converter reference and analog ground	
RPD	84	-	Timing pin for the return from interruptible power down mode and synchronous / asynchronous reset selection.	
V_{DD}	17, 46, 72,82,93, 109, 126, 136	-	Digital supply voltage = + 5V during normal operation, idle and power down modes. It can be turned off when Stand-by RAM mode is selected.	
V_{SS}	18,45, 55,71, 83,94, 110, 127, 139	-	Digital ground	
V_{18}	56	-	1.8V decoupling pin: a decoupling capacitor (typical value of 10nF, max 100nF) must be connected between this pin and nearest V_{SS} pin.	

3 Functional description

The architecture of the ST10F273Z4 combines advantages of both RISC and CISC processors and an advanced peripheral subsystem. The block diagram gives an overview of the different on-chip components and the high bandwidth internal bus structure of the ST10F273Z4.

Figure 3. Block diagram

4 Memory organization

The memory space of the ST10F273Z4 is configured in a unified memory architecture. Code memory, data memory, registers and I/O ports are organized within the same linear address space of 16 Mbytes. The entire memory space can be accessed Byte wise or Word wise. Particular portions of the on-chip memory have additionally been made directly bit addressable.

IFlash: 512 Kbytes of on-chip Flash memory. It is divided in 10 blocks (B0F0...B0F9) of the Bank 0 and two blocks of Bank 1 (B1F0, B1F1): read-while-write operations inside the same Bank are not allowed. When Bootstrap mode is selected, the Test-Flash Block B0TF (8 Kbyte) appears at address 00'0000h: refer to [Chapter 5: Internal Flash memory on page 25](#) for more details on memory mapping in boot mode. The summary of address range for IFlash is the following:

Table 3. Summary of IFlash address range

Blocks	User mode	Size
B0TF	Not visible	8 K
B0F0	00'0000h - 00'1FFFh	8 K
B0F1	00'2000h - 00'3FFFh	8 K
B0F2	00'4000h - 00'5FFFh	8 K
B0F3	00'6000h - 00'7FFFh	8 K
B0F4	01'8000h - 01'FFFFh	32K
B0F5	02'0000h - 02'FFFFh	64K
B0F6	03'0000h - 03'FFFFh	64K
B0F7	04'0000h - 04'FFFFh	64K
B0F8	05'0000h - 05'FFFFh	64K
B0F9	06'0000h - 06'FFFFh	64K
B1F0	07'0000h - 07'FFFFh	64K
B1F1	08'0000h - 08'FFFFh	64K

IRAM: 2 Kbytes of on-chip internal RAM (dual-port) is provided as a storage for data, system stack, general purpose register banks and code. A register bank is 16 Wordwide (R0 to R15) and / or Bytewise (RL0, RH0, ..., RL7, RH7) general purpose registers group.

XRAM: 32 K + 2 Kbytes of on-chip extension RAM (single port XRAM) is provided as a storage for data, user stack and code.

The XRAM is divided into two areas, the first 2 Kbytes named XRAM1 and the second 32 Kbytes named XRAM2, connected to the internal XBUS and are accessed like an external memory in 16-bit demultiplexed bus-mode without wait state or read/write delay (31.25ns access at 64 MHz CPU clock). Byte and Word accesses are allowed.

The XRAM1 address range is 00'E000h - 00'E7FFh if XPEN (bit 2 of SYSCON register), and XRAM1EN (bit 2 of XPERCON register) are set. If XRAM1EN or XPEN is cleared, then any access in the address range 00'E000h - 00'E7FFh will be directed to external memory

interface, using the BUSCONx register corresponding to address matching ADDRSELx register.

The XRAM2 address range is F'0000h-F'7FFFFh if XPEN (bit 2 of SYSCON register), and XRAM2EN (bit 3 of XPERCON register) are set. If bit XPEN is cleared, then any access in the address range programmed for XRAM2 will be directed to external memory interface, using the BUSCONx register corresponding to address matching ADDRSELx register.

The lower portion of the XRAM2 (address range F'0000h-F'3FFFFh) represents also the Stand-by RAM, which can be maintained biased through $\bar{E}A$ / VSTBY pin when main supply V_{DD} is turned off.

As the XRAM appears like external memory, it cannot be used as system stack or as register banks. The XRAM is not provided for single bit storage and therefore is not bit addressable.

SFR/ESFR: 1024 bytes (2 x 512 bytes) of address space is reserved for the special function register areas. SFRs are Wordwide registers which are used to control and to monitor the function of the different on-chip units.

CAN1: Address range 00'EF00h - 00'EFFh is reserved for the CAN1 Module access. The CAN1 is enabled by setting XPEN bit 2 of the SYSCON register and by setting CAN1EN bit 0 of the XPERCON register. Accesses to the CAN Module use demultiplexed addresses and a 16-bit data bus (only word accesses are possible). Two wait states give an access time of 62.5ns at 64 MHz CPU clock. No tri-state wait states are used.

CAN2: Address range 00'EE00h - 00'EEFFh is reserved for the CAN2 Module access. The CAN2 is enabled by setting XPEN bit 2 of the SYSCON register and by setting CAN2EN bit 1 of the new XPERCON register. Accesses to the CAN Module use demultiplexed addresses and a 16-bit data bus (only word accesses are possible). Two wait states give an access time of 62.5ns at 64 MHz CPU clock. No tri-state wait states are used.

If one or the two CAN modules are used, Port 4 cannot be programmed to output all eight segment address lines. Thus, only four segment address lines can be used, reducing the external memory space to 5 Mbytes (1 Mbyte per CS line).

RTC: Address range 00'ED00h - 00'EDFFh is reserved for the RTC Module access. The RTC is enabled by setting XPEN bit 2 of the SYSCON register and bit 4 of the XPERCON register. Accesses to the RTC Module use demultiplexed addresses and a 16-bit data bus (only word accesses are possible). Two waitstates give an access time of 62.5ns at 64 MHz CPU clock. No tristate waitstate is used.

PWM1: Address range 00'EC00h - 00'ECFFh is reserved for the PWM1 Module access. The PWM1 is enabled by setting XPEN bit 2 of the SYSCON register and bit 6 of the XPERCON register. Accesses to the PWM1 Module use demultiplexed addresses and a 16-bit data bus (only word accesses are possible). Two waitstates give an access time of 62.5ns at 64MHz CPU clock. No tristate waitstate is used. Only word access is allowed.

ASC1: Address range 00'E900h - 00'E9FFh is reserved for the ASC1 Module access. The ASC1 is enabled by setting XPEN bit 2 of the SYSCON register and bit 7 of the XPERCON register. Accesses to the ASC1 Module use demultiplexed addresses and a 16-bit data bus (only word accesses are possible). Two waitstates give an access time of 62.5 ns at 64 MHz CPU clock. No tristate waitstate is used.

SSC1: Address range 00'E800h - 00'E8FFh is reserved for the SSC1 Module access. The SSC1 is enabled by setting XPEN bit 2 of the SYSCON register and bit 8 of the XPERCON register. Accesses to the SSC1 Module use demultiplexed addresses and a 16-bit data bus

(only word accesses are possible). Two waitstates give an access time of 62.5ns at 64 MHz CPU clock. No tristate waitstate is used.

I2C: Address range 00'EA00h - 00'EAFh is reserved for the I2C Module access. The I2C is enabled by setting XPEN bit 2 of the SYSCON register and bit 9 of the XPERCON register. Accesses to the I2C Module use demultiplexed addresses and a 16-bit data bus (only word accesses are possible). Two waitstates give an access time of 62.5ns at 64 MHz CPU clock. No tristate waitstate is used.

X-Miscellaneous: Address range 00'EB00h - 00'EBFFh is reserved for the access to a set of XBUS additional features. They are enabled by setting XPEN bit 2 of the SYSCON register and bit 10 of the XPERCON register. Accesses to this additional features use demultiplexed addresses and a 16-bit data bus (only word accesses are possible). Two waitstates give an access time of 62.5ns at 64 MHz CPU clock. No tristate waitstate is used. The following set of features are provided:

- CLKOUT programmable divider
- XBUS interrupt management registers
- ADC multiplexing on P1L register
- Port1L digital disable register for extra ADC channels
- CAN2 multiplexing on P4.5/P4.6
- CAN1-2 main clock prescaler
- Main voltage regulator disable for Power-down mode
- TTL / CMOS threshold selection for Port0, Port1 and Port5.

In order to meet the needs of designs where more memory is required than is provided on chip, up to 16 Mbytes of external memory can be connected to the microcontroller.

Visibility of XBUS peripherals

In order to keep the ST10F273Z4 compatible with the ST10F168 / ST10F269, the XBUS peripherals can be selected to be visible on the external address / data bus. Different bits for X-peripheral enabling in XPERCON register must be set. If these bits are cleared before the global enabling with XPEN bit in SYSCON register, the corresponding address space, port pins and interrupts are not occupied by the peripherals, thus the peripheral is not visible and not available. Refer to [Chapter 23: Register set on page 111](#).

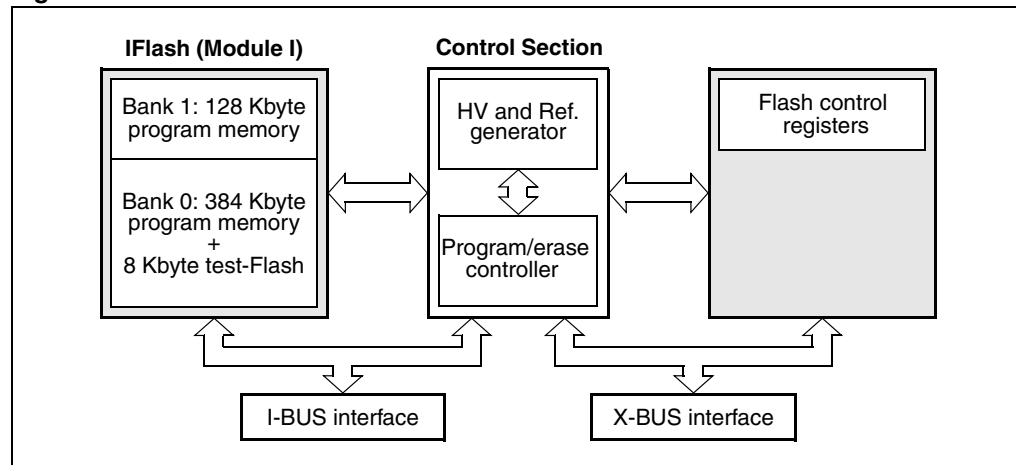

5 Internal Flash memory

5.1 Overview

The on-chip Flash is composed by one matrix module divided in two banks that can be read and modified independently one of the other: one bank can be read while another bank is under modification. Bank 0 is 384 Kbytes wide, Bank 1 is 128 Kbytes wide.

This module is on ST10 Internal bus, so it is called IFlash.

Figure 4. Flash structure

The programming operations of the flash are managed by an embedded Flash Program/Erase Controller (FPEC). The High Voltages needed for Program/Erase operations are internally generated.

The Data bus is 32-bit wide for fetch accesses to IFlash, while it is 16-bit wide for read accesses to IFlash. Read/write accesses to IFlash Control Registers area are 16-bit wide.

5.2 Functional description

5.2.1 Structure

Following table shows the Address space reserved to the Flash module.

Table 4. Address space of the Flash module

Description	Addresses	Size
IFlash sectors	0x00 0000 to 0x08 FFFF	512 Kbytes
Registers and Flash internal reserved area	0x0E 0000 to 0x0E FFFF	64 Kbytes

5.2.2 Modules structure

The IFlash module is composed by 2 banks: (Bank 0) contains 384 Kbytes of Program Memory divided in 10 sectors (B0F0...B0F7), Bank 0 contains also a reserved sector named Test-Flash. Bank 1 contains 128 Kbytes of Program Memory or Parameter divided in two sectors (B1F0, B1F1, 64 Kbytes each). Addresses from 0x0E 0000 to 0x0E FFFF are reserved for the Control Register Interface and other internal service memory space used by the Flash Program/Erase controller.

The following tables show the memory mapping of the Flash when it is accessed in read mode ([Table 5: Flash modules sectorization \(read operations\)](#)) and when accessed in write or erase mode ([Table 6: Flash modules sectorization](#)): Note that with this second mapping, the first four banks are remapped into code segment 1 (same as obtained setting bit ROMS1 in SYSCON register).

Table 5. Flash modules sectorization (read operations)

Bank	Description	Addresses	Size	ST10 Bus size
B0	Bank 0 Flash 0 (B0F0)	0x0000 0000 - 0x0000 1FFF	8 KB	32-bit (I-BUS)

	Bank 1 Flash 1 (B1F1)	0x0008 0000 - 0x0008 FFFF	64 KB	

1. Write operations or with ROMS1='1' or bootstrap mode

The table above refers to the configuration when bit ROMS1 of SYSCON register is set.

When Bootstrap mode is entered:

- Test-Flash is seen and available for code fetches (address 00'0000h)
- User I-Flash is only available for read and write accesses
- Write accesses must be made with addresses starting in segment 1 from 01'0000h, whatever ROMS1 bit in SYSCON value
- Read accesses are made in segment 0 or in segment 1 depending of ROMS1 value.

In Bootstrap mode, by default ROMS1 = 0, so the first 32 KBytes of IFlash are mapped in segment 0.

Example:

In default configuration, to program address 0, user must put the value 01'0000h in the FARL and FARH registers, but to verify the content of the address 0 a read to 00'0000h must be performed.

Next [Table 7](#) shows the Control Register interface composition: This set of registers can be addressed by the CPU.

Table 7. Control register interface

Name	Description	Addresses	Size	Bus size
FCR1-0	Flash control registers 1-0	0x000E 0000 - 0x000E 0007	8 byte	16-bit (XBUS)
FDR1-0	Flash data registers 1-0	0x000E 0008 - 0x000E 000F	8 byte	
FAR	Flash address registers	0x000E 0010 - 0x000E 0013	4 byte	
FER	Flash error register	0x000E 0014 - 0x000E 0015	2 byte	
FNVWPIR	Flash non volatile protection I register	0x000E DFB4 - 0x000E DFB7	4 byte	
FNVAPR0	Flash Non volatile access protection register 0	0x000E DFB8 - 0x000E DFB9	2 byte	
FNVAPR1	Flash non volatile access protection register 1	0x000E DFBC - 0x000E DFBF	4 byte	

5.2.3 Low power mode

The Flash module is automatically switched off executing PWRDN instruction. The consumption is drastically reduced, but exiting this state can require a long time (t_{PD}).

Recovery time from Power down mode for the Flash modules is anyway shorter than the main oscillator start-up time. To avoid any problem in restarting to fetch code from the Flash, it is important to size properly the external circuit on RPD pin.

Note: PWRDN instruction must not be executed while a Flash program/erase operation is in progress.

5.3 Write operation

The Flash module have one single register interface mapped in the memory space 0x0E 0000 to 0x0E 0015. All the operations are enabled through four 16-bit control registers: Flash Control Register 1-0 High/Low (FCR1H/L-FCR0H/L). Eight other 16-bit registers are used to store Flash Address and Data for Program operations (FARH/L and FDR1H/L-FDR0H/L) and Write Operation Error flags (FERH/L). All registers are accessible with 8 and 16-bit instructions (since operates in 16-bit mode when in read/ write).

Before accessing the Flash registers used for program/erasing operations, bit 5 (XFLASHEN) in XPERCON register shall be set.

The two banks have their own dedicated sense amplifiers, so that one bank can be read while the other is written.

During a Flash write operation, any attempt to read the bank under modification will output invalid data (software trap 009Bh). This means that the Flash bank is not fetchable when a programming operation is active: The write operation commands must be executed from another bank or from the other memory (internal RAM or external memory).

During a Write operation, when bit LOCK of FCR0 is set, it is forbidden to write into the Flash Control Registers.

Power supply drop

If, during a write operation, the internal low voltage supply drops below a certain internal voltage threshold, any write operation running is suddenly interrupted and the module is reset to Read mode. At following Power-on, the interrupted Flash write operation must be repeated.

5.4 Register description

5.4.1 Flash control register 0 low

The Flash Control Register 0 Low (FCR0L), together with the Flash Control Register 0 High (FCR0H), is used to enable and to monitor all the write operations on the IFlash. The user has no access in write mode to the Test-Flash (B0TF). Besides, Test-Flash block is seen by the user in Bootstrap mode only.

FCR0L (0x0E 0000)								FCR		Reset Value: 0000h					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
reserved									BSY1	BSY0	LOCK	res.	res.	res.	res.
									R	R	R				

Table 8. Flash control register 0 low

Bit	Function
BSY(1:0)	<p>Bank 0:1 Busy (IFlash)</p> <p>These bits indicate that a write operation is running on Bank 0 or Bank 1 (IFlash). They are automatically set when bit WMS is set. Setting Protection operation sets bits BSYx (since protection registers are in this Block). When this bits are set, every read access to the corresponding bank will output invalid data (software trap 009Bh), while every write access to the bank will be ignored. At the end of the write operation or during a Program or Erase Suspend these bits are automatically reset and the bank returns to read mode. After a Program or Erase Resume these bits is automatically set again.</p>
LOCK	<p>Flash registers access locked</p> <p>When this bit is set, it means that the access to the Flash Control Registers FCR0H/-FCR1H/L, FDR0H/L-FDR1H/L, FARH/L and FER is locked by the FPEC: any read access to the registers will output invalid data (software trap 009Bh) and any write access will be ineffective. LOCK bit is automatically set when the Flash bit WMS is set.</p> <p>This is the only bit the user can always access to detect the status of the Flash: once it is found low, the rest of FCR0L and all the other Flash registers are accessible by the user as well.</p> <p>Note that FER content can be read when LOCK is low, but its content is updated only when also BSYx bits are reset.</p>

5.4.2 Flash control register 0 high

The Flash Control Register 0 High (FCR0H) together with the Flash Control Register 0 Low (FCR0L) is used to enable and to monitor all the write operations on the IFlash. The user has no access in write mode to the Test-Flash (B0TF). Besides, Test-Flash block is seen by the user in Bootstrap mode only.

FCR0H (0x0E 0002)					FCR				Reset Value: 0000h						
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WMS	SUSP	WPG	DWPG	SER	reserved		SPR	SMOD	reserved						
RW	RW	RW	RW	RW			RW	RW							

Table 9. Flash control register 0 high

Bit	Function
SMOD	This must be set before every Write Operation except for writing in the Flash Non Volatile Protection Registers, SMOD is automatically reset at the end of the Write Operation.
SPR	Set protection This bit must be set to select the Set Protection operation. The Set Protection operation allows to program 0s in place of 1s in the Flash Non Volatile Protection Registers. The Flash Address in which to program must be written in the FARH/L registers, while the Flash Data to be programmed must be written in the FDR0H/L before starting the execution by setting bit WMS. A sequence error is flagged by bit SEQR of FER if the address written in FARH/L is not in the range 0x0EDFB0-0x0EDFBF. SPR bit is automatically reset at the end of the Set Protection operation.
SER	Sector erase This bit must be set to select the Sector Erase operation in the Flash modules. The Sector Erase operation allows to erase all the Flash locations to value 0xFF. From 1 to all the sectors of the same bank (excluded Test-Flash for Bank B0) can be selected to be erased through bits BxFy of FCR1H/L registers before starting the execution by setting bit WMS. It is not necessary to pre-program the sectors to 0x00, because this is done automatically. SER bit is automatically reset at the end of the Sector Erase operation.
DWPG	Double word program This bit must be set to select the Double Word (64 bits) Program operation in the Flash module. The Double Word Program operation allows to program 0s in place of 1s. The Flash Address in which to program (aligned with even words) must be written in the FARH/L registers, while the 2 Flash Data to be programmed must be written in the FDR0H/L registers (even word) and FDR1H/L registers (odd word) before starting the execution by setting bit WMS. DWPG bit is automatically reset at the end of the Double Word Program operation.
WPG	Word program This bit must be set to select the Word (32 bits) Program operation in the Flash module. The Word Program operation allows to program 0s in place of 1s. The Flash Address to be programmed must be written in the FARH/L registers, while the Flash Data to be programmed must be written in the FDR0H/L registers before starting the execution by setting bit WMS. WPG bit is automatically reset at the end of the Word Program operation.

Table 9. Flash control register 0 high (continued)

Bit	Function
SUSP	<p>Suspend</p> <p>This bit must be set to suspend the current Program (Word or Double Word) or Sector Erase operation in order to read data in one of the sectors of the bank under modification or to program data in another bank. The Suspend operation resets the Flash bank to normal read mode (automatically resetting bits BSYx). When in Program Suspend, the Flash module accepts only the following operations: Read and Program Resume. When in Erase Suspend the module accepts only the following operations: Read, Erase Resume and Program (Word or Double Word; Program operations cannot be suspended during Erase Suspend). To resume a suspended operation, the WMS bit must be set again, together with the selection bit corresponding to the operation to resume (WPG, DWPG, SER).⁽¹⁾</p>
WMS	<p>Write mode start</p> <p>This bit must be set to start every write operation in the Flash module. At the end of the write operation or during a Suspend, this bit is automatically reset. To resume a suspended operation, this bit must be set again. It is forbidden to set this bit if bit ERR of FER is high (the operation is not accepted). It is also forbidden to start a new write (program or erase) operation (by setting WMS high) when bit SUSP of FCR0 is high. Resetting this bit by software has no effect.</p>

1. It is forbidden to start a new Write operation with bit SUSP already set.

5.4.3 Flash control register 1 low

The Flash Control Register 1 Low (FCR1L), together with Flash Control Register 1 High (FCR1H), is used to select the sectors to Erase or, during any write operation, to monitor the status of each sector and bank.

FCR1L (0x0E 0004)						FCR						Reset value: 0000h

Table 18. Flash address register high

Bit	Function
ADD(20:16)	Address 20:16 These bits must be written with the Address of the Flash location to program in the following operations: Word Program and Double Word Program.

5.4.11 Flash error register

Flash Error register, as well as all the other Flash registers, can be properly read only once LOCK bit of register FCR0L is low. Nevertheless, its content is updated when also BSYx bits are reset as well; for this reason, it is definitively meaningful reading FER register content only when LOCK bit and BSYx bits are cleared.

FER (0xE 0014h)								FCR				Reset value: 0000h				
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

								RC	RC	RC			RC	RC	RC	RC

Table 19. Flash error register

Bit	Function
ERR	Write error This bit is automatically set when an error occurs during a Flash write operation or when a bad write operation setup is done. Once the error has been discovered and understood, ERR bit must be software reset.
ERER	Erase error This bit is automatically set when an Erase error occurs during a Flash write operation. This error is due to a real failure of a Flash cell, that can no more be erased. This kind of error is fatal and the sector where it occurred must be discarded. This bit has to be software reset.
PGER	Program error This bit is automatically set when a Program error occurs during a Flash write operation. This error is due to a real failure of a Flash cell, that can no more be programmed. The word where this error occurred must be discarded. This bit has to be software reset.
10ER	1 over 0 error This bit is automatically set when trying to program at 1 bits previously set at 0 (this does not happen when programming the Protection bits). This error is not due to a failure of the Flash cell, but only flags that the desired data has not been written. This bit has to be software reset.
SEQR	Sequence error This bit is automatically set when the control registers (FCR1H/L-FCR0H/L, FARH/L, FDR1H/L-FDR0H/L) are not correctly filled to execute a valid Write Operation. In this case no Write Operation is executed. This bit has to be software reset.

Table 19. Flash error register

Bit	Function
RESER	Resume error This bit is automatically set when a suspended Program or Erase operation is not resumed correctly due to a protocol error. In this case the suspended operation is aborted. This bit has to be software reset.
WPF	Write protection flag This bit is automatically set when trying to program or erase in a sector write protected. In case of multiple Sector Erase, the not protected sectors are erased, while the protected sectors are not erased and bit WPF is set. This bit has to be software reset.

5.5 Protection strategy

The protection bits are stored in Non Volatile Flash cells, that are read once at reset and stored in 5 Volatile registers. Before they are read from the Non Volatile cells, all the available protections are forced active during reset.

The protections can be programmed using the Set Protection operation (see Flash Control Registers paragraph), that can be executed from all the internal or external memories.

Two kind of protections are available: write protections to avoid unwanted writings and access protections to avoid piracy. In next paragraphs all different level of protections are shown, and architecture limitations are highlighted as well.

5.5.1 Protection registers

The 5 Non Volatile Protection Registers are one time programmable for the user.

Two register (FNVWPIRL/FNVWPIRH) are used to store the Write Protection fuses for each sector IFlash module. The other three Registers (FNVAPR0 and FNVAPR1L/H) are used to store the Access Protection fuses.

5.5.2 Flash non volatile write protection I register low

Table 24. Flash non volatile access protection register 1 high

Bit	Function
PEN15-0	Protections enable 15-0 If bit PENx is programmed at 0 and bit PDSx+1 is erased at 1, the action of bit ACCP is enabled again. Bit PENx can be programmed at 0 only if bit PDSx has already been programmed at 0.

5.5.7 Access protection

The I-Flash module has one level of access protection (access to data both in Reading and Writing): if bit ACCP of FNVAPR0 is programmed at 0, the I-Flash module becomes access protected: data in the I-Flash module can be read only if the current execution is from the I-Flash module itself.

Protection can be permanently disabled by programming bit PDS0 of FNVAPR1H, in order to analyze rejects. Protection can be permanently enabled again by programming bit PEN0 of FNVAPR1L. The action to disable and enable again Access Protections in a permanent way can be executed a maximum of 16 times.

Trying to write into the access protected Flash from internal RAM or external memories will be unsuccessful. Trying to read into the access protected Flash from internal RAM or external memories will output a dummy data (software trap 0x009Bh).

When the Flash module is protected in access, also the data access through PEC of a peripheral is forbidden. To read/write data in PEC mode from/to a protected bank, first it is necessary to temporarily unprotect the Flash module.

In the following table a summary of all levels of possible Access protection is reported: in particular, supposing to enable all possible access protections, when fetching from a

memory as listed in the first column, what is possible and what is not possible to do (see column headers) is shown in the table.

Table 25. Summary of access protection level

	Read IFlash / jump to IFlash	Read XRAMS or Ext Mem / Jump to XRAM or Ext Mem	Read Flash registers	Write Flash registers
Fetching from IFlash	Yes / Yes	Yes / Yes	Yes	Yes
Fetching from IRAM	No / Yes	Yes / Yes	Yes	No
Fetching from XRAM	No / Yes	Yes / Yes	Yes	No
Fetching from External memory	No / Yes	Yes / Yes	Yes	No

5.5.8 Write protection

The Flash modules have one level of Write Protections: Each sector of each bank can be Software Write Protected by programming at 0 the related bit WyPx in FNVWPIRL/H register.

5.5.9 Temporary unprotection

Bits WyPx of FNVWPIRL/H can be temporary unprotected by executing the Set Protection operation and writing 1 into these bits.

Bit ACCP can be temporary unprotected by executing the Set Protection operation and writing are executed from IFlash.

To restore the write access protection bits it is necessary to reset the microcontroller or to execute a Set Protection operation and write 0 into desired bits.

It is not necessary to temporary unprotect the access protected IFlash in order to update the code: it is, in fact, sufficient to execute the updating instructions from another Flash bank.

In reality, when a temporary unprotection operation is executed, the corresponding volatile register is written to 1, while the non volatile registers bits previously written to 0 (for a protection set operation), will continue to maintain the 0. For this reason, the user software must be in charge to track the current protection status (for instance using a specific RAM area), it is not possible to deduce it by reading the non volatile register content (a temporary unprotection cannot be detected).

5.6 Write operation examples

In the following, examples for each kind of Flash write operation are presented.

Note: *Moreover, direct addressing is not allowed for write accesses to IFlash control registers. This means that both address and data for a writing operation must be loaded in one of ST10 GPR register (R0...R15).*

Write operation on IBus registers is 16 bit wide.

Example of indirect addressing mode:

```
MOV  RWm, #ADDRESS;    /*Load Add in RWm*/
MOV  RWn, #DATA;        /*Load Data in RWn*/
MOV  [RWm], RWn;        /*Indirect addressing*/
```

Word program

Example: 32-bit Word Program of data 0xAAAAAAAA at address 0x025554

```
FCR0H |= 0x2080;        /*Set WPG in FCR0H, SMOD must be set*/
FARL  = 0x5554;          /*Load Add in FARL*/
FARH  = 0x0002;          /*Load Add in FARH*/
FDR0L = 0xAAAA;          /*Load Data in FDR0L*/
FDR0H = 0xAAAA;          /*Load Data in FDR0H*/
FCR0H |= 0x8000;          /*Operation start*/
```

Double word program

Example: Double Word Program (64-bit) of data 0x55AA55AA at address 0x035558 and data 0xAA55AA55 at address 0x03555C.

```
FCR0H |= 0x1080;        /*Set DWPG, SMOD must be set*/
FARL  = 0x5558;          /*Load Add in FARL*/
FARH  = 0x0003;          /*Load Add in FARH*/
FDR0L = 0x55AA;          /*Load Data in FDR0L*/
FDR0H = 0x55AA;          /*Load Data in FDR0H*/
FDR1L = 0xAA55;          /*Load Data in FDR1L*/
FDR1H = 0xAA55;          /*Load Data in FDR1H*/
FCR0H |= 0x8000;          /*Operation start*/
```

Double Word Program is always performed on the Double Word aligned on a even Word: bit ADD2 of FARL is ignored.

Sector erase

Example: Sector Erase of sectors B0F1 and B0F0 of Bank 0.

```
FCR0H |= 0x0880;        /*Set SER in FCR0H, SMOD must be set*/
FCR1L |= 0x0003;          /*Set B0F1, B0F0*/
FCR0H |= 0x8000;          /*Operation start*/
```

Suspend and resume

Word Program, Double Word Program, and Sector Erase operations can be suspended in the following way:

```
FCR0H |= 0x4000;          /*Set SUSP in FCR0H*/
```

Then the operation can be resumed in the following way:

```
FCR0H |= 0x0800; /*Set SER in FCR0H*/
FCR0H |= 0x8000; /*Operation resume*/
```

Before resuming a suspended Erase, FCR1H/FCR1L must be read to check if the Erase is already completed (FCR1H = FCR1L = 0x0000 if Erase is complete). Original setup of Select Operation bits in FCR0H/L must be restored before the operation resume, otherwise the operation is aborted and bit RESER of FER is set.

Erase suspend, program and resume

A Sector Erase operation can be suspended in order to program (Word or Double Word) another sector.

Example: Sector Erase of sector B0F1.

```
FCR0H |= 0x0880; /*Set SER in FCR0H, SMOD must be set*/
FCR1L |= 0x0002; /*Set B0F1*/
FCR0H |= 0x8000; /*Operation start*/
```

Example: Sector Erase Suspend.

```
FCR0H |= 0x4000; /*Set SUSP in FCR0H*/
do /*Loop to wait for LOCK=0 and WMS=0*/
{tmp1 = FCR0L;
 tmp2 = FCR0H;
} while ((tmp1 && 0x0010) || (tmp2 && 0x8000));
```

Example: Word Program of data 0x5555AAAA at address 0x045554.

```
FCR0H &= 0xBFFF; /*Rst SUSP in FCR0H*/
FCR0H |= 0x2080; /*Set WPG in FCR0H, SMOD must be set*/
FARL = 0x5554; /*Load Add in FARL*/
FARH = 0x0004; /*Load Add in FARH*/
FDR0L = 0xAAAA; /*Load Data in FDR0L*/
FDR0H = 0x5555; /*Load Data in FDR0H*/
FCR0H |= 0x8000; /*Operation start*/
```

Once the Program operation is finished, the Erase operation can be resumed in the following way:

```
FCR0H |= 0x0800; /*Set SER in FCR0H*/
FCR0H |= 0x8000; /*Operation resume*/
```

Notice that during the Program Operation in Erase suspend, bits SER and SUSP are low. A Word or Double Word Program during Erase Suspend cannot be suspended.

In summary:

A Sector Erase can be suspended by setting SUSP bit.

- To perform a Word Program operation during Erase Suspend, firstly bits SUSP and SER must be reset, then bit WPG and WMS can be set.
- To resume the Sector Erase operation bit SER must be set again.
- In any case it is forbidden to start any write operation with SUSP bit already set.

Set Protection

Example 1: Enable Write Protection of sectors B0F3-0 of Bank 0.

```
FCR0H  |= 0x0100;      /*Set SPR in FCR0H*/
FARL    = 0xDFB4;      /*Load Add of register FNVWPIR in FARL*/
FARH    = 0x000E;      /*Load Add of register FNVWPIR in FARH*/
FDR0L   = 0xFFFF0;     /*Load Data in FDR0L*/
FDR0H   = 0xFFFF;      /*Load Data in FDR0H*/
FCR0H   |= 0x8000;      /*Operation start*/
```

Notice that SMOD bit of FCR0H must NOT be set.

Example 2: Enable Access and Debug Protection.

```
FCR0H  |= 0x0100;      /*Set SPR in FCR0H*/
FARL    = 0xDFB8;      /*Load Add of register FNVAPR0 in FARL*/
FARH    = 0x000E;      /*Load Add of register FNVAPR0 in FARH*/
FDR0L   = 0xFFFC;      /*Load Data in FDR0L*/
FCR0H   |= 0x8000;      /*Operation start*/
```

Notice that SMOD bit of FCR0H must NOT be set.

Example 3: Disable in a permanent way Access and Debug Protection.

```
FCR0H  |= 0x0100;      /*Set SPR in FCR0H*/
FARL    = 0xDFBC;      /*Load Add of register FNVAPR1L in FARL*/
FARH    = 0x000E;      /*Load Add of register FNVAPR1L in FARH*/
FDR0L   = 0xFFFE;      /*Load Data in FDR0L for clearing PDS0*/
FCR0H   |= 0x8000;      /*Operation start*/
```

Notice that SMOD bit of FCR0H must NOT be set.

Example 4: Enable again in a permanent way Access and Debug Protection, after having disabled them.

```
FCR0H  |= 0x0100;      /*Set SPR in FCR0H*/
FARL    = 0xDFBC;      /*Load Add register FNVAPR1H in FARL*/
FARH    = 0x000E;      /*Load Add register FNVAPR1H in FARH*/
FDR0H   = 0xFFFE;      /*Load Data in FDR0H for clearing
PEN0*/
FCR0H   |= 0x8000;      /*Operation start*/
```

Notice that SMOD bit of FCR0H must NOT be set.

Disable and re-enable of Access and Debug Protection in a permanent way (as shown by examples 3 and 4) can be done for a maximum of 16 times.

5.7 Write operation summary

In general, each write operation is started through a sequence of 3 steps:

1. The first instruction is used to select the desired operation by setting its corresponding selection bit in the Flash Control Register 0.
2. The second step is the definition of the Address and Data for programming or the sectors or banks to erase, SMOD must be always set except for writing in Flash Non Volatile Protection registers.
3. The last instruction is used to start the write operation, by setting the start bit WMS in the FCR0.

Once selected, but not yet started, one operation can be canceled by resetting the operation selection bit.

A summary of the available Flash Module Write Operations are shown in the following [Table 26](#).

Table 26. Flash write operations

Operation	Select bit	Address and data	Start bit
Word program (32-bit)	WPG	FARL/FARH FDR0L/FDR0H	WMS
Double word program (64-bit)	DWPG	FARL/FARH FDR0L/FDR0H FDR1L/FDR1H	WMS
Sector erase	SER	FCR1L/FCR1H	WMS
Set protection	SPR	FDR0L/FDR0H	WMS
Program/Erase suspend	SUSP	None	None

6 Bootstrap loader

ST10F273Z4 implements Boot capabilities in order to:

- Support bootstrap via UART or bootstrap via CAN for the standard bootstrap.
- Support a selective bootstrap loader, to manage the bootstrap sequence in a different way.

6.1 Selection among user-code, standard or selective bootstrap

The boot modes are triggered with a special combination set on Port0L[5...4]. Those signals, as other configuration signals, are latched on the rising edge of RSTIN pin.

- Decoding of reset configuration (P0L.5 = 1, P0L.4 = 1) will select the normal mode (also called User mode) and select the user Flash to be mapped from address 00'0000h.
- Decoding of reset configuration (P0L.5 = 1, P0L.4 = 0) will select ST10 standard bootstrap mode (Test-Flash is active and overlaps user Flash for code fetches from address 00'0000h; user Flash is active and available for read accesses).
- Decoding of reset configuration (P0L.5 = 0, P0L.4 = 1) will activate new verifications to select which bootstrap software to execute:
 - if the User mode signature in the User Flash is programmed correctly, then a software reset sequence is selected and the User code is executed;
 - if the User mode signature is not programmed correctly in the user Flash, then the User key location is read again. Its value will determine which communication channel will be enabled for bootstrapping.

Table 27. ST10F273Z4 boot mode selection

P0.5	P0.4	ST10 decoding
1	1	User mode: user Flash mapped at 00'0000h
1	0	Standard bootstrap loader: User Flash mapped from 00'0000h, code fetches redirected to Test-Flash at 00'0000h
0	1	Selective boot mode: User Flash mapped from 00'0000h, code fetches redirected to Test-Flash at 00'0000h (different sequence execution in respect of Standard Bootstrap Loader)
0	0	Reserved

6.2 Standard bootstrap loader

After entering the standard BSL mode and the respective initialization, the ST10F273Z4 scans the RxD0 line and the CAN1_RxD line to receive either a valid dominant bit from CAN interface, or a start condition from UART line.

Start condition on UART RxD: ST10F273Z4 starts standard bootstrap loader. This bootstrap loader is identical to other ST10 devices (example: ST10F269, ST10F168).

Valid dominant bit on CAN1 RxD: ST10F273Z4 start bootstrapping via CAN1.

6.3 Alternate and selective boot mode (ABM & SBM)

6.3.1 Activation of the ABM and SBM

Alternate boot is activated with the combination '01' on Port0L[5..4] at the rising edge of $\overline{\text{RSTIN}}$.

6.3.2 User mode signature integrity check

The behavior of the Selective Boot mode is based on the computing of a signature between the content of 2 memory locations and a comparison with a reference signature. This requires that users who use Selective Boot have reserved and programmed the Flash memory locations.

6.3.3 Selective boot mode

When the user signature is not correct, instead of executing the Standard Bootstrap Loader (triggered by P0L.4 low at reset), additional check is made.

Depending on the value at the User key location, following behavior will occur:

- A jump is performed to the Standard Bootstrap Loader
- Only UART is enabled for bootstrapping
- Only CAN1 is enabled for bootstrapping
- The device enters an infinite loop.

7 Central processing unit (CPU)

The CPU includes a 4-stage instruction pipeline, a 16-bit arithmetic and logic unit (ALU) and dedicated SFRs. Additional hardware has been added for a separate multiply and divide unit, a bit-mask generator and a barrel shifter.

Most of the ST10F273Z4's instructions can be executed in one instruction cycle which requires 31.25ns at 64 MHz CPU clock. For example, shift and rotate instructions are processed in one instruction cycle independent of the number of bits to be shifted.

Multiple-cycle instructions have been optimized: branches are carried out in 2 cycles, 16 x 16-bit multiplication in 5 cycles and a 32/16-bit division in 10 cycles.

The jump cache reduces the execution time of repeatedly performed jumps in a loop, from 2 cycles to 1 cycle.

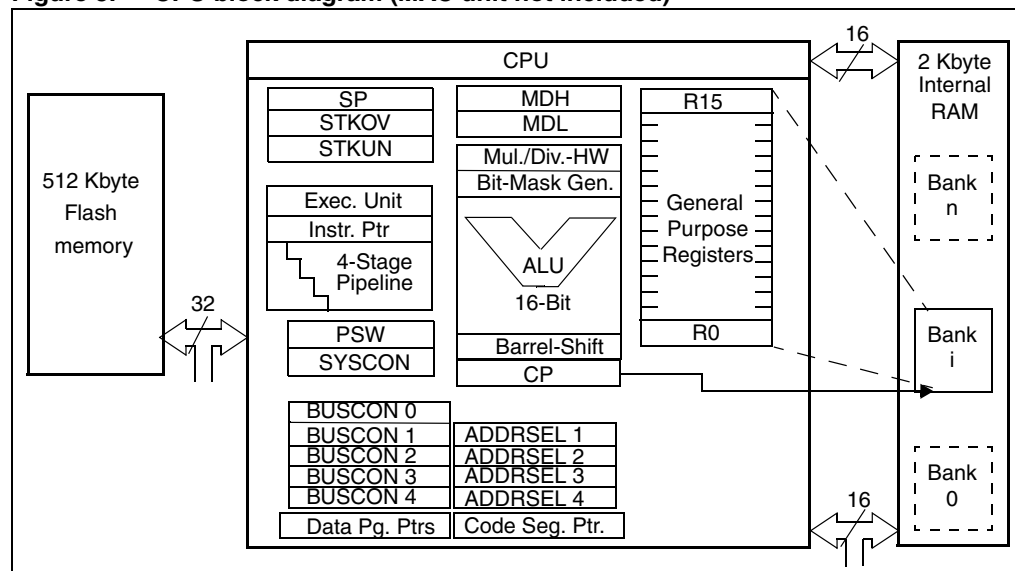

The CPU uses a bank of 16 word registers to run the current context. This bank of General Purpose Registers (GPR) is physically stored within the on-chip Internal RAM (IRAM) area. A Context Pointer (CP) register determines the base address of the active register bank to be accessed by the CPU.

The number of register banks is only restricted by the available Internal RAM space. For easy parameter passing, a register bank may overlap others.

A system stack of up to 2048 bytes is provided as a storage for temporary data. The system stack is allocated in the on-chip RAM area, and it is accessed by the CPU via the stack pointer (SP) register.

Two separate SFRs, STKOV and STKUN, are implicitly compared against the stack pointer value upon each stack access for the detection of a stack overflow or underflow.

Figure 5. CPU block diagram (MAC unit not included)

7.1 Multiplier-accumulator unit (MAC)

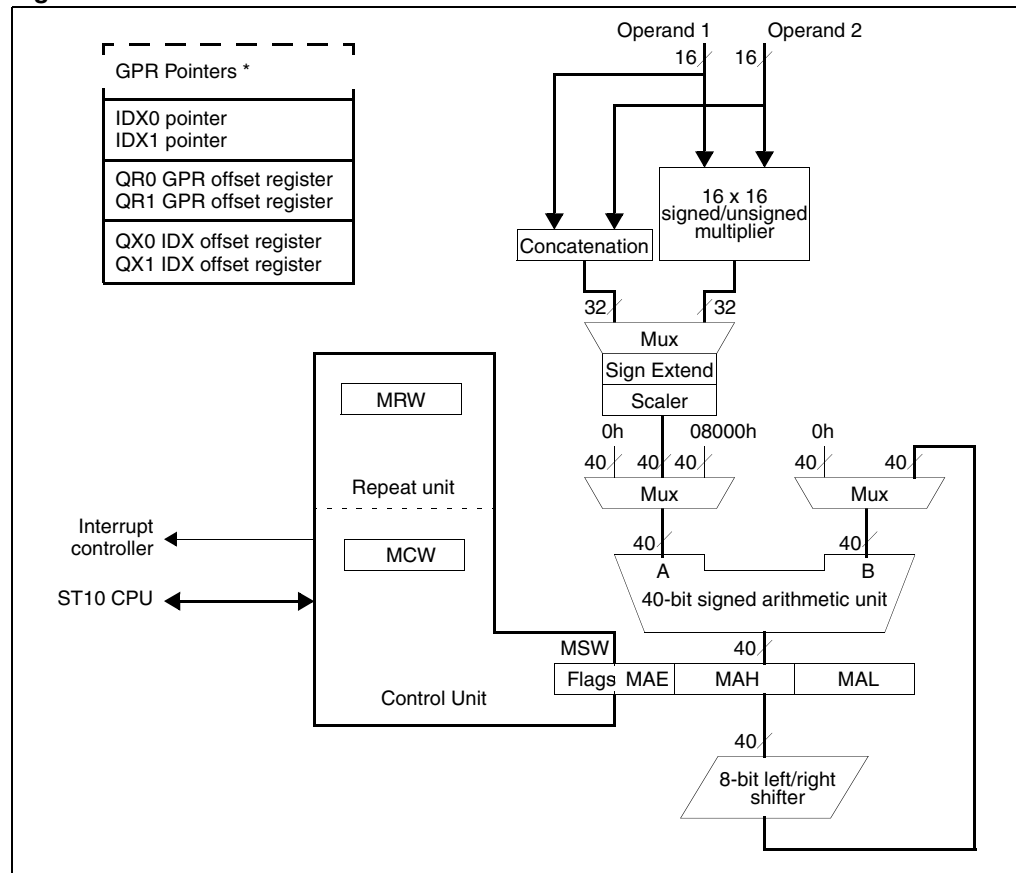

The MAC coprocessor is a specialized coprocessor added to the ST10 CPU Core in order to improve the performances of the ST10 Family in signal processing algorithms.

The standard ST10 CPU has been modified to include new addressing capabilities which enable the CPU to supply the new coprocessor with up to 2 operands per instruction cycle.

This new coprocessor (so-called MAC) contains a fast multiply-accumulate unit and a repeat unit.

The coprocessor instructions extend the ST10 CPU instruction set with multiply, multiply-accumulate, 32-bit signed arithmetic operations.

Figure 6. MAC unit architecture

7.2 Instruction set summary

The [Table 28](#) lists the instructions of the ST10F273Z4. The detailed description of each instruction can be found in the “ST10 Family Programming Manual”.

Table 28. Standard instruction set summary

Mnemonic	Description	Bytes
ADD(B)	Add word (byte) operands	2 / 4
ADDC(B)	Add word (byte) operands with Carry	2 / 4
SUB(B)	Subtract word (byte) operands	2 / 4
SUBC(B)	Subtract word (byte) operands with Carry	2 / 4
MUL(U)	(Un)Signed multiply direct GPR by direct GPR (16-16-bit)	2
DIV(U)	(Un)Signed divide register MDL by direct GPR (16-/16-bit)	2
DIVL(U)	(Un)Signed long divide reg. MD by direct GPR (32-/16-bit)	2
CPL(B)	Complement direct word (byte) GPR	2
NEG(B)	Negate direct word (byte) GPR	2
AND(B)	Bit-wise AND, (word/byte operands)	2 / 4
OR(B)	Bit-wise OR, (word/byte operands)	2 / 4
XOR(B)	Bit-wise XOR, (word/byte operands)	2 / 4
BCLR	Clear direct bit	2
BSET	Set direct bit	2
BMOV(N)	Move (negated) direct bit to direct bit	4
BAND, BOR, BXOR	AND/OR/XOR direct bit with direct bit	4
BCMP	Compare direct bit to direct bit	4
BFLDH/L	Bit-wise modify masked high/low byte of bit-addressable direct word memory with immediate data	4
CMP(B)	Compare word (byte) operands	2 / 4
CMPD1/2	Compare word data to GPR and decrement GPR by 1/2	2 / 4
CMPI1/2	Compare word data to GPR and increment GPR by 1/2	2 / 4
PRIOR	Determine number of shift cycles to normalize direct word GPR and store result in direct word GPR	2
SHL / SHR	Shift left/right direct word GPR	2
ROL / ROR	Rotate left/right direct word GPR	2
ASHR	Arithmetic (sign bit) shift right direct word GPR	2
MOV(B)	Move word (byte) data	2 / 4
MOVBS	Move byte operand to word operand with sign extension	2 / 4
MOVBSZ	Move byte operand to word operand with zero extension	2 / 4
JMPA, JMPI, JMPR	Jump absolute/indirect/relative if condition is met	4
JMPS	Jump absolute to a code segment	4

Table 28. Standard instruction set summary (continued)

Mnemonic	Description	Bytes
J(N)B	Jump relative if direct bit is (not) set	4
JBC	Jump relative and clear bit if direct bit is set	4
JNBS	Jump relative and set bit if direct bit is not set	4
CALLA, CALLI, CALLR	Call absolute/indirect/relative subroutine if condition is met	4
CALLS	Call absolute subroutine in any code segment	4
PCALL	Push direct word register onto system stack and call absolute subroutine	4
TRAP	Call interrupt service routine via immediate trap number	2
PUSH, POP	Push/pop direct word register onto/from system stack	2
SCXT	Push direct word register onto system stack and update register with word operand	4
RET	Return from intra-segment subroutine	2
RETS	Return from inter-segment subroutine	2
RETP	Return from intra-segment subroutine and pop direct word register from system stack	2
RETI	Return from interrupt service subroutine	2
SRST	Software reset	4
IDLE	Enter Idle mode	4
PWRDN	Enter power down mode (supposes $\overline{\text{NMI}}$ -pin being low)	4
SRVWDT	Service watchdog timer	4
DISWDT	Disable watchdog timer	4
EINIT	Signify end-of-initialization on $\overline{\text{RSTOUT}}$ -pin	4
ATOMIC	Begin ATOMIC sequence	2
EXTR	Begin EXTended register sequence	2
EXTP(R)	Begin EXTended page (and register) sequence	2 / 4
EXTS(R)	Begin EXTended segment (and register) sequence	2 / 4
NOP	Null operation	2

7.3 MAC coprocessor specific instructions

The [Table 29](#) lists the MAC instructions of the ST10F273Z4. The detailed description of each instruction can be found in the “ST10 Family Programming Manual”. Note that all MAC instructions are encoded on 4 bytes.

Table 29. MAC instruction set summary

Mnemonic	Description
CoABS	Absolute value of the accumulator
CoADD(2)	Addition
CoASHR(rnd)	Accumulator arithmetic shift right & optional round
CoCMP	Compare accumulator with operands
CoLOAD(-,2)	Load accumulator with operands
CoMAC(R,u,s,-,rnd)	(Un)signed/(Un)Signed Multiply-Accumulate & Optional Round
CoMACM(R)(u,s,-,rnd)	(Un)Signed/(Un)signed multiply-accumulate with parallel data move & optional round
CoMAX / CoMIN	maximum / minimum of operands and accumulator
CoMOV	Memory to memory move
CoMUL(u,s,-,rnd)	(Un)signed/(Un)signed multiply & optional round
CoNEG(rnd)	Negate accumulator & optional round
CoNOP	No-operation
CoRND	Round accumulator
CoSHL / CoSHR	Accumulator logical shift left / right
CoSTORE	Store a MAC unit register
CoSUB(2,R)	Substraction

8 External bus controller

All of the external memory accesses are performed by the on-chip external bus controller.

The EBC can be programmed to single chip mode when no external memory is required, or to one of four different external memory access modes:

- 16- / 18- / 20- / 24-bit addresses and 16-bit data, demultiplexed
- 16- / 18- / 20- / 24-bit addresses and 16-bit data, multiplexed
- 16- / 18- / 20- / 24-bit addresses and 8-bit data, multiplexed
- 16- / 18- / 20- / 24-bit addresses and 8-bit data, demultiplexed

In demultiplexed bus modes addresses are output on PORT1 and data is input / output on PORT0 or P0L, respectively. In the multiplexed bus modes both addresses and data use PORT0 for input / output.

Timing characteristics of the external bus interface (memory cycle time, memory tri-state time, length of ALE and read / write delay) are programmable giving the choice of a wide range of memories and external peripherals.

Up to four independent address windows may be defined (using register pairs ADDRSELx / BUSCONx) to access different resources and bus characteristics.

These address windows are arranged hierarchically where BUSCON4 overrides BUSCON3 and BUSCON2 overrides BUSCON1.

All accesses to locations not covered by these four address windows are controlled by BUSCON0. Up to five external \overline{CS} signals (four windows plus default) can be generated in order to save external glue logic. Access to very slow memories is supported by a 'Ready' function.

A \overline{HOLD} / \overline{HLDA} protocol is available for bus arbitration which shares external resources with other bus masters.

The bus arbitration is enabled by setting bit HLDEN in register PSW. After setting HLDEN once, pins P6.7...P6.5 (\overline{BREQ} , \overline{HLDA} , \overline{HOLD}) are automatically controlled by the EBC. In master mode (default after reset) the \overline{HLDA} pin is an output. By setting bit DP6.7 to '1' the slave mode is selected where pin \overline{HLDA} is switched to input. This directly connects the slave controller to another master controller without glue logic.

For applications which require less external memory space, the address space can be restricted to 1 Mbyte, 256 Kbytes or to 64 Kbytes. Port 4 outputs all eight address lines if an address space of 16M Bytes is used, otherwise four, two or no address lines.

Chip select timing can be made programmable. By default (after reset), the \overline{CSx} lines change half a CPU clock cycle after the rising edge of ALE. With the CSCFG bit set in the SYSCON register the \overline{CSx} lines change with the rising edge of ALE.

The active level of the READY pin can be set by bit RDYPOL in the BUSCONx registers. When the READY function is enabled for a specific address window, each bus cycle within the window must be terminated with the active level defined by bit RDYPOL in the associated BUSCON register.

9 Interrupt system

The interrupt response time for internal program execution is from 78ns to 187.5ns at 64 MHz CPU clock.

The ST10F273Z4 architecture supports several mechanisms for fast and flexible response to service requests that can be generated from various sources (internal or external) to the microcontroller. Any of these interrupt requests can be serviced by the Interrupt Controller or by the Peripheral Event Controller (PEC).

In contrast to a standard interrupt service where the current program execution is suspended and a branch to the interrupt vector table is performed, just one cycle is 'stolen' from the current CPU activity to perform a PEC service. A PEC service implies a single Byte or Word data transfer between any two memory locations with an additional increment of either the PEC source or destination pointer. An individual PEC transfer counter is implicitly decremented for each PEC service except when performing in the continuous transfer mode. When this counter reaches zero, a standard interrupt is performed to the corresponding source related vector location. PEC services are very well suited to perform the transmission or the reception of blocks of data. The ST10F273Z4 has 8 PEC channels, each of them offers such fast interrupt-driven data transfer capabilities.

An interrupt control register which contains an interrupt request flag, an interrupt enable flag and an interrupt priority bit-field is dedicated to each existing interrupt source. Thanks to its related register, each source can be programmed to one of sixteen interrupt priority levels. Once starting to be processed by the CPU, an interrupt service can only be interrupted by a higher prioritized service request. For the standard interrupt processing, each of the possible interrupt sources has a dedicated vector location.

Software interrupts are supported by means of the 'TRAP' instruction in combination with an individual trap (interrupt) number.

Fast external interrupt inputs are provided to service external interrupts with high precision requirements. These fast interrupt inputs feature programmable edge detection (rising edge, falling edge or both edges).

Fast external interrupts may also have interrupt sources selected from other peripherals; for example the CANx controller receive signals (CANx_RxD) and I²C serial clock signal can be used to interrupt the system.

Table 30 shows all the available ST10F273Z4 interrupt sources and the corresponding hardware-related interrupt flags, vectors, vector locations and trap (interrupt) numbers:

Table 30. Interrupt sources

Source of Interrupt or PEC Service Request	Request Flag	Enable Flag	Interrupt Vector	Vector Location	Trap Number
CAPCOM register 0	CC0IR	CC0IE	CC0INT	00'0040h	10h
CAPCOM register 1	CC1IR	CC1IE	CC1INT	00'0044h	11h
CAPCOM register 2	CC2IR	CC2IE	CC2INT	00'0048h	12h
CAPCOM register 3	CC3IR	CC3IE	CC3INT	00'004Ch	13h
CAPCOM register 4	CC4IR	CC4IE	CC4INT	00'0050h	14h
CAPCOM register 5	CC5IR	CC5IE	CC5INT	00'0054h	15h

Table 30. Interrupt sources (continued)

Source of Interrupt or PEC Service Request	Request Flag	Enable Flag	Interrupt Vector	Vector Location	Trap Number
CAPCOM register 6	CC6IR	CC6IE	CC6INT	00'0058h	16h
CAPCOM register 7	CC7IR	CC7IE	CC7INT	00'005Ch	17h
CAPCOM register 8	CC8IR	CC8IE	CC8INT	00'0060h	18h
CAPCOM register 9	CC9IR	CC9IE	CC9INT	00'0064h	19h
CAPCOM register 10	CC10IR	CC10IE	CC10INT	00'0068h	1Ah
CAPCOM register 11	CC11IR	CC11IE	CC11INT	00'006Ch	1Bh
CAPCOM register 12	CC12IR	CC12IE	CC12INT	00'0070h	1Ch
CAPCOM register 13	CC13IR	CC13IE	CC13INT	00'0074h	1Dh
CAPCOM register 14	CC14IR	CC14IE	CC14INT	00'0078h	1Eh
CAPCOM register 15	CC15IR	CC15IE	CC15INT	00'007Ch	1Fh
CAPCOM register 16	CC16IR	CC16IE	CC16INT	00'00C0h	30h
CAPCOM register 17	CC17IR	CC17IE	CC17INT	00'00C4h	31h
CAPCOM register 18	CC18IR	CC18IE	CC18INT	00'00C8h	32h
CAPCOM register 19	CC19IR	CC19IE	CC19INT	00'00CCh	33h
CAPCOM register 20	CC20IR	CC20IE	CC20INT	00'00D0h	34h
CAPCOM register 21	CC21IR	CC21IE	CC21INT	00'00D4h	35h
CAPCOM register 22	CC22IR	CC22IE	CC22INT	00'00D8h	36h
CAPCOM register 23	CC23IR	CC23IE	CC23INT	00'00DCh	37h
CAPCOM register 24	CC24IR	CC24IE	CC24INT	00'00E0h	38h
CAPCOM register 25	CC25IR	CC25IE	CC25INT	00'00E4h	39h
CAPCOM register 26	CC26IR	CC26IE	CC26INT	00'00E8h	3Ah

Hardware traps are exceptions or error conditions that arise during run-time. They cause immediate non-maskable system reaction similar to a standard interrupt service (branching to a dedicated vector table location).

The occurrence of a hardware trap is additionally signified by an individual bit in the trap flag register (TFR). Except when another higher prioritized trap service is in progress, a hardware trap will interrupt any other program execution. Hardware trap services cannot not be interrupted by standard interrupt or by PEC interrupts.

9.1 X-Peripheral interrupt

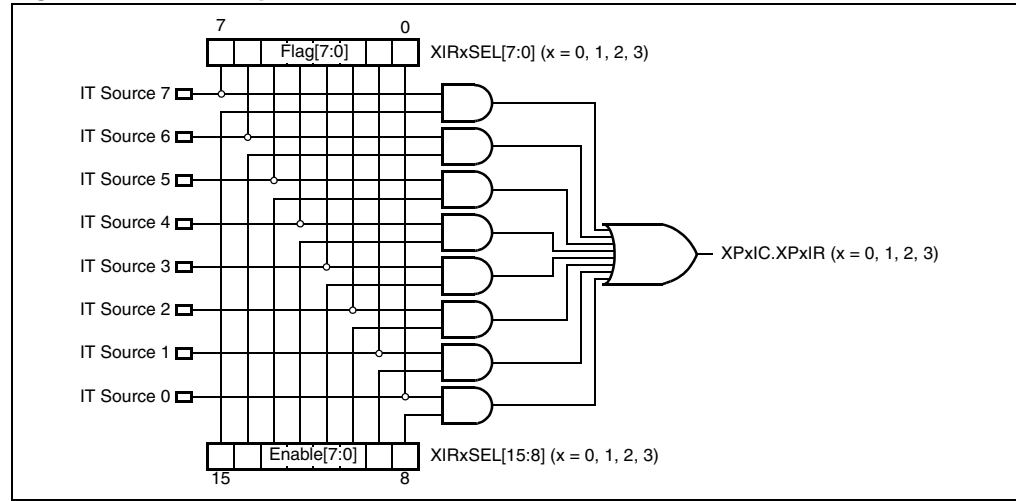

The limited number of X-Bus interrupt lines of the present ST10 architecture, imposes some constraints on the implementation of the new functionality. In particular, the additional X-Peripherals SSC1, ASC1, I²C, PWM1 and RTC need some resources to implement interrupt and PEC transfer capabilities. For this reason, a multiplexed structure for the interrupt management is proposed. In the next [Figure 7](#), the principle is explained through a simple diagram, which shows the basic structure replicated for each of the four X-interrupt available vectors (XP0INT, XP1INT, XP2INT and XP3INT).

It is based on a set of 16-bit registers XIRxSEL (x=0,1,2,3), divided in two portions each:

- Byte High XIRxSEL[15:8] Interrupt Enable bits
- Byte Low XIRxSEL[7:0] Interrupt Flag bits

When different sources submit an interrupt request, the enable bits (Byte High of XIRxSEL register) define a mask which controls which sources will be associated with the unique available vector. If more than one source is enabled to issue the request, the service routine will have to take care to identify the real event to be serviced. This can easily be done by checking the flag bits (Byte Low of XIRxSEL register). Note that the flag bits can also provide information about events which are not currently serviced by the interrupt controller (since masked through the enable bits), allowing an effective software management also in absence of the possibility to serve the related interrupt request: a periodic polling of the flag bits may be implemented inside the user application.

Figure 7. X-Interrupt basic structure

The [Table 31](#) summarizes the mapping of the different interrupt sources which shares the four X-interrupt vectors.

Table 31. X-Interrupt detailed mapping

	XP0INT	XP1INT	XP2INT	XP3INT
CAN1 interrupt	x			x
CAN2 interrupt		x		x
I2C receive	x	x	x	
I2C transmit	x	x	x	
I2C error				x
SSC1 receive	x	x	x	
SSC1 transmit	x	x	x	
SSC1 error				x
ASC1 receive	x	x	x	
ASC1 transmit	x	x	x	
ASC1 transmit buffer	x	x	x	
ASC1 error				x

Table 31. X-Interrupt detailed mapping (continued)

	XP0INT	XP1INT	XP2INT	XP3INT
PLL unlock / OWD				x
PWM1 channel 3...0			x	x

9.2 Exception and error traps list

[Table 32](#) shows all of the possible exceptions or error conditions that can arise during run-time.

Table 32. Trap priorities

Exception condition	Trap flag	Trap vector	Vector location	Trap number	Trap ⁽¹⁾ priority
Reset functions:					
Hardware reset		RESET	00'0000h	00h	III
Software reset		RESET	00'0000h	00h	III
Watchdog timer overflow		RESET	00'0000h	00h	III
Class A hardware traps:					
Non-maskable interrupt	NMI	NMITRAP	00'0008h	02h	II
Stack overflow	STKOF	STOTRAP	00'0010h	04h	II
Stack underflow	STKUF	STUTRAP	00'0018h	06h	II
Class B hardware traps:					
Undefined opcode	UNDOPC	BTRAP	00'0028h	0Ah	I
MAC interruption	MACTRP	BTRAP	00'0028h	0Ah	I
Protected instruction fault	PRTFLT	BTRAP	00'0028h	0Ah	I
Illegal word operand access	ILLOPA	BTRAP	00'0028h	0Ah	I
Illegal instruction access	ILLINA	BTRAP	00'0028h	0Ah	I
Illegal external bus access	ILLBUS	BTRAP	00'0028h	0Ah	I
Reserved			[002Ch - 003Ch]	[0Bh - 0Fh]	
Software traps			Any	Any	Current
TRAP instruction			0000h – 01FCh in steps of 4h	[00h - 7Fh]	CPU Priority

1. All the class B traps have the same trap number (and vector) and the same lower priority compared to the class A traps and to the resets.
Each class A traps has a dedicated trap number (and vector). They are prioritized in the second priority level.
The resets have the highest priority level and the same trap number.
The PSW.IVLV CPU priority is forced to the highest level (15) when these exceptions are serviced.

10 Capture / compare (CAPCOM) units

The ST10F273Z4 has two 16-channel CAPCOM units which support generation and control of timing sequences on up to 32 channels with a maximum resolution of 125ns at 64 MHz CPU clock.

The CAPCOM units are typically used to handle high speed I/O tasks such as pulse and waveform generation, pulse width modulation (PMW), Digital to Analog (D/A) conversion, software timing, or time recording relative to external events.

Four 16-bit timers (T0/T1, T7/T8) with reload registers provide two independent time bases for the capture/compare register array.

The input clock for the timers is programmable to several prescaled values of the internal system clock, or may be derived from an overflow/underflow of timer T6 in module GPT2.

This provides a wide range of variation for the timer period and resolution and allows precise adjustments to application specific requirements. In addition, external count inputs for CAPCOM timers T0 and T7 allow event scheduling for the capture/compare registers relative to external events.

Each of the two capture/compare register arrays contain 16 dual purpose capture/compare registers, each of which may be individually allocated to either CAPCOM timer T0 or T1 (T7 or T8, respectively), and programmed for capture or compare functions. Each of the 32 registers has one associated port pin which serves as an input pin for triggering the capture function, or as an output pin to indicate the occurrence of a compare event.

When a capture/compare register has been selected for capture mode, the current contents of the allocated timer will be latched (captured) into the capture/compare register in response to an external event at the port pin which is associated with this register. In addition, a specific interrupt request for this capture/compare register is generated.

Either a positive, a negative, or both a positive and a negative external signal transition at the pin can be selected as the triggering event. The contents of all registers which have been selected for one of the five compare modes are continuously compared with the contents of the allocated timers.

When a match occurs between the timer value and the value in a capture / compare register, specific actions will be taken based on the selected compare mode.

The input frequencies f_{Tx} , for the timer input selector Tx, are determined as a function of the CPU clocks. The timer input frequencies, resolution and periods which result from the selected pre-scaler option in TxI when using a 40 MHz and 64 MHz CPU clock are listed in the [Table 34](#) and [Table 35](#) respectively.

The numbers for the timer periods are based on a reload value of 0000h. Note that some numbers may be rounded to 3 significant figures.

Table 33. Compare modes

Compare modes	Function
Mode 0	Interrupt-only compare mode; several compare interrupts per timer period are possible
Mode 1	Pin toggles on each compare match; several compare events per timer period are possible
Mode 2	Interrupt-only compare mode; only one compare interrupt per timer period is generated
Mode 3	Pin set '1' on match; pin reset '0' on compare time overflow; only one compare event per timer period is generated
Double register mode	Two registers operate on one pin; pin toggles on each compare match; several compare events per timer period are possible.

Table 34. CAPCOM timer input frequencies, resolutions and periods at 40 MHz

$f_{\text{CPU}} = 40 \text{ MHz}$	Timer Input Selection TxI							
	000b	001b	010b	011b	100b	101b	110b	111b

11 General purpose timer unit

The GPT unit is a flexible multifunctional timer/counter structure which is used for time related tasks such as event timing and counting, pulse width and duty cycle measurements, pulse generation, or pulse multiplication. The GPT unit contains five 16-bit timers organized into two separate modules GPT1 and GPT2. Each timer in each module may operate independently in several different modes, or may be concatenated with another timer of the same module.

11.1 GPT1

Each of the three timers T2, T3, T4 of the GPT1 module can be configured individually for one of four basic modes of operation: **timer**, **gated timer**, **counter mode** and **incremental interface mode**.

In timer mode, the input clock for a timer is derived from the CPU clock, divided by a programmable prescaler.

In counter mode, the timer is clocked in reference to external events.

Pulse width or duty cycle measurement is supported in gated timer mode where the operation of a timer is controlled by the 'gate' level on an external input pin. For these purposes, each timer has one associated port pin (TxIN) which serves as gate or clock input.

Table 36 and Table 37 list the timer input frequencies, resolution and periods for each prescaler option at 40MHz and 64MHz CPU clock respectively.

In Incremental Interface mode, the GPT1 timers (T2, T3, T4) can be directly connected to the incremental position sensor signals A and B by their respective inputs TxIN and TxEUD.

Direction and count signals are internally derived from these two input signals so that the contents of the respective timer Tx corresponds to the sensor position. The third position sensor signal TOP0 can be connected to an interrupt input.

Timer T3 has output toggle latches (TxOTL) which changes state on each timer over flow / underflow. The state of this latch may be output on port pins (TxOUT) for time out monitoring of external hardware components, or may be used internally to clock timers T2 and T4 for high resolution of long duration measurements.

In addition to their basic operating modes, timers T2 and T4 may be configured as reload or capture registers for timer T3.

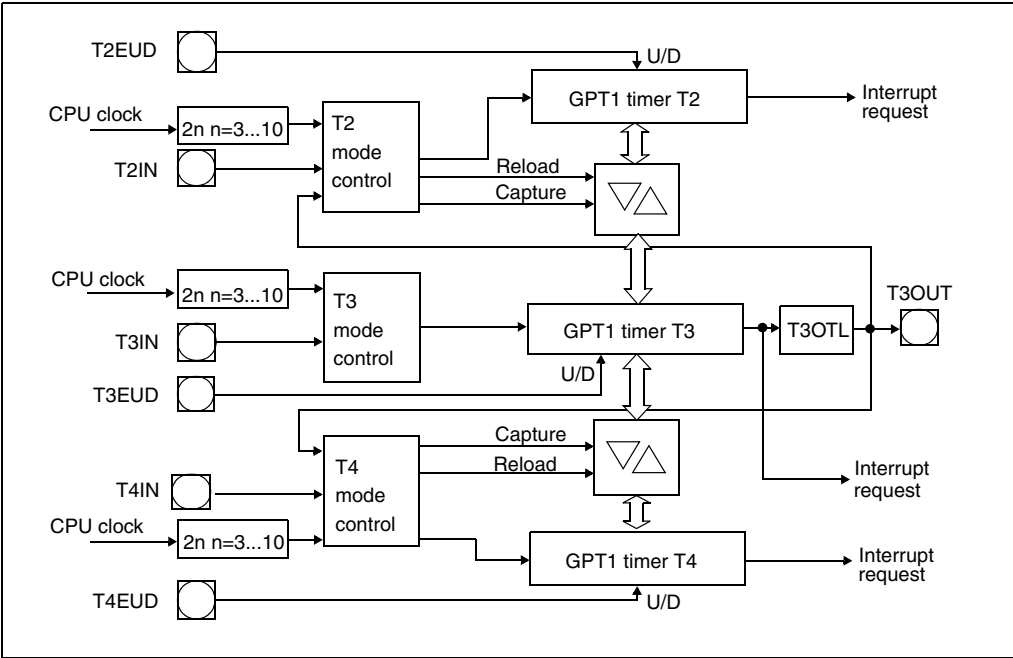

Table 36. GPT1 timer input frequencies, resolutions and periods at 40 MHz

f _{CPU} = 40 MHz	Timer Input Selection T2I / T3I / T4I							
	000b	001b	010b	011b	100b	101b	110b	111b
Pre-scaler factor	8	16	32	64	128	256	512	1024
Input frequency	5 MHz	2.5 MHz	1.25 MHz	625 kHz	312.5 kHz	156.25 kHz	78.125 kHz	39.1 kHz
Resolution	200 ns	400 ns	0.8 µs	1.6µs	3.2µs	6.4 µs	12.8 µs	25.6 µs
Period maximum	13.1 ms	26.2 ms	52.4 ms	104.8 ms	209.7 ms	419.4 ms	838.9 ms	1.678 s

Table 37. GPT1 timer input frequencies, resolutions and periods at 64 MHz

f _{CPU} = 64 MHz	Timer Input Selection T2I / T3I / T4I							
	000b	001b	010b	011b	100b	101b	110b	111b

Period maximum	8.2 ms	16.4 ms	32.8 ms	65.5 ms	131.1 ms	262.1ms	524.3 ms	1.049 s

Figure 8. Block diagram of GPT1

11.2 GPT2

The GPT2 module provides precise event control and time measurement. It includes two timers (T5, T6) and a capture/reload register (CAPREL). Both timers can be clocked with an input clock which is derived from the CPU clock via a programmable prescaler or with external signals. The count direction (up/down) for each timer is programmable by software or may additionally be altered dynamically by an external signal on a port pin (TxEUD). Concatenation of the timers is supported via the output toggle latch (T6OTL) of timer T6 which changes its state on each timer overflow/underflow.

The state of this latch may be used to clock timer T5, or it may be output on a port pin (T6OUT). The overflow / underflow of timer T6 can additionally be used to clock the CAPCOM timers T0 or T1, and to cause a reload from the CAPREL register. The CAPREL register may capture the contents of timer T5 based on an external signal transition on the corresponding port pin (CAPIN), and timer T5 may optionally be cleared after the capture procedure. This allows absolute time differences to be measured or pulse multiplication to be performed without software overhead.

The capture trigger (timer T5 to CAPREL) may also be generated upon transitions of GPT1 timer T3 inputs T3IN and/or T3EUD. This is advantageous when T3 operates in Incremental Interface mode.

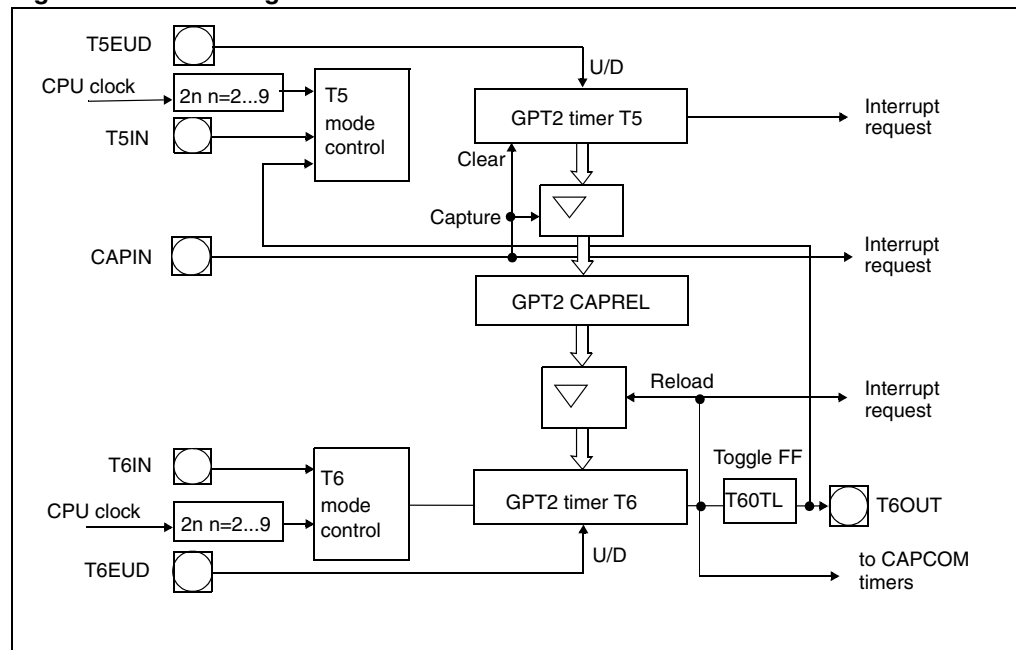

[Table 38](#) and [Table 39](#) list the timer input frequencies, resolution and periods for each pre-scaler option at 40MHz and 64MHz CPU clock respectively.

Table 38. GPT2 timer input frequencies, resolutions and periods at 40 MHz

$f_{\text{CPU}} = 40\text{MHz}$	Timer Input Selection T5I / T6I							
	000b	001b	010b	011b	100b	101b	110b	111b
Pre-scaler factor	4	8	16	32	64	128	256	512
Input frequency	10 MHz	5 MHz	2.5 MHz	1.25 MHz	625 kHz	312.5 kHz	156.25 kHz	78.125 kHz
Resolution	100ns	200ns	400ns	0.8µs	1.6 µs	3.2 µs	6.4 µs	12.8 µs

12 PWM modules

Two pulse width modulation modules are available on ST10F273Z4: standard PWM0 and XBUS PWM1. They can generate up to four PWM output signals each, using edge-aligned or centre-aligned PWM. In addition, the PWM modules can generate PWM burst signals and single shot outputs. The [Table 40](#) and [Table 41](#) show the PWM frequencies for different resolutions. The level of the output signals is selectable and the PWM modules can generate interrupt requests.

Figure 10. Block diagram of PWM module

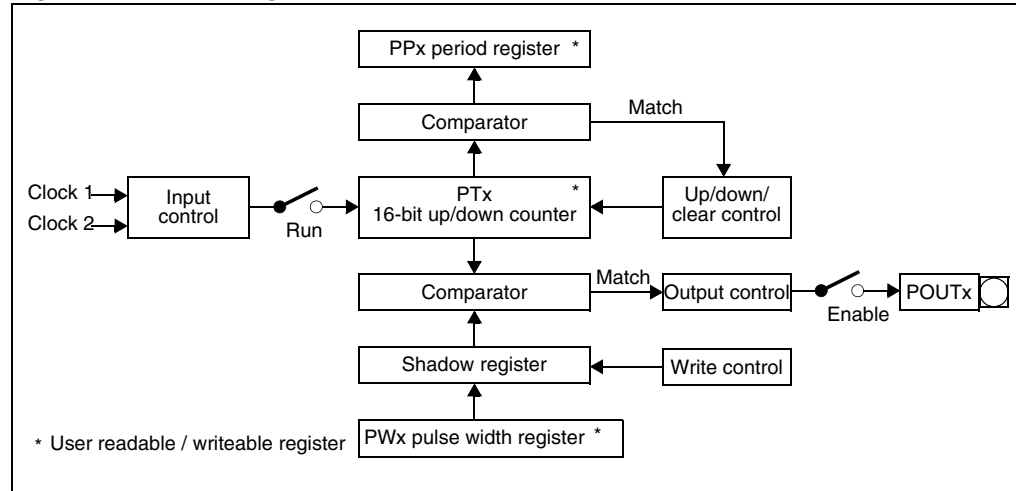

Table 40. PWM unit frequencies and resolutions at 40 MHz CPU clock

Mode 0	Resolution	8-bit	10-bit	12-bit	14-bit	16-bit
CPU Clock/1	25 ns	156.25 kHz	39.1 kHz	9.77 kHz	2.44 Hz	610 Hz

CPU clock/64	1.0 μ s	1.95 kHz	488.28 Hz	122.07 Hz	30.52 Hz	7.63 Hz

13 Parallel ports

13.1 Introduction

The ST10F273Z4 MCU provides up to 111 I/O lines with programmable features. These capabilities bring very flexible adaptation of this MCU to wide range of applications.

ST10F273Z4 has nine groups of I/O lines gathered as follows:

- Port 0 is a two time 8-bit port named P0L (Low as less significant byte) and P0H (high as most significant byte)
- Port 1 is a two time 8-bit port named P1L and P1H
- Port 2 is a 16-bit port
- Port 3 is a 15-bit port (P3.14 line is not implemented)
- Port 4 is a 8-bit port
- Port 5 is a 16-bit port input only
- Port 6, Port 7 and Port 8 are 8-bit ports

These ports may be used as general purpose bidirectional input or output, software controlled with dedicated registers.

For example, the output drivers of six of the ports (2, 3, 4, 6, 7, 8) can be configured (bit-wise) for push-pull or open drain operation using ODPx registers.

The input threshold levels are programmable (TTL/CMOS) for all the ports. The logic level of a pin is clocked into the input latch once per state time, regardless whether the port is configured for input or output. The threshold is selected with PICON and XPICON registers control bits.

A write operation to a port pin configured as an input causes the value to be written into the port output latch, while a read operation returns the latched state of the pin itself. A read-modify-write operation reads the value of the pin, modifies it, and writes it back to the output latch.

Writing to a pin configured as an output (DPx.y='1') causes the output latch and the pin to have the written value, since the output buffer is enabled. Reading this pin returns the value of the output latch. A read-modify-write operation reads the value of the output latch, modifies it, and writes it back to the output latch, thus also modifying the level at the pin.

I/O lines support an alternate function which is detailed in the following description of each port.

13.2 I/Os special features

13.2.1 Open drain mode

Some of the I/O ports of ST10F273Z4 support the open drain capability. This programmable feature may be used with an external pull-up resistor, in order to get an AND wired logical function. This feature is implemented for ports P2, P3, P4, P6, P7 and P8 (see respective sections) and is controlled through the respective Open Drain Control Registers ODPx.

13.2.2 Input threshold control

The standard inputs of the ST10F273Z4 determine the status of input signals according to TTL levels. In order to accept and recognize noisy signals, CMOS input thresholds can be selected instead of the standard TTL thresholds for all the pins. These CMOS thresholds are defined above the TTL thresholds and feature a higher hysteresis to prevent the inputs from toggling while the respective input signal level is near the thresholds.

The Port Input Control registers PICON and XPICON are used to select these thresholds for each Byte of the indicated ports, this means the 8-bit ports P0L, P0H, P1L, P1H, P4, P7 and P8 are controlled by one bit each while ports P2, P3 and P5 are controlled by two bits each.

All options for individual direction and output mode control are available for each pin, independent of the selected input threshold.

13.3 Alternate port functions

Each port line has one associated programmable alternate input or output function.

- PORT0 and PORT1 may be used as address and data lines when accessing external memory. Besides, PORT1 provides also:
 - Input capture lines
 - 8 additional analog input channels to the A/D converter
- Port 2, Port 7 and Port 8 are associated with the capture inputs or compare outputs of the CAPCOM units and/or with the outputs of the PWM0 module, of the PWM1 module and of the ASC1.
Port 2 is also used for fast external interrupt inputs and for timer 7 input.
- Port 3 includes the alternate functions of timers, serial interfaces, the optional bus control signal $\overline{\text{BHE}}$ and the system clock output (CLKOUT).
- Port 4 outputs the additional segment address bit A23...A16 in systems where more than 64 Kbytes of memory are to be access directly. In addition, CAN1, CAN2 and I²C lines are provided.
- Port 5 is used as analog input channels of the A/D converter or as timer control signals.
- Port 6 provides optional bus arbitration signals ($\overline{\text{BREQ}}$, $\overline{\text{HLDA}}$, $\overline{\text{HOLD}}$) and chip select signals and the SSC1 lines.

If the alternate output function of a pin is to be used, the direction of this pin must be programmed for output (DPx.y='1'), except for some signals that are used directly after reset and are configured automatically. Otherwise the pin remains in the high-impedance state and is not effected by the alternate output function. The respective port latch should hold a '1', because its output is ANDed with the alternate output data (except for PWM output signals).

If the alternate input function of a pin is used, the direction of the pin must be programmed for input (DPx.y='0') if an external device is driving the pin. The input direction is the default after reset. If no external device is connected to the pin, however, one can also set the direction for this pin to output. In this case, the pin reflects the state of the port output latch. Thus, the alternate input function reads the value stored in the port output latch. This can be used for testing purposes to allow a software trigger of an alternate input function by writing to the port output latch.

On most of the port lines, the user software is responsible for setting the proper direction when using an alternate input or output function of a pin.

This is done by setting or clearing the direction control bit DPx.y of the pin before enabling the alternate function.

There are port lines, however, where the direction of the port line is switched automatically.

For instance, in the multiplexed external bus modes of PORT0, the direction must be switched several times for an instruction fetch in order to output the addresses and to input the data.

Obviously, this cannot be done through instructions. In these cases, the direction of the port line is switched automatically by hardware if the alternate function of such a pin is enabled.

To determine the appropriate level of the port output latches check how the alternate data output is combined with the respective port latch output.

There is one basic structure for all port lines with only an alternate input function. Port lines with only an alternate output function, however, have different structures due to the way the direction of the pin is switched and depending on whether the pin is accessible by the user software or not in the alternate function mode.

All port lines that are not used for these alternate functions may be used as general purpose I/O lines.

14 A/D converter

A 10-bit A/D converter with 16+8 multiplexed input channels and a sample and hold circuit is integrated on-chip. An automatic self-calibration adjusts the A/D converter module to process parameter variations at each reset event. The sample time (for loading the capacitors) and the conversion time is programmable and can be adjusted to the external circuitry.

The ST10F273Z4 has 16+8 multiplexed input channels on Port 5 and Port 1. The selection between Port 5 and Port 1 is made via a bit in a XBus register. Refer to the User Manual for a detailed description.

A different accuracy is guaranteed (Total Unadjusted Error) on Port 5 and Port 1 analog channels (with higher restrictions when overload conditions occur); in particular, Port 5 channels are more accurate than the Port 1 ones. Refer to Electrical Characteristic section for details.

The A/D converter input bandwidth is limited by the achievable accuracy: supposing a maximum error of 0.5LSB (2mV) impacting the global TUE (TUE depends also on other causes), in worst case of temperature and process, the maximum frequency for a sine wave analog signal is around 7.5 kHz. Of course, to reduce the effect of the input signal variation on the accuracy down to 0.05LSB, the maximum input frequency of the sine wave shall be reduced to 800 Hz.

If static signal is applied during sampling phase, series resistance shall not be greater than 20k Ω (this taking into account eventual input leakage). It is suggested to not connect any capacitance on analog input pins, in order to reduce the effect of charge partitioning (and consequent voltage drop error) between the external and the internal capacitance: in case an RC filter is necessary the external capacitance must be greater than 10nF to minimize the accuracy impact.

Overflow error detection / protection is controlled by the ADDAT register. Either an interrupt request is generated when the result of a previous conversion has not been read from the result register at the time the next conversion is complete, or the next conversion is suspended until the previous result has been read. For applications which require less than 16+8 analog input channels, the remaining channel inputs can be used as digital input port pins.

The A/D converter of the ST10F273Z4 supports different conversion modes:

- **Single channel single conversion:** The analog level of the selected channel is sampled once and converted. The result of the conversion is stored in the ADDAT register.
- **Single channel continuous conversion:** The analog level of the selected channel is repeatedly sampled and converted. The result of the conversion is stored in the ADDAT register.
- **Auto scan single conversion:** The analog level of the selected channels are sampled once and converted. After each conversion the result is stored in the ADDAT register. The data can be transferred to the RAM by interrupt software management or using the powerful Peripheral Event Controller (PEC) data transfer.
- **Auto scan continuous conversion:** The analog level of the selected channels are repeatedly sampled and converted. The result of the conversion is stored in the ADDAT

register. The data can be transferred to the RAM by interrupt software management or using the PEC data transfer.

- **Wait for ADDAT read mode:** When using continuous modes, in order to avoid to overwrite the result of the current conversion by the next one, the ADWR bit of ADCON control register must be activated. Then, until the ADDAT register is read, the new result is stored in a temporary buffer and the conversion is on hold.
- **Channel injection mode:** When using continuous modes, a selected channel can be converted in between without changing the current operating mode. The 10-bit data of the conversion are stored in ADRES field of ADDAT2. The current continuous mode remains active after the single conversion is completed.

A full calibration sequence is performed after a reset. This full calibration lasts up to 40.630 CPU clock cycles. During this time, the busy flag ADBSY is set to indicate the operation. It compensates the capacitance mismatch, so the calibration procedure does not need any update during normal operation.

No conversion can be performed during this time: the bit ADBSY shall be polled to verify when the calibration is over, and the module is able to start a conversion.

15 Serial channels

Serial communication with other microcontrollers, microprocessors, terminals or external peripheral components is provided by up to four serial interfaces: two asynchronous / synchronous serial channels (ASC0 and ASC1) and two high-speed synchronous serial channel (SSC0 and SSC1). Dedicated Baud rate generators set up all standard Baud rates without the requirement of oscillator tuning. For transmission, reception and erroneous reception, separate interrupt vectors are provided for ASC0 and SSC0 serial channel. A more complex mechanism of interrupt sources multiplexing is implemented for ASC1 and SSC1 (XBUS mapped).

15.1 Asynchronous / synchronous serial interfaces

The asynchronous / synchronous serial interfaces (ASC0 and ASC1) provides serial communication between the ST10F273Z4 and other microcontrollers, microprocessors or external peripherals.

15.2 ASCx in asynchronous mode

In asynchronous mode, 8- or 9-bit data transfer, parity generation and the number of stop bits can be selected. Parity framing and overrun error detection is provided to increase the reliability of data transfers. Transmission and reception of data is double-buffered. Full-duplex communication up to 2M Bauds (at 64 MHz of f_{CPU}) is supported in this mode.

Table 42. ASC asynchronous baud rates by reload value and deviation errors ($f_{CPU} = 40$ MHz)

S0BRS = '0', $f_{CPU} = 40$ MHz			S0BRS = '1', $f_{CPU} = 40$ MHz

300	0.0% / 0.0%	1A09 / 1A0A	300	0.0% / 0.0%	115B / 115C
245	0.0% / 0.0%	1FE2 / 1FE3	163	0.0% / 0.0%	1FF2 / 1FF3

Note: The deviation errors given in the [Table 42](#) and [Table 43](#) are rounded. To avoid deviation errors use a Baud rate crystal (providing a multiple of the ASC0 sampling frequency).

15.3 ASCx in synchronous mode

In synchronous mode, data is transmitted or received synchronously to a shift clock which is generated by the ST10F273Z4. Half-duplex communication up to 8M Baud (at 40 MHz of f_{CPU}) is possible in this mode.

Table 44. ASC synchronous baud rates by reload value and deviation errors ($f_{CPU} = 40$ MHz)

S0BRS = '0', $f_{CPU} = 40$ MHz			S0BRS = '1', $f_{CPU} = 40$ MHz		
Baud rate (Baud)	Deviation error	Reload value (hex)	Baud rate (Baud)	Deviation Error	Reload value (hex)
5 000 000	0.0% / 0.0%	0000 / 0000	3 333 333	0.0% / 0.0%	0000 / 0000

2 400	0.0% / 0.0%	0D04 / 0D05	2 400	0.0% / 0.0%	08AD / 08AE
1 200	0.0% / 0.0%	1A09 / 1A0A	1 200	0.0% / 0.0%	115B / 115C
977	0.0% / 0.0%	1FFB / 1FFC	900	0.0% / 0.0%	1724 / 1725
			652	0.0% / 0.0%	1FF2 / 1FF3

Note: The deviation errors given in the [Table 44](#) and [Table 45](#) are rounded. To avoid deviation errors use a Baud rate crystal (providing a multiple of the ASC0 sampling frequency)

15.4 High speed synchronous serial interfaces

The High-Speed Synchronous Serial Interfaces (SSC0 and SSC1) provides flexible high-speed serial communication between the ST10F273Z4 and other microcontrollers, microprocessors or external peripherals.

The SSCx supports full-duplex and half-duplex synchronous communication. The serial clock signal can be generated by the SSCx itself (master mode) or be received from an external master (slave mode). Data width, shift direction, clock polarity and phase are programmable.

This allows communication with SPI-compatible devices. Transmission and reception of data is double-buffered. A 16-bit Baud rate generator provides the SSCx with a separate serial clock signal. The serial channel SSCx has its own dedicated 16-bit Baud rate generator with 16-bit reload capability, allowing Baud rate generation independent from the timers.

[Table 46](#) and [Table 47](#) list some possible Baud rates against the required reload values and the resulting bit times for 40 MHz and 64 MHz CPU clock respectively. The maximum is anyway limited to 8Mbaud.

Table 46. Synchronous baud rate and reload values ($f_{\text{CPU}} = 40 \text{ MHz}$)

Baud rate	Bit time	Reload value
Reserved	---	0000h
Can be used only with $f_{\text{CPU}} = 32 \text{ MHz}$ (or lower)	---	0001h
6.6M Baud	150ns	0002h
5M Baud	200ns	0003h
2.5M Baud	400ns	0007h
1M Baud	1 μ s	0013h
100K Baud	10 μ s	00C7h
10K Baud	100 μ s	07CFh
1K Baud	1ms	4E1Fh
306 Baud	3.26ms	FF4Eh

Table 47. Synchronous baud rate and reload values ($f_{\text{CPU}} = 64 \text{ MHz}$)

Baud rate	Bit time	Reload value
Reserved	---	0000h
Can be used only with $f_{\text{CPU}} = 32 \text{ MHz}$ (or lower)	---	0001h
Can be used only with $f_{\text{CPU}} = 48 \text{ MHz}$ (or lower)	---	0002h
8M Baud	125ns	0003h
4M Baud	250ns	0007h
1M Baud	1 μ s	001Fh
100K Baud	10 μ s	013Fh
10K Baud	100 μ s	0C7Fh
1K Baud	1ms	7CFFh
489 Baud	2.04ms	FF9Eh

16 I²C interface

The integrated I²C Bus Module handles the transmission and reception of frames over the two-line SDA/SCL in accordance with the I²C Bus specification. The I²C Module can operate in slave mode, in master mode or in multi-master mode. It can receive and transmit data using 7-bit or 10-bit addressing. Data can be transferred at speeds up to 400 Kbit/s (both Standard and Fast I²C bus modes are supported).

The module can generate three different types of interrupt:

- Requests related to bus events, like start or stop events, arbitration lost, etc.
- Requests related to data transmission
- Requests related to data reception

These requests are issued to the interrupt controller by three different lines, and identified as Error, Transmit, and Receive interrupt lines.

When the I²C module is enabled by setting bit XI2CEN in XPERCON register, pins P4.4 and P4.7 (where SCL and SDA are respectively mapped as alternate functions) are automatically configured as bidirectional open-drain: the value of the external pull-up resistor depends on the application. P4, DP4 and ODP4 cannot influence the pin configuration.

When the I²C cell is disabled (clearing bit XI2CEN), P4.4 and P4.7 pins are standard I/O controlled by P4, DP4 and ODP4.

The speed of the I²C interface may be selected between Standard mode (0 to 100 kHz) and Fast I²C mode (100 to 400 kHz).

17 CAN modules

The two integrated CAN modules (CAN1 and CAN2) are identical and handle the completely autonomous transmission and reception of CAN frames according to the CAN specification V2.0 part B (active). It is based on the C-CAN specification.

Each on-chip CAN module can receive and transmit standard frames with 11-bit identifiers as well as extended frames with 29-bit identifiers.

Because of duplication of the CAN controllers, the following adjustments are to be considered:

- Same internal register addresses of both CAN controllers, but with base addresses differing in address bit A8; separate chip select for each CAN module. Refer to [Chapter 4: Memory organization on page 22](#).
- The CAN1 transmit line (CAN1_TxD) is the alternate function of the Port P4.6 pin and the receive line (CAN1_RxD) is the alternate function of the Port P4.5 pin.
- The CAN2 transmit line (CAN2_TxD) is the alternate function of the Port P4.7 pin and the receive line (CAN2_RxD) is the alternate function of the Port P4.4 pin.
- Interrupt request lines of the CAN1 and CAN2 modules are connected to the XBUS interrupt lines together with other X-Peripherals sharing the four vectors.
- The CAN modules must be selected with corresponding CANxEN bit of XPERCON register before the bit XPEN of SYSCON register is set.
- The reset default configuration is: CAN1 enabled, CAN2 disabled.

Note: If one or both CAN modules is used, Port 4 cannot be programmed to output all 8 segment address lines. Thus, only four segment address lines can be used, reducing the external memory space to 5 Mbytes (1 Mbyte per \overline{CS} line).

17.1 Configuration support

It is possible that both CAN controllers are working on the same CAN bus, supporting together up to 64 message objects. In this configuration, both receive signals and both transmit signals are linked together when using the same CAN transceiver. This configuration is especially supported by providing open drain outputs for the CAN1_TxD and CAN2_TxD signals. The open drain function is controlled with the ODP4 register for port P4: in this way it is possible to connect together P4.4 with P4.5 (receive lines) and P4.6 with P4.7 (transmit lines configured to be configured as Open-Drain).

The user is also allowed to map internally both CAN modules on the same pins P4.5 and P4.6. In this way, P4.4 and P4.7 may be used either as general purpose I/O lines, or used for I²C interface. This is possible by setting bit CANPAR of XMISC register. To access this register it is necessary to set bit XMISCEN of XPERCON register and bit XPEN of SYSCON register.

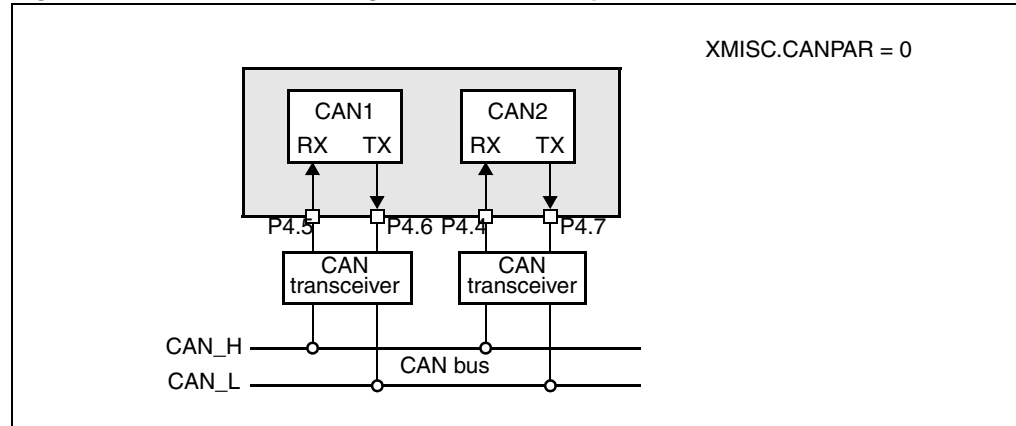

17.2 CAN bus configurations

Depending on application, CAN bus configuration may be one single bus with a single or multiple interfaces or a multiple bus with a single or multiple interfaces. The ST10F273Z4 is able to support these two cases.

Single CAN bus

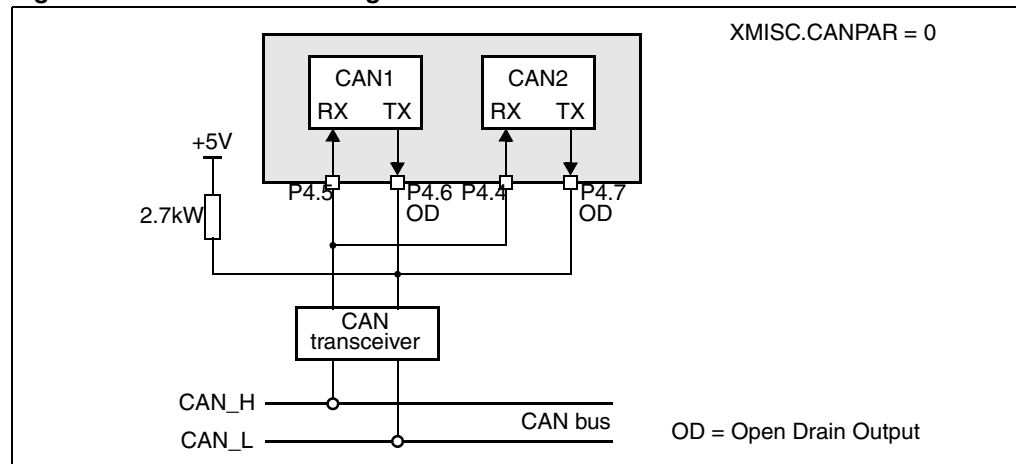

The single CAN Bus multiple interfaces configuration may be implemented using two CAN transceivers as shown in [Figure 11](#).

Figure 11. Connection to single CAN bus via separate CAN transceivers

The ST10F273Z4 also supports single CAN Bus multiple (dual) interfaces using the open drain option of the CANx_TxD output as shown in [Figure 12](#). Thanks to the OR-Wired Connection, only one transceiver is required. In this case the design of the application must take in account the wire length and the noise environment.

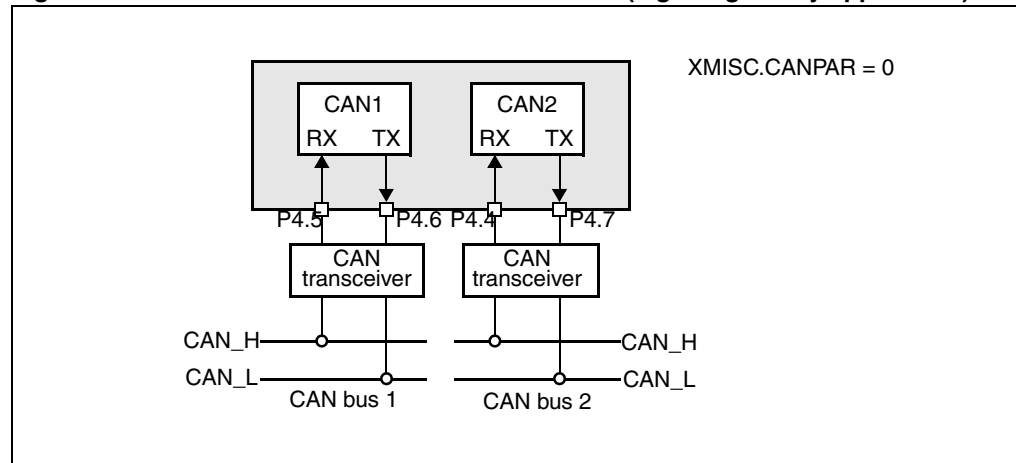

Figure 12. Connection to single CAN bus via common CAN transceivers

Multiple CAN bus

The ST10F273Z4 provides two CAN interfaces to support such kind of bus configuration as shown in [Figure 13](#).

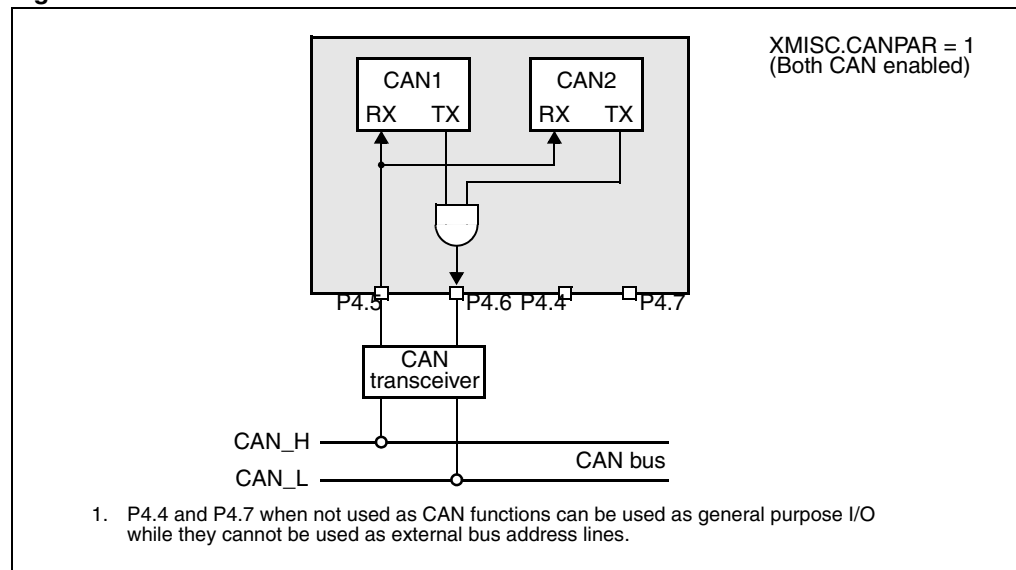

Figure 13. Connection to two different CAN buses (e.g. for gateway application)

Parallel mode

In addition to previous configurations, a parallel mode is supported. This is shown in [Figure 14](#).

Figure 14. Connection to one CAN bus with internal Parallel mode enabled

18 Real-time clock

The real-time clock is an independent timer, in which the clock is derived directly from the clock oscillator on XTAL1 (main oscillator) input or XTAL3 input (32 kHz low-power oscillator) so that it can be kept on running even in idle or power down mode (if enabled to). Registers access is implemented onto the XBUS. This module is designed with the following characteristics:

- Generation of the current time and date for the system
- Cyclic time based interrupt, on Port2 external interrupts every 'RTC basic clock tick' and after n 'RTC basic clock ticks' (n is programmable) if enabled
- 58-bit timer for long term measurement
- Capability to exit the ST10 chip from Power down mode (if PWDCFG of SYSCON set) after a programmed delay

The real-time clock is based on two main blocks of counters. The first block is a prescaler which generates a basic reference clock (for example a 1 second period). This basic reference clock is coming out of a 20-bit DIVIDER. This 20-bit counter is driven by an input clock derived from the on-chip CPU clock, pre-divided by a 1/64 fixed counter. This 20-bit counter is loaded at each basic reference clock period with the value of the 20-bit PRESCALER register. The value of the 20-bit RTCP register determines the period of the basic reference clock.

A timed interrupt request (RTCSI) may be sent on each basic reference clock period. The second block of the RTC is a 32-bit counter that may be initialized with the current system time. This counter is driven with the basic reference clock signal. In order to provide an alarm function the contents of the counter is compared with a 32-bit alarm register. The alarm register may be loaded with a reference date. An alarm interrupt request (RTCAI), may be generated when the value of the counter matches the alarm register.

The timed RTCSI and the alarm RTCAI interrupt requests can trigger a fast external interrupt via EXISEL register of port 2 and wake-up the ST10 chip when running power down mode. Using the RTCOFF bit of RTCCON register, the user may switch off the clock oscillator when entering the power down mode.

The last function implemented in the RTC is to switch off the main on-chip oscillator and the 32 kHz on chip oscillator if the ST10 enters the Power down mode, so that the chip can be fully switched off (if RTC is disabled).

At power on, and after Reset phase, if the presence of a 32 kHz oscillation on XTAL3 / XTAL4 pins is detected, then the RTC counter is driven by this low frequency reference clock: when Power down mode is entered, the RTC can either be stopped or left running, and in both the cases the main oscillator is turned off, reducing the power consumption of the device to the minimum required to keep on running the RTC counter and relative reference oscillator. This is valid also if Stand-by mode is entered (switching off the main supply V_{DD}), since both the RTC and the low power oscillator (32 kHz) are biased by the V_{STBY} . Vice versa, when at power on and after Reset, the 32 kHz is not present, the main oscillator drives the RTC counter, and since it is powered by the main power supply, it cannot be maintained running in Stand-by mode, while in Power down mode the main oscillator is maintained running to provide the reference to the RTC module (if not disabled).

19 Watchdog timer

The watchdog timer is a fail-safe mechanism which prevents the microcontroller from malfunctioning for long periods of time.

The watchdog timer is always enabled after a reset of the chip and can only be disabled in the time interval until the EINIT (end of initialization) instruction has been executed.

Therefore, the chip start-up procedure is always monitored. The software must be designed to service the watchdog timer before it overflows. If, due to hardware or software related failures, the software fails to do so, the watchdog timer overflows and generates an internal hardware reset. It pulls the $\overline{\text{RSTOUT}}$ pin low in order to allow external hardware components to be reset.

Each of the different reset sources is indicated in the WDTCON register:

- Watchdog timer reset in case of an overflow
- Software Reset in case of execution of the SRST instruction
- Short, long and power-on reset in case of hardware reset (and depending of reset pulse duration and RPD pin configuration)

The indicated bits are cleared with the EINIT instruction. The source of the reset can be identified during the initialization phase.

The watchdog timer is 16-bit, clocked with the system clock divided by 2 or 128. The high Byte of the watchdog timer register can be set to a pre-specified reload value (stored in WDTREL).

Each time it is serviced by the application software, the high byte of the watchdog timer is reloaded. For security, rewrite WDTCON each time before the watchdog timer is serviced

The [Table 48](#) and [Table 49](#) show the watchdog time range for 40 MHz and 64 MHz CPU clock respectively.

Table 48. WDTREL reload value ($f_{\text{CPU}} = 40 \text{ MHz}$)

Reload value in WDTREL	Prescaler for $f_{\text{CPU}} = 40 \text{ MHz}$	
	2 (WDTIN = '0')	128 (WDTIN = '1')
FFh	12.8 μs	819.2 μs
00h	3.277ms	209.7ms

Table 49. WDTREL reload value ($f_{\text{CPU}} = 64 \text{ MHz}$)

Reload value in WDTREL	Prescaler for $f_{\text{CPU}} = 64 \text{ MHz}$	
	2 (WDTIN = '0')	128 (WDTIN = '1')
FFh	8 μs	512 μs
00h	2.048ms	131.1ms

20 System reset

System reset initializes the MCU in a predefined state. There are six ways to activate a reset state. The system start-up configuration is different for each case as shown in [Table 50](#).

Table 50. Reset event definition

Reset Source	Flag	RPD Status	Conditions
Power-on reset	PONR	Low	Power-on
Asynchronous hardware reset	LHWR	Low	$t_{\overline{RSTIN}} > ^{(1)}$
Synchronous long hardware reset		High	$t_{\overline{RSTIN}} > (1032 + 12)TCL + \max(4 \text{ TCL}, 500\text{ns})$
Synchronous short hardware reset	SHWR	High	$t_{\overline{RSTIN}} > \max(4 \text{ TCL}, 500\text{ns})$ $t_{\overline{RSTIN}} \leq (1032 + 12)TCL + \max(4 \text{ TCL}, 500\text{ns})$
Watchdog timer reset	WDTR	⁽²⁾	WDT overflow
Software reset	SWR	⁽³⁾	SRST instruction execution

1. \overline{RSTIN} pulse should be longer than 500ns (Filter) and than settling time for configuration of Port0.
2. See next [Section 20.1](#) for more details on minimum reset pulse duration
3. The RPD status has no influence unless Bidirectional Reset is activated (bit BDRSTEN in SYSCON): RPD low inhibits the Bidirectional reset on SW and WDT reset events, that is \overline{RSTIN} is not activated (refer to Sections [20.4](#), [20.5](#) and [20.6](#)).

20.1 Input filter

On \overline{RSTIN} input pin an on-chip RC filter is implemented. It is sized to filter all the spikes shorter than 50ns. On the other side, a valid pulse shall be longer than 500ns to grant that ST10 recognizes a reset command. In between 50ns and 500ns a pulse can either be filtered or recognized as valid, depending on the operating conditions and process variations.

For this reason all minimum durations mentioned in this Chapter for the different kind of reset events shall be carefully evaluated taking into account of the above requirements.

In particular, for Short Hardware Reset, where only 4 TCL is specified as minimum input reset pulse duration, the operating frequency is a key factor. Examples:

- For a CPU clock of 64 MHz, 4 TCL is 31.25ns, so it would be filtered. In this case the minimum becomes the one imposed by the filter (that is 500ns).
- For a CPU clock of 4 MHz, 4 TCL is 500ns. In this case the minimum from the formula is coherent with the limit imposed by the filter.

20.2 Asynchronous reset

An asynchronous reset is triggered when $\overline{\text{RSTIN}}$ pin is pulled low while RPD pin is at low level. Then the ST10F273Z4 is immediately (after the input filter delay) forced in reset default state. It pulls low $\overline{\text{RSTOUT}}$ pin, it cancels pending internal hold states if any, it aborts all internal/external bus cycles, it switches buses (data, address and control signals) and I/O pin drivers to high-impedance, it pulls high Port0 pins.

Note: If an asynchronous reset occurs during a read or write phase in internal memories, the content of the memory itself could be corrupted: to avoid this, synchronous reset usage is strongly recommended.

Power-on reset

The asynchronous reset must be used during the power-on of the device. Depending on crystal or resonator frequency, the on-chip oscillator needs about 1ms to 10ms to stabilize (Refer to Electrical Characteristics Section), with an already stable V_{DD} . The logic of the ST10F273Z4 does not need a stabilized clock signal to detect an asynchronous reset, so it is suitable for power-on conditions. To ensure a proper reset sequence, the $\overline{\text{RSTIN}}$ pin and the RPD pin must be held at low level until the device clock signal is stabilized and the system configuration value on Port0 is settled.

At Power-on it is important to respect some additional constraints introduced by the start-up phase of the different embedded modules.

In particular the on-chip voltage regulator needs at least 1ms to stabilize the internal 1.8V for the core logic: this time is computed from when the external reference (V_{DD}) becomes stable (inside specification range, that is at least 4.5V). This is a constraint for the application hardware (external voltage regulator): the $\overline{\text{RSTIN}}$ pin assertion shall be extended to guarantee the voltage regulator stabilization.

A second constraint is imposed by the embedded FLASH. When booting from internal memory, starting from $\overline{\text{RSTIN}}$ releasing, it needs a maximum of 1ms for its initialization: before that, the internal reset (RST signal) is not released, so the CPU does not start code execution in internal memory.

Note: This is not true if external memory is used (pin $\overline{\text{EA}}$ held low during reset phase). In this case, once $\overline{\text{RSTIN}}$ pin is released, and after few CPU clock (Filter delay plus 3...8 TCL), the internal reset signal RST is released as well, so the code execution can start immediately after. Obviously, an eventual access to the data in internal Flash is forbidden before its initialization phase is completed: an eventual access during starting phase will return FFFFh (just at the beginning), while later 009Bh (an illegal opcode trap can be generated).

At Power-on, the $\overline{\text{RSTIN}}$ pin shall be tied low for a minimum time that includes also the start-up time of the main oscillator ($t_{\text{STUP}} = 1\text{ms}$ for resonator, 10ms for crystal) and PLL synchronization time ($t_{\text{PSUP}} = 200\mu\text{s}$): this means that if the internal FLASH is used, the $\overline{\text{RSTIN}}$ pin could be released before the main oscillator and PLL are stable to recover some time in the start-up phase (FLASH initialization only needs stable V_{18} , but does not need stable system clock since an internal dedicated oscillator is used).

Warning: It is recommended to provide the external hardware with a current limitation circuitry. This is necessary to avoid permanent damages of the device during the power-on transient, when the capacitance on V_{18} pin is charged. For the on-chip voltage regulator functionality 10nF are

sufficient: anyway, a maximum of 100nF on V₁₈ pin should not generate problems of over-current (higher value is allowed if current is limited by the external hardware). External current limitation is anyway recommended also to avoid risks of damage in case of temporary short between V₁₈ and ground: the internal 1.8V drivers are sized to drive currents of several tens of Ampere, so the current shall be limited by the external hardware. The limit of current is imposed by power dissipation considerations (Refer to Electrical Characteristics Section).

In next Figures 15 and 16 Asynchronous Power-on timing diagrams are reported, respectively with boot from internal or external memory, highlighting the reset phase extension introduced by the embedded FLASH module when selected.

Note: Never power the device without keeping \overline{RSTIN} pin grounded: the device could enter in unpredictable states, risking also permanent damages.

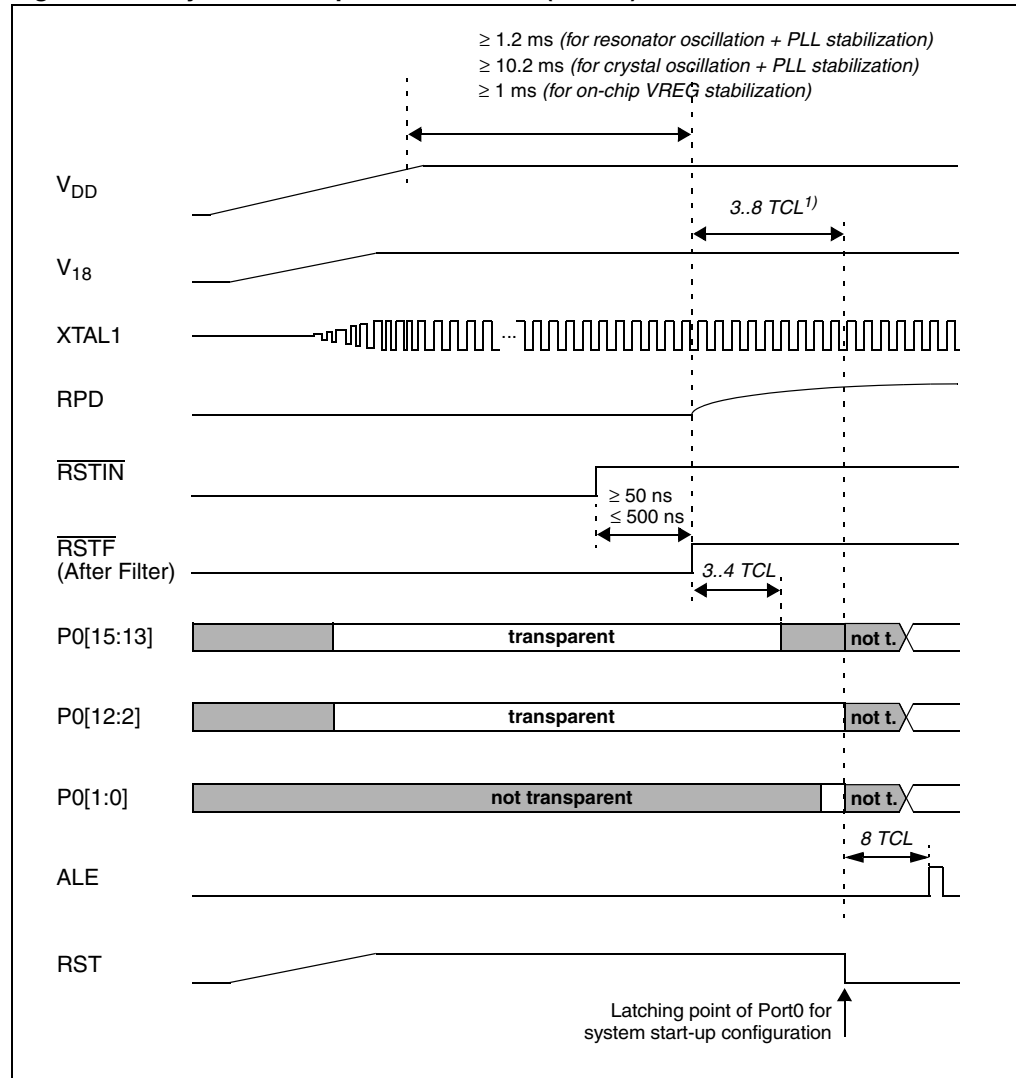

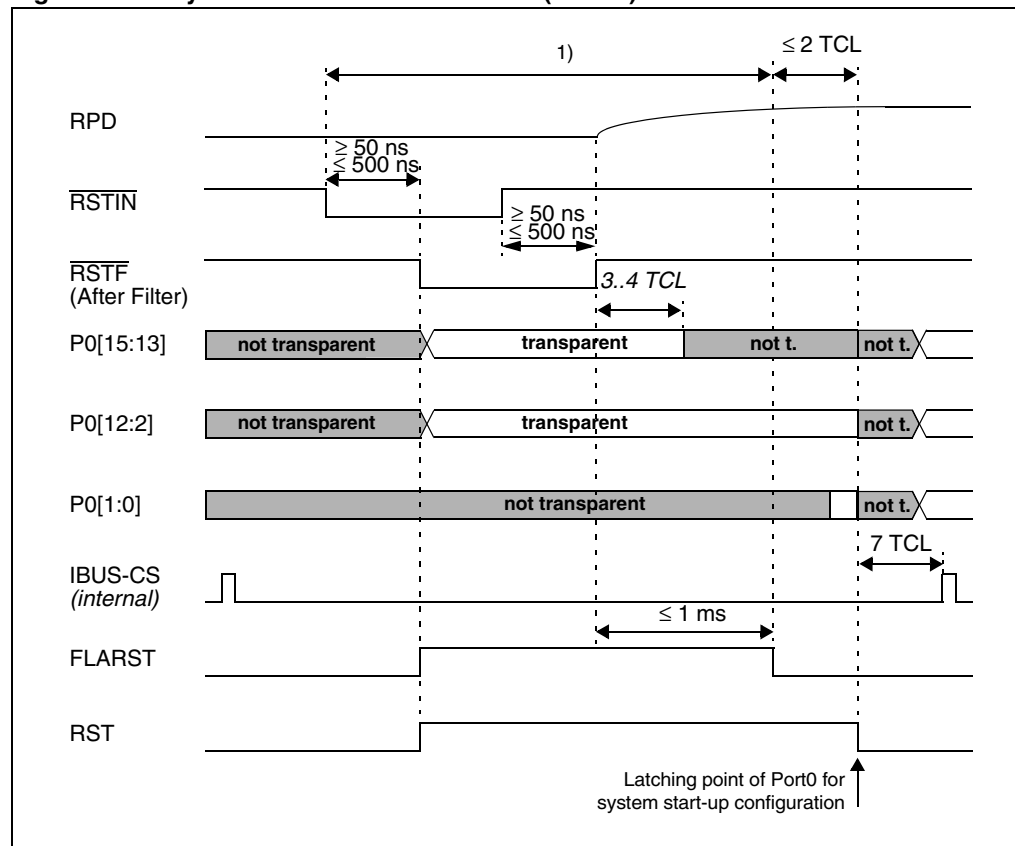

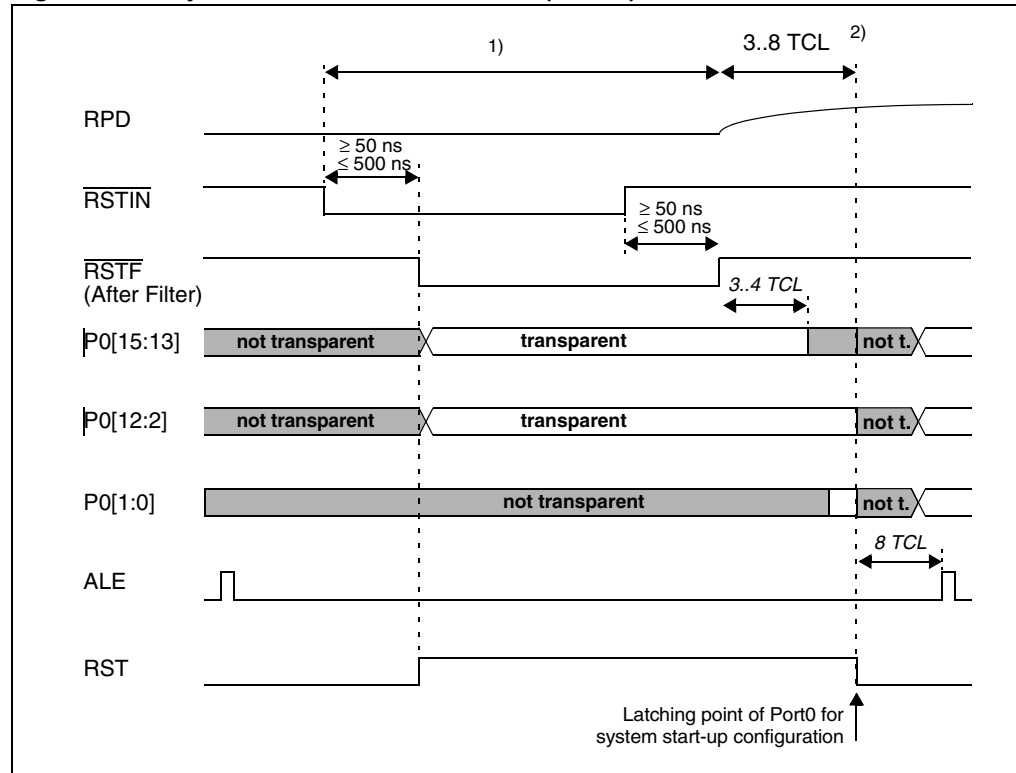

Figure 15. Asynchronous power-on RESET ($\overline{EA} = 1$)

Figure 16. Asynchronous power-on RESET ($\overline{EA} = 0$)**Hardware reset**

The asynchronous reset must be used to recover from catastrophic situations of the application. It may be triggered by the hardware of the application. Internal hardware logic and application circuitry are described in Reset circuitry chapter and Figures 28, 29 and 30. It occurs when \overline{RSTIN} is low and RPD is detected (or becomes) low as well.

Figure 17. Asynchronous hardware RESET ($\overline{EA} = 1$)

1) Longer than Port0 settling time + PLL synchronization (if needed, that is P0(15:13) changed). Longer than 500ns to take into account of Input Filter on RSTIN pin

Figure 18. Asynchronous hardware RESET ($\overline{EA} = 0$)

1) Longer than Port0 settling time + PLL synchronization (if needed, that is P0(15:13) changed). Longer than 500ns to take into account of Input Filter on RSTIN pin

2) 3 to 8 TCL depending on clock source selection.

Exit from asynchronous reset state

When the \overline{RSTIN} pin is pulled high, the device restarts: as already mentioned, if internal FLASH is used, the restarting occurs after the embedded FLASH initialization routine is completed. The system configuration is latched from Port0: ALE, \overline{RD} and $\overline{WR/WRL}$ pins are driven to their inactive level. The ST10F273Z4 starts program execution from memory location 00'0000h in code segment 0. This starting location will typically point to the general initialization routine. Timing of asynchronous Hardware Reset sequence are summarized in [Figure 17](#) and [Figure 18](#).

20.3 Synchronous reset (warm reset)

A synchronous reset is triggered when \overline{RSTIN} pin is pulled low while RPD pin is at high level. In order to properly activate the internal reset logic of the device, the \overline{RSTIN} pin must be held low, at least, during 4 TCL (2 periods of CPU clock): refer also to [Section 20.1](#) for details on minimum reset pulse duration. The I/O pins are set to high impedance and \overline{RSTOUT} pin is driven low. After \overline{RSTIN} level is detected, a short duration of a maximum of 12 TCL (six periods of CPU clock) elapses, during which pending internal hold states are cancelled and the current internal access cycle if any is completed. External bus cycle is aborted. The internal pull-down of \overline{RSTIN} pin is activated if bit BDRSTEN of SYSCON

register was previously set by software. Note that this bit is always cleared on power-on or after a reset sequence.

Short and long synchronous reset

Once the first maximum 16 TCL are elapsed (4+12TCL), the internal reset sequence starts. It is 1024 TCL cycles long: at the end of it, and after other 8TCL the level of $\overline{\text{RSTIN}}$ is sampled (after the filter, see $\overline{\text{RSTF}}$ in the drawings): if it is already at high level, only Short Reset is flagged (Refer to [Chapter 19](#) for details on reset flags); if it is recognized still low, the Long reset is flagged as well. The major difference between Long and Short reset is that during the Long reset, also P0(15:13) become transparent, so it is possible to change the clock options.

Warning: In case of a short pulse on $\overline{\text{RSTIN}}$ pin, and when Bidirectional reset is enabled, the $\overline{\text{RSTIN}}$ pin is held low by the internal circuitry. At the end of the 1024 TCL cycles, the $\overline{\text{RSTIN}}$ pin is released, but due to the presence of the input analog filter the internal input reset signal ($\overline{\text{RSTF}}$ in the drawings) is released later (from 50 to 500ns). This delay is in parallel with the additional 8 TCL, at the end of which the internal input reset line ($\overline{\text{RSTF}}$) is sampled, to decide if the reset event is Short or Long. In particular:

- If 8 TCL > 500 ns ($F_{\text{CPU}} < 8$ MHz), the reset event is always recognized as Short
- If 8 TCL < 500 ns ($F_{\text{CPU}} > 8$ MHz), the reset event could be recognized either as Short or Long, depending on the real filter delay (between 50 and 500ns) and the CPU frequency ($\overline{\text{RSTF}}$ sampled High means Short reset, $\overline{\text{RSTF}}$ sampled Low means Long reset). Note that in case a Long Reset is recognized, once the 8 TCL are elapsed, the P0(15:13) pins becomes transparent, so the system clock can be re-configured. The port returns not transparent 3-4TCL after the internal $\overline{\text{RSTF}}$ signal becomes high.

The same behavior just described, occurs also when unidirectional reset is selected and $\overline{\text{RSTIN}}$ pin is held low till the end of the internal sequence (exactly 1024TCL + max 16 TCL) and released exactly at that time.

Note: When running with CPU frequency lower than 40 MHz, the minimum valid reset pulse to be recognized by the CPU (4 TCL) could be longer than the minimum analog filter delay (50ns); so it might happen that a short reset pulse is not filtered by the analog input filter, but on the other hand it is not long enough to trigger a CPU reset (shorter than 4 TCL): this would generate a FLASH reset but not a system reset. In this condition, the FLASH answers always with FFFFh, which leads to an illegal opcode and consequently a trap event is generated.

Exit from synchronous reset state

The reset sequence is extended until $\overline{\text{RSTIN}}$ level becomes high. Besides, it is internally prolonged by the FLASH initialization when $\overline{\text{EA}}=1$ (internal memory selected). Then, the code execution restarts. The system configuration is latched from Port0, and ALE, $\overline{\text{RD}}$ and $\overline{\text{WR/WRL}}$ pins are driven to their inactive level. The ST10F273Z4 starts program execution from memory location 00'0000h in code segment 0. This starting location will typically point to the general initialization routine. Timing of synchronous reset sequence are summarized in Figures 19 and 20 where a Short Reset event is shown, with particular highlighting on the

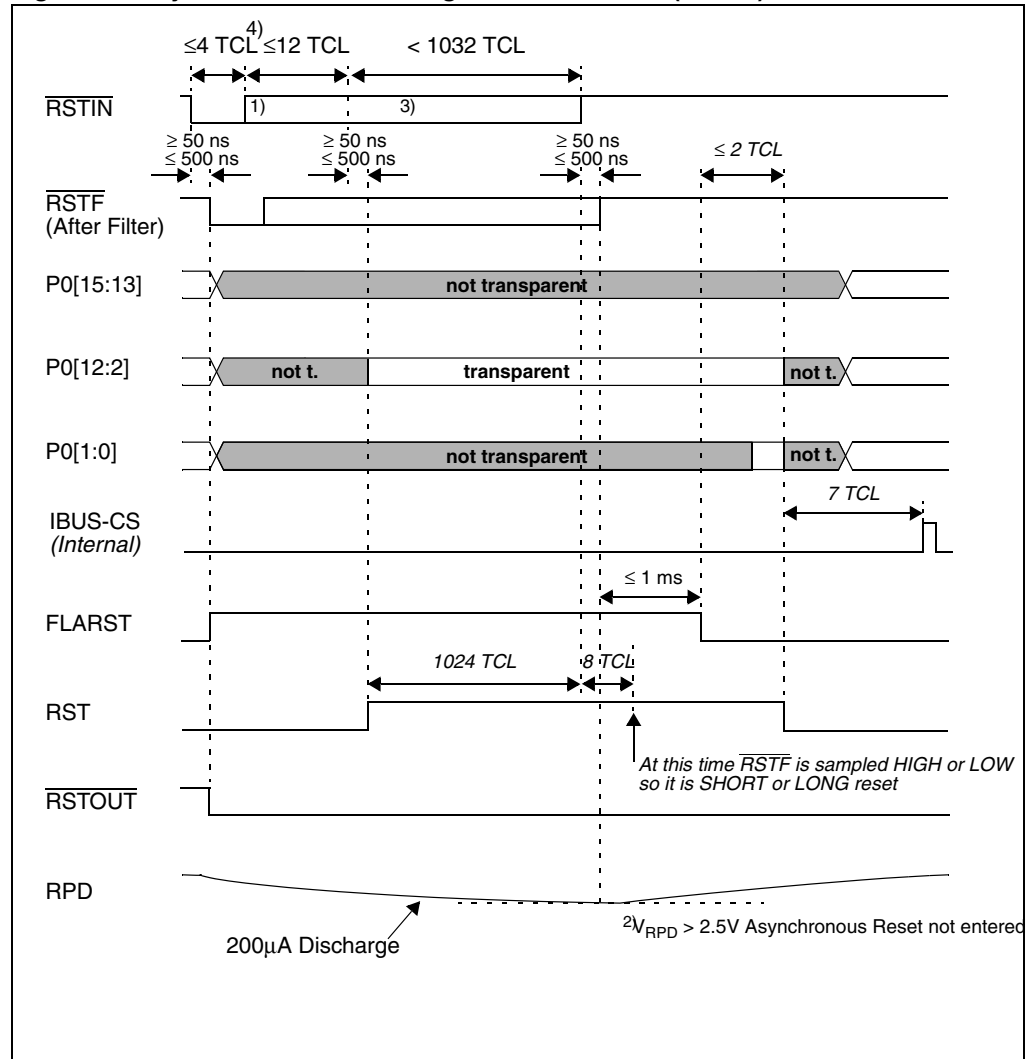

fact that it can degenerate into Long Reset: the two figures show the behavior when booting from internal or external memory respectively. Figures 21 and 22 reports the timing of a typical synchronous Long Reset, again when booting from internal or external memory.

Synchronous reset and RPD pin

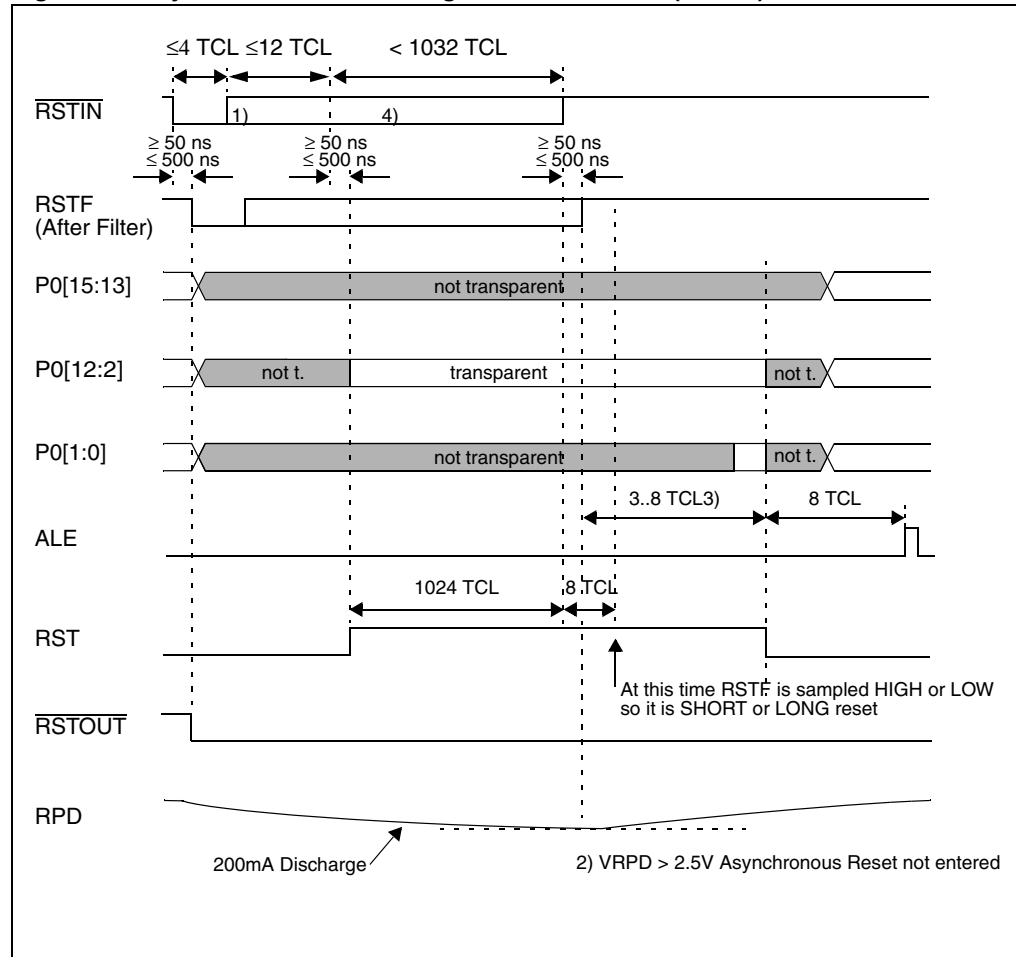

Whenever the $\overline{\text{RSTIN}}$ pin is pulled low (by external hardware or as a consequence of a Bidirectional reset), the RPD internal weak pull-down is activated. The external capacitance (if any) on RPD pin is slowly discharged through the internal weak pull-down. If the voltage level on RPD pin reaches the input low threshold (around 2.5V), the reset event becomes immediately asynchronous. In case of hardware reset (short or long) the situation goes immediately to the one illustrated in Figure 17. There is no effect if RPD comes again above the input threshold: the asynchronous reset is completed coherently. To grant the normal completion of a synchronous reset, the value of the capacitance shall be big enough to maintain the voltage on RPD pin sufficient high along the duration of the internal reset sequence.

For a Software or Watchdog reset events, an active synchronous reset is completed regardless of the RPD status.

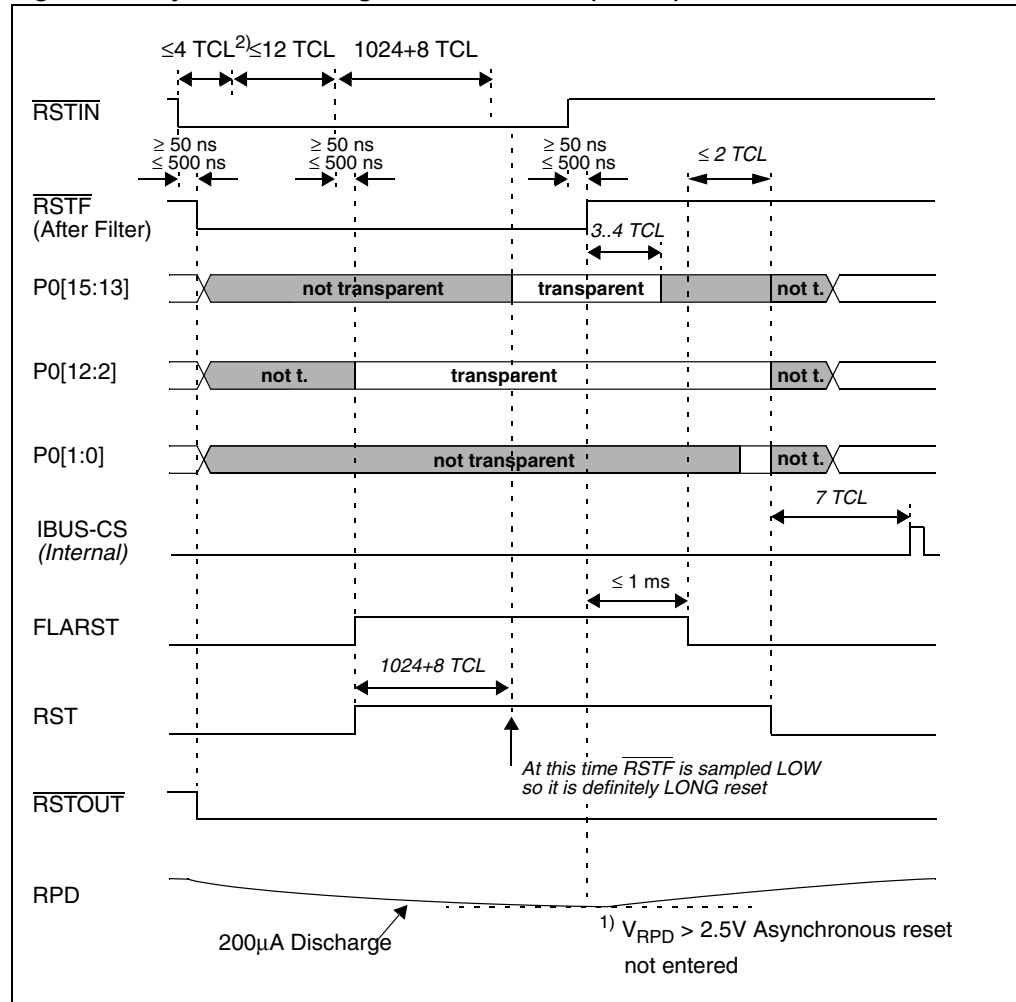

It is important to highlight that the signal that makes RPD status transparent under reset is the internal $\overline{\text{RSTF}}$ (after the noise filter).

Figure 19. Synchronous short / long hardware RESET ($\overline{EA} = 1$)

- 1) \overline{RSTIN} assertion can be released there. Refer also to Section 21.1 for details on minimum pulse duration.
- 2) If during the reset condition (\overline{RSTIN} low) RPD voltage drops below the threshold voltage (about 2.5V for 5V operation), the asynchronous reset is immediately entered.
- 3) \overline{RSTIN} pin is pulled low if bit BDRSTEN (bit 3 of SYSCON register) was previously set by software.
- 4) Bit BDRSTEN is cleared after reset.
- 5) Minimum \overline{RSTIN} low pulse duration shall also be longer than 500ns to guarantee the pulse is not masked by the internal filter (refer to Section 21.1).

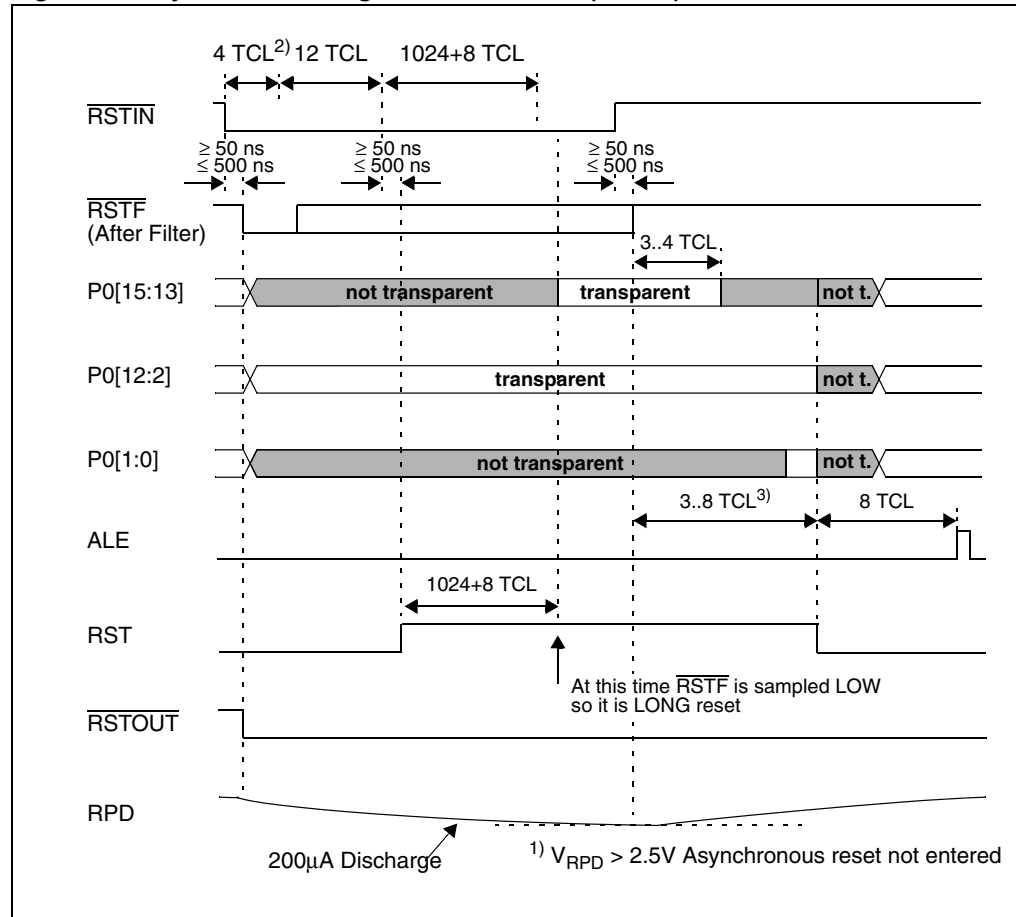

Figure 20. Synchronous short / long hardware RESET ($\overline{EA} = 0$)

- 1) $\overline{\text{RSTIN}}$ assertion can be released there. Refer also to Section 21.1 for details on minimum pulse duration.
- 2) If during the reset condition ($\overline{\text{RSTIN}}$ low), RPD voltage drops below the threshold voltage (about 2.5V for 5V operation), the asynchronous reset is then immediately entered.
- 3) 3 to 8 TCL depending on clock source selection.
- 4) $\overline{\text{RSTIN}}$ pin is pulled low if bit BDRSTEN (bit 3 of SYSCON register) was previously set by software. Bit BDRSTEN is cleared after reset.
- 5) Minimum $\overline{\text{RSTIN}}$ low pulse duration shall also be longer than 500ns to guarantee the pulse is not masked by the internal filter (refer to [Section 21.1](#)).

Figure 21. Synchronous long hardware RESET ($\overline{EA} = 1$)

1) If during the reset condition (\overline{RSTIN} low), RPD voltage drops below the threshold voltage (about 2.5V for 5V operation), the asynchronous reset is then immediately entered. Even if RPD returns above the threshold, the reset is definitely taken as asynchronous.

2) Minimum \overline{RSTIN} low pulse duration shall also be longer than 500ns to guarantee the pulse is not masked by the internal filter (refer to [Section 21.1](#)).

Figure 22. Synchronous long hardware RESET ($\overline{EA} = 0$)

- 1) If during the reset condition (\overline{RSTIN} low), RPD voltage drops below the threshold voltage (about 2.5V for 5V operation), the asynchronous reset is then immediately entered.
- 2) Minimum \overline{RSTIN} low pulse duration shall also be longer than 500ns to guarantee the pulse is not masked by the internal filter (refer to Section 21.1).
- 3) 3 to 8 TCL depending on clock source selection.

20.4 Software reset

A software reset sequence can be triggered at any time by the protected SRST (software reset) instruction. This instruction can be deliberately executed within a program, e.g. to leave bootstrap loader mode, or on a hardware trap that reveals system failure.

On execution of the SRST instruction, the internal reset sequence is started. The microcontroller behavior is the same as for a synchronous short reset, except that only bits P0.12...P0.8 are latched at the end of the reset sequence, while previously latched, bits P0.7...P0.2 are cleared (that is written at '1').

A Software reset is always taken as synchronous: there is no influence on Software Reset behavior with RPD status. In case Bidirectional Reset is selected, a Software Reset event pulls \overline{RSTIN} pin low: this occurs only if RPD is high; if RPD is low, \overline{RSTIN} pin is not pulled low even though Bidirectional Reset is selected.

Refer to next Figures 23 and 24 for unidirectional SW reset timing, and to Figures 25, 26 and 27 for bidirectional.

20.5 Watchdog timer reset

When the watchdog timer is not disabled during the initialization, or serviced regularly during program execution, it will overflow and trigger the reset sequence.

Unlike hardware and software resets, the watchdog reset completes a running external bus cycle if this bus cycle either does not use $\overline{\text{READY}}$, or if $\overline{\text{READY}}$ is sampled active (low) after the programmed wait states.

When $\overline{\text{READY}}$ is sampled inactive (high) after the programmed wait states the running external bus cycle is aborted. Then the internal reset sequence is started.

Bit P0.12...P0.8 are latched at the end of the reset sequence and bit P0.7...P0.2 are cleared (that is written at '1').

A Watchdog reset is always taken as synchronous: there is no influence on Watchdog Reset behavior with RPD status. In case Bidirectional Reset is selected, a Watchdog Reset event pulls $\overline{\text{RSTIN}}$ pin low: this occurs only if RPD is high; if RPD is low, $\overline{\text{RSTIN}}$ pin is not pulled low even though Bidirectional Reset is selected.

Refer to next Figures 23 and 24 for unidirectional SW reset timing, and to Figures 25, 26 and 27 for bidirectional.

Figure 23. SW / WDT unidirectional RESET ($\overline{\text{EA}} = 1$)

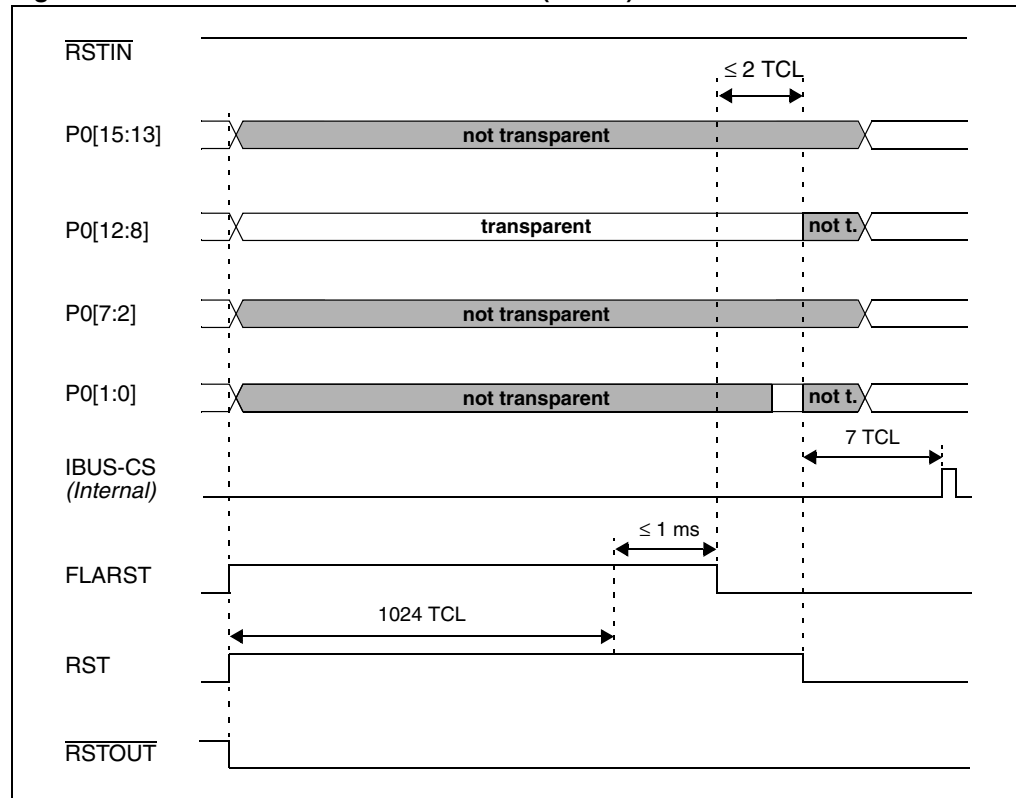

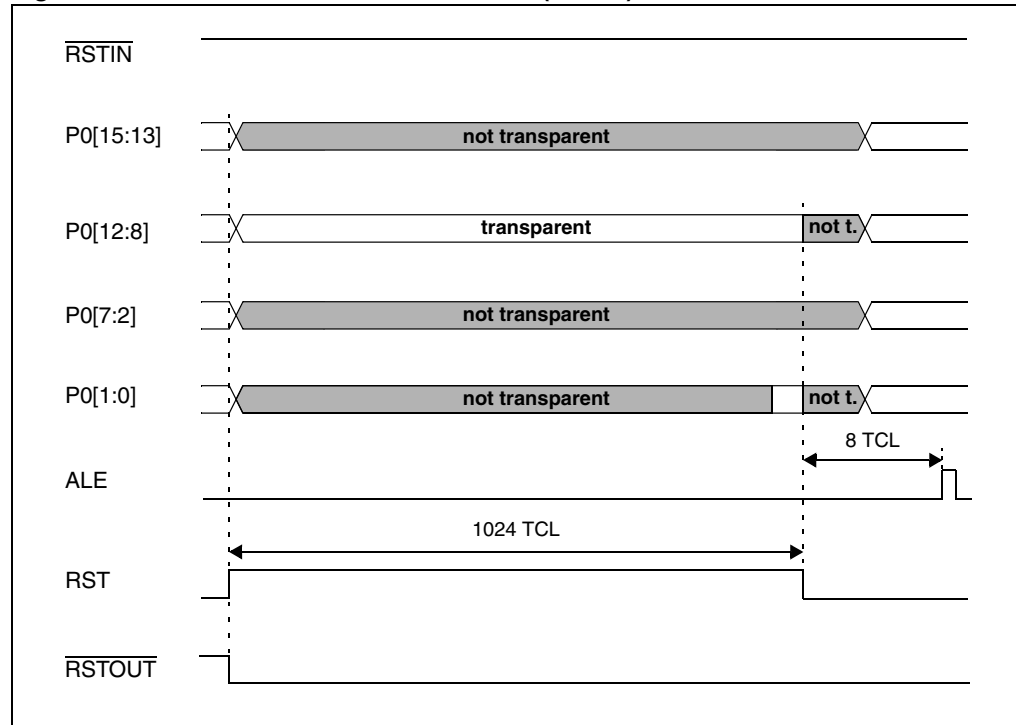

Figure 24. SW / WDT unidirectional RESET ($\overline{EA} = 0$)

20.6 Bidirectional reset

As shown in the previous sections, the \overline{RSTOUT} pin is driven active (low level) at the beginning of any reset sequence (synchronous/asynchronous hardware, software and watchdog timer resets). \overline{RSTOUT} pin stays active low beyond the end of the initialization routine, until the protected EINIT instruction (End of Initialization) is completed.

The Bidirectional Reset function is useful when external devices require a reset signal but cannot be connected to \overline{RSTOUT} pin, because \overline{RSTOUT} signal lasts during initialization. It is, for instance, the case of external memory running initialization routine before the execution of EINIT instruction.

Bidirectional reset function is enabled by setting bit 3 (BDRSTEN) in SYSCON register. It only can be enabled during the initialization routine, before EINIT instruction is completed.

When enabled, the open drain of the \overline{RSTIN} pin is activated, pulling down the reset signal, for the duration of the internal reset sequence (synchronous/asynchronous hardware, synchronous software and synchronous watchdog timer resets). At the end of the internal reset sequence the pull down is released and:

- After a Short Synchronous Bidirectional Hardware Reset, if \overline{RSTF} is sampled low 8 TCL periods after the internal reset sequence completion (refer to [Figure 19](#) and [Figure 20](#)), the Short Reset becomes a Long Reset. On the contrary, if \overline{RSTF} is sampled high the device simply exits reset state.
- After a Software or Watchdog Bidirectional Reset, the device exits from reset. If \overline{RSTF} remains still low for at least 4 TCL periods (minimum time to recognize a Short Hardware reset) after the reset exiting (refer to [Figure 25](#) and [Figure 26](#)), the Software

or Watchdog Reset become a Short Hardware Reset. On the contrary, if \overline{RSTF} remains low for less than 4 TCL, the device simply exits reset state.

The Bidirectional reset is not effective in case RPD is held low, when a Software or Watchdog reset event occurs. On the contrary, if a Software or Watchdog Bidirectional reset event is active and RPD becomes low, the \overline{RSTIN} pin is immediately released, while the internal reset sequence is completed regardless of RPD status change (1024 TCL).

Note: The bidirectional reset function is disabled by any reset sequence (bit BDRSTEN of SYSCON is cleared). To be activated again it must be enabled during the initialization routine.

WDTCN flags

Similarly to what already highlighted in the previous section when discussing about Short reset and the degeneration into Long reset, similar situations may occur when Bidirectional reset is enabled. The presence of the internal filter on \overline{RSTIN} pin introduces a delay: when \overline{RSTIN} is released, the internal signal after the filter (see \overline{RSTF} in the drawings) is delayed, so it remains still active (low) for a while. It means that depending on the internal clock speed, a short reset may be recognized as a long reset: the WDTCN flags are set accordingly.

Besides, when either Software or Watchdog bidirectional reset events occur, again when the \overline{RSTIN} pin is released (at the end of the internal reset sequence), the \overline{RSTF} internal signal (after the filter) remains low for a while, and depending on the clock frequency it is recognized high or low: 8TCL after the completion of the internal sequence, the level of \overline{RSTF} signal is sampled, and if recognized still low a Hardware reset sequence starts, and WDTCN will flag this last event, masking the previous one (Software or Watchdog reset). Typically, a Short Hardware reset is recognized, unless the \overline{RSTIN} pin (and consequently internal signal \overline{RSTF}) is sufficiently held low by the external hardware to inject a Long Hardware reset. After this occurrence, the initialization routine is not able to recognize a Software or Watchdog bidirectional reset event, since a different source is flagged inside WDTCN register. This phenomenon does not occur when internal FLASH is selected during reset ($\overline{EA} = 1$), since the initialization of the FLASH itself extend the internal reset duration well beyond the filter delay.

Next Figures 25, 26 and 27 summarize the timing for Software and Watchdog Timer Bidirectional reset events: In particular Figure 27 shows the degeneration into Hardware reset.

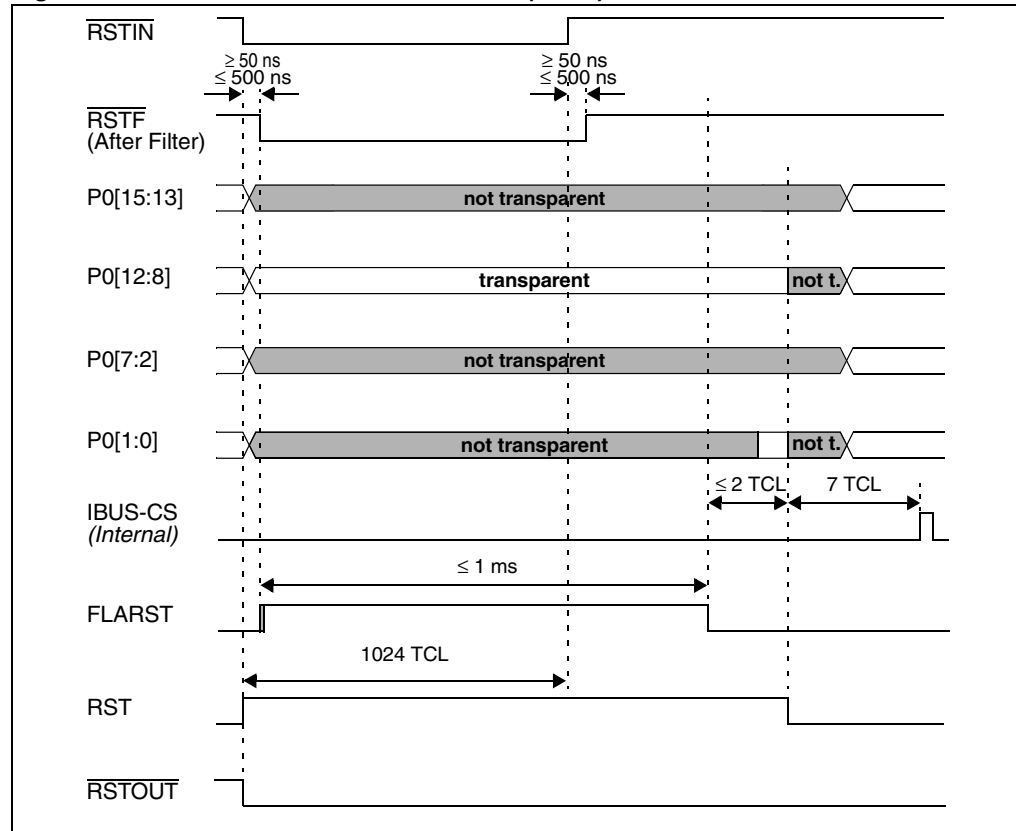

Figure 25. SW / WDT bidirectional RESET ($\overline{EA}=1$)

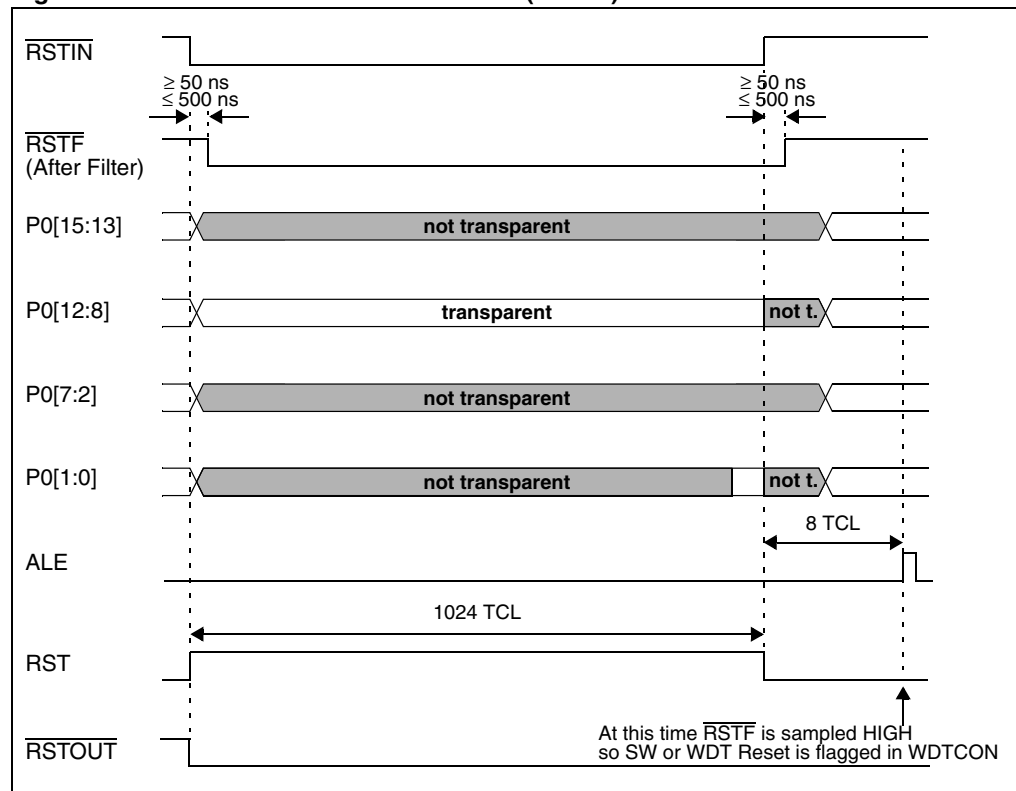

Figure 26. SW / WDT bidirectional RESET ($\overline{EA} = 0$)

Figure 27. SW / WDT bidirectional RESET ($\overline{EA}=0$) followed by a HW RESET

20.7 Reset circuitry

Internal reset circuitry is described in [Figure 30](#). The \overline{RSTIN} pin provides an internal pull-up resistor of 50k Ω to 250k Ω (The minimum reset time must be calculated using the lowest value).

It also provides a programmable (BDRSTEN bit of SYSCON register) pull-down to output internal reset state signal (synchronous reset, watchdog timer reset or software reset).

This bidirectional reset function is useful in applications where external devices require a reset signal but cannot be connected to \overline{RSTOUT} pin.

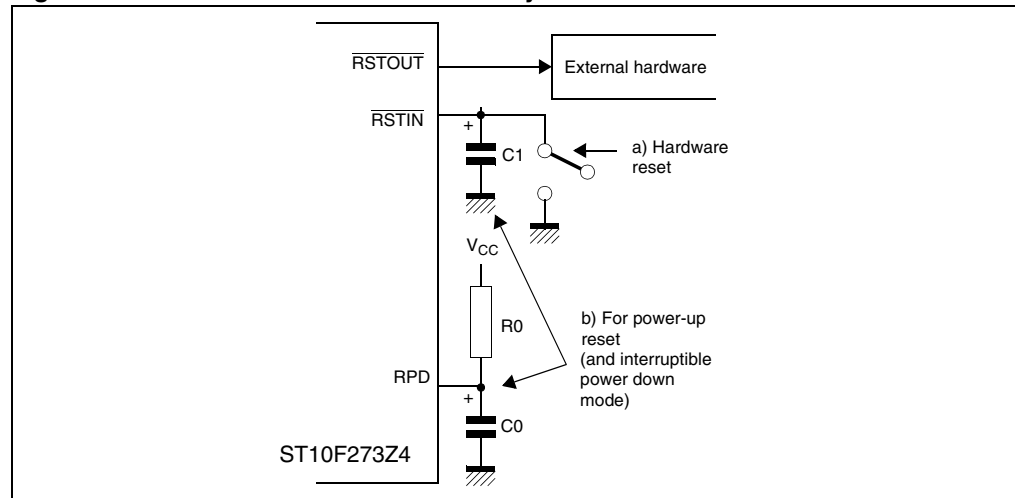

This is the case of an external memory running codes before EINIT (end of initialization) instruction is executed. \overline{RSTOUT} pin is pulled high only when EINIT is executed.

The RPD pin provides an internal weak pull-down resistor which discharges external capacitor at a typical rate of 200 μ A. If bit PWDCFG of SYSCON register is set, an internal pull-up resistor is activated at the end of the reset sequence. This pull-up will charge any capacitor connected on RPD pin.

The simplest way to reset the ST10F273Z4 is to insert a capacitor C1 between \overline{RSTIN} pin and V_{SS} , and a capacitor between RPD pin and V_{SS} (C0) with a pull-up resistor R0 between RPD pin and V_{DD} . The input \overline{RSTIN} provides an internal pull-up device equalling a resistor of 50k Ω to 250k Ω (the minimum reset time must be determined by the lowest value). Select C1 that produce a sufficient discharge time to permit the internal or external oscillator and / or internal PLL and the on-chip voltage regulator to stabilize.

To ensure correct power-up reset with controlled supply current consumption, specially if clock signal requires a long period of time to stabilize, an asynchronous hardware reset is required during power-up. For this reason, it is recommended to connect the external R0-C0 circuit shown in Figure 28 to the RPD pin. On power-up, the logical low level on RPD pin forces an asynchronous hardware reset when $\overline{\text{RSTIN}}$ is asserted low. The external pull-up R0 will then charge the capacitor C0. Note that an internal pull-down device on RPD pin is turned on when $\overline{\text{RSTIN}}$ pin is low, and causes the external capacitor (C0) to begin discharging at a typical rate of 100-200 μA . With this mechanism, after power-up reset, short low pulses applied on $\overline{\text{RSTIN}}$ produce synchronous hardware reset. If $\overline{\text{RSTIN}}$ is asserted longer than the time needed for C0 to be discharged by the internal pull-down device, then the device is forced in an asynchronous reset. This mechanism insures recovery from very catastrophic failure.

Figure 28. Minimum external reset circuitry

The minimum reset circuit of [Figure 28](#) is not adequate when the $\overline{\text{RSTIN}}$ pin is driven from the ST10F273Z4 itself during software or watchdog triggered resets, because of the capacitor C1 that will keep the voltage on $\overline{\text{RSTIN}}$ pin above V_{IL} after the end of the internal reset sequence, and thus will trigger an asynchronous reset sequence.

Figure 29 shows an example of a reset circuit. In this example, R1-C1 external circuit is only used to generate power-up or manual reset, and R0-C0 circuit on RPD is used for power-up reset and to exit from Power down mode. Diode D1 creates a wired-OR gate connection to the reset pin and may be replaced by open-collector Schmitt trigger buffer. Diode D2 provides a faster cycle time for repetitive power-on resets.

R2 is an optional pull-up for faster recovery and correct biasing of TTL Open Collector drivers.

1. It can degenerate into a Long Hardware Reset and consequently differently flagged (see [Section 20.3](#) for details).
2. When Bidirectional is active (and with RPD=0), it can be followed by a Short Hardware Reset and consequently differently flagged (see [Section 20.6](#) for details).

The start-up configurations and some system features are selected on reset sequences as described in [Table 52](#) and [Figure 33](#).

[Table 52](#) describes what is the system configuration latched on PORT0 in the six different reset modes. [Figure 33](#) summarizes the state of bits of PORT0 latched in RP0H, SYSCON, BUSCON0 registers.

Table 52. PORT0 latched configuration for the different reset events

21 Power reduction modes

Three different power reduction modes with different levels of power reduction have been implemented in the ST10F273Z4. In Idle mode only CPU is stopped, while peripheral still operate. In Power down mode both CPU and peripherals are stopped. In Stand-by mode the main power supply (V_{DD}) can be turned off while a portion of the internal RAM remains powered via V_{STBY} dedicated power pin.

Idle and Power down modes are software activated by a protected instruction and are terminated in different ways as described in the following sections.

Stand-by mode is entered simply removing V_{DD} , holding the MCU under reset state.

*Note: All external bus actions are completed before Idle or Power down mode is entered. However, Idle or Power down mode is **not** entered if READY is enabled, but has not been activated (driven low for negative polarity, or driven high for positive polarity) during the last bus access.*

21.1 Idle mode

Idle mode is entered by running IDLE protected instruction. The CPU operation is stopped and the peripherals still run.

Idle mode is terminate by any interrupt request. Whatever the interrupt is serviced or not, the instruction following the IDLE instruction will be executed after return from interrupt (RETI) instruction, then the CPU resumes the normal program.

21.2 Power down mode

Power down mode starts by running PWRDN protected instruction. Internal clock is stopped, all MCU parts are on hold including the watchdog timer. The only exception could be the Real-Time Clock if opportunely programmed and one of the two oscillator circuits as a consequence (either the main or the 32 kHz on-chip oscillator).

When Real-Time Clock module is used, when the device is in Power down mode a reference clock is needed. In this case, two possible configurations may be selected by the user application according to the desired level of power reduction:

- A 32 kHz crystal is connected to the on-chip low-power oscillator (pins XTAL3 / XTAL4) and running. In this case the main oscillator is stopped when Power down mode is entered, while the Real-Time Clock continue counting using 32 kHz clock signal as reference. The presence of a running low-power oscillator is detected after the Power-on: this clock is immediately assumed (if present, or as soon as it is detected) as reference for the Real-Time Clock counter and it will be maintained forever (unless specifically disabled via software).
- Only the main oscillator is running (XTAL1 / XTAL2 pins). In this case the main oscillator is not stopped when Power down is entered, and the Real-Time Clock continue counting using the main oscillator clock signal as reference.

There are two different operating Power down modes: protected mode and interruptible mode.

Before entering Power down mode (by executing the instruction PWRDN), bit VREGOFF in XMISC register must be set.

Note: Leaving the main voltage regulator active during Power down may lead to unexpected behavior (ex: CPU wake-up) and power consumption higher than what specified.

21.2.1 Protected power down mode

This mode is selected when PWDCFG (bit 5) of SYSCON register is cleared. The Protected Power down mode is only activated if the $\overline{\text{NMI}}$ pin is pulled low when executing PWRDN instruction (this means that the PWRDN instruction belongs to the $\overline{\text{NMI}}$ software routine). This mode is only deactivated with an external hardware reset on $\overline{\text{RSTIN}}$ pin.

21.2.2 Interruptible power down mode

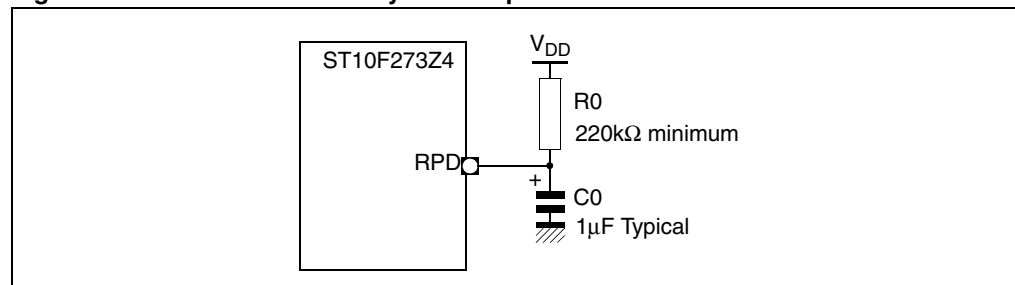

This mode is selected when PWDCFG (bit 5) of SYSCON register is set.

The Interruptible Power down mode is only activated if all the enabled Fast External Interrupt pins are in their inactive level.

This mode is deactivated with an external reset applied to $\overline{\text{RSTIN}}$ pin or with an interrupt request applied to one of the Fast External Interrupt pins, or with an interrupt generated by the Real-Time Clock, or with an interrupt generated by the activity on CAN's and I²C module interfaces. To allow the internal PLL and clock to stabilize, the $\overline{\text{RSTIN}}$ pin must be held low according the recommendations described in [Chapter 20: System reset on page 79](#).

An external RC circuit must be connected to RPD pin, as shown in the [Figure 34](#).

Figure 34. External RC circuitry on RPD pin

To exit Power down mode with an external interrupt, an EXxIN (x = 7...0) pin has to be asserted for at least 40ns.

21.3 Stand-by mode

In Stand-by mode, it is possible to turn off the main V_{DD} provided that V_{STBY} is available through the dedicated pin of the ST10F273Z4.

To enter Stand-by mode it is mandatory to held the device under reset: once the device is under reset, the RAM is disabled (see XRAM2EN bit of XPERCON register), and its digital interface is frozen in order to avoid any kind of data corruption.

A dedicated embedded low-power voltage regulator is implemented to generate the internal low voltage supply (about 1.65V in Stand-by mode) to bias all those circuits that shall remain active: the portion of XRAM (16Kbytes for ST10F273Z4), the RTC counters and 32 kHz on-chip oscillator amplifier.

In normal running mode (that is when main V_{DD} is on) the V_{STBY} pin can be tied to V_{SS} during reset to exercise the $\bar{E}A$ functionality associated with the same pin: the voltage supply for the circuitries which are usually biased with V_{STBY} (see in particular the 32 kHz oscillator used in conjunction with Real-Time Clock module), is granted by the active main V_{DD} .

It must be noted that Stand-by mode can generate problems associated with the usage of different power supplies in CMOS systems; particular attention must be paid when the ST10F273Z4 I/O lines are interfaced with other external CMOS integrated circuits: if V_{DD} of ST10F273Z4 becomes (for example in Stand-by mode) lower than the output level forced by the I/O lines of these external integrated circuits, the ST10F273Z4 could be directly powered through the inherent diode existing on ST10F273Z4 output driver circuitry. The same is valid for ST10F273Z4 interfaced to active/inactive communication buses during Stand-by mode: current injection can be generated through the inherent diode.

Furthermore, the sequence of turning on/off of the different voltage could be critical for the system (not only for the ST10F273Z4 device). The device Stand-by mode current (I_{STBY}) may vary while V_{DD} to V_{STBY} (and vice versa) transition occurs: some current flows between V_{DD} and V_{STBY} pins. System noise on both V_{DD} and V_{STBY} can contribute to increase this phenomenon.

21.3.1 Entering stand-by mode

As already said, to enter Stand-by mode XRAM2EN bit in the XPERCON Register must be cleared: this allows to freeze immediately the RAM interface, avoiding any data corruption. As a consequence of a RESET event, the RAM Power Supply is switched to the internal low-voltage supply V_{18SB} (derived from V_{STBY} through the low-power voltage regulator). The RAM interface will remain frozen until the bit XRAM2EN is set again by software initialization routine (at next exit from main V_{DD} power-on reset sequence).

Since V_{18} is falling down (as a consequence of V_{DD} turning off), it can happen that the XRAM2EN bit is no longer able to guarantee its content (logic "0"), being the XPERCON Register powered by internal V_{18} . This does not generate any problem, because the Stand-by mode switching dedicated circuit continues to confirm the RAM interface freezing, irrespective the XRAM2EN bit content; XRAM2EN bit status is considered again when internal V_{18} comes back over internal stand-by reference V_{18SB} .

If internal V_{18} becomes lower than internal stand-by reference (V_{18SB}) of about 0.3 to 0.45V with bit XRAM2EN set, the RAM Supply switching circuit is not active: in case of a temporary drop on internal V_{18} voltage versus internal V_{18SB} during normal code execution, no spurious Stand-by mode switching can occur (the RAM is not frozen and can still be accessed).

The ST10F273Z4 Core module, generating the RAM control signals, is powered by internal V_{18} supply; during turning off transient these control signals follow the V_{18} , while RAM is switched to V_{18SB} internal reference. It could happen that a high level of RAM write strobe from ST10F273Z4 Core (active low signal) is low enough to be recognized as a logic "0" by the RAM interface (due to V_{18} lower than V_{18SB}): The bus status could contain a valid address for the RAM and an unwanted data corruption could occur. For this reason, an extra interface, powered by the switched supply, is used to prevent the RAM from this kind of potential corruption mechanism.

Warning: During power-off phase, it is important that the external hardware maintains a stable ground level on $\overline{\text{RSTIN}}$ pin, without any glitch, in order to avoid spurious exiting from reset status with unstable power supply.

21.3.2 Exiting stand-by mode

After the system has entered the Stand-by mode, the procedure to exit this mode consists of a standard Power-on sequence, with the only difference that the RAM is already powered through $V_{18\text{SB}}$ internal reference (derived from V_{STBY} pin external voltage).

It is recommended to held the device under RESET ($\overline{\text{RSTIN}}$ pin forced low) until external V_{DD} voltage pin is stable. Even though, at the very beginning of the power-on phase, the device is maintained under reset by the internal low voltage detector circuit (implemented inside the main voltage regulator) till the internal V_{18} becomes higher than about 1.0V, **there is no warranty that the device stays under reset status if $\overline{\text{RSTIN}}$ is at high level during power ramp up. So, it is important the external hardware is able to guarantee a stable ground level on $\overline{\text{RSTIN}}$ along the power-on phase, without any temporary glitch.**

The external hardware shall be responsible to drive low the $\overline{\text{RSTIN}}$ pin until the V_{DD} is stable, even though the internal LVD is active.

Once the internal Reset signal goes low, the RAM (still frozen) power supply is switched to the main V_{18} .

At this time, everything becomes stable, and the execution of the initialization routines can start: XRAM2EN bit can be set, enabling the RAM.

21.3.3 Real-time clock and stand-by mode

When Stand-by mode is entered (turning off the main supply V_{DD}), the Real-Time Clock counting can be maintained running in case the on-chip 32 kHz oscillator is used to provide the reference to the counter. This is not possible if the main oscillator is used as reference for the counter: Being the main oscillator powered by V_{DD} , once this is switched off, the oscillator is stopped.

21.3.4 Power reduction modes summary

In the following [Table 53: Power reduction modes summary](#), a summary of the different Power reduction modes is reported.

Table 53. Power reduction modes summary

Mode	V _{DD}	V _{STBY}	CPU	Peripherals	RTC	Main OSC	32 kHz OSC	STBY XRAM	XRAM
Idle	on	on	off	on	off	run	off	biased	biased

	on	on	off	off	on	off	on	biased	biased
Stand-by	off	on	off	off	off	off	off	biased	off
	off	on	off	off	on	off	on	biased	off

22 Programmable output clock divider

A specific register mapped on the XBUS allows to choose the division factor on the CLKOUT signal (P3.15). This register is mapped on X-Miscellaneous memory address range.

When CLKOUT function is enabled by setting bit CLKEN of register SYSCON, by default the CPU clock is output on P3.15. Setting bit XMISCEN of register XPERCON and bit XPEN of register SYSCON, it is possible to program the clock prescaling factor: in this way on P3.15 a prescaled value of the CPU clock can be output.

When CLKOUT function is not enabled (bit CLKEN of register SYSCON cleared), P3.15 does not output any clock signal, even though XCLKOUTDIV register is programmed.

23 Register set

This section summarizes all registers implemented in the ST10F273Z4, ordered by name.

23.1 Special function registers

The following table lists all SFRs which are implemented in the ST10F273Z4 in alphabetical order.

Bit-addressable SFRs are marked with the letter “b” in column “Name”.

SFRs within the **Extended SFR-Space** (ESFRs) are marked with the letter “E” in column “Physical Address”.

Table 54. List of special function registers (continued)

Name	Physical address	8-bit address	Description	Reset value
PW1	FE32h	19h	PWM module pulse width register 1	0000h
PW2	FE34h	1Ah	PWM module pulse width register 2	0000h
PW3	FE36h	1Bh	PWM module pulse width register 3	0000h
PWMCON0 b	FF30h	98h	PWM module control register 0	0000h
PWMCON1 b	FF32h	99h	PWM module control register 1	0000h
PWMIC b	F17Eh E	BFh	PWM module interrupt control register	- - 00h
QR0	F004h E	02h	MAC unit offset register r0	0000h
QR1	F006h E	03h	MAC unit offset register R1	0000h
QX0	F000h E	00h	MAC unit offset register X0	0000h
QX1	F002h E	01h	MAC unit offset register X1	0000h
RP0H b	F108h E	84h	System start-up configuration register (read only)	- - XXh
S0BG	FEB4h	5Ah	Serial channel 0 baud rate generator reload register	0000h
S0CON b	FFB0h	D8h	Serial channel 0 control register	0000h
S0EIC b	FF70h	B8h	Serial channel 0 error interrupt control register	- - 00h
S0RBUF	FEB2h	59h	Serial channel 0 receive buffer register (read only)	- - XXh
S0RIC b	FF6Eh	B7h	Serial channel 0 receive interrupt control register	- - 00h
S0TBIC b	F19Ch E	CEh	Serial channel 0 transmit buffer interrupt control reg.	- - 00h
S0TBUF	FEB0h	58h	Serial channel 0 transmit buffer register (write only)	0000h
S0TIC b	FF6Ch	B6h	Serial channel 0 transmit interrupt control register	- - 00h
SP	FE12h	09h	CPU system stack pointer register	FC00h
SSCBR	F0B4h E	5Ah	SSC Baud rate register	0000h
SSCCON b	FFB2h	D9h	SSC control register	0000h
SSCEIC b	FF76h	BBh	SSC error interrupt control register	- - 00h
SSCRB	F0B2h E	59h	SSC receive buffer (read only)	XXXXh
SSCRIC b	FF74h	BAh	SSC receive interrupt control register	- - 00h
SSCTB	F0B0h E	58h	SSC transmit buffer (write only)	0000h
SSCTIC b	FF72h	B9h	SSC transmit interrupt control register	- - 00h
STKOV	FE14h	0Ah	CPU stack overflow pointer register	FA00h
STKUN	FE16h	0Bh	CPU stack underflow pointer register	FC00h
SYSCON b	FF12h	89h	CPU system configuration register	0xx0h ¹⁾
T0	FE50h	28h	CAPCOM timer 0 register	0000h
T01CON b	FF50h	A8h	CAPCOM timer 0 and timer 1 control register	0000h
T0IC b	FF9Ch	CEh	CAPCOM timer 0 interrupt control register	- - 00h
T0REL	FE54h	2Ah	CAPCOM timer 0 reload register	0000h

Table 54. List of special function registers (continued)

Name	Physical address	8-bit address	Description	Reset value
T1	FE52h	29h	CAPCOM timer 1 register	0000h
T1IC b	FF9Eh	CFh	CAPCOM timer 1 interrupt control register	- - 00h
T1REL	FE56h	2Bh	CAPCOM timer 1 reload register	0000h
T2	FE40h	20h	GPT1 timer 2 register	0000h
T2CON b	FF40h	A0h	GPT1 timer 2 control register	0000h
T2IC b	FF60h	B0h	GPT1 timer 2 interrupt control register	- - 00h
T3	FE42h	21h	GPT1 timer 3 register	0000h
T3CON b	FF42h	A1h	GPT1 timer 3 control register	0000h
T3IC b	FF62h	B1h	GPT1 timer 3 interrupt control register	- - 00h
T4	FE44h	22h	GPT1 timer 4 register	0000h
T4CON b	FF44h	A2h	GPT1 timer 4 control register	0000h
T4IC b	FF64h	B2h	GPT1 timer 4 interrupt control register	- - 00h
T5	FE46h	23h	GPT2 timer 5 register	0000h
T5CON b	FF46h	A3h	GPT2 timer 5 control register	0000h
T5IC b	FF66h	B3h	GPT2 timer 5 interrupt control register	- - 00h
T6	FE48h	24h	GPT2 timer 6 register	0000h
T6CON b	FF48h	A4h	GPT2 timer 6 control register	0000h
T6IC b	FF68h	B4h	GPT2 timer 6 interrupt control register	- - 00h
T7	F050h E	28h	CAPCOM timer 7 register	0000h
T78CON b	FF20h	90h	CAPCOM timer 7 and 8 control register	0000h
T7IC b	F17Ah E	BDh	CAPCOM timer 7 interrupt control register	- - 00h
T7REL	F054h E	2Ah	CAPCOM timer 7 reload register	0000h
T8	F052h E	29h	CAPCOM timer 8 register	0000h
T8IC b	F17Ch E	BEh	CAPCOM timer 8 interrupt control register	- - 00h
T8REL	F056h E	2Bh	CAPCOM timer 8 reload register	0000h
TFR b	FFACh	D6h	Trap Flag register	0000h
WDT	FEAEh	57h	Watchdog timer register (read only)	0000h
WDTCON b	FFAEh	D7h	Watchdog timer control register	00xxh ²⁾
XADRS3	F01Ch E	0Eh	XPER address select register 3	800Bh
XP0IC b	F186h E	C3h	See Section 9.1	- - 00h ³⁾
XP1IC b	F18Eh E	C7h	See Section 9.1	- - 00h ³⁾
XP2IC b	F196h E	CBh	See Section 9.1	- - 00h ³⁾
XP3IC b	F19Eh E	CFh	See Section 9.1	- - 00h ³⁾

Table 54. List of special function registers (continued)

Name	Physical address	8-bit address	Description	Reset value
XPERRCON b	F024h E	12h	XPERR configuration register	-- 05h
ZEROS b	FF1Ch	8Eh	Constant value 0's register (read only)	0000h

Note:

1. The system configuration is selected during reset. SYSCON reset value is 0000 0xx0 x000 0000b.
2. Reset Value depends on different triggered reset event.
3. The XPNIC Interrupt Control Registers control interrupt requests from integrated X-Bus peripherals. Some software controlled interrupt requests may be generated by setting the XPNIR bits (of XPNIC register) of the unused X-Peripheral nodes.

23.2 X-registers

The following table lists all X-Bus registers which are implemented in the ST10F273Z4 ordered by their name. The FLASH control registers are listed in a separate section, in spite of they also are physically mapped on X-Bus memory space. Note that all X-Registers are not bit-addressable.

Table 55. List of XBus registers

Name	Physical address	Description	Reset value
CAN1BRPER	EF0Ch	CAN1: BRP extension register	0000h
CAN1BTR	EF06h	CAN1: Bit timing register	2301h
CAN1CR	EF00h	CAN1: CAN control register	0001h

XSSCRB	E808h	XSSC receive buffer	XXXXh
XSSCTB	E806h	XSSC transmit buffer	0000h

23.3 Flash registers ordered by name

The following table lists all Flash Control Registers which are implemented in the ST10F273Z4 ordered by their name. These registers are physically mapped on the IBus, except for XFVTAUR0, which is mapped on XBus. Note that these registers are not bit-addressable.

Table 56. List of flash registers

Name	Physical address	Description	Reset value
FARH	0x000E 0012	Flash address register - high	0000h
FARL	0x000E 0010	Flash address register - low	0000h
FCR0H	0x000E 0002	Flash control register 0 - high	0000h
FCR0L	0x000E 0000	Flash control register 0 - low	0000h
FCR1H	0x000E 0006	Flash control register 1 - high	0000h
FCR1L	0x000E 0004	Flash control register 1 - low	0000h
FDR0H	0x000E 000A	Flash data register 0 - high	FFFFh
FDR0L	0x000E 0008	Flash data register 0 - low	FFFFh
FDR1H	0x000E 000E	Flash data register 1 - high	FFFFh
FDR1L	0x000E 000C	Flash data register 1 - low	FFFFh
FER	0x000E 0014	Flash error register	0000h
FNVAPR0	0x000E DFB8	Flash non volatile access protection reg.0	ACFFh
FNVAPR1H	0x000E DFBE	Flash non volatile access protection reg.1 - high	FFFFh
FNVAPR1L	0x000E DFBC	Flash non volatile access protection reg.1 - low	FFFFh
FNVWPIRH	0x000E DFB6	Flash non volatile protection i register high	FFFFh
FNVWPIRL	0x000E DFB4	Flash non volatile protection i register low	FFFFh

23.4 Identification registers

The ST10F273Z4 have four Identification registers, mapped in ESFR space. These registers contain:

- A manufacturer identifier
- A chip identifier with its revision
- A internal Flash and size identifier
- Programming voltage description

Note: The ST10F273Z4 device is a commercial version based on the ST10F276E silicon, the identification registers provide the values corresponding to the ST10F276E device.

IDMANUF (F07Eh / 3Fh)								ESFR				Reset Value: 0403h			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MANUF											0	0	0	1	1
R											R				

Table 57. IDMANUF

Bit	Function
MANUF	Manufacturer identifier 020h: STMicroelectronics manufacturer (JTAG worldwide normalization).

IDCHIP (F07Ch / 3Eh)								ESFR				Reset Value: 114Xh			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDCHIP											REVID				
R											R				

Table 58. IDCHIP

Bit	Function
IDCHIP	Device identifier 114h: ST10F273Z4 identifier (276).
REVID	Device revision identifier Xh: According to revision number.

IDMEM (F07Ah / 3Dh)								ESFR				Reset Value: 30D0h			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MEMTYP				MEMSIZE											
R				R											

Table 59. IDMEM

Bit	Function
MEMSIZE	Internal memory size Internal memory size is 4 x (MEMSIZE) (in Kbyte) 0D0h for 832 Kbytes (ST10F276E)
MEMTYP	Internal memory type '0h': ROM-Less '1h': (M) ROM memory '2h': (S) Standard Flash memory '3h': (H) High performance Flash memory (ST10F273Z4) '4h...Fh': Reserved

IDPROG (F078h / 3Ch)								ESFR								Reset Value: 0040h							
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0								
PROGVPP								PROGVDD															
R								R															

Table 60. IDPROG

Bit	Function
PROGVDD	Programming V_{DD} voltage V_{DD} voltage when programming EPROM or FLASH devices is calculated using the following formula: $V_{DD} = 20 \times [\text{PROGVDD}] / 256$ (volts) - 40h for ST10F273Z4 (5V).
PROGVPP	Programming V_{PP} voltage (no need of external V_{PP}) - 00h

Note: All identification words are read only registers.

The values written inside different Identification Register bits are valid only after the Flash initialization phase is completed. When code execution is started from internal memory (pin \overline{EA} held high during reset), the Flash has certainly completed its initialization, so the bits of Identification Registers are immediately ready to be read out. On the contrary, when code execution is started from external memory (pin \overline{EA} held low during reset), the Flash initialization is not yet completed, so the bits of Identification Registers are not ready. The user can poll bits 15 and 14 of IDMEM register: when both bits are read low, the Flash initialization is complete, so all Identification Register bits are correct.

Before Flash initialization completion, the default setting of the different Identification Registers are the following:

- IDMANUF 0403h
- IDCHIP 114xh (x = silicon revision)
- IDMEM F0D0h
- IDPROG 0040h

24 Electrical characteristics

24.1 Absolute maximum ratings

Table 61. Absolute maximum ratings

Symbol	Parameter	Values	Unit
V_{DD}	Voltage on V_{DD} pins with respect to ground (V_{SS})	-0.5 to +6.5	V
V_{STBY}	Voltage on V_{STBY} pin with respect to ground (V_{SS})	-0.5 to +6.5	
V_{AREF}	Voltage on V_{AREF} pins with respect to ground (V_{SS})	-0.5 to $V_{DD}+0.5$	
V_{AGND}	Voltage on V_{AGND} pins with respect to ground (V_{SS})	V_{SS}	
V_{IO}	Voltage on any pin with respect to ground (V_{SS})	-0.5 to $V_{DD} + 0.5$	
I_{OV}	Input current on any pin during overload condition	± 10	mA
I_{TOV}	Absolute sum of all input currents during overload condition	75	
T_{ST}	Storage temperature	-65 to +150	°C
ESD	ESD Susceptibility (Human Body Model)	2000	V

Note: Stresses above those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. During overload conditions ($V_{IN} > V_{DD}$ or $V_{IN} < V_{SS}$) the voltage on pins with respect to ground (V_{SS}) must not exceed the values defined by the Absolute Maximum Ratings.

During Power-on and Power-off transients (including Standby entering/exiting phases), the relationships between voltages applied to the device and the main V_{DD} shall be always respected. In particular power-on and power-off of V_{AREF} shall be coherent with V_{DD} transient, in order to avoid undesired current injection through the on-chip protection diodes.

24.2 Recommended operating conditions

Table 62. Recommended operating conditions

Symbol	Parameter	Value		Unit
		Min	Max	
V _{DD}	Operating supply voltage	4.5	5.5	V
V _{STBY}	Operating stand-by supply voltage ⁽¹⁾			
V _{AREF}	Operating analog reference voltage ⁽²⁾	0	V _{DD}	
T _A	Ambient temperature under bias	-40	+125	°C
T _J	Junction temperature under bias		+150	

1. The value of the V_{STBY} voltage is specified in the range 4.5 to 5.5 Volt. Nevertheless, it is acceptable to exceed the upper limit (up to 6.0 Volt) for a maximum of 100 hours over the global 300000 hours, representing the lifetime of the device (about 30 years). On the other hand, it is possible to exceed the lower limit (down to 4.0 Volt) whenever RTC and 32 kHz on-chip oscillator amplifier are turned off (only Stand-by RAM powered through VSTBY pin in Stand-by mode). When V_{STBY} voltage is lower than main V_{DD}, the input section of VSTBY/EA pin can generate a spurious static consumption on V_{DD} power supply (in the range of tenth of μ A).

2. For details on operating conditions concerning the usage of A/D Converter refer to [Section 24.7](#).

24.3 Power considerations

The average chip-junction temperature, T_J, in degrees Celsius, may be calculated using the following equation:

$$T_J = T_A + (P_D \times \Theta_{JA}) \quad (1)$$

Where:

T_A is the Ambient Temperature in °C,

Θ_{JA} is the Package Junction-to-Ambient Thermal Resistance, in °C/W,

P_D is the sum of P_{INT} and P_{I/O} (P_D = P_{INT} + P_{I/O}),

P_{INT} is the product of I_{DD} and V_{DD}, expressed in Watt. This is the Chip Internal Power,

P_{I/O} represents the Power Dissipation on Input and Output Pins; User Determined.

Most of the time for the applications P_{I/O} < P_{INT} and may be neglected. On the other hand, P_{I/O} may be significant if the device is configured to drive continuously external modules and/or memories.

An approximate relationship between P_D and T_J (if P_{I/O} is neglected) is given by:

$$P_D = K / (T_J + 273^\circ\text{C}) \quad (2)$$

Therefore (solving equations 1 and 2):

$$K = P_D \times (T_A + 273^\circ\text{C}) + \Theta_{JA} \times P_D^2 \quad (3)$$

Where:

K is a constant for the particular part, which may be determined from equation (3) by measuring P_D (at equilibrium) for a known T_A. Using this value of K, the values of P_D and T_J may be obtained by solving equations (1) and (2) iteratively for any value of T_A.

Table 63. Thermal characteristics

Symbol	Description	Value (typical)	Unit
Θ_{JA}	Thermal resistance junction-ambient		
	PQFP 144 - 28 x 28 x 3.4 mm / 0.65 mm pitch	30	°C/W
	LQFP 144 - 20 x 20 mm / 0.5 mm pitch	40	
	LQFP 144 - 20 x 20 mm / 0.5 mm pitch on four layer FR4 board (2 layers signals / 2 layers power)	35	

Based on thermal characteristics of the package and with reference to the power consumption figures provided in next tables and diagrams, the following product classification can be proposed. Anyhow, the exact power consumption of the device inside the application must be computed according to different working conditions, thermal profiles, real thermal resistance of the system (including printed circuit board or other substrata), I/O activity, and so on.

Table 64. Product classification

Package	Ambient temperature range	CPU frequency range
Die	-40°C to +125°C	1 to 64 MHz
PQFP 144	-40°C to +125°C	1 to 64 MHz
LQFP 144	-40°C to +125°C	1 to 40 MHz
	-40°C to +105°C	1 to 48 MHz

24.4 Parameter interpretation

The parameters listed in the following tables represent the characteristics of the ST10F273Z4 and its demands on the system.

Where the ST10F273Z4 logic provides signals with their respective timing characteristics, the symbol "CC" for Controller Characteristics, is included in the "Symbol" column. Where the external system must provide signals with their respective timing characteristics to the ST10F273Z4, the symbol "SR" for System Requirement, is included in the "Symbol" column.

24.5 DC characteristics

$V_{DD} = 5\text{ V} \pm 10\%$, $V_{SS} = 0\text{ V}$, $T_A = -40^\circ\text{C}$ to $+125^\circ\text{C}$

Table 65. DC characteristics

Symbol	Parameter	Test condition	Limit values		Unit
			Min.	Max.	
V_{IL} SR	Input low voltage (TTL mode) (except \overline{RSTIN} , \overline{EA} , \overline{NMI} , RPD, XTAL1, \overline{READY})	–	– 0.3	0.8	V
V_{ILS} SR	Input low voltage (CMOS mode) (except \overline{RSTIN} , \overline{EA} , \overline{NMI} , RPD, XTAL1, \overline{READY})	–	– 0.3	$0.3 V_{DD}$	V
V_{IL1} SR	Input low voltage \overline{RSTIN} , \overline{EA} , \overline{NMI} , RPD	–	– 0.3	$0.3 V_{DD}$	V
V_{IL2} SR	Input low voltage XTAL1 (CMOS only)	Direct drive mode	– 0.3	$0.3 V_{DD}$	V
V_{IL3} SR	Input low voltage \overline{READY} (TTL only)	–	– 0.3	0.8	V
V_{IH} SR	Input high voltage (TTL mode) (except \overline{RSTIN} , \overline{EA} , \overline{NMI} , RPD, XTAL1)	–	2.0	$V_{DD} + 0.3$	V
V_{IHS} SR	Input high voltage (CMOS mode) (except \overline{RSTIN} , \overline{EA} , \overline{NMI} , RPD, XTAL1)	–	$0.7 V_{DD}$	$V_{DD} + 0.3$	V
V_{IH1} SR	Input high voltage \overline{RSTIN} , \overline{EA} , \overline{NMI} , RPD	–	$0.7 V_{DD}$	$V_{DD} + 0.3$	V
V_{IH2} SR	Input high voltage XTAL1 (CMOS only)	Direct drive mode	$0.7 V_{DD}$	$V_{DD} + 0.3$	V
V_{IH3} SR	Input high voltage \overline{READY} (TTL only)	–	2.0	$V_{DD} + 0.3$	V
V_{HYS} CC	Input hysteresis (TTL mode) (except \overline{RSTIN} , \overline{EA} , \overline{NMI} , XTAL1, RPD)	3)	400	700	mV
V_{HYS2} CC	Input hysteresis (CMOS mode) (except \overline{RSTIN} , \overline{EA} , \overline{NMI} , XTAL1, RPD)	3)	750	1400	mV
V_{HYS1} CC	Input hysteresis \overline{RSTIN} , \overline{EA} , \overline{NMI}	3)	750	1400	mV
V_{HYS2} CC	Input hysteresis XTAL1	3)	0	50	mV
V_{HYS3} CC	Input hysteresis \overline{READY} (TTL only)	3)	400	700	mV
V_{HYS4} CC	Input hysteresis RPD	3)	500	1500	mV
V_{OL} CC	Output low voltage (P6[7:0], ALE, \overline{RD} , $\overline{WR/WRL}$, $\overline{BHE/WRH}$, CLKOUT, \overline{RSTIN} , \overline{RSTOUT})	$I_{OL} = 8\text{ mA}$ $I_{OL} = 1\text{ mA}$	–	0.4 0.05	V
V_{OL1} CC	Output low voltage (P0[15:0], P1[15:0], P2[15:0], P3[15,13:0], P4[7:0], P7[7:0], P8[7:0])	$I_{OL1} = 4\text{ mA}$ $I_{OL1} = 0.5\text{ mA}$	–	0.4 0.05	V
V_{OL2} CC	Output low voltage RPD	$I_{OL2} = 85\text{ }\mu\text{A}$ $I_{OL2} = 80\text{ }\mu\text{A}$ $I_{OL2} = 60\text{ }\mu\text{A}$	–	V_{DD} $0.5 V_{DD}$ $0.3 V_{DD}$	V
V_{OH} CC	Output high voltage (P6[7:0], ALE, \overline{RD} , $\overline{WR/WRL}$, $\overline{BHE/WRH}$, CLKOUT, \overline{RSTOUT})	$I_{OH} = -8\text{ mA}$ $I_{OH} = -1\text{ mA}$	$V_{DD} - 0.8$ $V_{DD} - 0.08$	–	V

Table 65. DC characteristics (continued)

Symbol	Parameter	Test condition	Limit values		Unit
			Min.	Max.

		$V_{STBY} = 5.5\text{ V}$ $T_A = 125\text{ }^{\circ}\text{C}$	–	500	μA
I_{SB3}	Stand-by supply current ⁽¹⁰⁾⁽⁸⁾ (V_{DD} transient condition)	–	–	2.5	mA

- This specification is not valid for outputs which are switched to open drain mode. In this case the respective output will float and the voltage is imposed by the external circuitry.
- Port 5 leakage values are granted for not selected A/D Converter channel. One channels is always selected (by default, after reset, P5.0 is selected). For the selected channel the leakage value is similar to that of other port pins.
- Consult your vendor to know which version of the on-chip oscillator amplifier is enabled (Low-Power or Wide-Swing). The leakage of P2.0 is higher than other pins due to the additional logic (pass gates active only in specific test modes) implemented on input path. Pay attention to not stress P2.0 input pin with negative overload beyond the specified limits: failures in Flash reading may occur (sense amplifier perturbation). Refer to next [Figure 35](#) for a scheme of the input circuitry.
- This specification is only valid during Reset, or during Hold- or Adapt-mode. Port 6 pins are only affected, if they are used for CS output and the open drain function is not enabled.
- The maximum current may be drawn while the respective signal line remains inactive.
- The minimum current must be drawn in order to drive the respective signal line active.
- The power supply current is a function of the operating frequency (f_{CPU} is expressed in MHz). This dependency is illustrated in the [Figure 36](#) below. This parameter is tested at V_{DDmax} and at maximum CPU clock frequency with all outputs disconnected and all inputs at V_{IL} or V_{IH} , RSTIN pin at V_{IH1min} : **this implies I/O current is not considered**. The device is doing the following:
 Fetching code from IRAM and XRAM1, accessing in read and write to both XRAM modules (**for ICC1**)
 Fetching code from all sectors of IFlash, accessing in read (few fetches) and write to XRAM (**for ICC2**)
 Watchdog Timer is enabled and regularly serviced
 RTC is running with main oscillator clock as reference, generating a tick interrupts every 192 clock cycles
 Four channel of XPWM are running (waves period: 2, 2.5, 3 and 4 CPU clock cycles): no output toggling
 Five General Purpose Timers are running in timer mode with prescaler equal to 8 (T2, T3, T4, T5, T6)
 ADC is in **Auto Scan Continuous Conversion mode** on all 16 channels of Port5
 All interrupts generated by XPWM, RTC, Timers and ADC are not serviced
- Not 100% tested, guaranteed by design characterization.
- The Idle mode supply current is a function of the operating frequency (f_{CPU} is expressed in MHz). This dependency is illustrated in the [Figure 36](#) below. These parameters are tested and at maximum CPU clock with all outputs disconnected and all inputs at V_{IL} or V_{IH} , RSTIN pin at V_{IH1min} .
- This parameter is tested including leakage currents. All inputs (including pins configured as inputs) at 0 V to 0.1 V or at $V_{DD} - 0.1\text{ V}$ to V_{DD} , $V_{AREF} = 0\text{ V}$, all outputs (including pins configured as outputs) disconnected. Besides, the Main Voltage Regulator is assumed off: in case it is not, additional 1mA shall be assumed. The value for this parameter shall be considered as "Target Value" to be confirmed by silicon characterization.
- Overload conditions occur if the standard operating conditions are exceeded, i.e. the voltage on any pin exceeds the specified range (i.e. $V_{OV} > V_{DD} + 0.3\text{ V}$ or $V_{OV} < -0.3\text{ V}$). The absolute sum of input overload currents on all port pins may not exceed 50mA. The supply voltage must remain within the specified limits.

Erase suspend request rate ⁽⁴⁾	20	20	20	ms	Minimum delay between 2 requests
Set protection ⁽⁴⁾	40	170	170	μs	

1. The figures are given after about 100 cycles due to testing routines (0 cycles at the final customer).
2. Word and Double Word Programming times are provided as average values derived from a full sector programming time: absolute value of a Word or Double Word Programming time could be longer than the average value.
3. Bank Erase is obtained through a multiple Sector Erase operation (setting bits related to all sectors of the Bank). As ST10F273Z4 implements only one bank, the Bank Erase operation is equivalent to Module and Chip Erase operations.
4. Not 100% tested, guaranteed by Design Characterization

Table 67. Flash data retention characteristics

Number of program / erase cycles ($-40\text{ °C} \leq T_A \leq 125\text{ °C}$)	Data retention time (average ambient temperature 60 °C)	
	256 Kbyte (code store)	64 Kbyte (EEPROM emulation)
0 - 100	> 20 years	> 20 years
1,000	-	> 20 years
10,000	-	10 years
100,000	-	1 year

24.7 A/D converter characteristics

$V_{DD} = 5V \pm 10\%$, $V_{SS} = 0V$, $T_A = -40$ to $+125^\circ\text{C}$, $4.5V \leq V_{AREF} \leq V_{DD}$,
 $V_{SS} \leq V_{AGND} \leq V_{SS} + 0.2V$

Table 68. A/D converter characteristics

Symbol	Parameter	Test condition	Limit values		Unit
			Min.	Max.	
V_{AREF} SR	Analog reference voltage ⁽¹⁾		4.5	V_{DD}	V
V_{AGND} SR	Analog ground voltage		V_{SS}	$V_{SS} + 0.2$	V
V_{AIN} SR	Analog input voltage ⁽²⁾		V_{AGND}	V_{AREF}	V
I_{AREF} CC	Reference supply current	Running mode ⁽³⁾ Power down mode	– –	5 1	mA μA
t_s CC	Sample time	⁽⁴⁾	1	–	μs
t_c CC	Conversion time	⁽⁵⁾	3	–	μs
DNL CC	Differential non linearity ⁽⁶⁾	No overload	–1	+1	LSB
INL CC	Integral non linearity ⁽⁶⁾	No overload	–1.5	+1.5	LSB
OFS CC	Offset error ⁽⁶⁾	No overload	–1.5	+1.5	LSB
TUE CC	Total unadjusted error ⁽⁶⁾	Port5 Port1 - No overload ⁽³⁾ Port1 - Overload ⁽³⁾	–2.0 –5.0 –7.0	+2.0 +5.0 +7.0	LSB
K CC	Coupling factor between inputs ^{(3) (7)}	On both Port5 and Port1	–	10^{-6}	–
C_{P1} CC	Input pin capacitance ^{(3) (8)}		–	3	pF
C_{P2} CC		Port5 Port1	– –	4 6	pF
C_S CC	Sampling capacitance ^{(3) (8)}		–	3.5	pF
R_{SW} CC	Analog switch resistance ^{(3) (8)}	Port5 Port1	– –	600 1600	W
R_{AD} CC			–	1300	W

- V_{AREF} can be tied to ground when A/D Converter is not in use: an extra consumption (around 200 μA) on main V_{DD} is added due to internal analogue circuitry not completely turned off: so, it is suggested to maintain the V_{AREF} at V_{DD} level even when not in use, and eventually switch off the A/D Converter circuitry setting bit ADOFF in ADCON register.
- V_{AIN} may exceed V_{AGND} or V_{AREF} up to the absolute maximum ratings. However, the conversion result in these cases will be 0x000_H or 0x3FF_H, respectively.
- Not 100% tested, guaranteed by design characterization.
- During the sample time the input capacitance C_{AIN} can be charged/discharged by the external source. The internal resistance of the analog source must allow the capacitance to reach its final voltage level within t_s . After the end of the sample time t_s , changes of the analog input voltage have no effect on the conversion result.
Values for the sample clock t_s depends on programming and can be taken from [Table 69: A/D converter programming](#).
- This parameter includes the sample time t_s , the time for determining the digital result and the time to load the result register with the conversion result. Values for the conversion clock t_{CC} depend on programming and can be taken from next [Table 69](#).

6. DNL, INL, OFS and TUE are tested at $V_{AREF} = 5.0\text{ V}$, $V_{AGND} = 0\text{ V}$, $V_{DD} = 5.0\text{ V}$. It is guaranteed by design characterization for all other voltages within the defined voltage range.
 'LSB' has a value of $V_{AREF}/1024$.
 For Port5 channels, the specified TUE ($\pm 2\text{ LSB}$) is guaranteed also with an overload condition (see I_{OV} specification) occurring on maximum 2 not selected analog input pins of Port5 and the absolute sum of input overload currents on all Port5 analog input pins does not exceed 10 mA.
 For Port1 channels, the specified TUE is guaranteed when no overload condition is applied to Port1 pins: when an overload condition occurs on maximum 2 not selected analog input pins of Port1 and the input positive overload current on all analog input pins does not exceed 10 mA (either dynamic or static injection), the specified TUE is degraded ($\pm 7\text{ LSB}$). To get the same accuracy, the negative injection current on Port1 pins shall not exceed -1mA in case of both dynamic and static injection.
7. The coupling factor is measured on a channel while an overload condition occurs on the adjacent not selected channels with the overload current within the different specified ranges (for both positive and negative injection current).
8. Refer to scheme reported in [Figure 38](#).

24.7.1 Conversion timing control

When a conversion is started, first the capacitances of the converter are loaded via the respective analog input pin to the current analog input voltage. The time to load the capacitances is referred to as sample time. Next the sampled voltage is converted to a digital value several successive steps, which correspond to the 10-bit resolution of the ADC. During these steps the internal capacitances are repeatedly charged and discharged via the V_{AREF} pin.

The current that has to be drawn from the sources for sampling and changing charges depends on the time that each respective step takes, because the capacitors must reach their final voltage level within the given time, at least with a certain approximation. The maximum current, however, that a source can deliver, depends on its internal resistance.

The time that the two different actions during conversion take (sampling, and converting) can be programmed within a certain range in the ST10F273Z4 relative to the CPU clock. The absolute time that is consumed by the different conversion steps therefore is independent from the general speed of the controller. This allows adjusting the A/D converter of the ST10F273Z4 to the properties of the system:

Fast Conversion can be achieved by programming the respective times to their absolute possible minimum. This is preferable for scanning high frequency signals. The internal resistance of analog source and analog supply must be sufficiently low, however.

High Internal Resistance can be achieved by programming the respective times to a higher value, or the possible maximum. This is preferable when using analog sources and supply with a high internal resistance in order to keep the current as low as possible. The conversion rate in this case may be considerably lower, however.

The conversion times are programmed via the upper four bits of register ADCON. Bit fields ADCTC and ADSTC are used to define the basic conversion time and in particular the partition between sample phase and comparison phases. The table below lists the possible combinations. The timings refer to the unit TCL, where $f_{CPU} = 1/2TCL$. A complete conversion time includes the conversion itself, the sample time and the time required to transfer the digital value to the result register.

Table 69. A/D converter programming

ADCTC	ADSTC	Sample	Comparison	Extra	Total conversion
00	00	TCL * 120	TCL * 240	TCL * 28	TCL * 388
00	01	TCL * 140	TCL * 280	TCL * 16	TCL * 436

10	10	TCL * 800	TCL * 1120	TCL * 196	TCL * 2116
10	11	TCL * 1600	TCL * 1120	TCL * 164	TCL * 2884

Note: *The total conversion time is compatible with the formula valid for ST10F269, while the meaning of the bit fields ADCTC and ADSTC is no longer compatible: the minimum conversion time is 388 TCL, which at 40 MHz CPU frequency corresponds to 4.85µs (see ST10F269).*

24.7.2 A/D conversion accuracy

The A/D Converter compares the analog voltage sampled on the selected analog input channel to its analog reference voltage (V_{AREF}) and converts it into 10-bit digital data. The absolute accuracy of the A/D conversion is the deviation between the input analog value and the output digital value. It includes the following errors:

- Offset error (OFS)
- Gain Error (GE)
- Quantization error
- Non-Linearity error (Differential and Integral)

These four error quantities are explained below using [Figure 37](#).

Offset error

Offset error is the deviation between actual and ideal A/D conversion characteristics when the digital output value changes from the minimum (zero voltage) 00 to 01 ([Figure 37](#), see OFS).

Gain error

Gain error is the deviation between the actual and ideal A/D conversion characteristics when the digital output value changes from the 3FE to the maximum 3FF, once offset error is subtracted. Gain error combined with offset error represents the so-called full-scale error ([Figure 37](#), OFS + GE).

Quantization error

Quantization error is the intrinsic error of the A/D converter and is expressed as 1/2 LSB.

Non-linearity error

Non-Linearity error is the deviation between actual and the best-fitting A/D conversion characteristics (see [Figure 37](#)):

- Differential Non-Linearity error is the actual step dimension versus the ideal one (1 LSB_{IDEAL}).
- Integral Non-Linearity error is the distance between the center of the actual step and the center of the bisector line, in the actual characteristics. Note that for Integral Non-Linearity error, the effect of offset, gain and quantization errors is not included.

Note: Bisector characteristic is obtained drawing a line from 1/2 LSB before the first step of the real characteristic, and 1/2 LSB after the last step again of the real characteristic.

24.7.3 Total unadjusted error

The Total Unadjusted Error specifies the maximum deviation from the ideal characteristic: the number provided in the Data Sheet represents the maximum error with respect to the entire characteristic. It is a combination of the Offset, Gain and Integral Linearity errors. The different errors may compensate each other depending on the relative sign of the Offset and Gain errors. Refer to [Figure 37](#), see TUE.

Figure 37. A/D conversion characteristic

24.7.4 Analog reference pins

The accuracy of the A/D converter depends on how accurate is its analog reference: a noise in the reference results in at least that much error in a conversion. A low pass filter on the A/D converter reference source (supplied through pins V_{AREF} and V_{AGND}), is recommended in order to clean the signal, minimizing the noise. A simple capacitive bypassing may be sufficient in most of the cases; in presence of high RF noise energy, inductors or ferrite beads may be necessary.

In this architecture, V_{AREF} and V_{AGND} pins represents also the power supply of the analog circuitry of the A/D converter: there is an effective DC current requirement from the reference voltage by the internal resistor string in the R-C DAC array and by the rest of the analog circuitry.

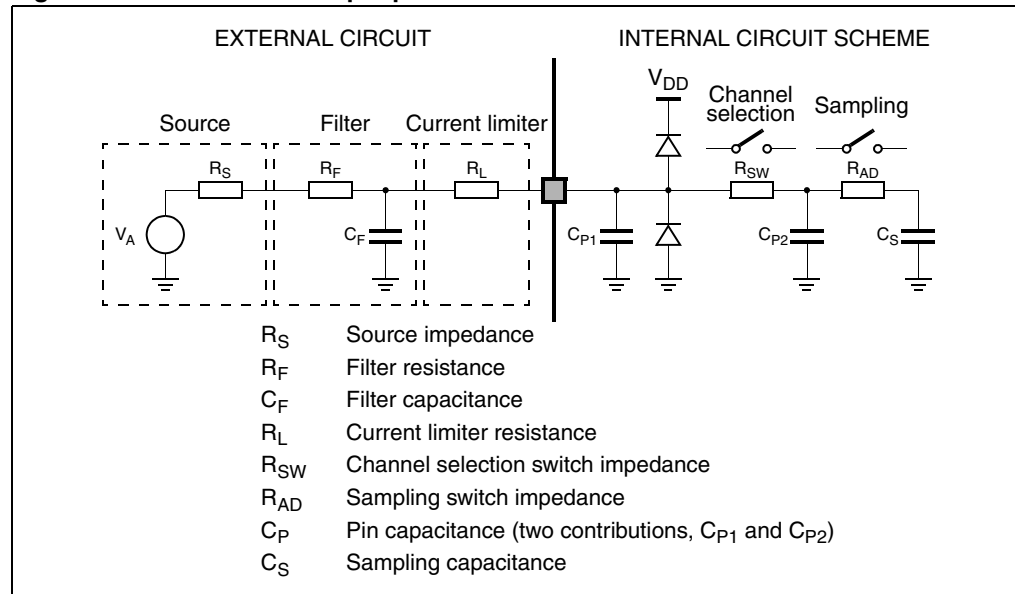

An external resistance on V_{AREF} could introduce error under certain conditions: for this reasons, series resistance are not advisable, and more in general any series devices in the filter network should be designed to minimize the DC resistance.

Analog input pins

To improve the accuracy of the A/D converter, it is definitively necessary that analog input pins have low AC impedance. Placing a capacitor with good high frequency characteristics at the input pin of the device, can be effective: the capacitor should be as large as possible, ideally infinite. This capacitor contributes to attenuating the noise present on the input pin; besides, it sources charge during the sampling phase, when the analog signal source is a high-impedance source.

A real filter, can typically be obtained by using a series resistance with a capacitor on the input pin (simple RC Filter). The RC filtering may be limited according to the value of source impedance of the transducer or circuit supplying the analog signal to be measured. The filter at the input pins must be designed taking into account the dynamic characteristics of the input signal (bandwidth).

Figure 38. A/D converter input pins scheme

Input leakage and external circuit

The series resistor utilized to limit the current to a pin (see R_L in [Figure 38](#)), in combination with a large source impedance can lead to a degradation of A/D converter accuracy when input leakage is present.

Data about maximum input leakage current at each pin are provided in the Data Sheet (Electrical Characteristics section). Input leakage is greatest at high operating temperatures, and in general it decreases by one half for each 10°C decrease in temperature.

Considering that, for a 10-bit A/D converter one count is about 5mV (assuming $V_{AREF} = 5V$), an input leakage of 100nA acting through an $R_L = 50k\Omega$ of external resistance leads to an error of exactly one count (5mV); if the resistance were 100k Ω the error would become two counts.

Eventual additional leakage due to external clamping diodes must also be taken into account in computing the total leakage affecting the A/D converter measurements. Another contribution to the total leakage is represented by the charge sharing effects with the sampling capacitance: being C_S substantially a switched capacitance, with a frequency equal to the conversion rate of a single channel (maximum when fixed channel continuous conversion mode is selected), it can be seen as a resistive path to ground. For instance, assuming a conversion rate of 250 kHz, with C_S equal to 4pF, a resistance of 1M Ω is obtained ($R_{EQ} = 1 / f_C C_S$, where f_C represents the conversion rate at the considered channel). To minimize the error induced by the voltage partitioning between this resistance

(sampled voltage on C_S) and the sum of $R_S + R_F + R_L + R_{SW} + R_{AD}$, the external circuit must be designed to respect the following relation:

$$V_A \cdot \frac{R_S + R_F + R_L + R_{SW} + R_{AD}}{R_{EQ}} < \frac{1}{2} \text{LSB}$$

The formula above provides a constraints for external network design, in particular on resistive path.

A second aspect involving the capacitance network shall be considered. Assuming the three capacitances C_F , C_{P1} and C_{P2} initially charged at the source voltage V_A (refer to the equivalent circuit reported in Figure 38), when the sampling phase is started (A/D switch close), a charge sharing phenomena is installed.

Figure 39. Charge sharing timing diagram during sampling phase

In particular two different transient periods can be distinguished (see Figure 39):

- A first and quick charge transfer from the internal capacitance C_{P1} and C_{P2} to the sampling capacitance C_S occurs (C_S is supposed initially completely discharged): considering a worst case (since the time constant in reality would be faster) in which C_{P2} is reported in parallel to C_{P1} (call $C_P = C_{P1} + C_{P2}$), the two capacitance C_P and C_S are in series, and the time constant is:

$$\tau_1 = (R_{SW} + R_{AD}) \cdot \frac{C_P \cdot C_S}{C_P + C_S}$$

This relation can again be simplified considering only C_S as an additional worst condition. In reality, the transient is faster, but the A/D Converter circuitry has been designed to be robust also in the very worst case: the sampling time T_S is always much longer than the internal time constant:

$$\tau_1 < (R_{SW} + R_{AD}) \cdot C_S T_S$$

The charge of C_{P1} and C_{P2} is redistributed also on C_S , determining a new value of the voltage V_{A1} on the capacitance according to the following equation:

$$V_{A1} \cdot (C_S + C_{P1} + C_{P2}) = V_A \cdot (C_{P1} + C_{P2})$$

- A second charge transfer involves also C_F (that is typically bigger than the on-chip capacitance) through the resistance R_L : again considering the worst case in which C_{P2} and C_S were in parallel to C_{P1} (since the time constant in reality would be faster), the

time constant is:

$$\tau_2 < R_L \cdot (C_S + C_{P1} + C_{P2})$$

In this case, the time constant depends on the external circuit: in particular imposing that the transient is completed well before the end of sampling time T_S , a constraints on R_L sizing is obtained:

$$10 \cdot \tau_2 = 10 \cdot R_L \cdot (C_S + C_{P1} + C_{P2}) \leq T_S$$

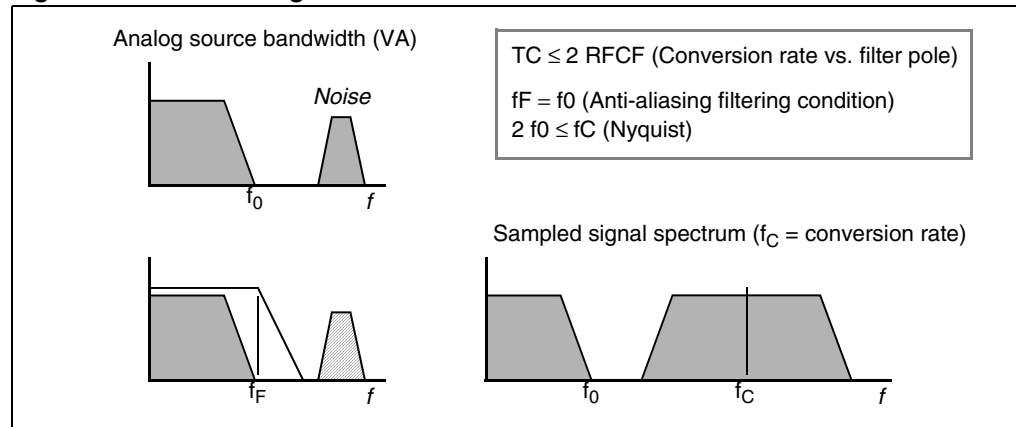

Of course, R_L shall be sized also according to the current limitation constraints, in combination with R_S (source impedance) and R_F (filter resistance). Being C_F definitively bigger than C_{P1} , C_{P2} and C_S , then the final voltage V_{A2} (at the end of the charge transfer transient) will be much higher than V_{A1} . The following equation must be respected (charge balance assuming now C_S already charged at V_{A1}):

$$V_{A2}(C_S + C_{P1} + C_{P2} + C_F) = V_A \cdot C_F + V_{A1}(C_{P1} + C_{P2} + C_S)$$

The two transients above are not influenced by the voltage source that, due to the presence of the $R_F C_F$ filter, is not able to provide the extra charge to compensate the voltage drop on C_S with respect to the ideal source V_A ; the time constant $R_F C_F$ of the filter is very high with respect to the sampling time (T_S). The filter is typically designed to act as anti-aliasing (see [Figure 40](#)).

Calling f_0 the bandwidth of the source signal (and as a consequence the cut-off frequency of the anti-aliasing filter, f_F), according to Nyquist theorem the conversion rate f_C must be at least $2f_0$; it means that the constant time of the filter is greater than or at least equal to twice the conversion period (T_C). Again the conversion period T_C is longer than the sampling time T_S , which is just a portion of it, even when fixed channel continuous conversion mode is selected (fastest conversion rate at a specific channel): in conclusion it is evident that the time constant of the filter $R_F C_F$ is definitively much higher than the sampling time T_S , so the charge level on C_S cannot be modified by the analog signal source during the time in which the sampling switch is closed

Figure 40. Anti-aliasing filter and conversion rate

The considerations above lead to impose new constraints to the external circuit, to reduce the accuracy error due to the voltage drop on C_S ; from the two charge balance equations

above, it is simple to derive the following relation between the ideal and real sampled voltage on C_S :

$$\frac{V_A}{V_{A2}} = \frac{C_{P1} + C_{P2} + C_F}{C_{P1} + C_{P2} + C_F + C_S}$$

From this formula, in the worst case (when V_A is maximum, that is for instance 5V), assuming to accept a maximum error of half a count ($\sim 2.44\text{mV}$), it is immediately evident a constraints on C_F value:

$$C_F > 2048 C_S$$

In the next section an example of how to design the external network is provided, assuming some reasonable values for the internal parameters and making hypothesis on the characteristics of the analog signal to be sampled.

24.7.4.1 Example of external network sizing

The following hypothesis are formulated in order to proceed in designing the external network on A/D Converter input pins:

- Analog Signal Source Bandwidth (f_0): 10 kHz
- Conversion Rate (f_C): 25 kHz
- Sampling Time (T_S): 1 μs
- Pin Input Capacitance (C_{P1}): 5 pF
- Pin Input Routing Capacitance (C_{P2}): 1 pF
- Sampling Capacitance (C_S): 4 pF
- Maximum Input Current Injection (I_{INJ}): 3 mA
- Maximum Analog Source Voltage (V_{AM}): 12 V
- Analog Source Impedance (R_S): 100 Ω
- Channel Switch Resistance (R_{SW}): 500 Ω
- Sampling Switch Resistance (R_{AD}): 200 Ω

1. Supposing to design the filter with the pole exactly at the maximum frequency of the signal, the time constant of the filter is:

$$R_C C_F = \frac{1}{2\pi f_0} = 15.9\mu s$$

2. Using the relation between C_F and C_S and taking some margin (4000 instead of 2048), it is possible to define C_F :

$$C_F = 4000 C_S = 16nF$$

3. As a consequence of step 1 and 2, R_C can be chosen:

$$R_F = \frac{1}{2\pi f_0 C_F} = 995\Omega \approx 1k\Omega$$

4. Considering the current injection limitation and supposing that the source can go up to 12V, the total series resistance can be defined as:

$$R_S + R_F + R_L = \frac{V_{AM}}{I_{INJ}} = 4k\Omega$$

from which is now simple to define the value of R_L :

$$R_L = \frac{V_{AM}}{I_{INJ}} - R_F - R_S = 2.9k\Omega$$

5. Now the three element of the external circuit R_F , C_F and R_L are defined. Some conditions discussed in the previous paragraphs have been used to size the component, the other must now be verified. The relation which allow to minimize the accuracy error introduced by the switched capacitance equivalent resistance is in this case:

$$R_{EQ} = \frac{1}{f_C C_S} = 10M\Omega$$

So the error due to the voltage partitioning between the real resistive path and C_S is less then half a count (considering the worst case when $V_A = 5V$):

$$V_A \cdot \frac{R_S + R_F + R_L + R_{SW} + R_{AD}}{R_{EQ}} = 2.35mV < \frac{1}{2}LSB$$

The other conditions to be verified is the time constants of the transients are really and significantly shorter than the sampling period duration T_S :

$$\tau_1 = (R_{SW} + R_{AD}) \cdot C_S = 2.8ns \quad T_S = 1\mu s$$

$$10 \tau_2 = 10 R_L (C_S + C_{P1} + C_{P2}) = 290ns \quad T_S = 1\mu s$$

For complete set of parameters characterizing the ST10F273Z4 A/D Converter equivalent circuit, refer to [Section 24.7: A/D converter characteristics on page 135](#).

24.8 AC characteristics

24.8.1 Test waveforms

Figure 41. Input/output waveforms

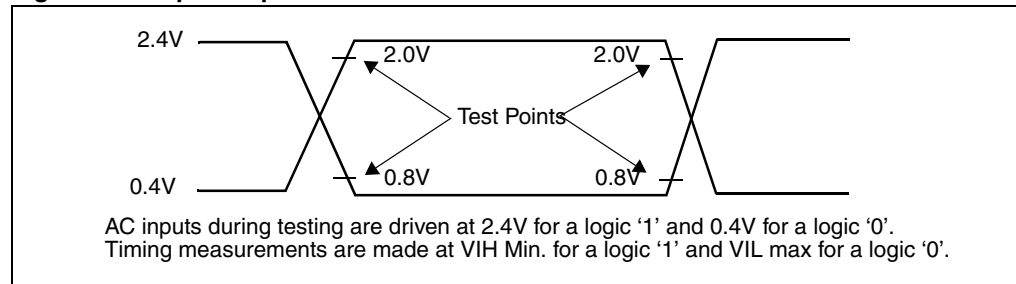

Figure 42. Float waveform

24.8.2 Definition of internal timing

The internal operation of the ST10F273Z4 is controlled by the internal CPU clock f_{CPU} . Both edges of the CPU clock can trigger internal (for example pipeline) or external (for example bus cycles) operations.

The specification of the external timing (AC Characteristics) therefore depends on the time between two consecutive edges of the CPU clock, called "TCL".

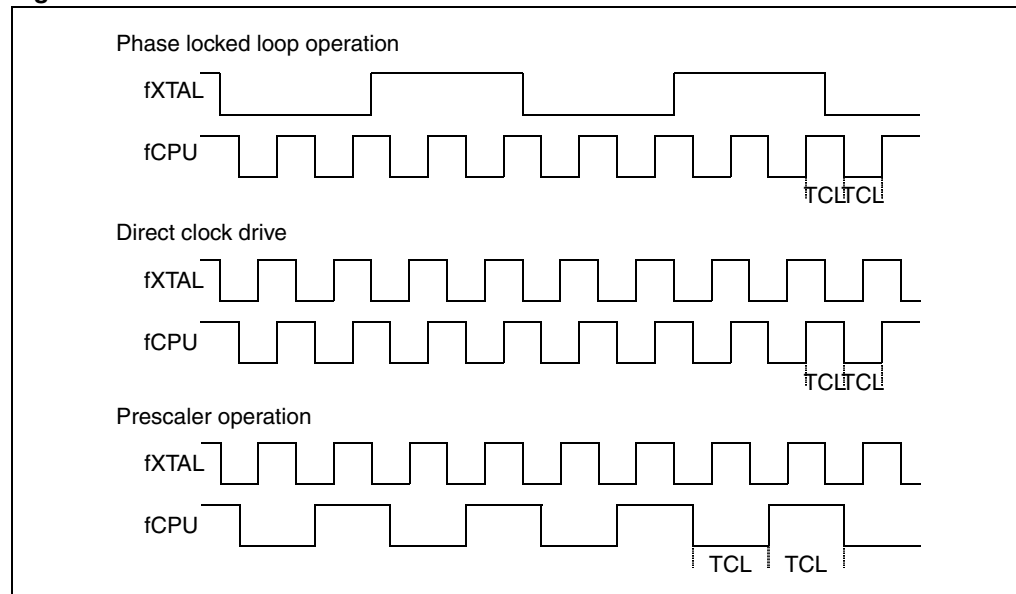

The CPU clock signal can be generated by different mechanisms. The duration of TCL and its variation (and also the derived external timing) depends on the mechanism used to generate f_{CPU} .

This influence must be regarded when calculating the timings for the ST10F273Z4.

The example for PLL operation shown in [Figure 43](#) refers to a PLL factor of 4.

The mechanism used to generate the CPU clock is selected during reset by the logic levels on pins P0.15-13 (POH.7-5).

Figure 43. Generation mechanisms for the CPU clock

24.8.3 Clock generation modes

Next [Table 70](#) associates the combinations of these three bits with the respective clock generation mode.

Table 70. On-chip clock generator selections

P0.15-13 (P0H.7-5)	CPU frequency $f_{\text{CPU}} = f_{\text{XTAL}} \times F$	External clock input range ^{(1) (2)}	Notes
		Main OSC (MHz)	
1 1 1	$F_{\text{XTAL}} \times 4$	4 to 8	Default configuration
1 1 0	$F_{\text{XTAL}} \times 3$	5.3 to 10.6	
1 0 1	$F_{\text{XTAL}} \times 8$	4 to 8	
1 0 0	$F_{\text{XTAL}} \times 5$	6.4 to 12	
0 1 1	$F_{\text{XTAL}} \times 1$	1 to 64	Direct drive (oscillator bypassed) ⁽³⁾
0 1 0	$F_{\text{XTAL}} \times 10$	4 to 6.4	
0 0 1	$F_{\text{XTAL}} / 2$	4 to 12	CPU clock via prescaler ⁽²⁾

1. The external clock input range refers to a CPU clock range of 1...64 MHz. Besides, the PLL usage is limited to 4 to 12 MHz input frequency range. All configurations need a crystal (or ceramic resonator) to generate the CPU clock through the internal oscillator amplifier (apart from Direct Drive): vice versa, the clock can be forced through an external clock source only in Direct Drive mode (on-chip oscillator amplifier disabled, so no crystal or resonator can be used).
2. The limits on input frequency are 4 to 12 MHz since the usage of the internal oscillator amplifier is required. Also when the PLL is not used and the CPU clock corresponds to $F_{\text{XTAL}}/2$, an external crystal or resonator shall be used: it is not possible to force any clock through an external clock source.
3. The maximum depends on the duty cycle of the external clock signal: When 64 MHz is used, 50% duty cycle shall be granted (low phase = high phase = 7.8ns); when 32 MHz is selected, a 25% duty cycle can be accepted (minimum phase, high or low, again equal to 7.8ns).

24.8.4 Prescaler operation

When pins P0.15-13 (P0H.7-5) equal '001' during reset, the CPU clock is derived from the internal oscillator (input clock signal) by a 2:1 prescaler.

The frequency of f_{CPU} is half the frequency of f_{XTAL} and the high and low time of f_{CPU} (i.e. the duration of an individual TCL) is defined by the period of the input clock f_{XTAL} .

The timings listed in the AC Characteristics that refer to TCL therefore can be calculated using the period of f_{XTAL} for any TCL.

Note that if the bit OWDDIS in SYSCON register is cleared, the PLL runs on its free-running frequency and delivers the clock signal for the Oscillator Watchdog. If bit OWDDIS is set, then the PLL is switched off.

24.8.5 Direct drive

When pins P0.15-13 (P0H.7-5) equal '011' during reset the on-chip phase locked loop is disabled, the on-chip oscillator amplifier is bypassed and the CPU clock is directly driven by the input clock signal on XTAL1 pin.

The frequency of CPU clock (f_{CPU}) directly follows the frequency of f_{XTAL} so the high and low time of f_{CPU} (i.e. the duration of an individual TCL) is defined by the duty cycle of the input clock f_{XTAL} .

Therefore, the timings given in this chapter refer to the minimum TCL. This minimum value can be calculated by the following formula:

$$TCL_{min} = 1/f_{XTAL} \times DC_{min}$$

DC = duty cycle

For two consecutive TCLs, the deviation caused by the duty cycle of f_{XTAL} is compensated, so the duration of 2TCL is always $1/f_{XTAL}$.

The minimum value TCL_{min} has to be used only once for timings that require an odd number of TCLs (1,3,...). Timings that require an even number of TCLs (2,4,...) may use the formula:

$$2TCL = 1/f_{XTAL}$$

The address float timings in Multiplexed bus mode (t_{11} and t_{45}) use the maximum duration of TCL ($TCL_{max} = 1/f_{XTAL} \times DC_{max}$) instead of TCL_{min} .

Similarly to what happen for Prescaler Operation, if the bit OWDDIS in SYSCON register is cleared, the PLL runs on its free-running frequency and delivers the clock signal for the Oscillator Watchdog. If bit OWDDIS is set, then the PLL is switched off.

24.8.6 Oscillator watchdog (OWD)

An on-chip watchdog oscillator is implemented in the ST10F273Z4. This feature is used for safety operation with external crystal oscillator (available only when using direct drive mode with or without prescaler, so the PLL is not used to generate the CPU clock multiplying the frequency of the external crystal oscillator). This watchdog oscillator operates as following.

The reset default configuration enables the watchdog oscillator. It can be disabled by setting the OWDDIS (bit 4) of SYSCON register.

When the OWD is enabled, the PLL runs at its free-running frequency, and it increments the watchdog counter. On each transition of external clock, the watchdog counter is cleared. If an external clock failure occurs, then the watchdog counter overflows (after 16 PLL clock cycles).

The CPU clock signal will be switched to the PLL free-running clock signal, and the oscillator watchdog Interrupt Request is flagged. The CPU clock will not switch back to the external clock even if a valid external clock exists on XTAL1 pin. Only a hardware reset (or bidirectional Software / Watchdog reset) can switch the CPU clock source back to direct clock input.

When the OWD is disabled, the CPU clock is always the external oscillator clock (in Direct Drive or Prescaler Operation) and the PLL is switched off to decrease consumption supply current.

24.8.7 Phase locked loop (PLL)

For all other combinations of pins P0.15-13 (P0H.7-5) during reset the on-chip phase locked loop is enabled and it provides the CPU clock (see [Table 70](#)). The PLL multiplies the input frequency by the factor F which is selected via the combination of pins P0.15-13 ($f_{\text{CPU}} = f_{\text{XTAL}} \times F$). With every F'th transition of f_{XTAL} the PLL circuit synchronizes the CPU clock to the input clock. This synchronization is done smoothly, so the CPU clock frequency does not change abruptly.

Due to this adaptation to the input clock the frequency of f_{CPU} is constantly adjusted so it is locked to f_{XTAL} . The slight variation causes a jitter of f_{CPU} which also effects the duration of individual TCLs.

The timings listed in the AC Characteristics that refer to TCLs therefore must be calculated using the minimum TCL that is possible under the respective circumstances.

The real minimum value for TCL depends on the jitter of the PLL. The PLL tunes f_{CPU} to keep it locked on f_{XTAL} . The relative deviation of TCL is the maximum when it is referred to one TCL period.

This is especially important for bus cycles using wait states and e.g. for the operation of timers, serial interfaces, etc. For all slower operations and longer periods (e.g. pulse train generation or measurement, lower Baud rates, etc.) the deviation caused by the PLL jitter is negligible. Refer to next [Section 24.8.9: PLL jitter](#) for more details.

24.8.8 Voltage controlled oscillator

The ST10F273Z4 implements a PLL which combines different levels of frequency dividers with a Voltage Controlled Oscillator (VCO) working as frequency multiplier. In the following table, a detailed summary of the internal settings and VCO frequency is reported.

Table 71. Internal PLL divider mechanism

P0.15-13 (P0H.7-5)	XTAL frequency	Input prescaler	PLL		Output prescaler	CPU frequency $f_{\text{CPU}} = f_{\text{XTAL}} \times F$
			Multiply by	Divide by		
1 1 1	4 to 8 MHz	$F_{\text{XTAL}} / 4$	64	4	–	$F_{\text{XTAL}} \times 4$
1 1 0	5.3 to 10.6 MHz		48			$F_{\text{XTAL}} \times 3$
1 0 1	4 to 8 MHz		64	2		$F_{\text{XTAL}} \times 8$
1 0 0	6.4 to 12 MHz		40			$F_{\text{XTAL}} \times 5$
0 1 1	1 to 64 MHz	–	PLL bypassed		–	$F_{\text{XTAL}} \times 1$
0 1 0	4 to 6.4 MHz	$F_{\text{XTAL}} / 2$	40	2		$F_{\text{XTAL}} \times 10$
0 0 1	4 to 12 MHz ¹⁾	–	PLL bypassed		$F_{\text{PLL}} / 2$	$F_{\text{XTAL}} / 2$
0 0 0	4 MHz	$F_{\text{XTAL}} / 2$	64	2	–	$F_{\text{XTAL}} \times 16$

The PLL input frequency range is limited to 1 to 3.5 MHz, while the VCO oscillation range is 64 to 128 MHz. The CPU clock frequency range when PLL is used is 16 to 64 MHz.

Example 1

- $F_{XTAL} = 4 \text{ MHz}$
- $P0(15:13) = '110'$ (multiplication by 3)
- PLL input frequency = 1 MHz
- VCO frequency = 48 MHz
- PLL output frequency = 12 MHz
(VCO frequency divided by 4)
- $F_{CPU} = 12 \text{ MHz}$ (no effect of Output Prescaler)

Example 2

- $F_{XTAL} = 8 \text{ MHz}$
- $P0(15:13) = '100'$ (multiplication by 5)
- PLL input frequency = 2 MHz
- VCO frequency = 80 MHz
- PLL output frequency = 40 MHz (VCO frequency divided by 2)
- $F_{CPU} = 40 \text{ MHz}$ (no effect of Output Prescaler)

24.8.9 PLL jitter

The following terminology is hereafter defined:

- **Self referred single period jitter**
Also called "Period Jitter", it can be defined as the difference of the T_{max} and T_{min} , where T_{max} is maximum time period of the PLL output clock and T_{min} is the minimum time period of the PLL output clock.
- **Self referred long term jitter**
Also called "N period jitter", it can be defined as the difference of T_{max} and T_{min} , where T_{max} is the maximum time difference between N+1 clock rising edges and T_{min} is the minimum time difference between N+1 clock rising edges. Here N should be kept sufficiently large to have the long term jitter. For N=1, this becomes the single period jitter.

Jitter at the PLL output can be due to the following reasons:

- Jitter in the input clock
- Noise in the PLL loop

Jitter in the input clock

PLL acts like a low pass filter for any jitter in the input clock. Input Clock jitter with the frequencies within the PLL loop bandwidth is passed to the PLL output and higher frequency jitter (frequency > PLL bandwidth) is attenuated @20dB/decade.

Noise in the PLL loop

This contribution again can be caused by the following sources:

- Device noise of the circuit in the PLL
- Noise in supply and substrate.

Device noise of the circuit in the PLL

The long term jitter is inversely proportional to the bandwidth of the PLL: the wider is the loop bandwidth, the lower is the jitter due to noise in the loop. Besides, the long term jitter is practically independent on the multiplication factor.

The most noise sensitive circuit in the PLL circuit is definitively the VCO (Voltage Controlled Oscillator). There are two main sources of noise: thermal (random noise, frequency independent so practically white noise) and flicker (low frequency noise, $1/f$). For the frequency characteristics of the VCO circuitry, the effect of the thermal noise results in a $1/f^2$ region in the output noise spectrum, while the flicker noise in a $1/f^3$. Assuming a noiseless PLL input and supposing that the VCO is dominated by its $1/f^2$ noise, the R.M.S. value of the accumulated jitter is *proportional to the square root of N*, where N is the number of clock periods within the considered time interval.

On the contrary, assuming again a noiseless PLL input and supposing that the VCO is dominated by its $1/f^3$ noise, the R.M.S. value of the accumulated jitter is *proportional to N*, where N is the number of clock periods within the considered time interval.

The jitter in the PLL loop can be modeled as dominated by the $1/f^2$ noise for N smaller than a certain value depending on the PLL output frequency and on the bandwidth characteristics of loop. Above this first value, the jitter becomes dominated by the $1/f^3$ noise component. Lastly, for N greater than a second value of N, a saturation effect is evident, so the jitter does not grow anymore when considering a longer time interval (jitter stable increasing the number of clock periods N). The PLL loop acts as a high pass filter for any noise in the loop, with cutoff frequency equal to the bandwidth of the PLL. The saturation value corresponds to what has been called self referred long term jitter of the PLL. In [Figure 44](#) the maximum jitter trend versus the number of clock periods N (for some typical CPU frequencies) is reported: the curves represent the very worst case, computed taking into account all corners of temperature, power supply and process variations: the real jitter is always measured well below the given worst case values.

Noise in supply and substrate

Digital supply noise adds deterministic components to the PLL output jitter, independent on multiplication factor. Its effects is strongly reduced thanks to particular care used in the physical implementation and integration of the PLL module inside the device. Anyhow, the contribution of the digital noise to the global jitter is widely taken into account in the curves provided in [Figure 44](#).

Figure 44. ST10F273Z4 PLL jitter

24.8.10 PLL lock / unlock

During normal operation, if the PLL gets unlocked for any reason, an interrupt request to the CPU is generated, and the reference clock (oscillator) is automatically disconnected from the PLL input: in this way, the PLL goes into free-running mode, providing the system with a backup clock signal (free running frequency F_{free}). This feature allows to recover from a crystal failure occurrence without risking to go in an undefined configuration: the system is provided with a clock allowing the execution of the PLL unlock interrupt routine in a safe mode.

The path between reference clock and PLL input can be restored only by a hardware reset, or by a bidirectional software or watchdog reset event that forces the \overline{RSTIN} pin low.

Note: *The external RC circuit on \overline{RSTIN} pin shall be properly sized in order to extend the duration of the low pulse to grant the PLL gets locked before the level at \overline{RSTIN} pin is recognized high: bidirectional reset internally drives \overline{RSTIN} pin low for just 1024 TCL (definitively not sufficient to get the PLL locked starting from free-running mode).*

Table 72. PLL characteristics [$V_{DD} = 5V \pm 10\%$, $V_{SS} = 0V$, $T_A = -40^\circ C$ to $+125^\circ C$]

Symbol	Parameter	Conditions	Value		Unit
			Min.	Max.	
T_{PSUP}	PLL start-up time ⁽¹⁾	Stable V_{DD} and reference clock	–	300	μs
T_{LOCK}	PLL lock-in time	Stable V_{DD} and reference clock, starting from free-running mode	–	250	
T_{JIT}	Single period jitter ⁽¹⁾ (cycle to cycle = 2 TCL)	6 sigma time period variation (peak to peak)	–500	+500	ps
F_{free}	PLL free running frequency	Multiplication factors: 3, 4 Multiplication factors: 5, 8, 10, 16	250 500	2000 4000	kHz

1. Not 100% tested, guaranteed by design characterization.

24.8.11 Main oscillator specifications

$V_{DD} = 5V \pm 10\%$, $V_{SS} = 0V$, $T_A = -40^\circ C$ to $+125^\circ C$

Table 73. Main oscillator characteristics

Sym bol	Parameter	Conditions	Value			Unit
			Min.	Typ.	Max.	
g_m	Oscillator transconductance		8	17	35	mA/V
V_{OSC}	Oscillation amplitude ⁽¹⁾	Peak to peak	–	$V_{DD} - 0.4$	–	V
V_{AV}	Oscillation voltage level ⁽¹⁾	Sine wave middle		$V_{DD} / 2 - 0.25$	–	
t_{STUP}	Oscillator start-up time ⁽¹⁾	Stable V_{DD} - crystal		3	4	ms
		Stable V_{DD} - resonator		2	3	

1. Not 100% tested, guaranteed by design characterization.

Figure 45. Crystal oscillator and resonator connection diagram

Table 74. Main oscillator negative resistance (module)

$C_A =$	12 pF	15 pF	18 pF	22 pF	27 pF	33 pF	39 pF	47 pF
4 MHz	460 Ω	550 Ω	675 Ω	800 Ω	840 Ω	1000 Ω	1180 Ω	1200 Ω
8 MHz	380 Ω	460 Ω	540 Ω	640 Ω	580 Ω	-	-	-
12 MHz	370 Ω	420 Ω	360 Ω	-	-	-	-	-

The given values of C_A do not include the stray capacitance of the package and of the printed circuit board: the negative resistance values are calculated assuming additional 5pF to the values in the table. The crystal shunt capacitance (C_0), the package and the stray capacitance between XTAL1 and XTAL2 pins is globally assumed equal to 4pF.

The external resistance between XTAL1 and XTAL2 is not necessary, since already present on the silicon.

24.8.12 32 kHz oscillator specifications

$V_{DD} = 5V \pm 10\%$, $V_{SS} = 0V$, $T_A = -40\text{ }^\circ\text{C}$ to $+125\text{ }^\circ\text{C}$

Table 75. 32 kHz oscillator characteristics

Symbol	Parameter	Conditions	Value			Unit
			Min.	Typ.	Max.	
g_{m32}	Oscillator transconductance ⁽¹⁾	Start-up	20	31	50	$\mu\text{A/V}$
		Normal run	8	17	30	
V_{OSC32}	Oscillation amplitude ⁽²⁾	Peak to peak	0.5	1.0	2.4	V
V_{AV32}	Oscillation voltage level ⁽²⁾	Sine wave middle	0.7	0.9	1.2	
t_{STUP32}	Oscillator start-up time ⁽²⁾	Stable V_{DD}	—	1	5	s

1. At power-on a high current biasing is applied for faster oscillation start-up. Once the oscillation is started, the current biasing is reduced to lower the power consumption of the system.

2. Not 100% tested, guaranteed by design characterization.

Figure 46. 32 kHz crystal oscillator connection diagram

Table 76. Minimum values of negative resistance (module) for 32 kHz oscillator

	$C_A = 6\text{pF}$	$C_A = 12\text{pF}$	$C_A = 15\text{pF}$	$C_A = 18\text{pF}$	$C_A = 22\text{pF}$	$C_A = 27\text{pF}$	$C_A = 33\text{pF}$
32 kHz	-	-	-	-	150 k Ω	120 k Ω	90 k Ω

The given values of C_A do not include the stray capacitance of the package and of the printed circuit board: the negative resistance values are calculated assuming additional 5pF to the values in the table. The crystal shunt capacitance (C_0) and the package capacitance between XTAL3 and XTAL4 pins is globally assumed equal to 4pF. The external resistance between XTAL3 and XTAL4 is not necessary, since already present on the silicon.

Warning: Direct driving on XTAL3 pin is not supported. Always use a 32 kHz crystal oscillator.

24.8.13 External clock drive XTAL1

When Direct Drive configuration is selected during reset, it is possible to drive the CPU clock directly from the XTAL1 pin, without particular restrictions on the maximum frequency, since the on-chip oscillator amplifier is bypassed. The speed limit is imposed by internal logic that targets a maximum CPU frequency of 64 MHz.

In all other clock configurations (Direct Drive with Prescaler or PLL usage) the on-chip oscillator amplifier is not bypassed, so it determines the input clock speed limit. Then, when the on-chip oscillator is enabled it is forbidden to use any external clock source different from crystal or ceramic resonator.

Table 77. External clock drive XTAL1 timing

Parameter	Symbol	Direct drive $f_{\text{CPU}} = f_{\text{XTAL}}$		Direct drive with prescaler $f_{\text{CPU}} = f_{\text{XTAL}} / 2$		PLL usage $f_{\text{CPU}} = f_{\text{XTAL}} \times F$		Unit
		Min.	Max.	Min.	Max.	Min.	Max.	
XTAL1 period ^{1, 2}	t_{OSC} SR	15.625	—	83.3	250	83.3	250	ns
High time ³	t_1 SR	6	—	3	—	6	—	
Low time ³	t_2 SR	6	—	3	—	6	—	
Rise time ³	t_3 SR	—	2	—	2	—	2	
Fall time ³	t_4 SR	—	2	—	2	—	2	

1. The minimum value for the XTAL1 signal period shall be considered as the theoretical minimum. The real minimum value depends on the duty cycle of the input clock signal.
2. 4 to 8 MHz is the input frequency range when using an external clock source. 64 MHz can be applied with an external clock source only when Direct Drive mode is selected: in this case, the oscillator amplifier is bypassed so it does not limit the input frequency.
3. The input clock signal must reach the defined levels V_{IL2} and V_{IH2} .

Figure 47. External clock drive XTAL1

Note: When Direct Drive is selected, an external clock source can be used to drive XTAL1. The maximum frequency of the external clock source depends on the duty cycle: when 64 MHz is used, 50% duty cycle shall be granted (low phase = high phase = 7.8ns); when for instance 32 MHz is used, a 25% duty cycle can be accepted (minimum phase, high or low, again equal to 7.8ns).

24.8.14 Memory cycle variables

The tables below use three variables which are derived from the BUSCONx registers and represent the special characteristics of the programmed memory cycle. The following table describes, how these variables are to be computed.

Description	Symbol	Values
ALE extension	t_A	$TCL \times [ALECTL]$
Memory cycle time wait states	t_C	$2TCL \times (15 - [MCTC])$
Memory tri-state time	t_F	$2TCL \times (1 - [MTTC])$

24.8.15 External memory bus timing

In next sections the external memory bus timings are reported. The given values are computed for a maximum CPU clock of 40 MHz.

It is evident that when higher CPU clock frequency is used (up to 64 MHz), some numbers in the timing formulas become zero or negative, that in most of the cases is not acceptable or not meaningful at all. In these cases, it is necessary to relax the speed of the bus setting properly t_A , t_C and t_F .

Note: All external memory bus timings and SSC timings reported in the following tables are granted by design characterization and not fully tested in production.

24.8.16 Multiplexed bus

$V_{DD} = 5V \pm 10\%$, $V_{SS} = 0V$, $T_A = -40\text{ }^{\circ}\text{C}$ to $+125\text{ }^{\circ}\text{C}$, $CL = 50\text{ pF}$,

ALE cycle time = $6\text{ TCL} + 2t_A + t_C + t_F$ (75ns at 40 MHz CPU clock without wait states)

Table 78. Multiplexed bus timings

Symbol	Parameter	$f_{CPU} = 40\text{ MHz}$ $TCL = 12.5\text{ ns}$		Variable CPU clock $1/2\text{ TCL} = 1\text{ to }64\text{ MHz}$		Unit

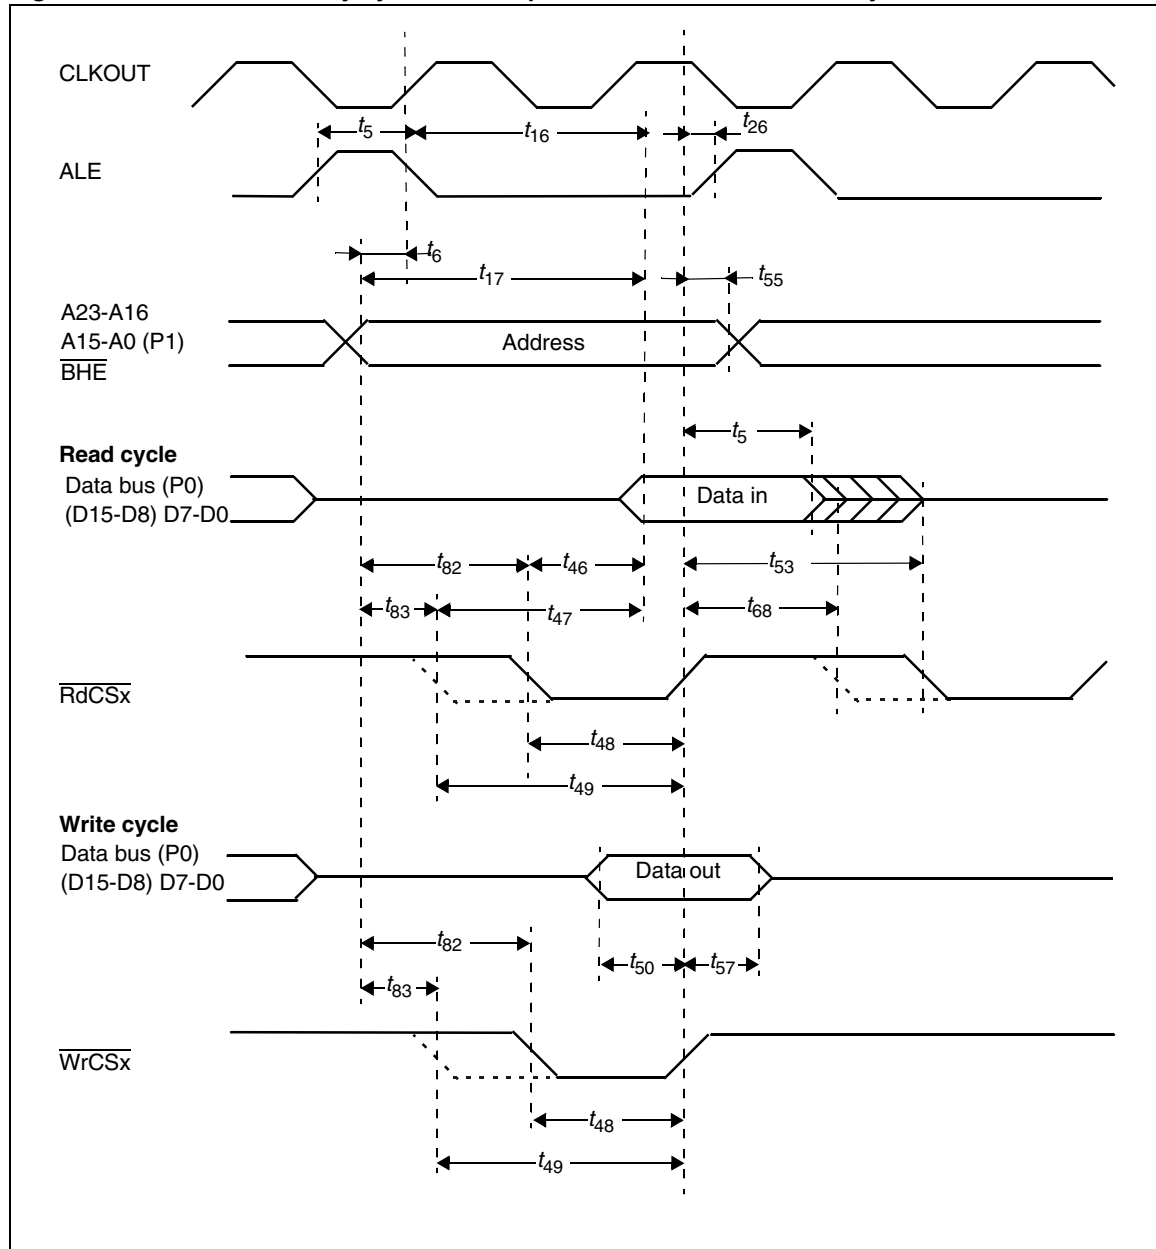

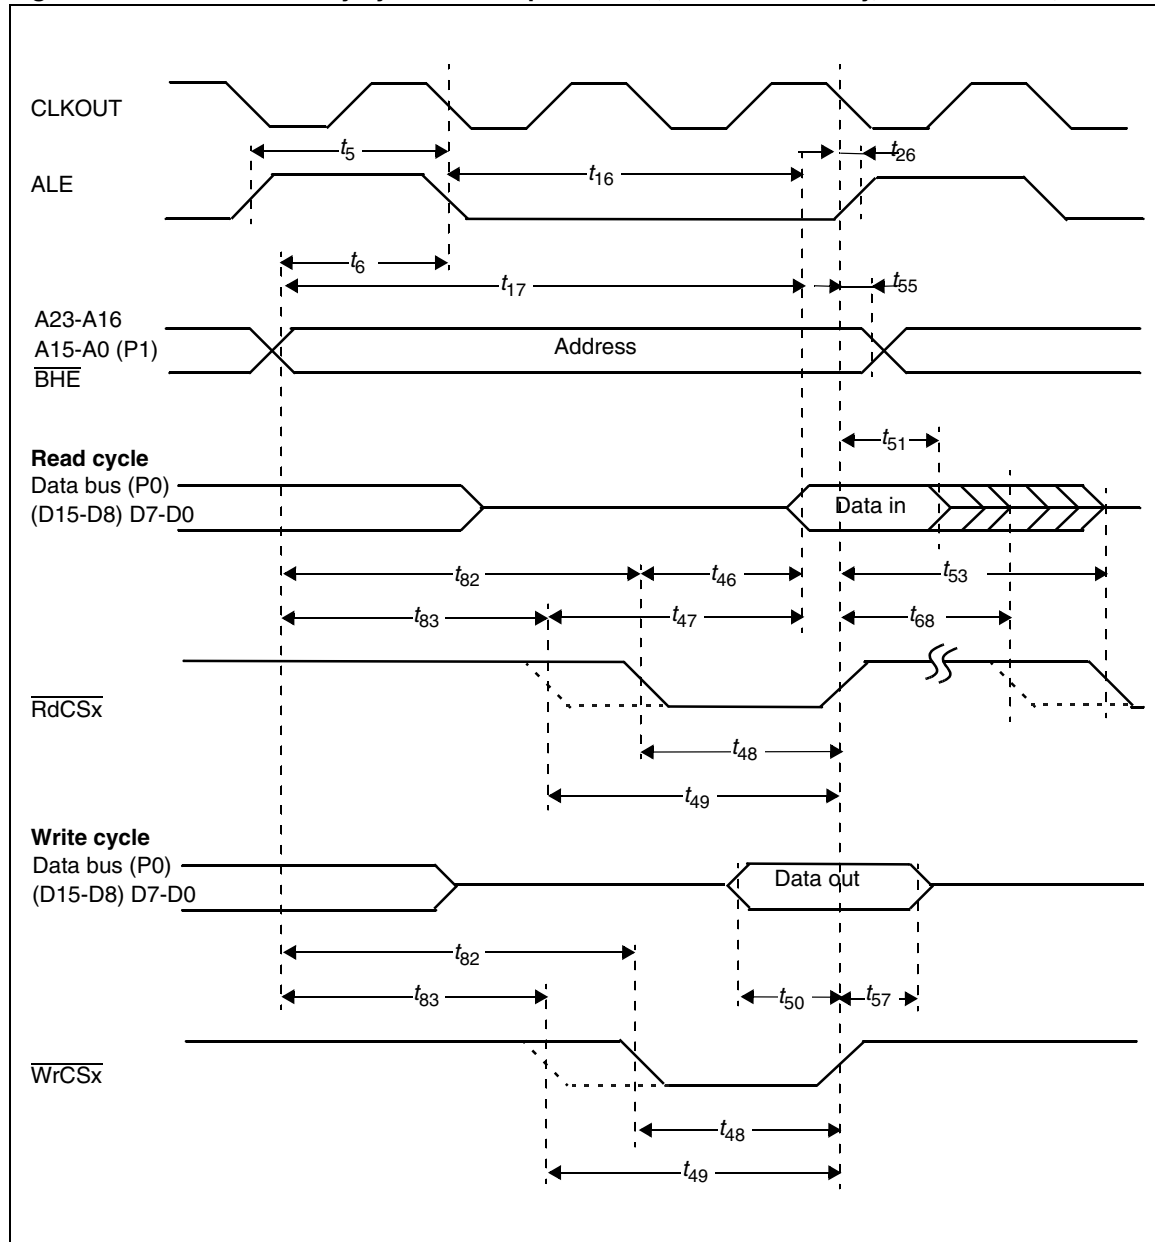

Figure 55. External memory cycle: demultiplexed bus, without r/w delay, extended ALE, r/w CS

24.8.18 CLKOUT and $\overline{\text{READY}}$

$V_{DD} = 5V \pm 10\%$, $V_{SS} = 0V$, $T_A = -40^\circ\text{C}$ to $+125^\circ\text{C}$, $C_L = 50\text{ pF}$

Table 80. CLKOUT and $\overline{\text{READY}}$ timings

Symbol	Parameter	$F_{CPU} = 40\text{ MHz}$ $TCL = 12.5\text{ ns}$		Variable CPU clock $1/2\text{ TCL} = 1\text{ to }64\text{ MHz}$		Unit
		Min.	Max.	Min.	Max.	
t_{29} CC	CLKOUT cycle time	25	25	2TCL	2TCL	ns
t_{30} CC	CLKOUT high time	9	—	$TCL - 3.5$	—	
t_{31} CC	CLKOUT low time	10	—	$TCL - 2.5$	—	
t_{32} CC	CLKOUT rise time	—	4	—	4	
t_{33} CC	CLKOUT fall time	—	4	—	4	
t_{34} CC	CLKOUT rising edge to ALE falling edge	$-2 + t_A$	$8 + t_A$	$-2 + t_A$	$8 + t_A$	
t_{35} SR	Synchronous $\overline{\text{READY}}$ setup time to CLKOUT	17	—	17	—	
t_{36} SR	Synchronous $\overline{\text{READY}}$ hold time after CLKOUT	2	—	2	—	
t_{37} SR	Asynchronous $\overline{\text{READY}}$ low time	35	—	$2TCL + 10$	—	
t_{58} SR	Asynchronous $\overline{\text{READY}}$ setup time ⁽¹⁾	17	—	17	—	
t_{59} SR	Asynchronous $\overline{\text{READY}}$ hold time ⁽¹⁾	2	—	2	—	
t_{60} SR	Async. $\overline{\text{READY}}$ hold time after $\overline{\text{RD}}$, $\overline{\text{WR}}$ high (Demultiplexed bus) ⁽²⁾	0	$2t_A + t_C + t_F$	0	$2t_A + t_C + t_F$	

1. These timings are given for characterization purposes only, in order to assure recognition at a specific clock edge.
2. Demultiplexed bus is the worst case. For multiplexed bus 2TCL are to be added to the maximum values. This adds even more time for deactivating $\overline{\text{READY}}$. $2t_A$ and t_C refer to the next following bus cycle, t_F refers to the current bus cycle.

Figure 56. CLKOUT and $\overline{\text{READY}}$ 

1. Cycle as programmed, including MCTC wait states (Example shows 0 MCTC WS).
2. The leading edge of the respective command depends on RW-delay.
3. $\overline{\text{READY}}$ sampled HIGH at this sampling point generates a $\overline{\text{READY}}$ controlled wait state, $\overline{\text{READY}}$ sampled LOW at this sampling point terminates the currently running bus cycle.
4. $\overline{\text{READY}}$ may be deactivated in response to the trailing (rising) edge of the corresponding command ($\overline{\text{RD}}$ or $\overline{\text{WR}}$).
5. If the Asynchronous $\overline{\text{READY}}$ signal does not fulfill the indicated setup and hold times with respect to CLKOUT (e.g. because CLKOUT is not enabled), it must fulfill t_{37} in order to be safely synchronized. This is guaranteed, if $\overline{\text{READY}}$ is removed in response to the command (see Note 4).
6. Multiplexed bus modes have a MUX wait state added after a bus cycle, and an additional MTTC wait state may be inserted here.
For a multiplexed bus with MTTC wait state this delay is two CLKOUT cycles, for a demultiplexed bus without MTTC wait state this delay is zero.
7. The next external bus cycle may start here.

24.8.19 External bus arbitration

$V_{DD} = 5V \pm 10\%$, $V_{SS} = 0V$, $T_A = -40^\circ\text{C}$ to $+125^\circ\text{C}$, $C_L = 50\text{ pF}$

Table 81. External bus arbitration timings

1. Partially tested, guaranteed by design characterization

Figure 57. External bus arbitration (releasing the bus)

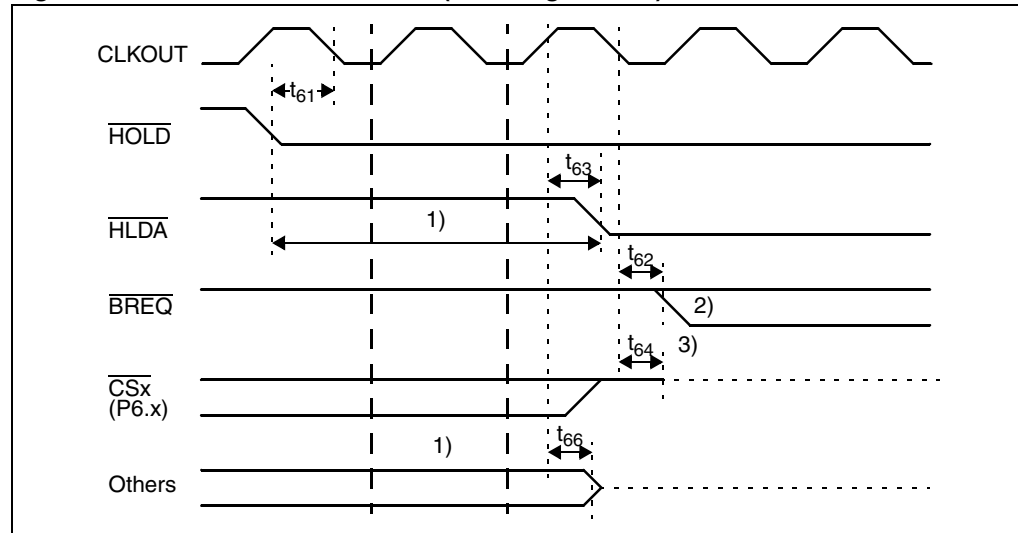

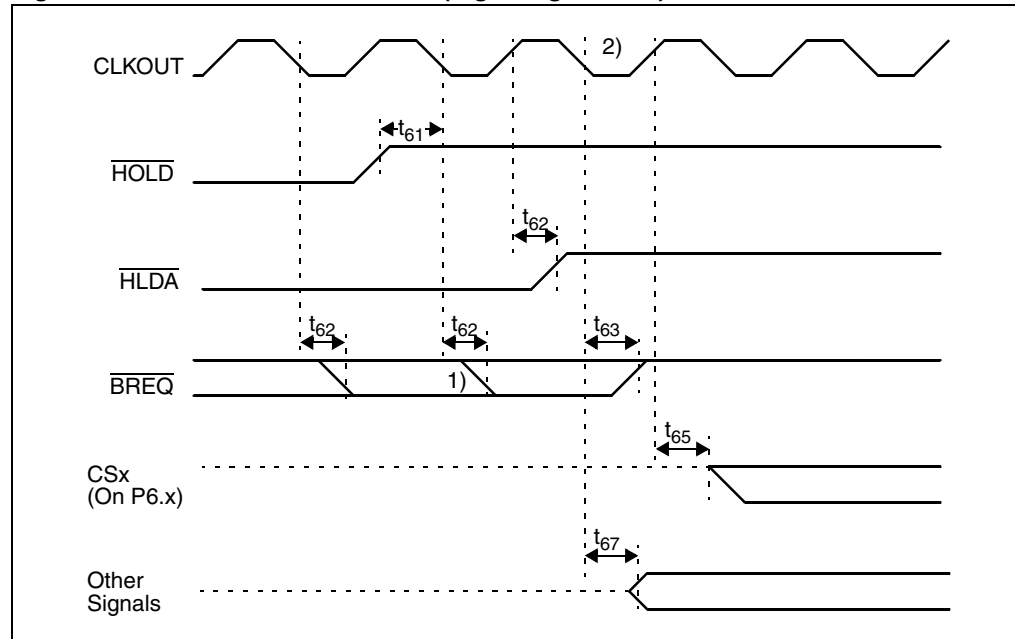

Figure 58. External bus arbitration (regaining the bus)

1. This is the last chance for $\overline{\text{BREQ}}$ to trigger the indicated regain-sequence. Even if $\overline{\text{BREQ}}$ is activated earlier, the regain-sequence is initiated by $\overline{\text{HOLD}}$ going high. Please note that $\overline{\text{HOLD}}$ may also be deactivated without the ST10F273Z4 requesting the bus.
2. The next ST10F273Z4 driven bus cycle may start here.

24.8.20 High-speed synchronous serial interface (SSC) timing

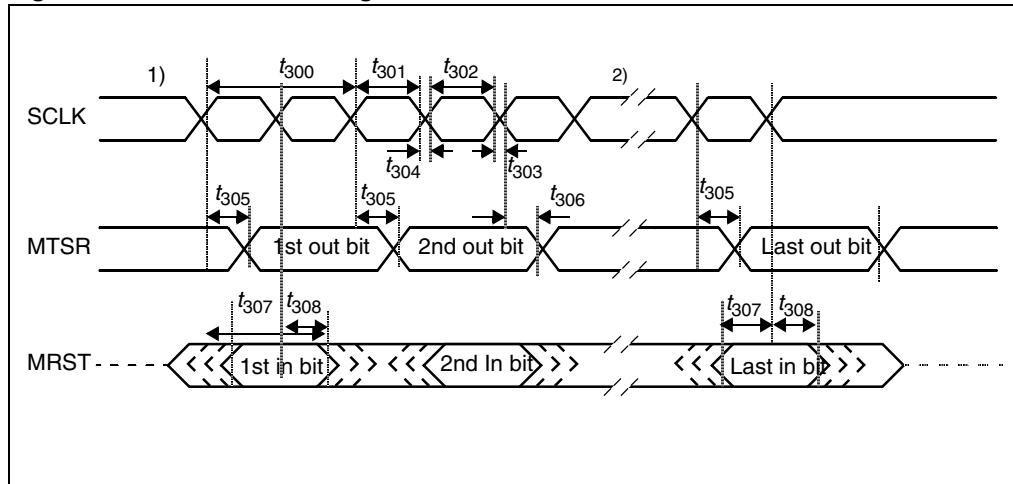

Master mode

$V_{DD} = 5V \pm 10\%$, $V_{SS} = 0V$, $T_A = -40^\circ\text{C}$ to $+125^\circ\text{C}$, $C_L = 50\text{ pF}$

Table 82. SSC master mode timings

Symbol		Parameter	Max.Baud rate 6.6MBd ⁽¹⁾ @ $F_{CPU} = 40\text{ MHz}$ ($\langle SSCBR \rangle = 0002h$)		Variable Baud rate ($\langle SSCBR \rangle = 0001h - FFFFh$)		Unit
			Min.	Max.	Min.	Max.	
t_{300}	CC	SSC clock cycle time ⁽²⁾	150	150	8TCL	262144 TCL	ns
t_{301}	CC	SSC clock high time	63	–	$t_{300} / 2 - 12$	–	
t_{302}	CC	SSC clock low time	63	–	$t_{300} / 2 - 12$	–	
t_{303}	CC	SSC clock rise time	–	10	–	10	
t_{304}	CC	SSC clock fall time	–	10	–	10	
t_{305}	CC	Write data valid after shift edge	–	15	–	15	
t_{306}	CC	Write data hold after shift edge ⁽³⁾	– 2	–	– 2	–	
t_{307p}	SR	Read data setup time before latch edge, phase error detection on (SSCPEN = 1)	37.5	–	2TCL + 12.5	–	
t_{308p}	SR	Read data hold time after latch edge, phase error detection on (SSCPEN = 1)	50	–	4TCL	–	
t_{307}	SR	Read data setup time before latch edge, phase error detection off (SSCPEN = 0)	25	–	2TCL	–	
t_{308}	SR	Read data hold time after latch edge, phase error detection off (SSCPEN = 0)	0	–	0	–	

1. Maximum Baud rate is in reality 8Mbaud, that can be reached with 64 MHz CPU clock and $\langle SSCBR \rangle$ set to '3h', or with 48 MHz CPU clock and $\langle SSCBR \rangle$ set to '2h'. When 40 MHz CPU clock is used the maximum baudrate cannot be higher than 6.6Mbaud ($\langle SSCBR \rangle = '2h'$) due to the limited granularity of $\langle SSCBR \rangle$. Value '1h' for $\langle SSCBR \rangle$ can be used only with CPU clock equal to (or lower than) 32 MHz.
2. Formula for SSC Clock Cycle time: $t_{300} = 4\text{ TCL} \times (\langle SSCBR \rangle + 1)$ Where $\langle SSCBR \rangle$ represents the content of the SSC Baudrate register, taken as unsigned 16-bit integer. Minimum limit allowed for t_{300} is 125ns (corresponding to 8Mbaud)
3. Partially tested, guaranteed by design characterization

Figure 59. SSC master timing

1. The phase and polarity of shift and latch edge of SCLK is programmable. This figure uses the leading clock edge as shift edge (drawn in bold), with latch on trailing edge (SSCPH = 0b), Idle clock line is low, leading clock edge is low-to-high transition (SSCPO = 0b).
2. The bit timing is repeated for all bits to be transmitted or received.

Slave mode

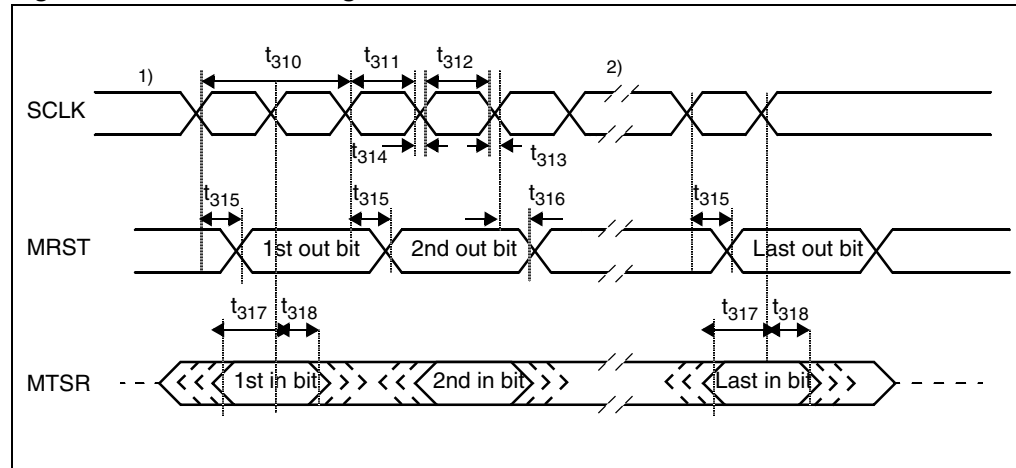

$V_{DD} = 5V \pm 10\%$, $V_{SS} = 0V$, $T_A = -40\text{ }^{\circ}\text{C}$ to $+125\text{ }^{\circ}\text{C}$, $C_L = 50\text{ pF}$

Table 83. SSC slave mode timings

Symbol		Parameter	Max. Baud rate 6.6 MBd ⁽¹⁾ @ $F_{CPU} = 40\text{ MHz}$ ($\langle SSCBR \rangle = 0002h$)		Variable Baudrate ($\langle SSCBR \rangle = 0001h - FFFFh$)		Unit
			Min.	Max.	Min.	Max.	
t_{310}	SR	SSC clock cycle time ⁽²⁾	150	150	8TCL	262144 TCL	ns

t_{312}	SR	SSC clock low time	63	–	$t_{310} / 2 - 12$	–	
t_{313}	SR	SSC clock rise time	–	10	–	10	
t_{314}	SR	SSC clock fall time	–	10	–	10	
t_{315}	CC	Write data valid after shift edge	–	55	–	2TCL + 30	
t_{316}	CC	Write data hold after shift edge	0	–	0	–	
t_{317p}	SR	Read data setup time before latch edge, phase error detection on (SSCPEN = 1)	62	–	4TCL + 12	–	
t_{318p}	SR	Read data hold time after latch edge, phase error detection on (SSCPEN = 1)	87	–	6TCL + 12	–	
t_{317}	SR	Read data setup time before latch edge, phase error detection off (SSCPEN = 0)	6	–	6	–	
t_{318}	SR	Read data hold time after latch edge, phase error detection off (SSCPEN = 0)	31	–	2TCL + 6	–	

1. Maximum Baudrate is in reality 8Mbaud, that can be reached with 64 MHz CPU clock and $\langle SSCBR \rangle$ set to '3h', or with 48 MHz CPU clock and $\langle SSCBR \rangle$ set to '2h'. When 40 MHz CPU clock is used the maximum baudrate cannot be higher than 6.6Mbaud ($\langle SSCBR \rangle = '2h'$) due to the limited granularity of $\langle SSCBR \rangle$. Value '1h' for $\langle SSCBR \rangle$ may be used only with CPU clock lower than 32 MHz (after checking that resulting timings are suitable for the master).

2. Formula for SSC Clock Cycle time: $t_{310} = 4\text{ TCL} * (\langle SSCBR \rangle + 1)$
Where $\langle SSCBR \rangle$ represents the content of the SSC Baudrate register, taken as unsigned 16-bit integer.
Minimum limit allowed for t_{310} is 125ns (corresponding to 8Mbaud).

Figure 60. SSC slave timing

1. The phase and polarity of shift and latch edge of SCLK is programmable. This figure uses the leading clock edge as shift edge (drawn in bold), with latch on trailing edge (SSCPH = 0b), Idle clock line is low, leading clock edge is low-to-high transition (SSCPO = 0b).
2. The bit timing is repeated for all bits to be transmitted or received.

25 Known limitations

This section describes the functional and electrical limitations identified on the CEG silicon revision of the ST10F273Z4.

The major revision of the device is contained in the device identification register, IDCHIP, located at address F07Ch. For Cxx versions, IDCHIP is set to 1143h.

25.1 Functional limitations

The functional limitations identified on the ST10F273Z4 are the following:

- Injected conversion stalling the A/D converter (see [Section 25.1.1: Injected conversion stalling the A/D converter](#))
- Concurrent transmission requests in DAR mode (C-CAN module) (see [Section 25.1.2: Concurrent transmission requests in DAR-mode \(C-CAN module\)](#))
- Disabling transmission requests (see [Section 25.1.3: Disabling the transmission requests \(C-CAN module\)](#))
- Spurious $\overline{\text{BREQ}}$ pulse in slave mode during external bus arbitration phase (see [Section 25.1.4: Spurious BREQ pulse in slave mode during external bus arbitration phase](#))
- Executing PWRDN instructions (see [Section 25.1.5: Executing PWRDN instructions](#))
- Behavior of capture/compare (CAPCOM) outputs in COMPARE mode 3 (see [Section 25.1.6: Behavior of CAPCOM outputs in COMPARE mode 3](#))

25.1.1 Injected conversion stalling the A/D converter

Description

The A/D converter is stalled and no further conversions are performed when a new injection request is issued before the CPU reads the ADDAT2 register (that is when the CPU has not read the result of the previous injection request).

Workarounds and recovery actions

The following actions allow to unlock the A/D converter:

1. Read the ADDAT2 register twice at the end of every injected conversion. This action also prevents the ADC from being stalled.
2. Disable and then enable again the wait for read mode.

Application conditions

This problem occurs if all the following conditions are fulfilled:

- Injection requests are hardware triggered (via CapCom CC31).
- The results of injected conversions are read by performing a PEC transfer. This prevents from reading twice the ADDAT2 register by software.
- A high level task is disabling the PEC transfer for a long time (time needed for 2 analog conversions plus time between 2 injection requests).

Therefore, to prevent the locking situation from occurring, it is important to make sure that no task can disable interrupts for a period of time during which 2 injection requests can occur before a read operation is performed.

Detailed analysis

Channel Injection mode allows to convert a specific analog channel without changing the current operating mode. It can also be used when the A/D converter is running in continuous or auto scan mode.

The following main points need to be highlighted:

- The A/D converter must be in Wait for ADDAT read mode in order for the Channel Injection mode to operate properly.
- At the end of the injected conversion the data is available in the alternate result register, ADDAT2, and a Channel Injection Complete Interrupt request is generated (ADEIR Flag).
- If the temporary data register used for ADDAT2 read mode is full, the next conversion (standard or injected) is suspended. The temporary register then stores the content of ADDAT (standard conversion) or ADDAT2 (injected conversion).

If the temporary data register used for ADDAT2 read mode is full and a new injection request occurs, then the new converted value is stored into a temporary data register until the previous one is read from ADDAT2 register.

To ensure correct operation as soon as ADDAT2 register is read, the last converted value should be moved from temporary register to ADDAT2 and the ADEINT interrupt should be generated. This allows the CPU to read the last converted value (see [Figure 61](#)).

In real circumstances, as soon as the ADDAT2 register is read, the last converted value is correctly moved from the temporary register to the ADDAT2, but no ADEINT interrupt request is sent to the Interrupt controller (see [Figure 62](#)). As a consequence the CPU/PEC does not know that a new converted value is available in the ADDAT2 register. When the next injection request is issued, the A/D converter fills the temporary register again without generating any ADEINT interrupt request and the converter is stalled. The A/D converter stays in the “wait for read ADDAT2 register” condition forever.

Figure 61. ADC injection theoretical operation

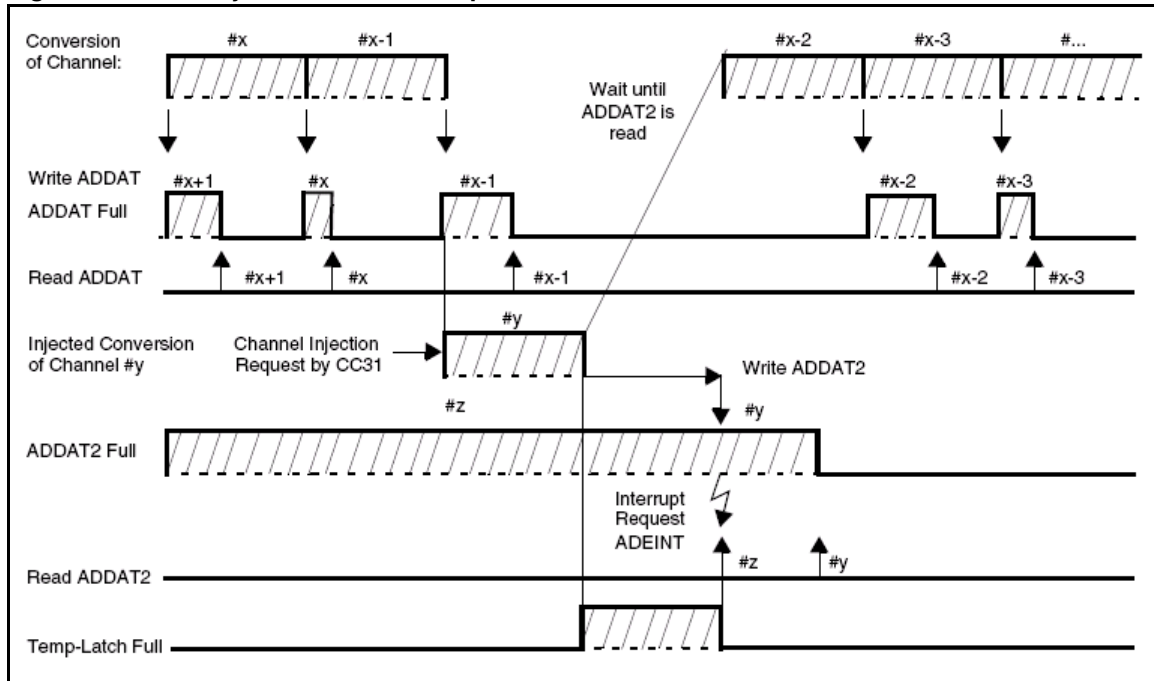

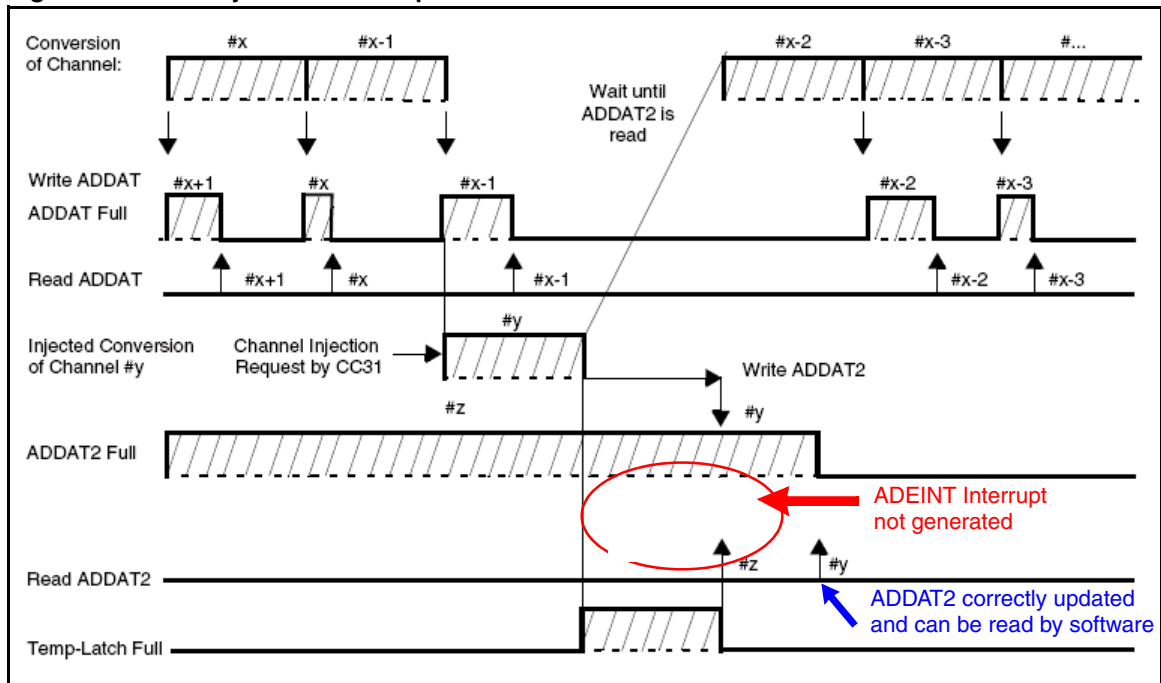

Figure 62. ADC injection actual operation

25.1.2 Concurrent transmission requests in DAR-mode (C-CAN module)

Description

When the C-CAN module is configured to operate in DAR mode (Disable Automatic Retransmission) and the host requests the transmission of several messages at the same time, only two of these messages are transmitted. For all other message transmission requests the TxRqst bits are reset, no transmission is started, and NewDat and IntPnd are kept unchanged. For the two messages which are transmitted, the TxRqst and NewDat bits are reset and IntPnd is set if it has been enabled by TxIE. TxRqst, NewDat and IntPnd are bits of the message interface control registers.

The normal operation mode (DAR = 0) is not affected by this phenomenon.

Workaround

The DAR mode is intended to support time-triggered operation (TTCAN level 1) supporting the transmission of a message only in its dedicated time window. It is an error to request the transmission of several messages at the same time, and no workarounds should consequently be necessary for TTCAN applications.

The progress of a requested transmission can be monitored by checking the message object TxRqst and NewDat [optionally IntPnd] bits. In DAR mode, when a message transmission has failed either because the transmission was disturbed or because it has not started, it is necessary to request the message transmission again.

For details on DAR mode and message control registers, refer to user manual UM0409.

25.1.3 Disabling the transmission requests (C-CAN module)

Description

If the host disables the pending transmission request of the lowest-priority message (number 32 by default) in the short time window during which the message handler state machine prepares the transmission, but before the transmission has actually started, then this transmission request may remain disabled. It remains in this state even if the host immediately re-enables it.

The status of the message object transmission request bit does not show that the transmission is disabled. This only happens when the message object is the only one with a pending transmission request.

If the transmission request is blocked in the disabled state, it will be re-enabled by the first activity detected on the CAN bus or by setting the transmission request of any other message object.

The other message objects are not affected by this phenomenon.

Workaround

It is usually not necessary to disable the transmission request of a message object. If the message object is to be used for another message, it is sufficient to prepare the new content corresponding to this message in the CPU interface register (Identifier, DLC, Data, with TxRqst and NewDat [optionally TxIE] bits) and to transfer it into the message object. The new content is then transmitted at the next opportunity, and is not altered by a possibly ongoing transmission of the previous content of the same message object.

25.1.4 Spurious $\overline{\text{BREQ}}$ pulse in slave mode during external bus arbitration phase

Description

Sporadic bus errors may occur when the device operates as a slave and the $\overline{\text{HOLD}}$ signal is used for external bus arbitration.

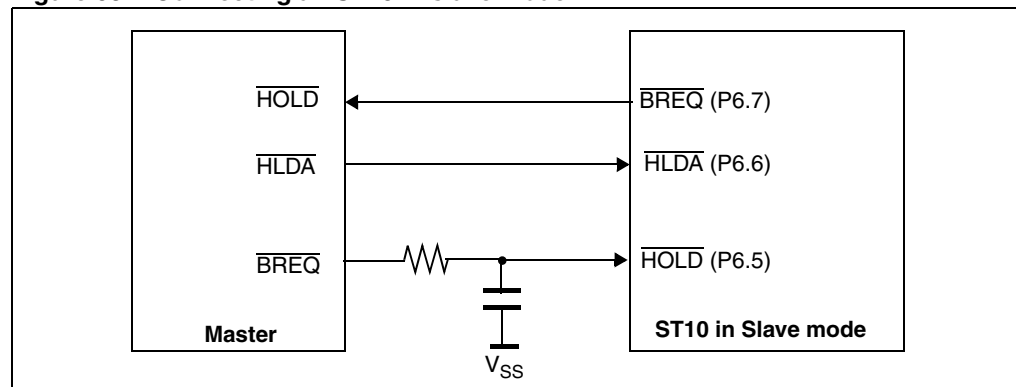

After the slave has been granted the bus, it deactivates sporadically $\overline{\text{BREQ}}$ signal for a short time, even though its access to the bus has not been completed. The master then starts accessing the bus, thus causing a bus conflict between master and slave.

Workaround

To avoid producing any spurious $\overline{\text{BREQ}}$ pulse during slave external bus arbitrations, it is necessary to ensure that the time between the $\overline{\text{HLDA}}$ assertion (Bus Acknowledge from Master device) and the following $\overline{\text{HOLD}}$ falling edge (Bus Request from Master) is longer than three clock cycles.

This can be achieved by delaying the $\overline{\text{HOLD}}$ signal with an RC circuit (see [Figure 63](#)).

Figure 63. Connecting an ST10 in slave mode

25.1.5 Executing PWRDN instructions

Description

The Power-down mode is not entered and the PWRDN instruction is ignored in the following cases:

- The PWRDN instruction is executed while $\overline{\text{NMI}}$ is high (PWDCFG bit of the SYSCON register cleared)
- The PWRDN instruction is executed while at least one of the Port 2 pins used to exit from Power-down mode (PWDCFG bit of the SYSCON register is set) is at the active level.

However, in certain cases, the PWRDN instruction is not ignored, no further instructions are fetched from external memory, and the CPU is in a quasi-idle state. This problem only occurs in the following situations:

1. The instructions following the PWRDN instruction are located in an external memory and a multiplexed bus configuration with memory tri-state waitstate (bit MTTCx = 0) is used.
2. The instruction preceding the PWRDN instruction writes to the external memory or to an XPeripheral (such as XRAM or CAN) and the instructions following the PWRDN instruction are located in external memory area. In this case, the problem occurs for all bus configurations.

Note: The on-chip peripherals, such as the watchdog timer, still operate properly. If the watchdog timer is not disabled, it resets the device upon an overflow event. However, interrupts and PEC transfers cannot be processed. Power-down mode is entered if the $\overline{\text{NMI}}$ signal is asserted low while the device is in this quasi-idle state.

No problem occurs and the device normally enters Power-down mode if the $\overline{\text{NMI}}$ pin is held low (PWDCFG = 0) or if all Port 2 pins used to exit from Power-down mode are at inactive level (PWDCFG = 1).

Workaround

To prevent this problem from occurring, the PWRDN instruction must be preceded by instructions performing write operations to external memory area or to an XPeripheral. Otherwise, it is recommended to insert a NOP instruction before PWRDN.

When using a multiplexed bus with memory tri-state wait state, the PWRDN instruction must be executed from internal RAM or XRAM.

25.1.6 Behavior of CAPCOM outputs in COMPARE mode 3

Description

When a CAPCOM channel is configured in compare mode 3, then the related output level switches to high when the allocated timer, Tx, matches the related CAPCOM register, CCy. When an overflow occurs on the CAPCOM timer Tx, it is reloaded with TxREL content and the output pin is cleared. The output pin level does not change if TxREL and CCy have the same value.

The related CAPCOM output stays low when the CAPCOM channel is configured in compare mode 3 and TxREL and Tx related timer registers are loaded with the same value as CCy. This is obtained by executing the following instructions:

```
MOV TxREL, #CCy value x = 0,1,7,8
MOV Tx, #CCy value x = 0,1,7,8
MOV TxxCON, #data or bfl dl/bfl dh TxxCON, #mask, #data i.e. an
access is made to the T01CON or T78CON register.
```

Workarounds

The following workarounds make the CAPCOM output toggle as expected:

1) Invert the TxREL and Tx configuration as follow:

```
MOV Tx, #CCy value
MOV TxREL, #CCy value
bflldl/bfldh TxxCON , #mask, #data or MOV TxxCON, #data
```

2) Insert a NOP instruction before the T01CON or T78CON configuration:

```
MOV Tx, #value
MOV TxREL, #value
NOP
bflldl/bfldh TxxCON , #mask, #data or MOV TxxCON, #data
```

3) Load the Tx timer with the CCy register minus 1:

```
MOV TxREL, #value
MOV Tx, #( value-1)
bflldl/bfldh TxxCON , #mask, #data or MOV TxxCON, #data
```

25.2 Electrical limitations

The PLL lock-time, T_{LOCK} , for x10 multiplication factor is 300 μ s instead of 250 μ s (see [Table 72](#)).

26 Package information

In order to meet environmental requirements, ST offers these devices in ECOPACK® packages. These packages have a Lead-free second level interconnect. The category of second Level Interconnect is marked on the package and on the inner box label, in compliance with JEDEC standard JESD97. The maximum ratings related to soldering conditions are also marked on the inner box label.

ECOPACK is an ST trademark. ECOPACK specifications are available at: www.st.com.
