# TOSHIBA

TOSHIBA Original CMOS 32-Bit Microcontroller

# TLCS-900/H1 Series

# TMP92CH21FG

## TOSHIBA CORPORATION

Semiconductor Company

## Preface

Thank you very much for making use of Toshiba microcomputer LSIs. Before use this LSI, refer the section, "Points of Note and Restrictions".

CMOS 32-bit Microcontroller

## TMP92CH21FG/JTMP92CH21

## 1. Outline and Device Characteristics

The TMP92CH21 is a high-speed advanced 32-bit Microcontroller developed for controlling equipment which processes mass data.

The TMP92CH21 has a high-performance CPU (900/H1 CPU) and various built-in I/Os.

The TMP92CH21FG is housed in a 144-pin flat package. The JTMP92CH21 is a chip form product.

Device characteristics are as follows:

- (1) CPU: 32-bit CPU (900/H1 CPU)
  - Compatible with TLCS-900/L1 instruction code
  - 16 Mbytes of linear address space
  - General-purpose register and register banks
  - Micro DMA: 8 channels (250 ns/4 bytes at fsys = 20 MHz, best case)
- (2) Minimum instruction execution time: 50 ns (at  $f_{SYS} = 20 \text{ MHz}$ )
- (3) Internal memory
  - Internal RAM: 16 Kbytes (can be used for program, data and display memory)
  - Internal ROM: 8 Kbytes (used as boot program) Possible downloading of user program through either USB, UART or NAND flash.
- (4) External memory expansion
  - Expandable up to 512 Mbytes (shared program/data area)
  - Can simultaneously support 8,- 16- or 32-bit width external data bus ... dynamic data bus sizing
  - Separate bus system
- (5) Memory controller
  - Chip select output: 4 channels
- (6) 8-bit timers: 4 channels
- (7) 16-bit timer/event counter: 1 channel
- (8) General-purpose serial interface: 2 channels
  - UART/synchronous mode: 2 channels (channel 0 and 1)
  - IrDA ver.1.0 (115 kbps) mode selectable: 1 channel (channel 0)

- (9) USB (universal serial bus) controller: 1 channel
  - Compliant with USB ver.1.1
  - Full-speed (12 Mbps) (Low-speed is not supported.)
  - Endpoints spec
    - Endpoint 0: Control 64 bytes\* 1-FIFO
    - Endpoint 1: BULK (out) 64 bytes\* 2-FIFO
    - Endpoint 2: BULK (in) 64 bytes\* 2-FIFO
    - Endpoint 3: Interrupt (in) 8 bytes\* 1-FIFO
  - Descriptor RAM: 384 bytes

(10) I<sup>2</sup>S (Inter-IC sound) interface: 1 channel

- $\bullet \quad I^2S \ \text{bus mode/SIO mode selectable (Master, transmission only)}$
- 32-byte FIFO buffer

(11) LCD controller

- Supports up to 4096 color for TFT, 256 color, 16, 8, 4 gray levels and B/W for STN
- Shift register/built-in RAM LCD driver

(12) SDRAM controller: 1 channel

- Supports 16 M, 64 M, 128 M, 256 M, and up to 512-Mbit SDR (Single Data Rate)-SDRAM
- Possible to execute instruction on SDRAM

(13) Timer for real-time clock (RTC)

- (14) Key-on wakeup (Interrupt key input)
- (15) 10-bit AD converter: 4 channels
- (16) Touch screen interface
  - Available to reduce external components

(17) Watchdog timer

(18) Melody/alarm generator

- Melody: Output of clock 4 to 5461 Hz
- Alarm: Output of 8 kinds of alarm pattern and 5 kinds of interval interrupt

(19) MMU

- Expandable up to 512 Mbytes (3 local area/8 bank method)
- Independent bank for each program, read data, write data and LCD display data

(20) Interrupts: 50 interrupt

- 9 CPU interrupts: Software interrupt instruction and illegal instruction
- 34 internal interrupts: Seven selectable priority levels
- 7 external interrupts: Seven selectable priority levels (6-edge selectable)

(21) Input/output ports: 82 pins (Except Data bus (16bit), Address bus (24bit) and  $\overline{RD}$  pin)

(22) NAND flash interface: 2 channels

- Direct NAND flash connection capability
- ECC calculation (for SLC- type)

(23) Stand-by function

- Three HALT modes: IDLE2 (programmable), IDLE1, STOP
- Each pin status programmable for stand-by mode

(24) Triple-clock controller

- Clock doubler (PLL) supplies 48 MHz for USB, 36 MHz system-clock for others
- Clock gear function: Select high-frequency clock fc to fc/16
- RTC (fs = 32.768 kHz)

(25) Operating voltage:

- VCC = 3.0 V to 3.6 V (fc max = 40 MHz)
- VCC = 2.7 V to 3.6 V (fc max = 27 MHz)

(26) Package:

- 144-pin QFP (LQFP144-P-1616-0.40C)
- 144-pin chip form is also available. For details, contact your local Toshiba sales representative.

## 2.3 Pin Names and Functions

## The following table shows the names and functions of the input/output pins

Table 2.3.1 I	Pin Names and	Functions (1/5)
---------------	---------------	-----------------

Pin Name	Number of Pins	I/O	Function
D0 to D7	8	I/O	Data: Data bus 0 to 7
P10 to P17		I/O	Port 1: I/O port input or output specifiable in units of bits
D8 to D15	8	I/O	Data: Data bus 8 to 15
P20 to P27		I/O	Port 2: I/O port input or output specifiable in units of bits
D16 to D23	8	I/O	Data: Data bus 16 to 23
KO0 to KO7		Output	Key output 0 to 7: Pins used of key-scan strobe (Open-drain output programmable)
P30 to P37	0	I/O	Port 3: I/O port input or output specifiable in units of bits
D24 to D31	8	I/O	Data24: Data bus 24 to 31
P40 to P47	0	Output	Port 4: Output port
A0 to A7	8	Output	Address: Address bus 0 to 7
P50 to P57	0	Output	Port 5: Output port
A8 to A15	8	Output	Address: Address bus 8 to 15
P60 to P67	8	I/O	Port 6: I/O port input or output specifiable in units of bits
A16 to A23	o Output		Address: Address bus 16 to 23
P70	1	Output	Port70: Output port
RD	1	Output	Read: Outputs strobe signal to read external memory
P71		I/O	Port 71: I/O port
WRLL	1	Output	Write: Output strobe signal for writing data on pins D0 to D7
NDRE	Output		NAND flash read: Outputs strobe signal to read external NAND flash
P72		I/O	Port 72: I/O port
WRLU	1	Output	Write: Output strobe signal for writing data on pins D8 to D15
NDWE		Output	Write Enable for NAND flash
P73	1	Output	Port 73: Output port
EA24	I	Output	Extended Address 24
P74	1	Output	Port 74: Output port
EA25	I	Output	Extended Address 25
P75		I/O	Port 75: I/O port
$R/\overline{W}$	1	Output	Read/Write: 1 represents read or dummy cycle; 0 represents write cycle
NDR/B		Input	NAND flash ready (1)/Busy (0) input
P76	1	I/O	Port 76: I/O port
WAIT	'	Input	Wait: Signal used to request CPU bus wait

Pin Name	Number of Pins	I/O	Function	
P80	1	Output	Port80: Output port	
<u>CS0</u>		Output	Chip select 0: Outputs "low" when address is within specified address area	
P81	1	Output	Port81: Output port	
CS1		Output	Chip select 1: Outputs "low" when address is within specified address area	
SDCS		Output	Chip select for SDRAM: Outputs "0" when address is within SDRAM address area	
P82	1	Output	Port82: Output port	
CS2		Output	Chip select 2: Outputs "Low" when address is within specified address area	
CSZA		Output	Expand chip select: ZA: Outputs "0" when address is within specified address area	
SDCS		Output	Chip select for SDRAM: Outputs "0" when address is within SDRAM address area	
P83	1	Output	Port83: Output port	
<del> CS3</del>		Output	Chip select 3: Outputs "low" when address is within specified address area	
P84	1	Output	Port84: Output port	
WRUL		Output	Write: Output strobe signal for writing data on pins D16 to D23	
CSZB		Output	Expand chip select: ZB: Outputs "0" when address is within specified address area	
NDOCE		Output	Chip select for NAND flash 0: Outputs "0" when NAND flash 0 is enabled	
P85	1	Output	Port85: Output port	
WRUU		Output	Write: Output strobe signal for writing data on pins D24 to D31	
CSZC		Output	Expand chip select: ZC: Outputs "0" when address is within specified address area	
ND1CE		Output	Chip select for NAND flash 1: Outputs "0" when NAND flash 1 is enabled	
P86	1	Output	Port86: Output port	
CSZD		Output	Expand chip select: ZD: outputs "0" when address is within specified address area	
SRULB		Output	Data enable for SRAM on pins D16 to D23	
P87	1	Output	Port87: Output port	
CSZE		Output	Expand chip select: ZE: Outputs "0" when address is within specified address area	
SRUUB		Output	Data enable for SRAM on pins D24 to D31	
P90	1	I/O	Port90: I/O port	
TXD0		Output	Serial 0 send data: Open-drain output programmable	
I2SCKO		Output	I <sup>2</sup> S clock output	
P91	1	I/O	Port91: I/O port (Schmitt-input)	
RXD0		Input	Serial 0 receive data	
I2SDO		Output	I <sup>2</sup> S data output	
P92	1	I/O	Port92: I/O port (Schmitt-input)	
SCLK0		I/O	Serial 0 clock I/O	
CTS0		Input	Serial 0 data send enable (Clear to send)	
I2SWS		Output	I <sup>2</sup> S word select output	
P93	1	I/O	Port93: I/O port	
LGOE0		Output	Output enable-0 for external TFT-LCD driver	
P94 LGOE1	1	I/O Output	Port94: I/O port Output enable-1 for external TFT-LCD driver Dertage	
P95	1	Output	Port95: Output port	
CLK32KO		Output	Output fs (32.768 kHz) clock	
LGOE2		Output	Output enable-2 for external TFT-LCD driver	
P96	1	Input	Port 96: Input port (Schmitt-input)	
INT4		Input	Interrupt request pin4: Interrupt request with programmable rising/falling edge	
PX		Output	X-Plus: Pin connectted to X+ for touch screen panel	
P97	1	Input	Port 97: Input port (Schmitt-input)	
INT5		Input	Interrupt request pin5: Interrupt request with programmable rising/falling edge	
PY		Output	Y-Plus: Pin connectted to Y+ for touch screen panel	
PA0 to PA2	3	Input	Port: A0 to A2 port: Pin used to input ports (Schmitt input, with pull-up resistor)	
KI0 to KI2		Input	Key input 0 to 2: Pin used for key-on wakeup 0 to 2	
PA3 to PA6	4	Input	Port: A3 to A6 port: Pin used to input ports (Schmitt input, with pull-up resistor)	
KI3 to KI6		Input	Key input 3 to 6: Pin used for key-on wakeup 3 to 6	
LD8 to LD11		Output	Data bus 8 to 11for LCD driver	
PA7	1	Input	Port: A7 port: Pin used to input ports (Schmitt input, with pull-up resistor)	
KI7		Input	Key input 7: Pin used for key-on wakeup 7	

#### Table 2.3.2 Pin Names and Functions (2/5)

1

Table 2.3.3 Pin Names and Functions (3/5)

Pin Name	Number of Pins	I/O	Function	
PC0		I/O	Port C0: I/O port (Schmitt-input)	
INT0	1	Input	Interrupt request pin 0: Interrupt request pin with programmable level/rising/falling edge	
TA1OUT		Output	8-bit timer 1 output: Timer 1 output	
PC1		I/O	Port C1: I/O port (Schmitt-input)	
INT1	1	Input	Interrupt request pin 1: Interrupt request pin with programmable rising/falling edge	
<b>TA3OUT</b>		Output	8-bit timer 3 output: Timer 3 output	
PC2		I/O	Port C2: I/O port (Schmitt-input)	
INT2	1	Input	Interrupt request pin 2: Interrupt request pin with programmable rising/falling edge	
TB0OUT0		Output	Timer B0 output	
PC3	4	I/O	Port C3: I/O port (Schmitt-input)	
INT3	1	Input	Interrupt request pin 3: Interrupt request pin with programmable rising/falling edge	
PC6		I/O	Port C6: I/O port	
KO8	1	Output	Key Output 8: Pin used of key-scan strobe (Open-drain output programmable)	
LDIV		Output	Data invert enable for external TFT-LCD driver	
PC7		I/O	Port C7: I/O port	
CSZF	1	Output	Expand chip select: ZF: Outputs "0" when address is within specified address area	
LCP1		Output	Shift-clock-1 for external TFT-LCD driver	
PF0		I/O	Port F0: I/O port (Schmitt-input)	
TXD0	1	Output	Serial 0 send data: Open-drain output programmable	
TXD1		Output	Serial 1 send data: Open-drain output programmable	
PF1		I/O	Port F1: I/O port (Schmitt-input)	
RXD0	1	Input	Serial 0 receive data	
RXD1		Input	Serial 1 receive data	
PF2		I/O	Port F2: I/O port (Schmitt-input)	
SCLK0		I/O	Serial 0 clock I/O	
CTS0	1	Input	Serial 0 data send enable (Clear to send)	
SCLK1		I/O	Serial 1 clock I/O	
CTS1		Input	Serial 1 data send enable (Clear to send)	
PF7	4	Output	Port F7: Output port	
SDCLK	1	Output	Clock for SDRAM (When SDRAM is not used, SDCLK can be used as system clock)	
PG0 to PG1	2	Input	Port G0 to G1 port: Pin used to input ports	
AN0 to AN1	2	Input	Analog input 0 to 1: Pin used to Input to AD conveter	
PG2		Input	Port G2 port: Pin used to input ports	
AN2	1	Input	Analog input 2: Pin used to Input to AD conveter	
MX		Output	X-Minus: Pin connectted to X– for touch screen panel	
PG3		Input	Port G3 port: Pin used to input ports	
AN3	4	Input	Analog input 3: Pin used to input to AD conveter	
MY	1	Output	Y-Minus: Pin connectted to Y- for touch screen panel	
ADTRG		Intput	AD trigger: Signal used to request AD start	

Pin Name	Number of Pins	I/O	Function
PJ0		Output	Port J0: Output port
SDRAS	1	Output	Row address strobe for SDRAM
SRLLB		Output	Data enable for SRAM on pins D0 to D7
PJ1		Output	Port J1: Output port
SDCAS	1	Output	Column address strobe for SDRAM
SRLUB		Output	Data enable for SRAM on pins D8 to D15
PJ2		Output	Port J2: Output port
SDWE	1	Output	Write enable for SDRAM
SRWR		Output	Write for SRAM: Strobe signal for writing data
PJ3	1	Output	Port J3: Output port
SDLLDQM	I	Output	Data enable for SDRAM on pins D0 to D7
PJ4	1	Output	Port J4: Output port
SDLUDQM	I	Output	Data enable for SDRAM on pins D8 to D15
PJ5		I/O	Port J5: I/O port
SDULDQM	1	Output	Data enable for SDRAM on pins D16 to D23
NDALE		Output	Address latch enable for NAND flash
PJ6		I/O	Port J6: I/O port
SDUUDQM	1	Output	Data enable for SDRAM on pins D24 to D31
NDCLE		Output	Command latch enable for NAND flash
PJ7	1	Output	Port J7: Output port
SDCKE		Output	Clock enable for SDRAM
PK0	1	Output	Port K0: Output port
LCP0	I	Output	LCD driver output pin
PK1	1	Output	Port K1: Output port
LLP	I	Output	LCD driver output pin
PK2	1	Output	Port K2: Output port
LFR	I	Output	LCD driver output pin
PK3	1	Output	Port K3: Output port
LBCD	I	Output	LCD driver output pin
PL0 to PL3	4	Output	Port L0 to L3: Output port
LD0 to LD3	4	Output	Data bus for LCD driver
PL4 to PL7	4	I/O	Port L4 to L7: I/O port
LD4 to LD7	4	Output	Data bus for LCD driver
TEST	1	Input	Connect to VCC.
PM1	1	Output	Port M1: Output port
MLDALM	1	Output	Melody/alarm output pin
PM2		Output	Port M2: Output port
ALARM	1	Output	RTC alarm output pin
MLDALM		Output	Melody/alarm output pin (inverted)

Note: The output functions SDULDQM, NDALE of PJ5-pin and SDUUDQM, NDCLE of PJ6-pin cannot be used simultaneously. Therefore, 32-bit SDRAM and NAND-Flash cannot be used at the same time.

Pin Name	Number of Pins	I/O	Function	
D+, D-	2	I/O	JSB-data connecting pin Connect pull-up resistor to both pins to avoid through current when USB is not in use.	
AM0, AM1	2	Input	Operation mode: Fix to AM1 = "0", AM0 = "1" for 16-bit external bus starting Fix to AM1 = "1", AM0 = "0" for 32-bit external bus starting Fix to AM1 = "1", AM0 = "1" for BOOT (32-bit internal MROM) starting	
X1/X2	2	I/O	High-frequency oscillator connection pins	
XT1/XT2	2	I/O	Low-frequency oscillator connection pins	
RESET	1	Input	Reset: Initializes TMP92CH21 (with pull-up resistor, Schmitt input)

## Table 2.3.5 Pin Names and Functions (5/5)

Note: Use a 9.0 MHz oscillator at pins X1/X2 when USB is used.

## 3. Operation

This section describes the basic components, functions and operation of the TMP92CH21.

3.1 CPU

The TMP92CH21 contains an advanced high-speed 32-bit CPU (TLCS-900/H1 CPU)

## 3.1.1 CPU Outline

The TLCS-900/H1 CPU is a high-speed, high-performance CPU based on the TLCS-900/L1 CPU. The TLCS-900/H1 CPU has an expanded 32-bit internal data bus to process instructions more quickly.

The following is an outline of the CPU:

Parameter	TMP92CH21
Width of CPU address bus	24 bits
Width of CPU data bus	32 bits
Internal operating frequency	Max 20 MHz
Minimum bus cycle	1-clock access (50 ns at f <sub>SYS</sub> = 20MHz)
Internal RAM	32-bit 1-clock access
Internal boot ROM	32-bit 2-clock access
Internal I/O	8- or 16-bit 2-clock access or
	8- or 16-bit 5 to 6-clock access
External SPAM Maakad POM	8- or 16- or 32-bit 2-clock access
External SRAM, Masked ROM	(waits can be inserted)
External SDRAM	16- or 32-bit min. 1-clock access
	8-bit min. 4-clock access
External NAND flash	(waits can be inserted)
Minimum instruction execution cycle	1-clock (50 ns at f <sub>SYS</sub> =20MHz)
Conditional jump	2-clock (100 ns at f <sub>SYS</sub> =20MHz)
Instruction queue buffer	12 bytes
	Compatible with TLCS-900/L1
Instruction set	(LDX instruction is deleted)
CPU mode	Maximum mode only
Micro DMA	8 channels

Table 3.1.1 TMP92CH21 Outline

## 3.1.2 Reset Operation

When resetting the TMP92CH21, ensure that the power supply voltage is within the operating voltage range, and that the internal high-frequency oscillator has stabilized. Then hold the  $\overline{\text{RESET}}$  input low for at least 20 system clocks (16 µs at fc = 40 MHz).

At reset, since the clock doubler (PLL) is bypassed and the clock-gear is set to 1/16, the system clock operates at 1.25 MHz (fc = 40 MHz).

When the reset has been accepted, the CPU performs the following:

• Sets the program counter (PC) as follows in accordance with the reset vector stored at address FFFF00H to FFFF02H:

PC<7:0>	$\leftarrow$ data in location FFFF00H
PC<15:8>	$\leftarrow$ data in location FFFF01H
PC<23:16>	$\leftarrow$ data in location FFFF02H

- Sets the stack pointer (XSP) to 00000000H.
- Sets bits <IFF2:0> of the status register (SR) to 111 (thereby setting the interrupt level mask register to level 7).
- Clears bits <RFP1:0> of the status register to 00 (there by selecting register bank 0).

When the reset is released, the CPU starts executing instructions according to the program counter settings. CPU internal registers not mentioned above do not change when the reset is released.

When the reset is accepted, the CPU sets internal I/O, ports and other pins as follows.

- Initializes the internal I/O registers as shown in the "Special Function Register" table in section 5.
- Sets the port pins, including the pins that also act as internal I/O, to general-purpose input or output port mode.

Internal reset is released as soon as external reset is released.

Memory controller operation cannot be ensured until the power supply becomes stable after power-on reset. External RAM data provided before turning on the TMP92CH21 may be corrupted because the control signals are unstable until the power supply becomes stable after power on reset.

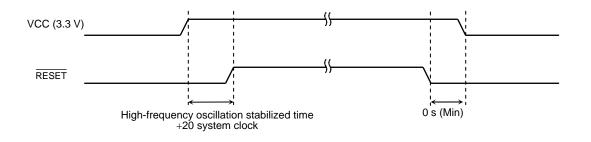

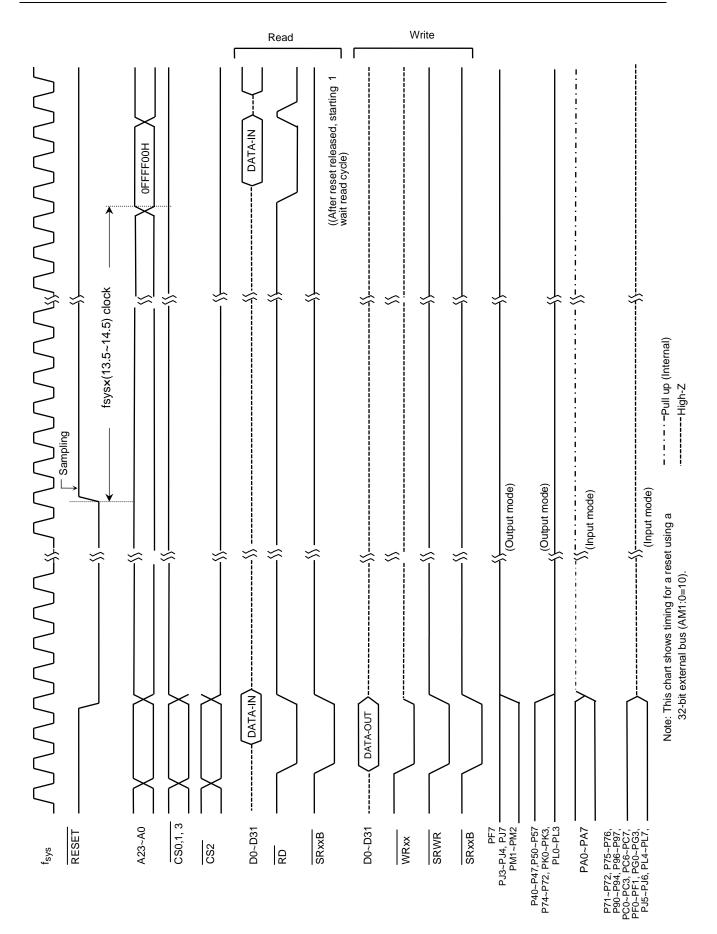

Figure 3.1.1 Power on Reset Timing Example

## 3.1.3 Setting of AM0 and AM1

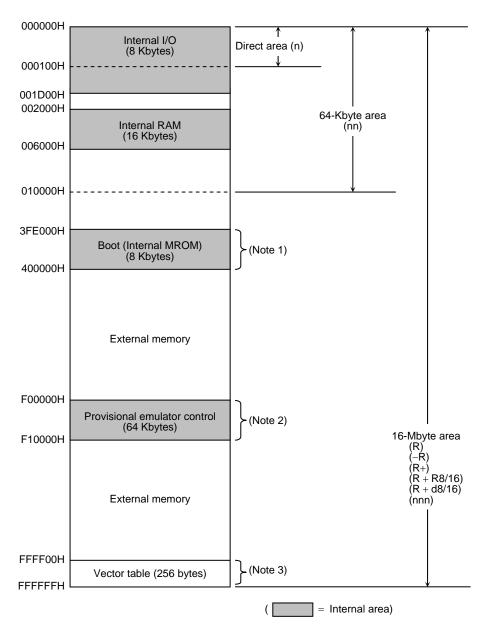

Set AM1 and AM0 pins as shown in Table 3.1.2 according to system usage.

Operation Mode	Mode Setup Input Pin			
Operation mode	RESET	AM1	AM0	
16-bit external bus starting (MULTI 16 mode)		0	1	
32-bit external bus starting (MULTI 32 mode)		1	0	
Boot (32-bit internal MROM) starting (BOOT mode)		1	1	

Table 3.1.2 Operation Mode Setup Table

## 3.2 Memory Map

Figure 3.2.1 is a memory map of the TMP92CH21.

- Note 1: Boot program (Internal MROM) is mapped only for BOOT mode. For other starting modes, its area (3FE000H to 3FFFFH) is mapped to external-memory.
- Note 2: The Provisional emulator control area, mapped F00000H to F0FFFH after reset, is for emulator use and so is not available. When emulator  $\overline{WR}$  signal and  $\overline{RD}$  signal are asserted, this area is accessed. Ensure external memory is used.
- Note 3: Do not use the last 16-byte area (FFFF0H to FFFFFFH). This area is reserved for an emulator.

## 3.3 Clock Function and Stand-by Function

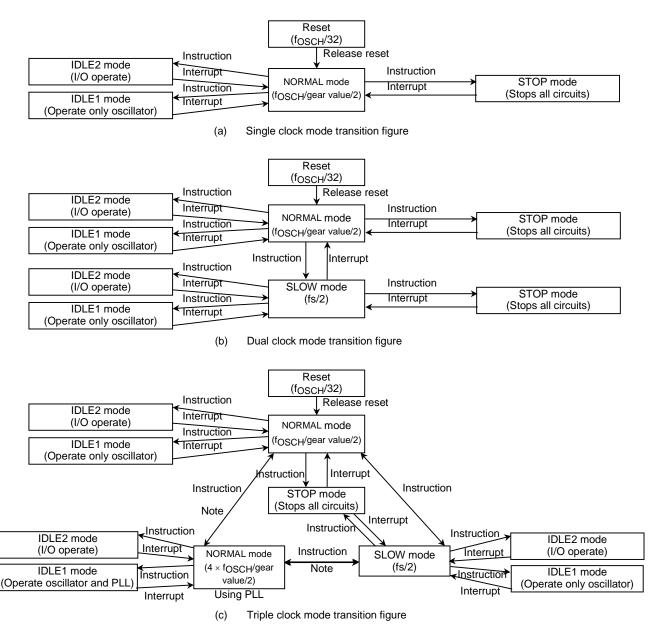

The TMP92CH21 contains (1) clock gear, (2) clock doubler (PLL), (3) stand-by controller and (4) noise reduction circuits. They are used for low power, low noise systems.

This chapter is organized as follows:

- 3.3.1 Block diagram of system clock
- 3.3.2 SFR
- 3.3.3 System clock controller
- 3.3.4 Clock doubler (PLL)
- 3.3.5 Noise reduction circuits
- 3.3.6 Stand-by controller

The clock operating modes are as follows: (a) single clock mode (X1, X2 pins only), (b) dual clock mode (X1, X2, XT1 and XT2 pins) and (c) triple clock mode (X1, X2, XT1 and XT2 pins and PLL).

Figure 3.3.1 shows a transition figure.

- Note 1: It is not possible to control PLL in SLOW mode when shifting from SLOW mode to NORMAL mode with use of PLL. (PLL start up/stop/change write to PLLCR0<PLLON>, PLLCR1<FCSEL> register)
- Note 2: When shifting from NORMAL mode with use of PLL to NORMAL mode, execute the following setting in the same order. 1) Change CPU clock (PLLCR0<FCSEL> ← "0")
  - 2) Stop PLL circuit (PLLCR1<PLLON>  $\leftarrow$  "0")
- Note 3: It is not possible to shift from NORMAL mode with use of PLL to STOP mode directly.
  - NORMAL mode should be set once before shifting to STOP mode. (Sstop the high-frequency oscillator after stopping PLL.)

#### Figure 3.3.1 System Clock Block Diagram

The clock frequency input from the X1 and X2 pins is called fc and the clock frequency input from the XT1 and XT2 pins is called fs. The clock frequency selected by SYSCR1<SYSCK> is called the clock  $f_{FPH}$ . The system clock  $f_{SYS}$  is defined as the divided clock of  $f_{FPH}$ , and one cycle of  $f_{SYS}$  is defined as one state.

## 3.3.1 Block Diagram of System Clock

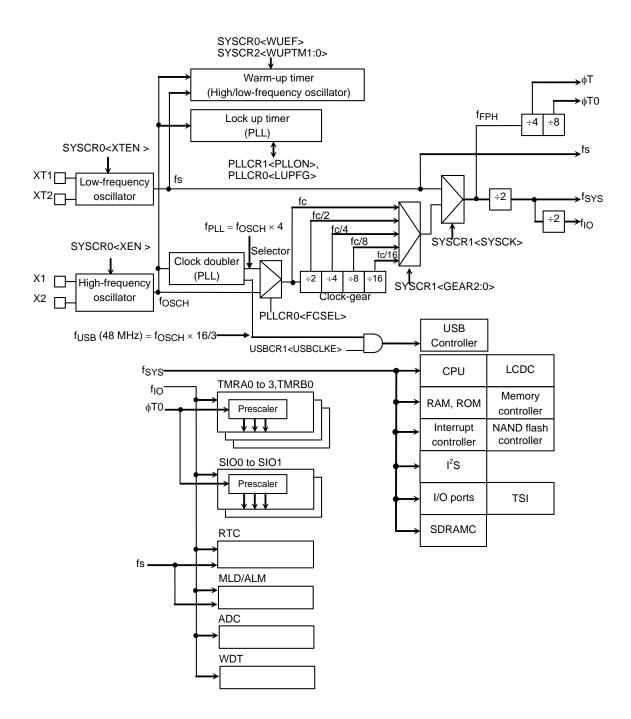

Figure 3.3.2 Block Diagram of System Clock

	Function	Output/input buffer drive-register for stand-by mode									

(Purpose and use)

This register is used to set each pin status at stand-by mode.

All ports have registers of the format shown above. ("x" indicates the port name.)

For each register, refer to "3.5 Function of ports".

Before "Halt" instruction is executed, set each register according to the expected pin-status. They will be effective after the CPU has executed the "Halt" instruction.

This is the case regardless of stand-by mode (IDLE2, IDLE1 or STOP).

The output/input buffer control table is shown below.

OE	PxnD	Output Buffer	Input Buffer
0	0	OFF	OFF
0	1	OFF	ON
1	0	OFF	OFF
1	1	ON	OFF

Note 1: OE denotes an output enable signal before stand-by mode.

Basically, PxCR is used as OE.

Note 2: "n" in PxnD denotes the bit number of PORTx.

Figure 3.3.6 SFR for Drive Register

## 3.3.3 System Clock Controller

The system clock controller generates the system clock signal (f<sub>SYS</sub>) for the CPU core and internal I/O. It contains two oscillation circuits and a clock gear circuit for high-frequency (fc) operation. The register SYSCR1<SYSCK> changes the system clock to either fc or fs, SYSCR0<XEN> and SYSCR0<XTEN> control enabling and disabling of each oscillator, and SYSCR1<GEAR2:0> sets the high-frequency clock gear to either 1, 2, 4, 8 or 16 (fc, fc/2, fc/4, fc/8 or fc/16). These functions can reduce the power consumption of the equipment in which the device is installed.

The combination of settings  $\langle XEN \rangle = 1$ ,  $\langle SYSCK \rangle = 0$  and  $\langle GEAR2:0 \rangle = 100$  will cause the system clock (f<sub>SYS</sub>) to be set to fc/32 (fc/16 × 1/2) after reset.

For example, f<sub>SYS</sub> is set to 1.25 MHz when the 40 MHz oscillator is connected to the X1 and X2 pins.

(1) Switching from normal mode to slow mode

When the resonator is connected to the X1 and X2 pins, or to the XT1 and XT2 pins, the warm-up timer can be used to change the operation frequency after stable oscillation has been attained.

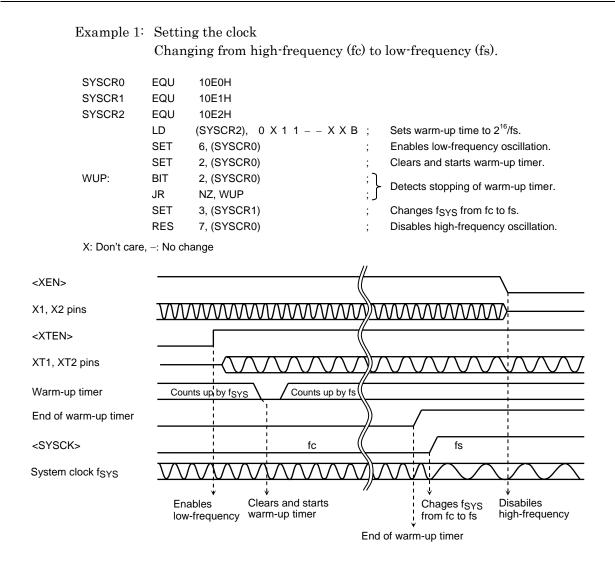

The warm-up time can be selected using SYSCR2<WUPTM1:0>.

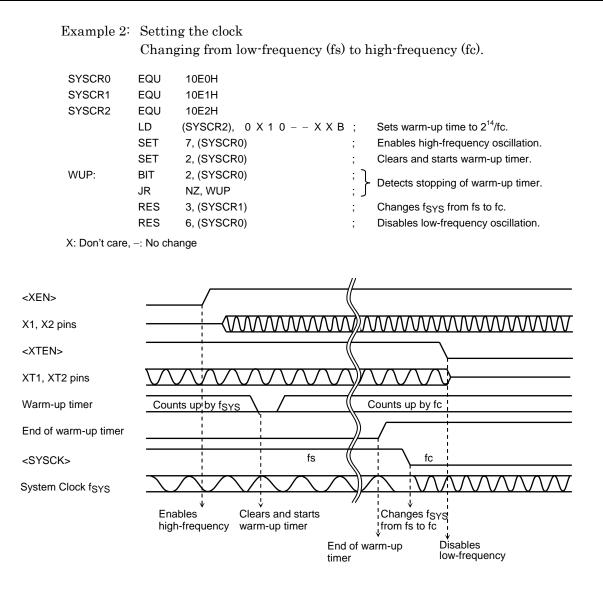

This warm-up timer can be programmed to start and stop as shown in the following examples 1 and 2.

Table 3.3.2 shows the warm-up time.

- Note 1: When using an oscillator (other than a resonator) with stable oscillation, a warm-up timer is not needed.
- Note 2: The warm-up timer is operated by an oscillation clock. Hence, there may be some variation in warm-up time.

	at	t f <sub>OSCH</sub> = 40 MHz, fs = 32.768 kHz
Warm-up Time SYSCR2 <wuptm1:0></wuptm1:0>	Change to Normal Mode	Change to Slow Mode
01 (2 <sup>8</sup> /frequency)	6.4 (μs)	7.8 (ms)
10 (2 <sup>14</sup> /frequency)	409.6 (μs)	500 (ms)
11 (2 <sup>16</sup> /frequency)	1.638 (ms)	2000 (ms)

(2) Clock gear controller

 $f_{FPH}$  is set according to the contents of the clock gear select register SYSCR1<GEAR2:0> to either fc, fc/2, fc/4, fc/8 or fc/16. Using the clock gear to select a lower value of  $f_{FPH}$  reduces power consumption.

Example 3: Changing to a high-frequency gear

SYSCR1 EQU 10E1H

LD (SYSCR1), XXXX0000B ; Changes f<sub>SYS</sub> to fc/2. LD (DUMMY), 00H ; Dummy instruction X: Don't care

(High-speed clock gear changing)

To change the clock gear, write the register value to the SYSCR1<GEAR2:0> register. It is necessary for the warm-up time to elapse before the change occurs after writing the register value.

There is the possibility that the instruction following the clock gear changing instruction is executed by the clock gear before changing. To execute the instruction following the clock gear switching instruction by the clock gear after changing, input the dummy instruction as follows (instruction to execute the write cycle).

Example:

 SYSCR1
 EQU
 10E1H

 LD
 (SYSCR1), XXXX0001B
 ;
 Changes f<sub>SYS</sub> to fc/4.

 LD
 (DUMMY), 00H
 ;
 Dummy instruction

 Instruction to be executed after clock gear has changed

#### 3.3.4 Clock Doubler (PLL)

PLL outputs the fPLL clock signal, which is four times as fast as fOSCH. A low-speed-frequency oscillator can be used, even though the internal clock is high-frequency.

A reset initializes PLL to stop status, so setting to PLLCR0, PLLCR1 register is needed before use.

As with an oscillator, this circuit requires time to stabilize. This is called the lock up time and it is measured by a 16-stage binary counter. Lock up time is about 1.6 ms at  $f_{OSCH} = 10$  MHz.

Note 1: Input frequency range for PLL

The input frequency range (High-frequency oscillation) for PLL is as follows:  $f_{OSCH} = 6$  to 10 MHz (V<sub>CC</sub> = 3.0 to 3.6 V)

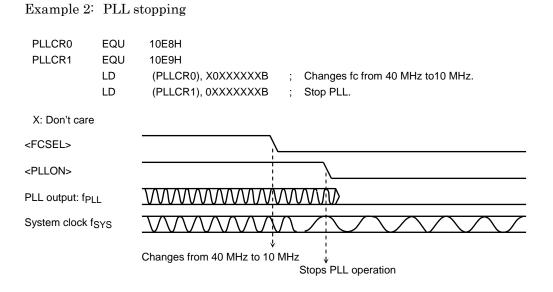

Note 2: PLLCR0<LUPFG>

The logic of PLLCR0<LUPFG> is different from 900/L1's DFM. Exercise care in determining the end of lock up time. The following is an example of settings for PLL starting and PLL stopping.

Example 1: PLL starting

PLLCR0 PLLCR1	EQU EQU LD	10E8H 10E9H (PLLCR1), 1 X X X X X X X B ; Enables PLL operation and starts lock up.
LUP:	BIT JR LD	5, (PLLCR0) ; Z, LUP ; (PLLCR0), X 1 X X X X X B ; Changes fc from 10 MHz to 40 MHz.
X: Don't care		

		11
<pllon></pllon>	!	
<fcsel></fcsel>		
PLL output: f <sub>PLL</sub>		
Lock up timer	Counts up by fOSCH	
<lupfg></lupfg>	During lock up	After lock up
System clock f <sub>SYS</sub>		
	Starts PLL operation and starts lock up	Changes from 10 MHz to 40 MHz Lock up ends

Limitations on the use of PLL

- It is not possible to execute PLL enable/disable control in the SLOW mode (fs) (writing to PLLCR0 and PLLCR1). PLL should be controlled in the NORMAL mode.
- 2. When stopping PLL operation during PLL use, execute the following settings in the same order.

LD	(PLLCR0), 00H	;	Change the clock fPLL to fOSCH
LD	(PLLCR1), 00H	;	PLL stop

3. When stopping the high-frequency oscillator during PLL use, stop PLL before stopping the high-frequency oscillator.

Examples of settings are shown below:

- (1) Start up/change control
  - (OK) Low-frequency oscillator operation mode (fs) (high-frequency oscillator STOP)  $\rightarrow$  High-frequency oscillator start up  $\rightarrow$  High-frequency oscillator operation mode (fosch)  $\rightarrow$  PLL start up  $\rightarrow$  PLL use mode (fpLL)

### 3.3.5 Noise Reduction Circuits

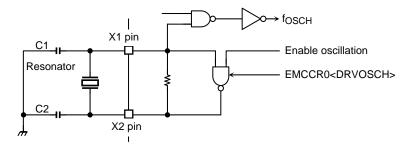

Noise reduction circuits are built-in, allowing implementation of the following features.

- (1) Reduced drivability for high-frequency oscillator
- (2) Reduced drivability for low-frequency oscillator
- (3) Single drive for high-frequency oscillator
- (4) SFR protection of register contents
- (1) Reduced drivability for high-frequency oscillator

### (Purpose)

Reduces noise and power for oscillator when a resonator is used.

(Block diagram)

(Setting method)

The drive ability of the oscillator is reduced by writing "0" to EMCCR0<DRVOSCH> register. At reset, <DRVOSCH> is initialized to "1" and the oscillator starts oscillation by normal drivability when the power-supply is on.

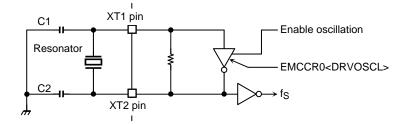

Note: This function (EMCCR0<DRVOSCH> = "0") is available when  $f_{OSCH} = 6$  to 10 MHz.

(2) Reduced drivability for low-frequency oscillator

#### (Purpose)

Reduces noise and power for oscillator when a resonator is used.

#### (Block diagram)

(Setting method)

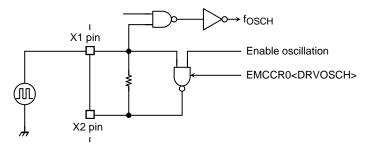

The drive ability of the oscillator is reduced by writing 0 to the EMCCR0<DRVOSCL> register. At reset, <DRVOSCL> is initialized to "1".

(3) Single drive for high-frequency oscillator

### (Purpose)

Remove the need for twin drives and prevent operational errors caused by noise input to X2 pin when an external oscillator is used.

(Block diagram)

(Setting method)

The oscillator is disabled and starts operation as buffer by writing "1" to EMCCR0<EXTIN> register. X2 pin's output is always "1".

At reset, <EXTIN> is initialized to "0".

(4) Runaway prevention using SFR protection register

#### (Purpose)

Prevention of program runaway caused by introduction of noise.

Write operations to a specified SFR are prohibited so that the program is protected from runaway caused by stopping of the clock or by changes to the memory control register (memory controller, MMU) which prevent fetch operations.

Runaway error handling is also facilitated by INTP0 interruption.

Specified SFR list

1. Memory controller

B0CSL/H, B1CSL/H, B2CSL/H, B3CSL/H, BECSL/H MSAR0, MSAR1, MSAR2, MSAR3, MAMR0, MAMR1, MAMR2, MAMR3, PMEMCR, BROMCR

- 2. MMU LOCALPX/PY/PZ, LOCALLX/LY/LZ, LOCALRX/RY/RZ, LOCALWX/WY/WZ,
- 3. Clock gear SYSCR0, SYSCR1, SYSCR2, EMCCR0
- 4. PLL

PLLCR0, PLLCR1

#### (Operation explanation)

Execute and release of protection (write operation to specified SFR) becomes possible by setting up a double key to EMCCR1 and EMCCR2 registers.

#### (Double key)

1st KEY: writes in sequence, 5AH at EMCCR1 and A5H at EMCCR2 2nd KEY: writes in sequence, A5H at EMCCR1 and 5AH at EMCCR2

Protection state can be confirmed by reading EMCCR0<PROTECT>.

At reset, protection becomes OFF.

INTPO interruption also occurs when a write operation to the specified SFR is executed with protection in the ON state.

### 3.3.6 Stand-by Controller

(1) HALT modes and port drive register

When the HALT instruction is executed, the operating mode switches to IDLE2, IDLE1 or STOP mode, depending on the contents of the SYSCR2<HALTM1:0> register and each pin-status is set according to the PxDR register, as shown below:

PxDR (xxxxH)

	7	6	5	4	3	2	1	0
Bit symbol	Px7D	Px6D	Px5D	Px4D	Px3D	Px2D	Px1D	Px0D
Read/Write		R/W						
Reset state	1	1 1 1 1 1 1 1 1						
Function		Output/input buffer drive register for stand-by mode						

(Purpose and use)

- This register is used to set each pin status at stand-by mode.
- All ports have this registers of the format shown above. ("x" indicates the port name.)
- For each register, refer to 3.5 function of ports.
- Before "Halt" instruction is executed, set each register according to the expected pin status. They will be effective after the CPU has executed the "Halt" instruction.
- This is the case regardless of stand-by mode (IDLE2, IDLE1 or STOP).
- The Output/Input buffer control table is shown below.

OE	PxnD	Output Buffer	Input Buffer
0	0	OFF	OFF
0	1	OFF	ON
1	0	OFF	OFF
1	1	ON	OFF

Note 1: OE denotes an output enable signal before stand-by mode.

Basically, PxCR is used as OE.

Note 2: "n" in PxnD denotes the bit number of PORTx

The subsequent actions performed in each mode are as follows:

1. IDLE2: only the CPU halts.

The internal I/O is available to select operation during IDLE2 mode by setting the following register.

Table 3.3.3 shows the register setting operation during IDLE2 mode.

Internal I/O	SFR
TMRA01	TA01RUN <i2ta01></i2ta01>
TMRA23	TA23RUN <i2ta23></i2ta23>

	Interrupt controller, USBC,	Operate			
	RTC, MLD		Operate		

Table 3.3.4 I/O Operation during HALT Modes

#### (2) How to release the HALT mode

These halt states can be released by resetting or requesting an interrupt. The halt release sources are determined by the combination of the states of the interrupt mask register  $\langle IFF2:0 \rangle$  and the HALT modes. The details for releasing the halt status are shown in Table 3.3.5.

#### Release by interrupt requesting

The HALT mode release method depends on the status of the enabled interrupt .When the interrupt request level set before executing the HALT instruction exceeds the value of the interrupt mask register, the interrupt is processed depending on its status after the HALT mode is released, and the CPU status executing the instruction that follows the HALT instruction. When the interrupt request level set before executing the HALT instruction is less than the value of the interrupt mask register, HALT mode release is not executed. (in non-maskable interrupts, interrupt processing is processed after releasing the HALT mode regardless of the value of the mask register.) However only for INT0 to INT4, INTKEY, INTRTC, INTALM and INTUSB interrupts, even if the interrupt request level set before executing the halt instruction is less than the value of the interrupt mask register, HALT mode release is executed. In this case, the interrupt is processed, and the CPU starts executing the instruction following the HALT instruction, but the interrupt request flag is held at "1".

Release by resetting

Release of all halt statuses is executed by resetting.

When the STOP mode is released by RESET, it is necessary to allow enough resetting time (see Table 3.3.6) for operation of the oscillator to stabilize.

When releasing the HALT mode by resetting, the internal RAM data keeps the state before the HALT instruction is executed. However the other settings contents are initialized. (Releasing due to interrupts keeps the state before the HALT instruction is executed.)

Status of Received Interrupt		Interrupt Enabled			Interrupt Disabled

RESET			Initialize LSI					

- •: After clearing the HALT mode, CPU starts interrupt processing.
- o: After clearing the HALT mode, CPU resumes executing starting from the instruction following the HALT instruction.
- $\times:$  Cannot be used to release the HALT mode.
- -: The priority level (interrupt request level) of non-maskable interrupts is fixed to 7, the highest priority level. This combination is not available.
- \*1: Release of the HALT mode is executed after warm-up time has elapsed.
- \*2: 6 interrupts of all 24 INTUSB sources can release Halt state from IDLE1 mode, allowing for the construction of low power dissipation systems. However, the method of use is limited as below. Shift to IDLE1 mode :

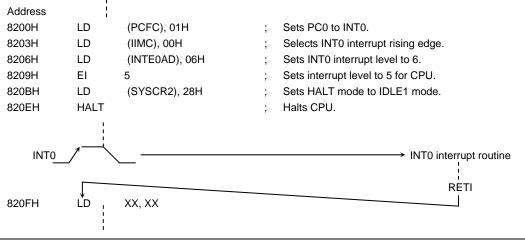

```
Execute Halt instruction when the flag of INT_SUS or INT_CLKSTOP is "1" (SUSPEND state)
```

Release from IDLE1 mode :

Release Halt state by INT\_RESUME or INT\_CLKON request (release SUSPEND request) Release Halt state by INT\_URST\_STR or INT\_URST\_END request (RESET request)

Example: Releasing IDLE1 mode

An INTO interrupt clears the halt state when the device is in IDLE1 mode.

#### (3) Operation

1. IDLE2 mode

In IDLE2 mode only specific internal I/O operations, as designated by the IDLE2 setting register, can take place. Instruction execution by the CPU stops.

Figure 3.3.7 illustrates an example of the timing for clearance of the IDLE2 mode halt state by an interrupt.

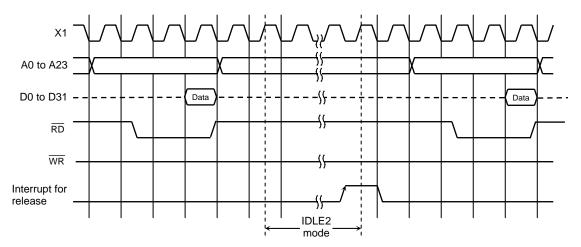

Figure 3.3.7 Timing Chart for IDLE2 Mode Halt State Cleared by Interrupt

2. IDLE1 mode

In IDLE1 mode, only the internal oscillator and the RTC and MLD continue to operate. The system clock stops.

In the halt state, the interrupt request is sampled asynchronously with the system clock; however, clearance of the halt state (e.g., restart of operation) is synchronous with it.

Figure 3.3.8 illustrates the timing for clearance of the IDLE1 mode halt state by an interrupt.

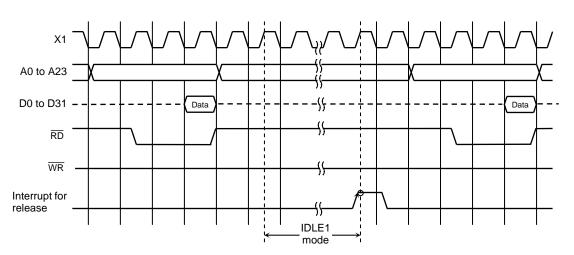

Figure 3.3.8 Timing Chart for IDLE1 Mode Halt State Cleared by Interrupt

3. STOP mode

When STOP mode is selected, all internal circuits stop, including the internal oscillator.

After STOP mode has been cleared system clock output starts when the warm-up time has elapsed, in order to allow oscillation to stabilize.

Figure 3.3.9 illustrates the timing for clearance of the STOP mode halt state by an interrupt.

## 3.4 Interrupts

Interrupts are controlled by the CPU Interrupt mask register  $\langle IFF2:0 \rangle$  (bits12 to 14 of the status register) and by the built-in interrupt controller.

The TMP92CH21 has a total of 50 interrupts divided into the following five types:

Interrupts generated by CPU: 9 sources Software interrupts: 8 sources Illegal instruction interrupt: 1 source Internal interrupts: 34 sources Internal I/O interrupts: 26 sources Micro DMA transfer end interrupts: 8 sources External interrupts: 7 sources Interrupts on external pins (INT0 to INT5, INTKEY)

A fixed individual interrupt vector number is assigned to each interrupt source.

Any one of six levels of priority can also be assigned to each maskable interrupt. Non-maskable interrupts have a fixed priority level of 7, the highest level.

When an interrupt is generated, the interrupt controller sends the priority of that interrupt to the CPU. When more than one interrupt is generated simultaneously, the interrupt controller sends the priority value of the interrupt with the highest priority to the CPU. (The highest priority level is 7, the level used for non-maskable interrupts.)

The CPU compares the interrupt priority level which it receives with the value held in the CPU interrupt mask register <IFF2:0>. If the priority level of the interrupt is greater than or equal to the value in the interrupt mask register, the CPU accepts the interrupt.

However, software interrupts and illegal instruction interrupts generated by the CPU are processed irrespective of the value in <IFF2:0>.

The value in the interrupt mask register <IFF2:0> can be changed using the EI instruction (EI num sets <IFF2:0> to num). For example, the command EI 3 enables the acceptance of all non-maskable interrupts and of maskable interrupts whose priority level, as set in the interrupt controller, is 3 or higher. The commands EI and EI 0 enable the acceptance of all non-maskable interrupts and of maskable interrupts with a priority level of 1 or above (hence both are equivalent to the command EI 1).

The DI instruction (sets <IFF2:0> to 7) is exactly equivalent to the EI 7 instruction. The DI instruction is used to disable all maskable interrupts (since the priority level for maskable interrupts ranges from 1 to 6). The EI instruction takes effect as soon as it is executed.

In addition to the general purpose interrupt processing mode described above, there is also a micro DMA processing mode.

In micro DMA mode the CPU automatically transfers data in one-byte, two-byte or four-byte blocks; this mode allows high-speed data transfer to and from internal and external memory and internal I/O ports.

In addition, the TMP92CH21 also has a software start function in which micro DMA processing is requested in software rather than by an interrupt.

Figure 3.4.1 is a flowchart showing overall interrupt processing.

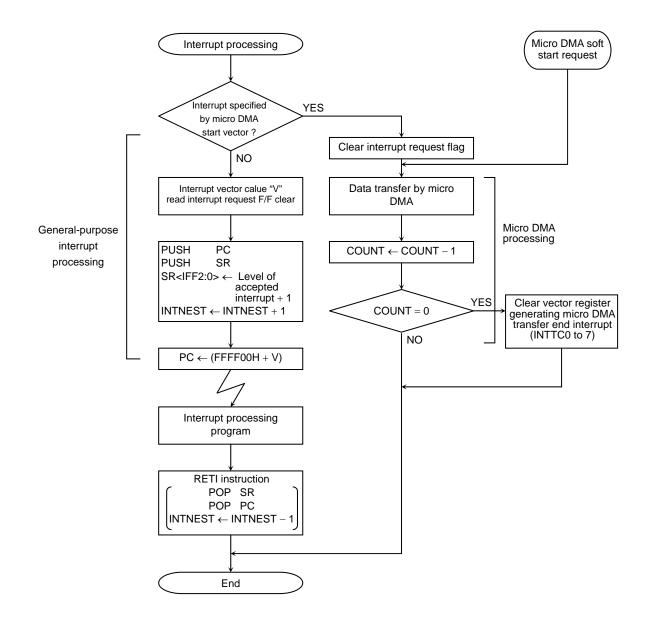

Figure 3.4.1 Interrupt and Micro DMA Processing Sequence

### 3.4.1 General-purpose Interrupt Processing

When the CPU accepts an interrupt, it usually performs the following sequence of operations. However, in the case of software interrupts and illegal instruction interrupts generated by the CPU, the CPU skips steps (1) and (3), and executes only steps (2), (4) and (5).

(1) The CPU reads the interrupt vector from the interrupt controller.

When more than one interrupt with the same priority level has been generated simultaneously, the interrupt controller generates an interrupt vector in accordance with the default priority and clears the interrupt requests.

(The default priority is determined as follows: the smaller the vector value, the higher the priority.)

- (2) The CPU pushes the program counter (PC) and status register (SR) onto the top of the stack (pointed to by XSP).
- (3) The CPU sets the value of the CPU's interrupt mask register <IFF2:0> to the priority level for the accepted interrupt plus 1. However, if the priority level for the accepted interrupt is 7, the register's value is set to 7.
- (4) The CPU increments the interrupt nesting counter INTNEST by 1.
- (5) The CPU jumps to the address given by adding the contents of address FFFF00H + the interrupt vector, then starts the interrupt processing routine.

On completion of interrupt processing, the RETI instruction is used to return control to the main routine. RETI restores the contents of the program counter and the status register from the stack and decrements the interrupt nesting counter INTNEST by 1.

Non-maskable interrupts cannot be disabled by a user program. Maskable interrupts, however, can be enabled or disabled by a user program. A program can set the priority level for each interrupt source. (A priority level setting of 0 or 7 will disable an interrupt request.)

If an interrupt request is received for an interrupt with a priority level equal to or greater than the value set in the CPU interrupt mask register <IFF2:0>, the CPU will accept the interrupt. The CPU interrupt mask register <IFF2:0> is then set to the value of the priority level for the accepted interrupt plus 1.

If during interrupt processing, an interrupt is generated with a higher priority than the interrupt currently being processed, or if, during the processing of a non-maskable interrupt processing, a non-maskable interrupt request is generated from another source, the CPU will suspend the routine which it is currently executing and accept the new interrupt. When processing of the new interrupt has been completed, the CPU will resume processing of the suspended interrupt.

If the CPU receives another interrupt request while performing processing steps (1) to (5), the new interrupt will be sampled immediately after execution of the first instruction of its interrupt processing routine. Specifying DI as the start instruction disables nesting of maskable interrupts.

A reset initializes the interrupt mask register <IFF2:0> to 111, disabling all maskable interrupts.

Table 3.4.1 shows the TMP92CH21 interrupt vectors and micro DMA start vectors. FFFF00H to FFFFFFH (256 bytes) is designated as the interrupt vector area.

Note 1: Micro DMA default priority.

Micro DMA initiation takes priority over other maskable interrupts.

Note 2: When initiating micro DMA, set at edge detect mode.

#### 3.4.2 Micro DMA Processing

In addition to general purpose interrupt processing, the TMP92CH21 also includes a micro DMA function. Micro DMA processing for interrupt requests set by micro DMA is performed at the highest priority level for maskable interrupts (level 6), regardless of the priority level of the interrupt source.

Because the micro DMA function is implemented through the CPU, when the CPU is placed in a stand-by state by a Halt instruction, the requirements of the micro DMA will be ignored (pending).

Micro DMA supports 8 channels and can be transferred continuously by specifying the micro DMA burst function as below.

Note: When using the micro DMA transfer end interrupt, always write "1" to bit 7 of SIMC register.

(1) Micro DMA operation

When an interrupt request is generated by an interrupt source specified by the micro DMA start vector register, the micro DMA triggers a micro DMA request to the CPU at interrupt priority level 6 and starts processing the request. The eight micro DMA channels allow micro DMA processing to be set for up to eight types of interrupt at once.

When micro DMA is accepted, the interrupt request flip-flop assigned to that channel is cleared. Data in one-byte, two-byte or four-byte blocks, is automatically transferred at once from the transfer source address to the transfer destination address set in the control register, and the transfer counter is decremented by 1. If the value of the counter after it has been decremented is not 0, DMA processing ends with no change in the value of the micro DMA start vector register. If the value of the decremented counter is 0, a micro DMA transfer end interrupt (INTTCO to INTTC7) is sent from the CPU to the interrupt controller. In addition, the micro DMA start vector register is cleared to 0, the next micro DMA operation is disabled and micro DMA processing terminates.

If micro DMA requests are set simultaneously for more than one channel, priority is not based on the interrupt priority level but on the channel number: the lower the channel number, the higher the priority (channel 0 thus has the highest priority and channel 7 the lowest).

If an interrupt request is triggered for the interrupt source in use during the interval between the time at which the micro DMA start vector is cleared and the next setting, general purpose interrupt processing is performed at the interrupt level set. Therefore, if the interrupt is only being used to initiate micro DMA (and not as a general-purpose interrupt), the interrupt level should first be set to 0 (i.e., interrupt requests should be disabled).

If micro DMA and general purpose interrupts are being used together as described above, the level of the interrupt which is being used to initiate micro DMA processing should first be set to a lower value than all the other interrupt levels. (Note) In this case, edge triggered interrupts are the only kinds of general interrupts which can be accepted.

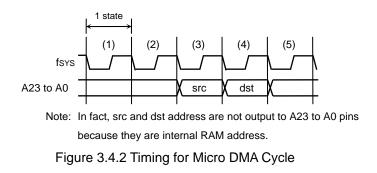

Note: If the priority level of micro DMA is set higher than that of other interrupts, CPU operates as follows. In case INTxxx interrupt is generated first and then INTyyy interrupt is generated between checking "Interrupt specified by micro DMA start vector" (in the Figure 3.4.1) and reading interrupt vector with setting below. The vector shifts to that of INTyyy at the time. This is because the priority level of INTyyy is higher than that of INTxxx. In the interrupt routine, CPU reads the vector of INTyyy because cheking of micro DMA has finished. And INTyyy is generated regardless of transfer counter of micro DMA. INTxxx: level 1 without micro DMA INTyyy: level 6 with micro DMA Although the control registers used for setting the transfer source and transfer destination addresses are 32 bits wide, this type of register can only output 24-bit addresses. Accordingly, micro DMA can only access 16 Mbytes (the upper eight bits of a 32-bit address are not valid).

Three micro DMA transfer modes are supported: one-byte transfers, two-byte (one-word) transfer and four-byte transfer. After a transfer in any mode, the transfer source and transfer destination addresses will either be incremented or decremented, or will remain unchanged. This simplifies the transfer of data from memory to memory, from I/O to memory, from memory to I/O, and from I/O to I/O. For details of the various transfer modes, see section 3.4.2 (1), detailed description of the transfer mode register.

Since a transfer counter is a 16-bit counter, up to 65536 micro DMA processing operations can be performed per interrupt source (provided that the transfer counter for the source is initially set to 0000H).

Micro DMA processing can be initiated by any one of 34 different interrupts – the 33 interrupts shown in the micro DMA start vectors in Table 3.4.1 and a micro DMA soft start.

Figure 3.4.2 shows a 2-byte transfer carried out using a micro DMA cycle in transfer destination address INC mode (micro DMA transfers are the same in every mode except counter mode). (The conditions for this cycle are as follows: Both source and destination memory are internal RAM and multiples by 4 numbered source and destination addresses.)

- State (1), (2): Instruction fetch cycle (Prefetches the next instruction code)
- State (3): Micro DMA read cycle
- State (4): Micro DMA write cycle
- State (5): (The same as in state (1), (2))

#### (2) Soft start function

The TMP92CH21 can initiate micro DMA either with an interrupt or by using the micro DMA soft start function, in which micro DMA is initiated by a write cycle which writes to the register DMAR.

Writing 1 to any bit of the register DMAR causes micro DMA to be performed once. (If write "0" to each bit, micro DMA doesn't operate). On completion of the transfer, the bits of DMAR which support the end channel are automatically cleared to 0.

Only one channel can be set once for DMA request. (Do not write "1" to plural bits.)

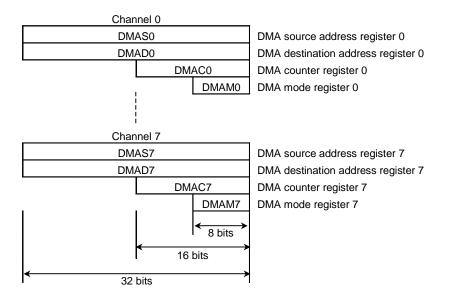

When writing again 1 to the DMAR register, check whether the bit is "0" before writing "1". If read "1", micro DMA transfer isn't started yet.

When a burst is specified by the DMAB register, data is transferred continuously from the initiation of micro DMA until the value in the micro DMA transfer counter is 0. If execatee soft start during micro DMA transfer by interrupt source, micro DMA transfer counter doesn't change. Don't use Read-modify-write instruction to avoid writign to other bits by mistake.

Symbol	Name	Address	7	6	5	4	3	2	1	0

				1: DMA request in software							

(3) Transfer control registers

The transfer source address and the transfer destination address are set in the following registers. An instruction of the form LDC cr, r can be used to set these registers.

(4) Detailed description of the transfer mode register

0 0 0	Mode DMAM0 to DMAM7	
DMAMn[4:0]	Mode Description	Execution State Number
0 0 0 z z	Destination INC mode $(DMADn+) \leftarrow (DMASn)$ $DMACn \leftarrow DMACn - 1$ If $DMACn = 0$ then INTTCn	5 states
0 0 1 z z	Destination DEC mode (DMADn–) ← (DMASn) DMACn ← DMACn – 1 If DMACn = 0 then INTTCn	5 states
0 1 0 z z	Source INC mode (DMADn) $\leftarrow$ (DMASn+) DMACn $\leftarrow$ DMACn - 1 If DMACn = 0 then INTTCn	5 states
0 1 1 z z	Source DEC mode $(DMADn) \leftarrow (DMASn-)$ $DMACn \leftarrow DMACn - 1$ If DMACn = 0 then INTTCn	5 states
1 0 0 z z	Source and destination INC mode $(DMADn+) \leftarrow (DMASn+)$ $DMACn \leftarrow DMACn - 1$ If $DMACn = 0$ then INTTCn	6 states
1 0 1 z z	Source and destination DEC mode (DMADn–) $\leftarrow$ (DMASn–) DMACn $\leftarrow$ DMACn – 1 If DMACn = 0 then INTTCn	6 states
1 1 0 z z	Source and destination Fixed mode (DMADn) $\leftarrow$ (DMASn) DMACn $\leftarrow$ DMACn - 1 If DMACn = 0 then INTTCn	5 states
11100	Counter mode $DMASn \leftarrow DMASn + 1$ $DMACn \leftarrow DMACn - 1$ If $DMACn = 0$ then INTTCn	5 states

- ZZ: 00 = 1-byte transfer
  - 01 = 2-byte transfer

10 = 4-byte transfer

11 = (Reserved)

Note1: N stands for the micro DMA channel number (0 to 7)

DMADn+/DMASn+: Post-increment (register value is incremented after transfer)

DMADn-/DMASn-: Post-decrement (register value is decremented after transfer)

"I/O" signifies fixed memory addresses; "memory" signifies incremented or decremented memory addresses.

Note2: The transfer mode register should not be set to any value other than those listed above.

Note3: The execution state number shows number of best case (1-state memory access).

#### 3.4.3 Interrupt Controller Operation

The block diagram in Figure 3.4.3 shows the interrupt circuits. The left hand side of the diagram shows the interrupt controller circuit. The right hand side shows the CPU interrupt request signal circuit and the halt release circuit.

For each of the 52 interrupts channels there is an interrupt request flag (consisting of a flip-flop), an interrupt priority setting register and a micro DMA start vector register. The interrupt request flag latches interrupt requests from the peripherals. The flag is cleared to zero in the following cases: when a reset occurs, when the CPU reads the channel vector of an interrupt it has received, when the CPU receives a micro DMA request (when micro DMA is set), when a micro DMA burst transfer is terminated, and when an instruction that clears the interrupt for that channel is executed (by writing a micro DMA start vector to the INTCLR register).

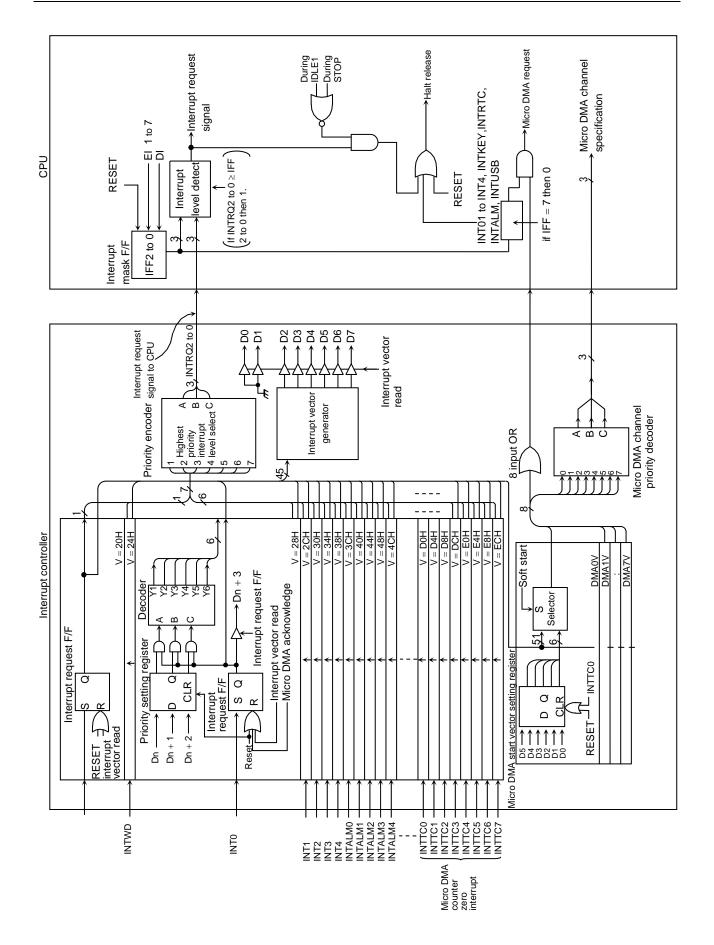

An interrupt priority can be set independently for each interrupt source by writing the priority to the interrupt priority setting register (e.g., INTE0AD or INTE12). 6 interrupt priorities levels (1 to 6) are provided. Setting an interrupt source's priority level to 0 (or 7) disables interrupt requests from that source. The priority of non-maskable interrupt (watchdog timer interrupts) is fixed at 7. If more than one interrupt request with a given priority level are generated simultaneously, the default priority (the interrupt with the lowest priority or, in other words, the interrupt with the lowest vector value) is used to determine which interrupt request is accepted first.

The 3rd and 7th bit of the interrupt priority setting register indicate the state of the interrupt request flag and thus whether an interrupt request for a given channel has occurred.

If several interrupts are generated simultaneously, the interrupt controller sends the interrupt request for the interrupt with the highest priority and the interrupt's vector address to the CPU. The CPU compares the mask value set in  $\langle IFF2:0 \rangle$  of the status register (SR) with the priority level of the requested interrupt; if the latter is higher, the interrupt is accepted. Then the CPU sets SR $\langle IFF2:0 \rangle$  to the priority level of the accepted interrupt + 1. Hence, during processing of the accepted interrupt, new interrupt requests with a priority value equal to or higher than the value set in SR $\langle IFF2:0 \rangle$  (e.g., interrupts with a priority higher than the interrupt being processed) will be accepted.

When interrupt processing has been completed (e.g., after execution of a RETI instruction), the CPU restores to SR<IFF2:0> the priority value which was saved on the stack before the interrupt was generated.

The interrupt controller also includes eight registers which are used to store the micro DMA start vector. Writing the start vector of the interrupt source for the micro DMA processing (see Table 3.4.1), enables the corresponding interrupts to be processed by micro DMA processing. The values must be set in the micro DMA parameter registers (e.g., DMAS and DMAD) prior to micro DMA processing.

#### INTRX1 level enable

0	Edge detect INTRX1
1	"H" level INTRX1

## INTRX0 rising edge enable

0	Edge detect INTRX0
1	"H" level INTRX0

(4) Interrupt request flag clear register

The interrupt request flag is cleared by writing the appropriate micro DMA start vector, as given in Table 3.4.1, to the register INTCLR.

For example, to clear the interrupt flag INTO, perform the following register operation after execution of the DI instruction.

Symbol	Name	Address	7	6	5	4	3	2	1	0
	_	F8H (Prohibit RMW)	CLRV7	CLRV6	CLRV5	CLRV4	CLRV3	CLRV2	CLRV1	CLRV0
INTCLR	Interrupt clear control		W							
INTOLK			0	0	0	0	0	0	0	0
			Interrupt vector							

INTCLR  $\leftarrow$  0AH Clears interrupt request flag INT0.

#### (5) Micro DMA start vector registers

These registers assign micro DMA processing to sets which source corresponds to DMA. The interrupt source whose micro DMA start vector value matches the vector set in one of these registers is designated as the micro DMA start source.

When the micro DMA transfer counter value reaches zero, the micro DMA transfer end interrupt corresponding to the channel is sent to the interrupt controller, the micro DMA start vector register is cleared, and the micro DMA start source for the channel is cleared. Therefore, in order for micro DMA processing to continue, the micro DMA start vector register must be set again during processing of the micro DMA transfer end interrupt.

If the same vector is set in the micro DMA start vector registers of more than one channel, the lowest numbered channel takes priority.

Accordingly, if the same vector is set in the micro DMA start vector registers for two different channels, the interrupt generated on the lower numbered channel is executed until micro DMA transfer is complete. If the micro DMA start vector for this channel has not been set in the channel's micro DMA start vector register again, micro DMA transfer for the higher-numbered channel will be commenced. (This process is known as micro DMA chaining.)

(6) Specification of a micro DMA burst

Specifying the micro DMA burst function causes micro DMA transfer, once started, to continue until the value in the transfer counter register reaches zero. Setting any of the bits in the register DMAB which correspond to a micro DMA channel (as shown below) to 1 specifies that any micro DMA transfer on that channel will be a burst transfer.

Symbol	Name	Address	7	6	5	4	3	2	1	0
		108H	DBST7	DBST6	DBST5	DBST4	DBST3	DBST2	DBST1	DBST0
DMAB	DMA burst		R/W							
DIVIAD			0	0	0	0	0	0	0	0
			1: DMA burst request							

#### (7) Notes

The instruction execution unit and the bus interface unit in this CPU operate independently. Therefore, immediately before an interrupt is generated, if the CPU fetches an instruction which clears the corresponding interrupt request flag, the CPU may execute this instruction in between accepting the interrupt and reading the interrupt vector. In this case, the CPU will read the default vector 0004H and jump to interrupt vector address FFFF04H.

To avoid this, an instruction which clears an interrupt request flag should always be placed after a DI instruction. And in the case of setting an interrupt enable again by EI instruction after the execution of clearing instruction, execute EI instruction after clearing and more than 3-instructions (e.g., "NOP" × 3 times).

If it placed EI instruction without waiting NOP instruction after execution of clearing instruction, interrupt will be enabled before request flag is cleared.

In the case of changing the value of the interrupt mask register <IFF2:0> by execution of POP SR instruction, disable an interrupt by DI instruction before execution of POP SR instruction.

In addition, please note that the following two circuits are exceptional and demand special attention.

INT0 level mode	In level mode INT0 is not an edge triggered interrupt. Hence, in level mode the interrupt request flip-flop for INT0 does not function. The peripheral interrupt request passes through the S input of the flip-flop and becomes the Q output. If the interrupt input mode is changed from edge mode to level mode, the interrupt request flag is cleared automatically.
	If the CPU enters the interrupt response sequence as a result of INT0 going from 0 to 1, INT0 must then be held at 1 until the interrupt response sequence has been completed. If INT0 is set to level mode so as to release a halt state, INT0 must be held at 1 from the time INT0 changes from 0 to 1 until the halt state is released. (Hence, it is necessary to ensure that input noise is not interpreted as a 0, causing INT0 to revert to 0 before the halt state has been released.) When the mode changes from level mode to edge mode, interrupt request flags which were set in level mode will not be cleared. Interrupt request flags must be cleared using the following sequence. DI LD (IIMC), 00H ; Switches from level to edge. LD (INTCLR), 0AH ; Clears interrupt request flag. NOP ; Wait EI execution NOP EI
INTRX	In level mode (the register SIMC <irxle> set to "0"), the interrupt request flip-flop can only be cleared by a reset or by reading the serial channel receive buffer. It cannot be cleared by writing INTCLR register.</irxle>

Note: The following instructions or pin input state changes are equivalent to instructions which clear the interrupt request flag.

INT0: Instructions which switch to level mode after an interrupt request has been generated in edge mode.
 The pin input changes from high to low after an interrupt request has been generated in level mode. ("H" → "L")

INTRX: Instructions which read the receive buffer.

INTRX: Instructions which read the receive buffer.

## 3.5 Function of Ports

The TMP92CH21 I/O port pins are shown in Table 3.5.1 and Table 3.5.2. In addition to functioning as general-purpose I/O ports, these pins are also used by the internal CPU and I/O functions. Table 3.5.3 to Table 3.5.5 list the I/O registers and their specifications.

	(R: PD =	with program	mable pull-	down re	sistor, U = with pu	III-up resistor)
Port Name	Pin Name	Number of Pins	I/O	R	I/O Setting	Pin Name for Built-in Function

## 3.5.1 Port 1 (P10 to P17)

Port 1 is an 8-bit general-purpose I/O port. Bits can be individually set as either inputs or outputs by control register P1CR and function register P1FC.

In addition to functioning as a general-purpose I/O port, port1 can also function as a data bus (D8 to D15).

# 3.5.6 Port 6 (P60 to P67)

Port 6 is an 8-bit general-purpose I/O port. Bits can be individually set as either inputs or outputs by control register P6CR and function register P6FC.

In addition to functioning as a general-purpose I/O port, port 6 can also function as an address bus (A16 to A23).

## 3.5.7 Port 7 (P70 to P76)

Port 7 is a 7-bit general-purpose I/O port (P70, P73 and P74 are used for output only).

Bits can be individually set as either inputs or outputs by control register P7CR and function register P7FC.

In addition to functioning as a general-purpose I/O port, P70 to P76 pins can also function as interface pins for external memory.

A reset initializes P70, P73 and P74 pins to output port mode, and P71, P72, P75 and P76 pin to input port mode.

Port 7 register

Note 1: Read-modify-write is prohibited for P7CR and P7FC.

1

Note 2: It is set to "Port" or "  $\overline{\texttt{RD}}$  " by AM pin setting.

Note 3: When NDRE and NDWE are used, set registers in the following order to avoid outputting a negative glitch.

Order	Register	Bit2	Bit1
(1)	P7	0	0
(2)	P7FC	1	1

(2) P7FC 1 (3) P7CR 1

Figure 3.5.15 Register for Port 7

### 3.5.8 Port 8 (P80 to P87)

Ports 80 to 87 are 8-bit output ports. Resetting sets the output latch of P82 to "0" and the output latches of P80 to P81, P83 to P87 to "1".

Port 8 can also be set to function as an interface pin for external memory using function register P8FC.

Writing "1" in the corresponding bit of P8FC and P8FC2 enables the respective functions. Resetting <P80F> to <P87F> of P8FC to "0" and P8FC2 to "0", sets all bits to output ports.

1	WRUU output	ND1CE output	1	WRUL output	ND0CE output	1	CSZA output	$\overline{\text{SDCS}}$ output

Note 1: Read-modify-write is prohibited for P8FC and P8FC2.

Note 2: It is set to "0" or "1" by AM pin setting.

Note 3: In MULTI16 or MULTI32 mode, do not write "1" to P8<P82> register before setting P82 pin to  $\overline{CS2}$  or  $\overline{CSZA}$  because, on reset, P82 pin outputs "0" as  $\overline{CE}$  for program memory.

Figure 3.5.17 Register for Port 8

#### 3.5.9 Port 9 (P90 to P97)

P90 to P94 are 5-bit general-purpose I/O ports. I/O can be set on a bit basis using the control register. Resetting sets P90 to P94 to input port and all bits of output latch to"1".

P95 is 1-bit general-purpose output port and P96 to P97 are 2-bit general-purpose input ports. P90 to P92 function as SIO or I<sup>2</sup>S, P93 to 95 as output pins for an LCD controller and P96 to P97 as input pins for external interruption (INT4, INT5). In addition, P95 functions as the output pin for a low frequency oscillator, P96 to P97 as PX and PY pins for a touch screen interface.

Setting the corresponding bits of P9CR and P9FC enables the respective functions. Resetting resets the P9FC to "0", and sets all bits except P95 to input ports.

(1) Port 90 (TXD0, I2SCKO), Port91 (RXD0, I2SDO), Port 92 (SCLK0, CTS0 I2SWS)

Ports 90 to 92 are general-purpose I/O ports. They also function as either SIO0 or I<sup>2</sup>S. Each pin is detailed below.

	SIO mode	UART, IrDA mode	I <sup>2</sup> S mode	SIO mode
	(SIO0 module)	(SIO0 module)	(I <sup>2</sup> S module)	(I <sup>2</sup> S module)

Figure 3.5.23 Register for Port 9

### 3.5.10 Port A (PA0 to PA7)

Ports A0 to A7 are 8-bit input ports with pull-up resistor. In addition to functioning as general-purpose I/O ports, ports A0 to A7 can also, as a keyboard interface, operate a key-on wakeup function. The various functions can each be enabled by writing a "1" to the corresponding bit of the port A function register (PAFC).

Resetting resets all bits of the register PAFC to "0" and sets all pins to be input port.

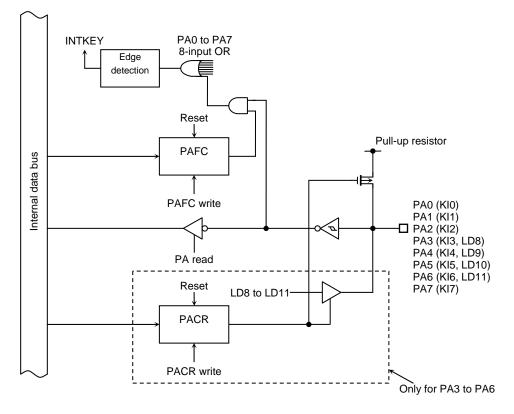

Figure 3.5.24 Port A

When PAFC = "1", if the input of any of KI0 to KI7 pins fall down, an INTKEY interrupt is generated. An INTKEY interrupt can be used to release all HALT modes.

### 3.5.11 Port C (PC0 to PC3, PC6 to PC7)

PC0 to PC3, PC6 and PC7 are 6-bit general-purpose I/O ports. Each bit can be set individually for input or output. Resetting sets port C to an input port.

In addition to functioning as a general-purpose I/O port, port C can also function as an output pin for timers (TA1OUT, TA3OUT and TB0OUT0), input pin for external interruption (INT0 to INT3), output pin for memory ( $\overline{\text{CSZF}}$ ), output pin for key (KO8) and output pin for LCD driver (LDIV, LCP1). These settings are made using the function register PCFC. The edge select for external interruption is determined by the IIMC register in the interruption controller.

### 3.5.12 Port F (PF0 to PF2, PF7)

Ports F0 to F2 are 3-bit general-purpose I/O ports. Each bit can be set individually for input or output. Resetting sets PF0 to PF2 to be input ports. It also sets all bits of the output latch register to "1". In addition to functioning as general-purpose I/O port pins, PF0 to PF2 can also function as the I/O for serial channels 0 and 1. A pin can be enabled for I/O by writing a "1" to the corresponding bit of the port F function register (PFFC).

Port F7 is a 1-bit general-purpose output port. In addition to functioning as a general-purpose output port, PF7 can also function as the SDCLK output. Resetting sets PF7 to be an SDCLK output port.

#### (1) Port F0 (TXD0, TXD1), F1 (RXD0, RXD1), F2 (SCLK0, CTS0 SCLK1, CTS1)

Ports F0 to F2 are general-purpose I/O ports. They also function as either SIO0 or SIO1. Each pin is detailed below.

	SIO mode	UART, IrDA mode	SIO mode	UART mode
	(SIO0 module)	(SIO0 module)	(SIO1 module)	(SIO1 module)
PF0	TXD0	TXD0	TXD1	TXD1

## 3.5.13 Port G (PG0 to PG3)

PG0 to PG3 are 4-bit input ports and can also be used as the analog input pins for the internal AD converter. PG3 can also be used as the ADTRG pin for the AD converter. PG2 and PG3 can also be used as the MX and MY pins for a touch screen interface.

### 3.5.14 Port J (PJ0 to PJ7)

PJ0 to PJ4 and PJ7 are 6-bit output ports. Resetting sets the output latch PJ to "1", and they output "1". PJ5 to PJ6 are 2-bit I/O ports.

In addition to functioning as a port, port J also functions as output pins for SDRAM (SDRAS, SDCAS, SDWE, SDLLDQM, SDLUDQM, SDULDQM, SDUUDQM and SDCKE), SRAM (SRWR, SRLLB SRLUB) and NAND flash (NDALE and NDCLE).

The above settings are made using the function register PJFC.

However, H either SDRAM or SRAM output signals for PJ0 to PJ2 are selected automatically according to the setting of the memory controller.

Figure 3.5.40 Register for Port J

### 3.5.15 Port K (PK0 to PK3)

Port K is a 4-bit output port. Resetting sets the output latch PK to "0", and PK0 to PK3 pins output "0".

In addition to functioning as an output port, port K also functions as output pins for an LCD controller (LCP0, LLP, LFR and LBCD).

The above settings are made using the function register PKFC.

Figure 3.5.42 Register for Port K

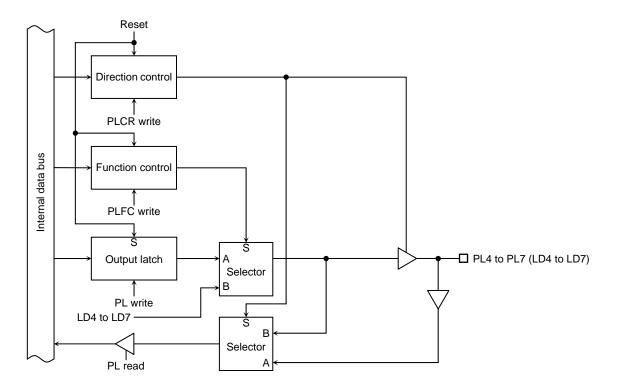

### 3.5.16 Port L (PL0 to PL7)

PL0 to PL3 are 4-bit output ports. Resetting sets the output latch PL to "0", and PL0 to PL3 pins output "0".

PL4 to PL7 are 4-bit general-purpose I/O ports. Each bit can be set individually for input or output using the control register PLCR. Resetting resets the control register PLCR to "0" and sets PL4 to PL7 to input ports. In addition to functioning as a general-purpose I/O port, port L can also function as a data bus for an LCD controller (LD0 to LD7). The above settings are made using the function register PLFC.

Figure 3.5.45 Port L Register

#### 3.5.17 Port M (PM1 to PM2)

PM1 and PM2 are 2-bit output ports. Resetting sets the output latch PM to "1", and PM1 and PM2 pins output "1".

In addition to functioning as a port, port M also functions as output pins for the RTC alarm ( $\overline{\text{ALARM}}$ ), and as the output pin for the melody/alarm generator (MLDALM,  $\overline{\text{MLDALM}}$ ).

The above settings are made using the function register PMFC.

Only PM2 has two output functions -  $\overline{ALARM}$  and  $\overline{MLDALM}$ . These are selected using PM<PM2>.

# 3.6 Memory Controller

### 3.6.1 Functions

The TMP92CH21 has a memory controller with a variable 4-block address area that controls as follows.

(1) 4-block address area support

Specifies a start address and a block size for the 4-block address area (block 0 to 3).

- SRAM or ROM: All CS blocks (CS0 to CS3) are supported.
- SDRAM : Only either CS1 or CS2 blocks are supported.
- Page ROM : Only CS2 blocks are supported.
- NAND flash
   CS0 is recommended for NAND flash (ND0/1FDTR, 001D00H to 001EFFH), RAM built-in LCD driver (001FE0H to 001FEFH). (Regarding NAND flash area, refer to 3.6.6 (2).)
- (2) Connecting memory specifications

Specifies SRAM, ROM and SDRAM as memories that connect with the selected address areas.

(3) Data bus width selection

Whether 8 bits, 16 bits or 32 bits is selected as the data bus width of the respective block address areas.

(4) Wait control

Wait specification bit in the control register and  $\overline{WAIT}$  input pin control the number of waits in the external bus cycle. Read cycle and write cycle can specify the number of waits individually.

The number of waits is controlled in the 6 modes listed below.

0 waits, 1 wait,

2 waits, 3 waits, 4 waits

N waits (controls with  $\overline{WAIT}$  pin)

### 3.6.2 Control Register and Operation after Reset Release

This section describes the registers that control the memory controller, the state following reset release and the necessary settings.

(1) Control register

The control registers of the memory controller are as follows and in Table 3.6.1 and Table 3.6.2.

- Control register: BnCSH/BnCSL (n = 0 to 3, EX) Sets the basic functions of the memory controller; the memory type that is connected, the number of waits which are read and written.
- Memory start address register: MSARn (n = 0 to 3) Sets a start address in the selected address areas.
- Memory address mask register: MAMR (n = 0 to 3) Sets a block size in the selected address areas.
- Page ROM control register: PMEMCR Sets the method of accessing page ROM.
- Internal boot ROM controls register: BROMCR Sets the method of accessing boot ROM.

Table 3.6.2 Control Register

Note: Read-modify-write is prohibited for BEXCSH and BEXCSL registers.

(2) Operation after reset release

The start data bus width is determined by the state of AM1/AM0 pins just after reset release. The external memory is then accessed as follows

AM1	AM0	Start Mode
0	0	Don't use this setting
0	1	Start with 16-bit data bus (Note)
1	0	Start with 32-bit data bus (Note)
1	1	Start with boot (32-bit internal MROM)

Note: The memory to be used on starting after reset must be either NOR flash or masked ROM. NAND flash and SDRAM cannot be used.

AM1/AM0 pins are valid only just after reset release. In other cases, the data bus width is set by the control register  $<\!BnBUS1:0\!>$  .

On reset, only the control register (B2CSH/B2CSL) of the block address area 2 becomes effective automatically (B2CSH<B2E> is set to "1" on reset).

The data bus width which is specified by AM1/AM0 pins is loaded to the bit for specification of the bus width of the control register in the block address area 2.

The block address area 2 is set to 000000H to FFFFFFH address on reset (B2CSH<B2M> is reset to "0").

After reset release, the block address areas are specified by the memory start address register (MSARn) and the memory address mask register (MAMRn). The control register (BnCS) is then set.

Set the enable bit (BnE) of the control register to "1" to enable the setting.

# 3.6.3 Basic Functions and Register Setting

This section describes the setting of the block address area, the connecting memory and the number of waits out of the memory controller's functions.

(1) Block address area specification

The block address area is specified by two registers.

The memory start address register (MSARn) sets the start address of the block address areas. The memory controller compares the register value and the address every bus cycle. The address bit which is masked by the memory address mask register (MAMRn) is not compared by the memory controller. The block address area size is determined by setting the memory address mask register. The value that is set to the register is compared with the block address area on the bus. If the result is a match, the memory controller sets the chip select signal (CSn) to "low".

(i) Memory start address register setting

The MS23 to MS 16 bits of the memory start address register correspond with addresses A23 to A16 respectively. The lower start addresses A15 to A0 are always set to address 0000H.

Therefore the start addresses of the block address area are set to all 64 Kbytes of addresses 000000H to FF0000H.

(ii) Memory address mask register setting

The memory address mask register determines whether an address bit is compared or not. In register setting, "0" is "compare", and "1" is "do not compare".

The address bits that can be set depends on the block address area.

Block address area  $0^{\vdots}\operatorname{A20}$  to A8

Block address area 1: A21 to A8

Block address area 2 to 3: A22 to A15

The upper bits are always compared. The block address area size is determined by the result of the comparison.

Size (bytes) CS area	256	512	32 K	64 K	128 K	256 K	512 K	1 M	2 M	4 M	8 M
CS0	0	0	0	0	0	0	0	0	0		
CS1	0	0		0	0	0	0	0	0	0	
CS2 to CS3			0	0	0	0	0	0	0	0	0

The size to be set depending on the block address area is as follows.

Note: After reset release, only the control register of the block address area 2 is valid. The control register of block address area 2 has the <B2M> bit. If the <B2M> bit is set to "0", block address area 2 is set to addresses 000000H to FFFFFFH. (This is the state following reset release .) If the <B2M> bit is set to "1", the start address and the address area size are set, as in the other block address areas.

#### (iii) Example of register setting

To set the block address area 64 Kbytes from address 110000H, set the register as follows.

Bit	7	6	5	4	3	2	1	0
Bit symbol	M1S23	M1S22	M1S21	M1S20	M1S19	M1S18	M1S17	M1S16
Specified value	0	0	0	1	0	0	0	1

M1S23 to M1S16 bits of the memory start address register MSAR1 correspond with address A23 to A16.

A15 to A0 are set to "0". Therefore, if MSAR1 is set to the above mentioned value, the start address of the block address area is set to address 110000H.

				i ti i togioto	-			
Bit	7	6	5	4	3	2	1	0
Bit symbol	M1V21	M1V20	M1V19	M1V18	M1V17	M1V16	M1V15 to M1V9	M1V8
Specified value	0	0	0	0	0	0	0	1

MAMR1 Register

M1V21 to M1V16 and M1V8 bits of the memory address mask register MAMR1 are set whether addresses A21 to A16 and A8 are compared or not. In register setting, "0" is "compare", and "1" is "do not compare". M1V15 to M1V9 bits determine whether addresses A15 to A9 are compared or not with bit 1. A23 and A22 are always compared.

When set as above, A23 to A9 are compared with the value that is set as the start addresses. Therefore, 512 bytes (addresses 110000H to 1101FFH) are set as block address area 1, and if it is compared with the addresses on the bus, the chip select signal CS1 is set to "low".

The other block address area sizes are specified in the same way.

A23 and A22 are always compared with block address area 0. Whether A20 to A8 are compared or not is determined by the register.

Similarly, A23 is always compared with block address areas 2 to 5. Whether A22 to A15 are compared or not is determined by the register.

Note 1: When the set block address area overlaps with the built-in memory area, or both two address areas overlap, the block address area is processed according to priority as follows.

Built-in I/O > Built-in memory > Block address area 0 > 1 > 2 > 3

Note 2: If an address area other than  $\overline{CS0}$  to  $\overline{CS3}$  is accessed, this area is regarded as  $\overline{CSEX}$ . Therefore, wait number and data bus width controls follow the setting of  $\overline{CSEX}$  (BEXCSH, BEXCSL register). (2) Connection memory specification

Setting the <BnOM1:0> bit of the control register (BnCSH) specifies the memory type that is connected with the block address areas. The interface signal is outputted according to the set memory as follows.

<bnom1></bnom1>	<bnom0></bnom0>	Function
0	0	SRAM/ROM (Default)
0	1	(Reserved)
1	0	(Reserved)
1	1	SDRAM

#### <BnOM1: 0> Bit (BnCSH Register)

Note 1: SDRAM should be set to block either 1 or 2.

Note 2: Set "00" for NAND flash, RAM built-in LCDD.

(3) Data bus width specification

The data bus width is set for every block address area. The bus size is set by setting the control register (BnCSH)<BnBUS1:0> as follows.

		τ σ,
BnBUS 1	BnBUS 0	Function
0	0	8-bit bus mode (Default)
0	1	16-bit bus mode
1	0	32-bit bus mode
1	1	Don't use this setting

<BnBUS1:0> bit (BnCSH Register)

Note: SDRAM should be set to either "01" (16-bit bus) or "10" (32-bit bus).

This method of changing the data bus width depending on the accessing address is called "dynamic bus sizing". The part of the data bus to which the data is output depends on the data size, baus width and start address.

Note: Since there is a possibility of abnormal writing/reading of the data if two memories with different bus width are put in consecutive addresses, do not execute an access to both memories with one command.

Operand Data	Operand Start	Memory Data Size			CPU	Data	
Size (bit)	Address	(bit)	CPU Address	D31 to D24	D23 to D16	D15 to D8	D7 to D0

			(2) 4n + 4	XXXXX	XXXXX	XXXXX	b15 to b8
			(3) 4n + 5	XXXXX	XXXXX	XXXXX	b23 to b16
		40	(4) 4n + 6	XXXXX	XXXXX	XXXXX	b31 to b24
		16	(1) 4n + 3 (2) 4n + 4	XXXXX	XXXXX	b7 to b0 b23 to b16	xxxxx b15 to b8
			(2) 4n + 4 (3) 4n + 6	XXXXX XXXXX	XXXXX XXXXX	XXXXX	b15 to b8 b31 to b24
		32	(1) 4n + 3	b7 to b0	XXXXX	XXXXX	XXXXX
			(2) 4n + 4	XXXXX	b31 to b24	b23 to b16	b15 to b8

xxxxx: During a read, data input to the bus ignored. At write, the bus is at high impedance and the write strobe signal remains non active.

(4) Wait control

The external bus cycle completes a wait of at least two states (100 ns at  $f_{SYS} = 20$  MHz).

Setting the <BnWW2:0> and <BnWR2:0> of BnCSL specifies the number of waits in the write cycle and the read cycle. <BnWW2:0> is set using the same method as <BnWR2:0>.

<bnww2> <bnwr2></bnwr2></bnww2>	<bnww1> <bnwr1></bnwr1></bnww1>	<bnww0> <bnwr0></bnwr0></bnww0>	Function
0	0	1	2 states (0 waits) access fixed mode
0	1	0	3 states (1 wait) access fixed mode (Default)
1	0	1	4 states (2 waits) access fixed mode
1	1	0	5 states (3 waits) access fixed mode
1	1	1	6 states (4 waits) access fixed mode
0	0 1		WAIT pin input mode
	Others		(Reserved)

<BnWW>/<BnWR> (BnCSL Register)

Note 1: For SDRAM, the above setting is ineffective. Refer to 3.16 SDRAM controller.

Note 2: For NAND flash, this setting is ineffective. For RAM built-in LCDD, this setting is effective.

(i) Waits number fixed mode

The bus cycle is completed following the number of states set. The number of states is selected from 2 states (0 waits) to 6 states (4 waits).

(ii)  $\overline{WAIT}$  pin input mode

This mode samples the  $\overline{\text{WAIT}}$  input pins. In this mode, a wait is inserted continuously while the signal is active. The bus cycle is a minimum 2 states. The bus cycle is completed if the wait signal is non active ("High" level) at the second state. The bus cycle continues if the wait signal is active after 2 states or more.

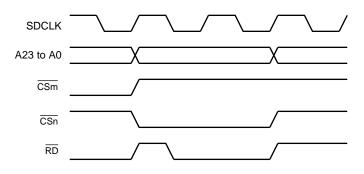

(5) Recovery (Data hold) cycle control

Some memory is defined by AC specification about data hold time by  $\overline{CE}$  or  $\overline{OE}$  for read cycle. Therefore, a data conflict problem may occur. To avoid this problem, 1-dummy cycle can be inserted after CSm-block access cycle by setting "1" to BmCSH<BmREC> register.

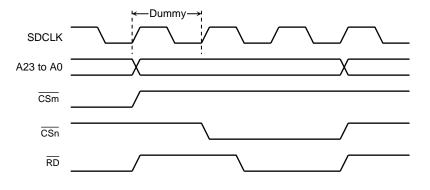

This 1-dummy cycle is inserted when the next cycle is for another CS-block.

	<bnrec> (BnCSH register)</bnrec>
0	No dummy cycle is inserted (Default).
1	Dummy cycle is inserted.

• When no dummy cycle is inserted (0 waits)

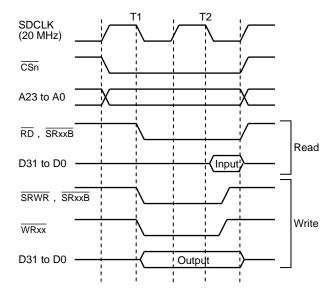

• When inserting a dummy cycle (0 waits)

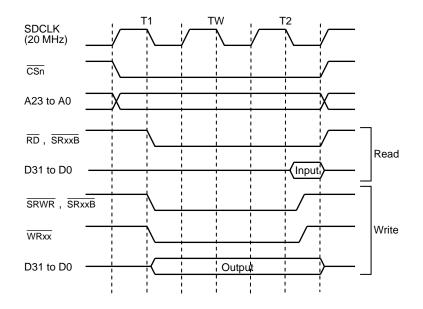

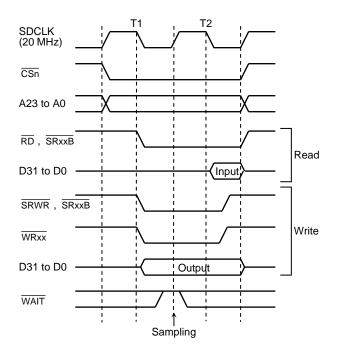

### (6) Basic bus timing

(a) External read/write cycle (0 waits)

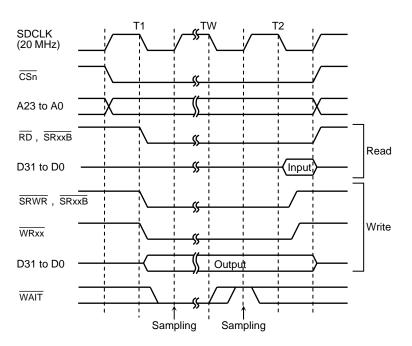

(b) External read/write cycle (1 wait)

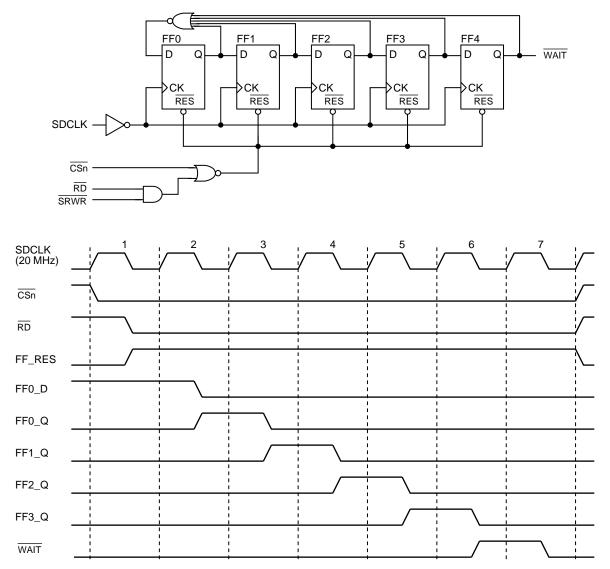

(c) External read/write cycle (0 waits at  $\overline{WAIT}$  pin input mode)

(d) External read/write cycle (n waits at  $\overline{WAIT}$  pin input mode)

(7) Connecting external memory

Figure 3.6.1 shows an example of how to connect an external 16-bit SRAM and 16-bit NOR flash to the TMP92CH21.

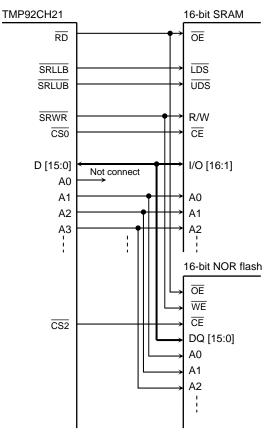

Figure 3.6.1 Example of External 16-Bit SRAM and NOR Flash Connection

### 3.6.4 ROM Control (Page mode)

This section describes ROM page mode accessing and how to set registers. ROM page mode is set by the page ROM control register.

(1) Operation and how to set the registers

The TMP92CH21 supports ROM access of the page mode. ROM access of the page mode is specified only in block address area 2.

ROM page mode is set by the page ROM control register (PMEMCR). Setting <OPGE> of the PMEMCR register to "1" sets the memory access of the block address area to ROM page mode access.

The number of read cycles is set by the <OPWR1:0> of the PMEMCR register.

		0 /
<opwr1></opwr1>	<opwr0></opwr0>	Number of Cycle in a Page
0	0	1 state (n-1-1-1 mode) (n ≥ 2)
0	1	2 state (n-2-2-2 mode) (n ≥ 3)
1	0	3 state (n-3-3-3 mode) (n ≥ 4)
1	1	(Reserved)

<OPWR1:0> (PMEMCR register)

Note: Set the number of waits ("n") using the control register (BnCSL) in each block address area.

The page size (the number of bytes) of ROM in the CPU size is set by the <PR1:0> of the PMEMCR register. When data is read out up to the border of the set page, the controller completes the page reading operation. The start data of the next page is read in the normal cycle. The following data is set to page read again.

<pr1></pr1>	<pr0></pr0>	ROM Page Size
0	0	64 bytes
0	1	32 bytes
1	0	16 bytes (Default)
1	1	8 bytes

<PR1:0> Bit (PMEMCR register)

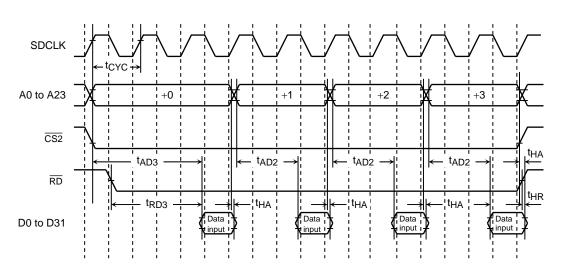

Figure 3.6.2 Page mode access Timing (8-byte example)

# 3.6.5 Internal Boot ROM Control

This section describes the built-in boot ROM. For the specification of S/W in boot ROM, refer to 3.20 boot ROM sections.

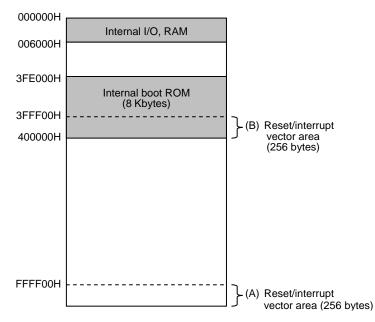

(1) BOOT mode

BOOT mode is started by following AM1 and AM0 pins condition with reset.

AM1	AM0	Start mode						
0	0	Don't use this setting						
0	1	Start with 16-bit data bus						
1	0	Start with 32-bit data bus						
1	1	Start with boot (32-bit internal MROM)						

#### (2) Boot ROM memory map

Boot ROM consists of an 8-Kbyte masked ROM and is assigned to address 3FE000H to 3FFFFFH.

(3) Reset/interrupt address conversion circuit

The Reset/interrupt vector area is assigned to FFFF00H to FFFFEFH ((A) area) in the TLCS-900/H1.

Since the boot ROM is assigned to another area, a reset/interrupt vector address conversion circuit is provided.

In BOOT mode, the reset/interrupt vector area is assigned to 3FFF00H to 3FFFEFH ((B) area). Following boot sequence, the area can be changed to (A) area by setting BROMCR<VACE> to "0". Therefore, (A) area can be used only for the application system program.

This <VACE> is initialized to "1" in BOOT mode. In any other starting mode, this register has no effect.

Note: As the last 16-byte area (FFFF0H to FFFFFH) is reserved for an emulator, this area is not changed by the <VACE> register.

(4) Bypassing boot ROM

After boot sequence in BOOT mode, an application system program may continue to run without reset asserting. In this case, an external memory which is mapped to address 3FE000H to 3FFFFFH cannot be accessed because the boot ROM is assigned.

To solve this, the internal boot ROM can be bypassed by setting BROMCR<ROMLESS> to "1".

This <ROMLESS> is initialized to "0" in BOOT mode. In any other starting mode, this register is initialized to "1".

If this register has been set to "1", writing "0" is prohibited.

	/	7	6	5	4	3	2	1	0
BROMCR	Bit symbol	/	/			/	/	ROMLESS	VACE
(0167H)	Read/Write					/		R/\	N
	Reset State		/			/	/	0/1	1/0
	Function							Boot ROM 0: Use 1: Bypass	Vector address conversion 0: Disable 1: Enable

Note: Reset states differ depending on start modes.

### 3.6.6 Cautions

(1) Note on timing between  $\overline{CS}$  and  $\overline{RD}$ 

If the parasitic capacitance of the  $\overline{\text{RD}}$  (Read signal) is greater than that of the  $\overline{\text{CS}}$  (Chip select signal), it is possible that an unintended read cycle occurs due to a delay in the read signal. Such an unintended read cycle may cause a problem, as in the case of (a) in Figure 3.6.3.

Example: When using an externally connected NOR flash which uses JEDEC standard commands, note that the toggle bit may not be read out correctly. If the read signal in the cycle immediately preceding the access to the NOR flash does not go high in time, as shown in Figure 3.6.4, an unintended read cycle like the one shown in (b) may occur.

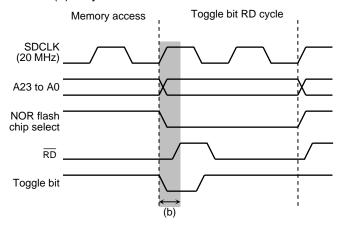

Figure 3.6.4 NOR Flash Toggle Bit Read Cycle

When the toggle bit is reversed by this unexpected read cycle, the CPU cannot read the toggle bit correctly since it always reads same value for the toggle bit. To avoid this phenomenon, data polling function control is recommended. (2) Note on NAND flash area setting

Figure 3.6.5 shows a memory map for a NAND flash and RAM built-in LCD driver.

Ssince it is recommended that CS3 area be assigned to the address 000000H to 3FFFFFH, the following explanation is given.

In this case, the NAND flash and RAM built-in LCD driver overlap with CS3 area.

However, each access control circuit in the TMP92CH21 operates independently.

So, if a program on CS3 area accesses NAND flash, both  $\overline{CS3}$  and NAND flash will be accessed at the same time and a problem such as data conflict will occur.

To avoid this phenomenon, it is recommended that CS0 area be assigned to the 32 Kbytes of address 000000H to 007FFFH as the  $\overline{\text{CS0}}$  pin will not be needed.

Since CS0 has priority over CS3, only NAND flash will be accessed correctly by this setting.

Note: In this case, the 32 Kbytes of address 000000H to 007FFFH in CS3's memory cannot be used.

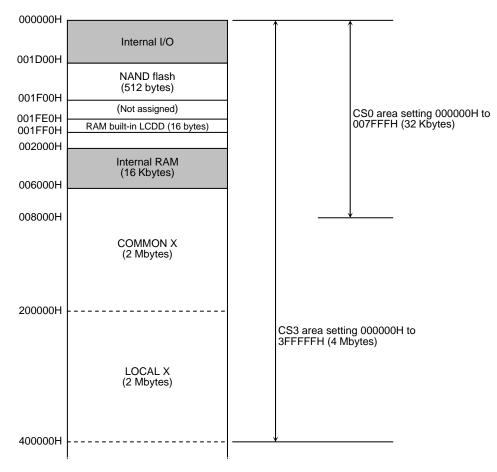

Figure 3.6.5 Recommended CS3 and CS0 Setting

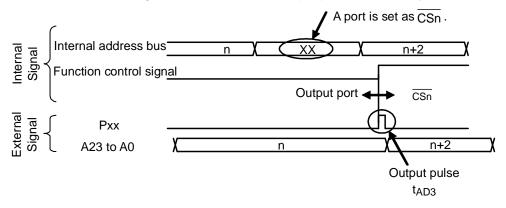

(3) The cautions at the time of the functional change of a  $\overline{\text{CSn}}$ .

A chip select signal output has the case of a combination terminal with a general-purpose port function. In this case, an output latch register and a function control register are initialized by the reset action, and an object terminal is initialized by the port output ("1" or "0") by it.

Functional change

Although an object terminal is changed from a port to a chip select signal output by setting up a function control register (PnFC register), the short pulse for several ns may be outputted to the changing timing. Although it does not become especially a problem when using the usual memory, it may become a problem when using a special memory.

\* XX is a function register address.(When an output port is initialized by "0")

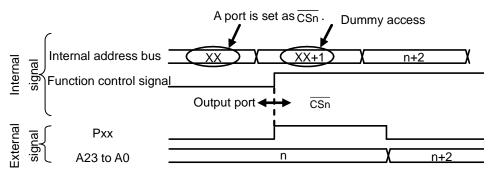

### The measure by software

The countermeasures in S/W for avoiding this phenomenon are explained.

Since CS signal decodes the address of the access area and is generated, an unnecessary pulse is outputted by access to the object CS area immediately after setting it as a CSn function. Then, if internal area is accessed also immediately after setting a port as CS function, an unnecessary pulse will not output.

- 1. The ban on interruption under functional change (DI command)
- 2. A dummy command is added in order to carry out continuous internal access.
- 3. (Access to a functional change register is corresponded by 16-bit command. (LDW command))

# 3.7 8-Bit Timers (TMRA)

The TMP92CH21 features 4 built-in 8-bit timers (TMRA0-TMRA3). These timers are paired into two modules: TMRA01 and TMRA23. Each module consists of two channels and can operate in any of the following four operating modes.

- 8-bit interval timer mode
- 16-bit interval timer mode
- 8-bit programmable square wave pulse generation output mode (PPG: Variable duty cycle with variable period)
- 8-bit pulse width modulation output mode (PWM: Variable duty cycle with constant period)

Figure 3.7.1 and Figure 3.7.2 show block diagrams for TMRA01 and TMRA23.

Each channel consists of an 8-bit up counter, an 8-bit comparator and an 8-bit timer register. In addition, a timer flip-flop and a prescaler are provided for each pair of channels.

The operation mode and timer flip-flops are controlled by a five-byte SFR (special function register).

Each of the two modules (TMRA01 and TMRA23) can be operated independently. All modules operate in the same manner; hence only the operation of TMRA01 is explained here.

The contents of this chapter are as follows.

- 3.7.1 Block Diagrams
- 3.7.2 Operation of Each Circuit
- 3.7.3 SFR
- 3.7.4 Operation in Each Mode
  - (1) 8-bit timer mode
  - (2) 16-bit timer mode
  - (3) 8-bit PPG (programmable pulse generation) output mode
  - (4) 8-bit PWM (pulse width modulation) output mode
  - (5) Mode settings

Table 3.7.1 Registers and P	Pins for Each Module
-----------------------------	----------------------

	Module	TMRA01	TMRA23	
External	Input pin for external clock	No	No	
pin	Output pin for timer flip-flop	TA1OUT (Shared with PC0)	TA3OUT (Shared with PC1)	
	Timer run register	TA01RUN (1100H)	TA23RUN (1108H)	
SFR (Address)	Timer register	TA0REG (1102H) TA1REG (1103H)	TA2REG (110AH) TA3REG (110BH)	
(Audiess)	Timer mode register	TA01MOD (1104H)	TA23MOD (110CH)	
	Timer flip-flop control register	TA1FFCR (1105H)	TA3FFCR (110DH)

# 3.7.2 Operation of Each Circuit

#### (1) Prescalers

A 9-bit prescaler generates the input clock to TMRA01.

The clock  $\phi T0$  is divided into 8 by the CPU clock fsys and input to this prescaler.

The prescaler operation can be controlled using TA01RUN<TA01PRUN> in the timer control register. Setting <TA01PRUN> to "1" starts the count; setting <TA01PRUN> to "0" clears the prescaler to "0" and stops operation. Table 3.7.2 shows the various prescaler output clock resolutions.

System clock selection SYSCR1	Clock gear selection SYSCR1	_	Timer counter input clock TMRA prescaler TAxMOD <taxclk1:0></taxclk1:0>						
<sysck></sysck>	<gear2:0></gear2:0>		φT1(1/2)	φT4(1/8)	φT16(1/32)	φT256(1/512)

xxx: Don't care

(2) Up counters (UC0 and UC1)

These are 8-bit binary counters which count up the input clock pulses for the clock specified by TA01MOD.

The input clock for UC0 is selectable and can be either the external clock input via the TA0IN pin or one of the three internal clocks  $\phi$ T1,  $\phi$ T4 or  $\phi$ T16. The clock setting is specified by the value set in TA01MOD<TA01CLK1:0>.

The input clock for UC1 depends on the operation mode. In 16-bit timer mode, the overflow output from UC0 is used as the input clock. In any mode other than 16-bit timer mode, the input clock is selectable and can either be one of the internal clocks  $\phi$ T1,  $\phi$ T16 or  $\phi$ T256, or the comparator output (the match detection signal) from TMRA0.

For each interval timer the timer operation control register bits TA01RUN<TA0RUN> and TA01RUN<TA1RUN> can be used to stop and clear the up counters and to control their count. A reset clears both up counters, stopping the timers.

(3) Timer registers (TA0REG and TA1REG)

These are 8-bit registers, which can be used to set a time interval. When the value set in the timer register TAOREG or TA1REG matches the value in the corresponding up counter, the comparator match detect signal goes Active. If the value set in the timer register is 00H, the signal goes Active when the up counter overflows.

TAOREG has a double buffer structure, making a pair with the register buffer.

The setting of the bit TA01RUN<TA0RDE> determines whether TA0REG's double buffer structure is enabled or disabled. It is disabled if  $\langle TA0RDE \rangle = "0"$  and enabled if  $\langle TA0RDE \rangle = "1"$ .

When the double buffer is enabled, data is transferred from the register buffer to the timer register when a  $2^n$  overflow occurs in PWM mode, or at the start of the PPG cycle in PPG mode. Hence the double buffer cannot be used in timer mode.

A reset initializes <TAORDE> to "0", disabling the double buffer. To use the double buffer, write data to the timer register, set <TAORDE> to "1", and write the following data to the register buffer. Figure 3.7.3 show the configuration of TAOREG.

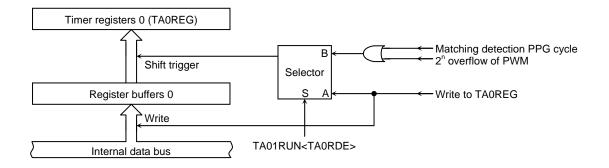

Figure 3.7.3 Configuration of TA0REG

Note: The same memory address is allocated to the timer register and the register buffer. When <TA0RDE> = 0, the same value is written to the register buffer and the timer register; when <TA0RDE> = 1, only the register buffer is written to.

The address of each timer register is as follows.

TA0REG: 001102H	TA1REG: 001103H
TA2REG: 00110AH	TA3REG: 00110BH

All these registers are write only and cannot be read.

(4) Comparator (CP0)

The comparator compares the value in an up counter with the value set in a timer register. If they match, the up counter is cleared to "0" and an interrupt signal (INTTA0 or INTTA1) is generated. If timer flip-flop inversion is enabled, the timer flip-flop is inverted at the same time.

(5) Timer flip-flop (TA1FF)

The timer flip-flop (TA1FF) is a flip-flop inverted by the match detect signals (8-bit comparator output) of each interval timer.

Whether inversion is enabled or disabled is determined by the setting of the bit TA1FFCR<TA1FFIE> in the timer flip-flops control register. A reset clears the value of TA1FF to "0". Writing "01" or "10" to TA1FFCR<TA1FFC1:0> sets TA1FF to "0" or "1". Writing "00" to these bits inverts the value of TA1FF (this is known as software inversion).

The TA1FF signal is output via the TA1OUT pin (which can also be used as PC0).

When this pin is used as the timer output, the timer flip-flop should be set beforehand using the port C function register PCCR and PCFC.

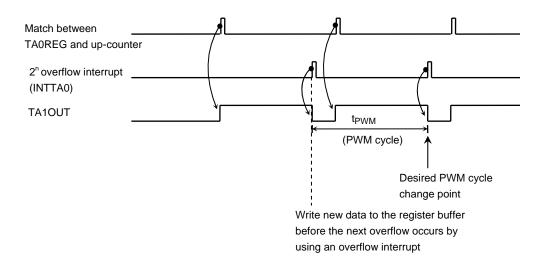

Note: When the double buffer is enabled for an 8-bit timer in PWM or PPG mode, caution is required as explained below.

If new data is written to the register buffer immediately before an overflow occurs by a match between the timer register value and the up-counter value, the timer flip-flop may output an unexpected value.

For this reason, make sure that in PWM mode new data is written to the register buffer by six cycles ( $f_{SYS} \times 6$ ) before the next overflow occurs by using an overflow interrupt.

When using PPG mode, make sure that new data is written to the register buffer by six cycles before the next cycle compare match occurs by using a cycle compare match interrupt.

#### Example when using PWM mode

Figure 3.7.9 8-Bit Timers Register

# 3.7.4 Operation in Each Mode

(1) 8-bit timer mode

Both TMRA0 and TMRA1 can be used independently as 8-bit interval timers.

1. Generating interrupts at a fixed interval (using TMRA1)

To generate interrupts at constant intervals using TMRA1 (INTTA1), first stop TMRA1 then set the operation mode, input clock and a cycle to TA01MOD and TA1REG register, respectively. Then, enable the interrupt INTTA1 and start TMRA1 counting.

Example: To generate an INTTA1 interrupt every 40  $\mu s$  at  $f_C$  = 40 MHz, set each register as follows:

		MSE	3						LS	SB	
_			7	6	5	4	3	2	1	0	
	TA01RUN	← -	_	Х	Х	Х	-	-	0	-	Stop TMRA1 and clear it to "0".
	TA01MOD	← (	0	0	Х	Х	0	1	-	-	Select 8-bit timer mode and select $\phi T1$ (=(16/fc)s at $f_C$ = 40 MHz) as the input clock.
	TA1REG	← (	0	1	1	0	0	1	0	0	Set TREG1 to 40 $\mu$ s ÷ $\phi$ T1 = 100 = 64H.
	INTETA01	← .	Х	1	0	1	-	-	-	-	Enable INTTA1 and set it to level 5.
	TA01RUN	$\leftarrow$	_	Х	Х	Х	-	1	1	-	Start TMRA1 counting.
_	X: Don't care,	-: No	ch	ang	е						

Select the input clock using Table 3.7.3.

Inpu	it Clock	Interrupt Interval (at f <sub>SYS</sub> = 20 MHz)	Resolution		
φT1	(8/f <sub>SYS</sub> )	0.4 μs to 102.4 μs	0.4 μs		
<b>φ</b> Τ4	(32/f <sub>SYS</sub> )	1.6 μs to 409.6 μs	1.6 μs		
φT16	(128/f <sub>SYS</sub> )	6.4 μs to 1.638 ms	6.4 μs		
φT256	(2048/f <sub>SYS</sub> )	102.4 μs to 26.21 ms	102.4 μs		

Note: The input clocks for TMRA0 and TMRA1 differ as follows:

TMRA0: Uses TMRA0 input (TA0IN) and can be selected from  $\phi$ T1,  $\phi$ T4 or  $\phi$ T16 TMRA1: Matches output of TMRA0 (TA0TRG) and can be selected from  $\phi$ T1,  $\phi$ T16,  $\phi$ T256 2. Generating a 50 % duty ratio square wave pulse

The state of the timer flip-flop (TA1FF1) is inverted at constant intervals and its status output via the timer output pin (TA1OUT).

Example: To output a 2.4- $\mu$ s square wave pulse from the TA1OUT pin at fc = 40 MHz, use the following procedure to make the appropriate register settings. This example uses TMRA1; however, either TMRA0 or TMRA1 may be used.

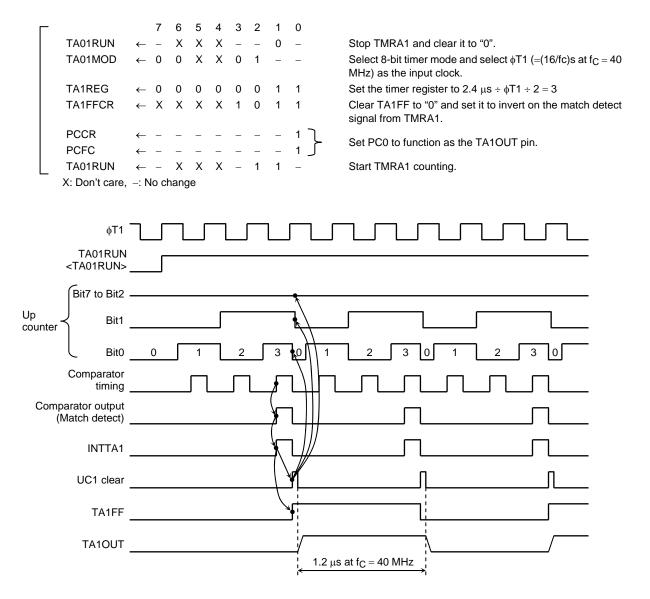

Figure 3.7.10 Square Wave Output Timing Chart (50 % Duty)

3. Making TMRA1 count up on the match signal from the TMRA0 comparator Select 8-bit timer mode and set the comparator output from TMRA0 to be

Select 8-bit timer mode and set the comparator output from TMRA0 to be the input clock to TMRA1.

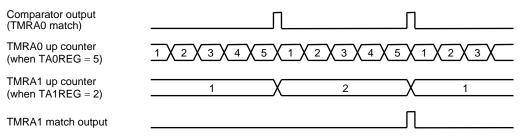

Figure 3.7.11 TMRA1 Count Up on Signal from TMRA0

(2) 16-bit timer mode

A 16-bit interval timer is configured by pairing the two 8-bit timers TMRA0 and TMRA1.

To make a 16-bit interval timer in which TMRA0 and TMRA1 are cascaded together, set TA01MOD<TA01M1:0> to "01".

In 16-bit timer mode, the overflow output from TMRA0 is used as the input clock for TMRA1, regardless of the value set in TA01MOD<TA01CLK1:0>. Table 3.7.2 shows the relationship between the timer (interrupt) cycle and the input clock selection.

To set the timer interrupt interval, set the lower eight bits in timer register TAOREG and the upper eight bits in TA1REG. Be sure to set TA0REG first (as entering data in TA0REG temporarily disables the compare, while entering data in TA1REG starts the compare).

Setting example: To generate an INTTA1 interrupt every 0.4 s at  $f_C = 40$  MHz, set the timer registers TA0REG and TA1REG as follows:

If  $\phi$ T16 (=(256/fc)s at f<sub>C</sub> = 40 MHz) is used as the input clock for counting, set the following value in the registers: 0.4 s ÷ =(256/fc)s = 62500 = F424H; e.g. set TA1REG to F4H and TA0REG to 24H.

The comparator match signal is output from TMRA0 each time the up counter UC0 matches TA0REG, though the up counter UC0 is not cleared.

In the case of the TMRA1 comparator, the match detect signal is output on each comparator pulse on which the values in the up counter UC1 and TA1REG match. When the match detect signal is output simultaneously from both the comparator TMRA0 and TMRA1, the up counters UC0 and UC1 are cleared to "0" and the interrupt INTTA1 is generated. Also, if inversion is enabled, the value of the timer flip-flop TA1FF is inverted.

Example: When TA1REG = 04H and TA0REG = 80H

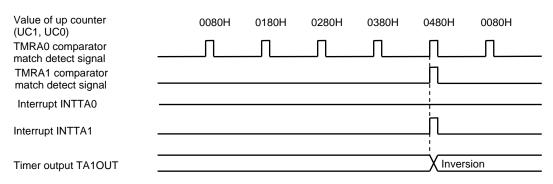

Figure 3.7.12 Timer Output by 16-Bit Timer Mode

(3) 8-bit PPG (Programmable pulse generation) output mode

Square wave pulses can be generated at any frequency and duty ratio by TMRA0. The output pulses may be active low or active high. In this mode TMRA1 cannot be used.

TMRA0 outputs pulses on the TA1OUT pin (which can also be used as PC0).

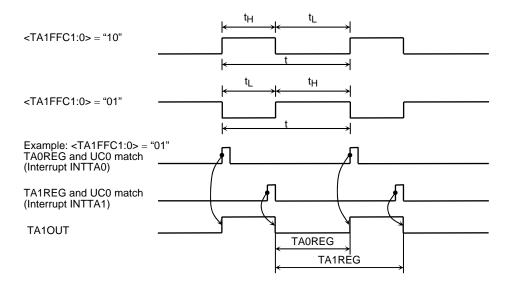

Figure 3.7.13 8-Bit PPG Output Waveforms

In this mode a programmable square wave is generated by inverting the timer output each time the 8-bit up counter (UC0) matches the value in one of the timer registers TA0REG or TA1REG.

The value set in TA0REG must be smaller than the value set in TA1REG.

Although the up counter for TMRA1 (UC1) is not used in this mode, TA01RUN<TA1RUN> should be set to "1" so that UC1 is set for counting.

Figure 3.7.14 shows a block diagram representing this mode.

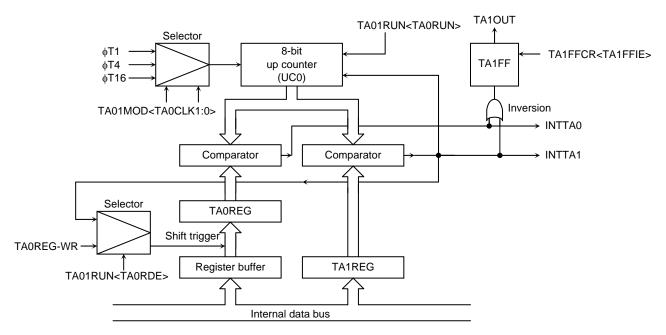

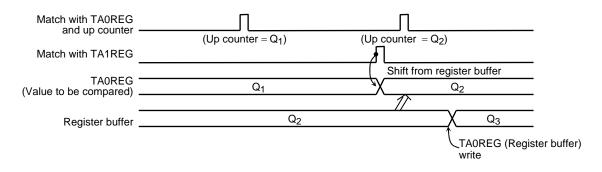

Figure 3.7.14 Block Diagram of 8-Bit PPG Output Mode

If the TAOREG double buffer is enabled in this mode, the value of the register buffer will be shifted into TAOREG each time TA1REG matches UCO.

Use of the double buffer facilitates the handling of low duty waves (when duty is varied).

Example: To generate 1/4 duty 62.5 kHz pulses (at  $f_C = 40$  MHz) 16 μs Calculate the value which should be set in the timer register. To obtain a frequency of 62.5 kHz, the pulse cycle t should be: t = 1/62.5 kHz = 16  $\mu$ s  $\phi$ T1 (=(16/fc)s (at f<sub>C</sub> = 40 MHz);  $16 \ \mu s \div (16/fc)s = 40$ Therefore set TA1REG to 40 (28H) The duty is to be set to 1/4: t  $\times$  1/4 = 16  $\mu s$   $\times$  1/4 = 4  $\mu s$  $4 \ \mu s \div (16/fc)s = 10$ Therefore, set TA0REG = 10 = 0AH. 7 6 543 2 1 0 TA01RUN ← 0 0 0 Stop TMRA0 and TMRA1 and clear it to "0". ХХХ – 0 TA01MOD 0 X X X X 0 Set the 8-bit PPG mode, and select  $\phi$ T1 as input clock. 1 1 ← TAOREG 0 0 0 0 1 0 1 0 Write 0AH. ← Write 28H. TA1REG ← 0 0 1 0 1 0 0 0 TA1FFCR 0 1 1 Х Х Х Х Х Set TA1FF, enabling both inversion and the double buffer. 10 generates a negative logic pulse. PCCR 1 Set PC0 as the TA1OUT pin. PCFC ← \_ \_ \_ 1 TA01RUN ← 1 х х х 1 1 Start TMRA0 and TMRA1 counting. X: Don't care, -: No change

(4) 8-bit PWM output mode

This mode is only valid for TMRA0. In this mode, a PWM pulse with the maximum resolution of 8 bits can be output.

When TMRA0 is used the PWM pulse is output on the TA1OUT pin (which is also used as PC1). TMRA1 can also be used as an 8-bit timer.

The timer output is inverted when the up counter (UC0) matches the value set in the timer register TA0REG or when  $2^n$  counter overflow occurs (n = 6, 7 or 8 as specified by TA01MOD<PWM01:00>). The up counter UC0 is cleared when  $2^n$  counter overflow occurs. The following conditions must be satisfied before this PWM mode can be used.

Value set in TAOREG < value set for 2<sup>n</sup> counter overflow

Value set in TAOREG  $\neq 0$ 

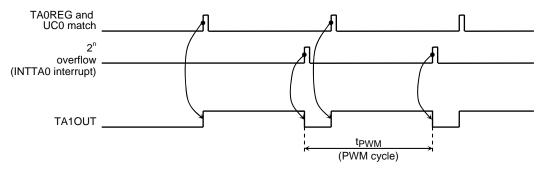

Figure 3.7.16 8-Bit PWM Waveforms

Figure 3.7.17 shows a block diagram representing this mode.

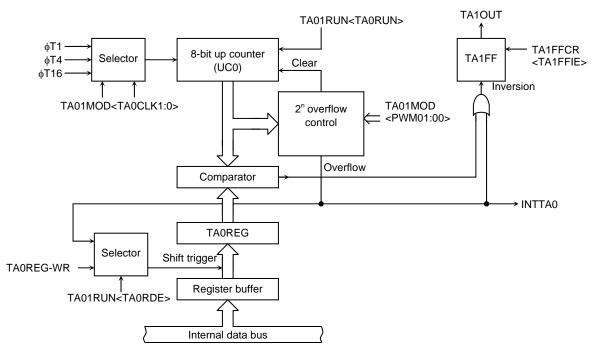

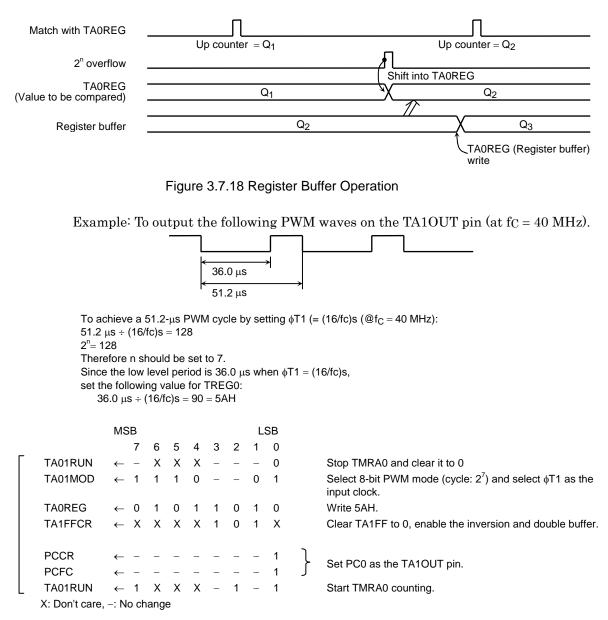

Figure 3.7.17 Block Diagram of 8-Bit PWM Mode

In this mode the value of the register buffer will be shifted into TAOREG if  $2^n$  overflow is detected when the TAOREG double buffer is enabled.

Use of the double buffer facilitates the handling of low duty ratio waves.

# Table 3.7.5 Timer Mode Setting Registers

-: Don't care

# 3.8 External Memory Extension Function (MMU)

By providing 3 local areas, the MMU function allows for the expansion of the program/data area up to 512 Mbytes.

The recommended address memory map is shown in Figure 3.8.1 and Figure 3.8.2.

However, when the memory used is less than 16 Mbytes, it is not necessary to set the MMU register. In this case, please refer to the Memory Controller section.

An area which can be set as a bank is called a local area. Since the address for local areas is fixed, it cannot be changed.

It is not possible for a program to branch between different banks of the same local area.

The TMP92CH21 has the following external pins for memory LSI connection.

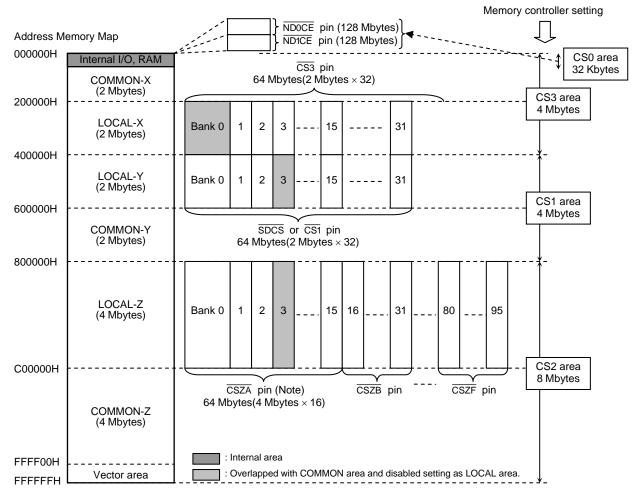

Address bus: EA25, EA24 and A23 to A0

Chip select:  $\overline{CS0}$  to  $\overline{CS3}$ ,  $\overline{CSZA}$  to  $\overline{CSZF}$ ,  $\overline{SDCS}$   $\overline{ND0CE}$  and  $\overline{ND1CE}$ Data bus: D31 to D0

## 3.8.1 Recommended Memory Map

Figure 3.8.1 shows one recommended address memory map. This is for maximum expanded memory size and for a system in which an internal boot ROM with NAND flash is not needed.

Figure 3.8.3 also shows a recommended address memory map for a simple memory system such as an internal boot ROM with NAND flash and SDRAM.

Note:  $\overline{\text{CSZA}}$  is a chip select for not only bank 0 to 15 of LOCAL-Z but also COMMON-Z.

Figure 3.8.1 Recommended Memory Map for Maximum Specification (Logical address)

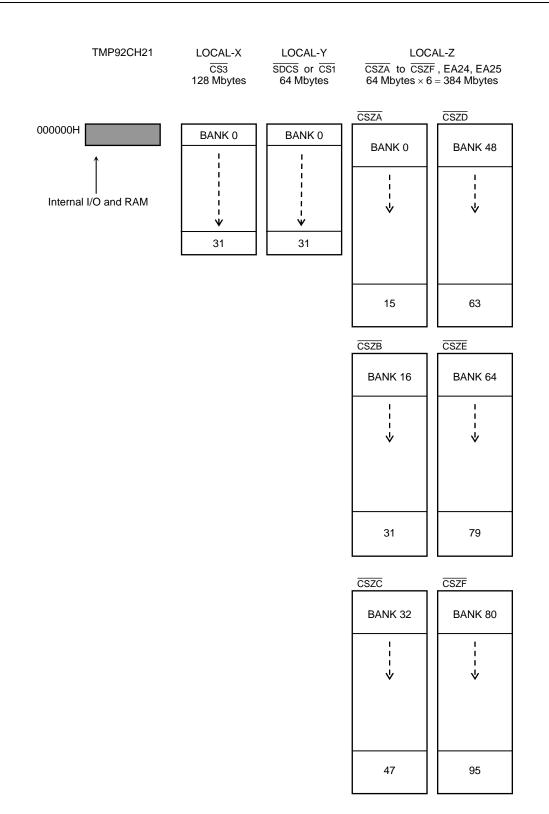

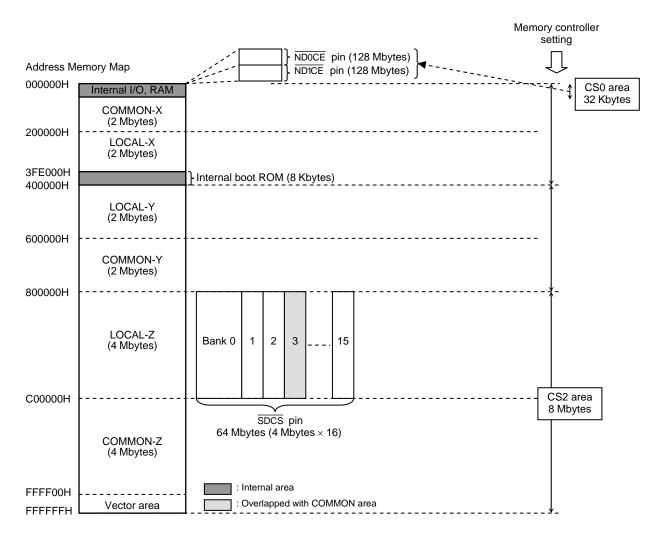

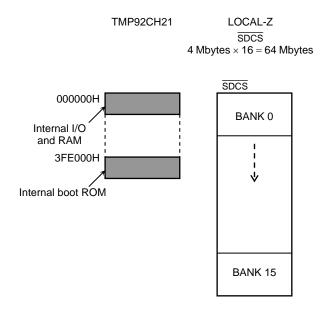

Figure 3.8.2 Recommended Memory Map for Maximum Specification (Physical address)

#### 3.8.2 Control Registers

There are 12 MMU registers, covering 4 functions (program, data read, data write and LCDC display data), in each of 3 local areas (Local-X, Y and Z), providing easy data access.

(Instructions for use)

First, set the enable register and bank number for each LOCAL register.

The relevant pin and memory settings should then be set to the ports and memory controller.

When the CPU or LCDC outputs a local area logical address, the MMU converts and outputs this to the physical address according to the bank number. The physical address bus is output to the external address bus pin, thereby enabling access to external memory.

- Note 1: Since the common area cannot be used as local area, do not set a bank number to LOCAL register which overlaps with the common area.
- Note 2: Changing program BANK number (LOCALPX, Y or Z) is disabled in the LOCAL area. The program bank setting for each local area must be changed in the common area. (But bank setting of read data, write data and data for LCD display can be changed in the local area.)
- Note 3: After data bank number register (LOCALRn, LOCALWn or LOCALLn; where "n" means X, Y or Z) is set by an instruction, do not access its memory by the following instruction because several clocks are required for effective MMU setting. For this reason, insert between them a dummy instruction which accesses SFR or another memory, as in the following example.

(Example)

ld	xix, 200000H	;	
ld	(localrx), 81H	;	Data bank number is set
ld	wa, (localrx)	;	$\leftarrow \text{Inserted dummy instruction which accesses SFR}$
ld	wa, (xix)	;	Instruction which reads BANK 1 of LOCAL-X area.

Note 4: When LOCAL-Z area is used, chip select signal CSZA should be assigned to P82 pin.

In this case,  $\overline{CSZA}$  works as chip select signal for not only BANK 0 to 15 but also COMMON-Z.

The following setting after reset is required before setting Port82.

	5 5	
ld	(localpz), 80H ;	LOCAL-Z bank enable for program
ld	(localrz), 80H ;	LOCAL-Z bank enable for data read
ld	(localwz), 80H ;	LOCAL-Z bank enable for data write (*1)
ld	(locallz), 80H ;	LOCAL-Z bank enable for LCD display memory (*2)
ld	(p8fc),0B;	Set P82 pin to CSZA output
ld	(p8fc2),1B ;	

- (\*1) If COMMON-Z area is not used as data write memory, this setting is not required.
- (\*2) If COMMON-Z area is not used as LCD display memory, this setting is not required.

(1) Program bank register

The bank number used as program memory is set to these registers. It is not possible to change program bank number in the same local area.

				0

	Reset State	0	0	0	0	0	0	0	0
	Function	Bank for LOCAL-Z 0: Disable 1: Enable	Specify the bank number for the LOCAL-Z area (Since bank 3 is overlapping with the COMMON area, this filed must not be specified as 3.)						cified as 3.)

# 3.8.3 Setting Example

Below is	s a setting	example.
----------	-------------	----------

No.	Used as	Memory	Setting	MMU Area	Logical	Physical
NO.	0360 83	Wernory	Setting	NINO Alea	Address	Address
(a)	Main routine	NOR flash (16 Mbytes,	CSZA, 32 bits,	COMMON-Z	C00000H to FFFFFH	
(b)	Character ROM	1 pcs)	1 wait	Bank 0 in LOCAL-Z	800000H to BFFFFFH	000000H to 3FFFFFH
(c)	Sub routine	SRAM	CS1 , 16 bits,	Bank 0 in LOCAL-Y	400000H to 5FFFFFH	000000H to 1FFFFFH
(d)	LCD display RAM	(16 Mbytes, 1 pcs)	0 waits	Bank 1 in LOCAL-Y		200000H to 3FFFFFH
(e)	Stack RAM	Internal RAM (16 Kbytes)	_ (32 bits, 1 clock)	Bank 2 in LOCAL-Y	002000H to	005FFFH

#### (a) Main routine (COMMON-Z)

Logical Address	Physical Address	No		Instruction		Comment
		1	org	C00000H	;	
C00000H	← (Same)	2	ldw	(mamr2), 80FFH	;	CS2 800000-FFFFF/8 Mbytes
C000xxH	←	3	ldw	(b2csl), C222H	;	CS2 32-bit ROM, 1 wait
		4	ldw	(mamr1), 40FFH	;	CS1 400000-7FFFF/4 Mbytes
		5	ldw	(b1csl), 8111H	;	CS1 16-bit RAM, 0 waits
		5.1	ld	(localpz), 80H	;	LOCAL-Z bank enable for program
		5.2	ld	(localrz), 80H	;	LOCAL-Z bank enable for data read
		6	ld	(p8fc), 02H	;	P81: CS1
		7	ld	(p8fc2), 04H	;	P82: CSZA
		8	ld	(pjfc), 07H	;	PJ2: SRWR , PJ1: SRLUB , PJ0: SRLLB
		9	ld	xsp, 6000H	;	Stack pointer = 6000H
		10	ld	(localpy), 80H	;	BANK 0 in LOCAL-Y is set as program for sub routine
		11	:		;	
C000yyH	←	12	call	400000H	;	Call sub routine
		13	:		;	
		14	:		;	
		15	:		;	

- Instructions from No.2 to No.8 are settings for ports and memory controller.
- No.9 is a setting for stack pointer. It is assigned to internal RAM.
- No.10 is a setting to execute No.12's instruction.
- No.12 is an instruction to call sub routine. When CPU outputs 400000H address, this MMU will convert and output 000000H address to external address bus: A23 to A0. And CS1 for SRAM will be asserted because its logical address is in the CS1area at the same time. These instructions allow the CPU to branch to sub routine.

(Note) This example assumes a sub routine program is already written on SRAM.

(b) Sub routine (Bank 0 in LOCAL-Y)

 No.17 and No.18 are settings for BANK 1 of LOCAL-Y. In this case, LCD display data is written to SRAM by CPU.

So, (LOCALWY) and (LOCALLY) should be set to the same BANK 1.

- No.19 is a setting for BANK 0 of LOCAL-Z to read data from character ROM.
- No.20 and No.21 are instructions to read data from character ROM. When CPU outputs 800000H address, this MMU will convert and output 000000H address to external address bus: A23 to A0. And CSZA for NOR flash will be asserted because its logical address is in the CS2 area at the same time.
   These instructions allow the CPU to read data from character ROM.

These instructions allow the CPU to read data from character ROM.

- No.23 is an instruction which changes the program BANK number in the local area. <u>This</u> <u>setting is disabled.</u>
- No.24 and No.25 are instructions to write data to SRAM. When CPU outputs 400000H address, this MMU will convert and output 200000H address to external address bus: A23 to A0. And CS1 for SRAM will be asserted because its logical address is in the CS1area at the same time.

These instructions allow the CPU to write data to SRAM.

No.28 and No.29 are settings to set LCD starting address to LCD controller. When LCDC outputs 400000H address in DMA cycle, this MMU will convert and output 200000H address to external address bus: A23 to A0. And CS1 for SRAM will be asserted because its logical address is in the CS1 area at the same time.
 These instructions allow the LCDC to read data from SRAM.

These instructions allow the LCDC to read data from SRAM

• No.30 is an instruction to start LCD display operation.

# 3.9 Serial Channels

The TMP92CH21 includes 2 serial I/O channels. For each channel, either UART mode (asynchronous transmission) or I/O interface mode (synchronous transmission) can be selected.

I/O interface mode ———	Mode 0:	For transmitting and receiving I/O data using the synchronizing signal SCLK for extending I/O.
UART mode	Mode 1: Mode 2: Mode 3:	7-bit data 8-bit data 9-bit data

In mode 1 and mode 2 a parity bit can be added. Mode 3 has a wakeup function for making the master controller start slave controllers via a serial link (a multi controller system).

Figure 3.9.2, Figure 3.9.3 are block diagrams for each channel.

Each channel can be used independently.

Each channel operates in the same fashion except for the following points; hence only the operation of channel 0 is explained below.

	Channel 0	Channel 1
Pin name	TXD0 (P90 or PF0) RXD0 (P91 or PF1) CTS0 , SCLK0 (P92 or PF2)	TXD1 (PF0) RXD1 (PF1) CTS1, SCLK1 (PF2)
IrDA mode	Yes	No

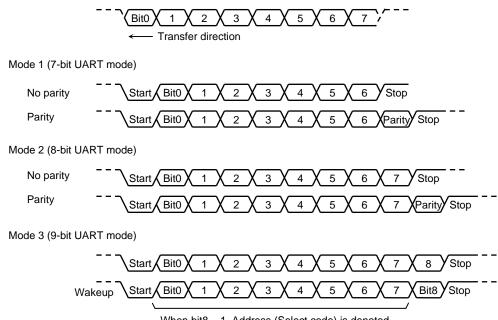

Table 3.9.1 Differences between Channels 0 to 1

This chapter contains the following sections:

- 3.9.1 Block diagram
- 3.9.2 Operation of each circuit
- 3.9.3 SFR
- 3.9.4 Operation in each mode
- 3.9.5 Support for IrDA mode

•

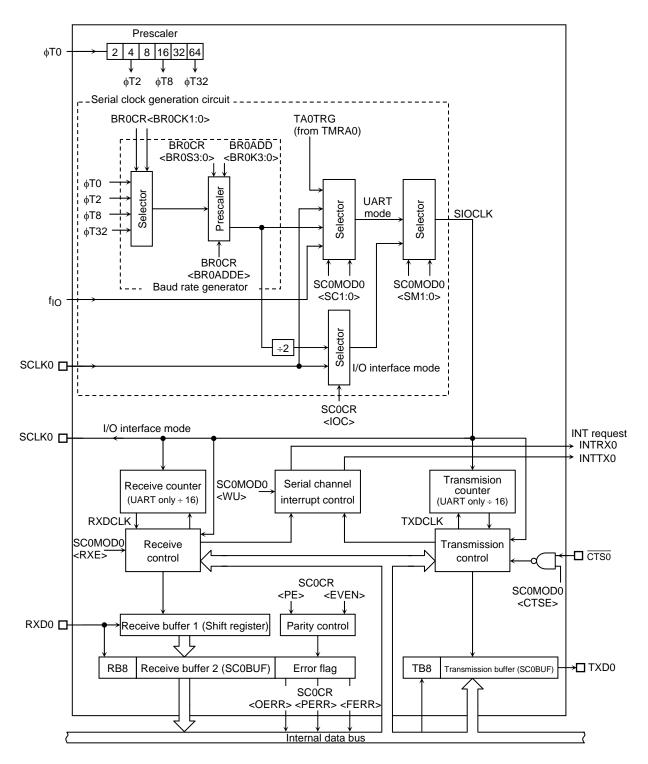

• Mode 0 (I/O interface mode)

When bit8 = 1, Address (Select code) is denoted. When bit8 = 0, Data is denoted.

## 3.9.1 Block Diagrams

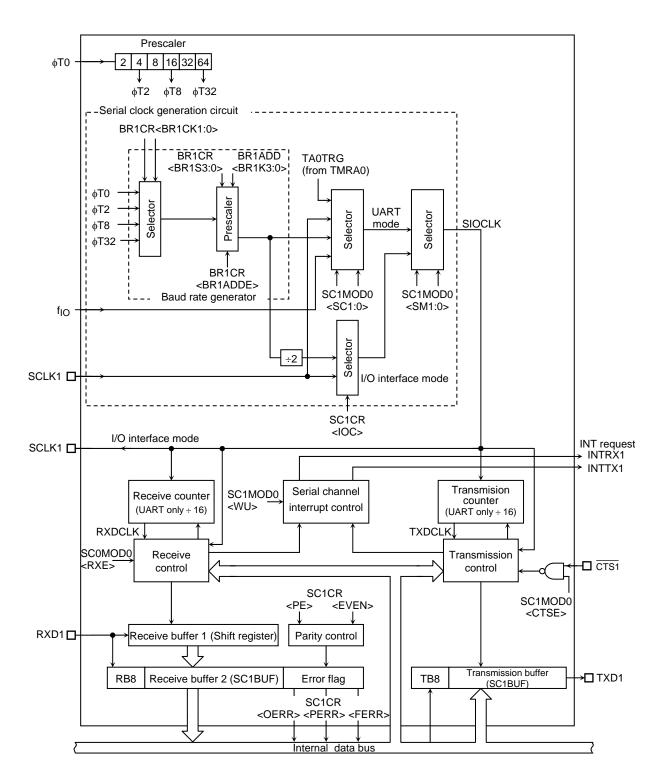

Figure 3.9.3 Block Diagram of Serial Channel 1

# 3.9.2 Operation for Each Circuit

(1) SIO Prescaler and prescaler clock select

There is a 6-bit prescaler for waking serial clock.

The prescaler can be run by selecting the baud rate generator as the waking serial clock.

Table 3.9.2 shows prescaler clock resolution into the baud rate generator.

System clock selection SYSCR1	Clock gear selection SYSCR1	_	Baud rate generator input clock SIO prescaler BR0CR <br0ck1:0></br0ck1:0>				
<sysck></sysck>	<gear2:0></gear2:0>		<b>φ</b> Τ0	φT2(1/4)	φT8(1/16)	φT32(1/64)	
1 (fs)	-		fs/8	fs/32	fs/128	fs/512	
	000(1/1)		fc/8	fc/32	fc/128	fc/512	
	001(1/2)	1/8	fc/16	fc/64	fc/256	fc/1024	
0 (fc)	010(1/4)	1/0	fc/32	fc/128	fc/512	fc/2048	
	011(1/8)		fc/64	fc/256	fc/1024	fc/4096	
	100(1/16)		fc/128	fc/512	fc/2048	fc/8192	

Table 3.9.2 Prescaler Clock Resolution to Baud Rate Generator

The baud rate generator selects between 4 clock inputs:  $\phi T0, \ \phi T2, \ \phi T8, \ and \ \phi T32$  among the prescaler outputs.

(2) Baud rate generator

The baud rate generator is a circuit which generates transmission and receiving clocks that determine the transfer rate of the serial channels.

The input clock to the baud rate generator,  $\phi T0$ ,  $\phi T2$ ,  $\phi T8$  or  $\phi T32$ , is generated by the 6-bit SIO prescaler, which is shared by the timers. One of these input clocks is selected using the BR0CR<BR0CK1:0> field in the baud rate generator control register.

The baud rate generator includes a frequency divider, which divides the frequency by 1 or N + (16 - K)/16 or 16 values, thereby determining the transfer rate.

The transfer rate is determined by the settings of BR0CR<BR0ADDE, BR0S3:0> and BR0ADD<BR0K3:0>.

- In UART mode
- (1) When BROCR < BROADDE > = 0

The settings BR0ADD<BR0K3:0> are ignored. The baud rate generator divides the selected prescaler clock by N, which is set in BR0CK<BR0S3:0>. (N = 1, 2, 3 ...16)

(2) When BROCR < BROADDE > = 1

The N + (16 – K)/16 division function is enabled. The baud rate generator divides the selected prescaler clock by N + (16 – K)/16 using the value of N set in BR0CR<BR0S3:0> (N = 2, 3...15) and the value of K set in BR0ADD<BR0K3:0> (K = 1, 2, 3...15)

Note: If N = 1 or N = 16, the N + (16 - K)/16 division function is disabled. Set BR0CR<BR0ADDE> to 0.

• In I/O interface mode

The N + (16 - K)/16 division function is not available in I/O interface mode. Set BR0CR<BR0ADDE> to 0 before dividing by N.

The method for calculating the transfer rate when the baud rate generator is used is explained below.

• In UART mode

Baud rate = 
$$\frac{\text{Input clock of baud rate generator}}{\text{Frequency divider for baud rate generator}} \div 16$$

• In I/O interface mode

Baud rate =  $\frac{\text{Input clock of baud rate generator}}{\text{Frequency divider for baud rate generator}} \div 2$ 

Integer divider (N divider)

For example, when the source clock frequency (f<sub>C</sub>) is 39.3216 MHz, the input clock is  $\phi$ T2 (f<sub>C</sub>/32), the frequency divider N (BR0CR<BR0S3:0>) = 8, and BR0CR<BR0ADDE> = 0, the baud rate in UART mode is as follows:

\* Clock condition Clock gear : 1/1 Baud rate = Input clock of baud rate generator Frequency divider for baud rate generator  $\div$  16 =  $\frac{fC/32}{8} \div$  16 = 39.3216 × 10<sup>6</sup>  $\div$  16  $\div$  8  $\div$  16 = 9600 (bps)

Note: The N + (16 - K)/16 division function is disabled and setting BR0ADD<BR0K3:0> is invalid.

• N + (16 – K)/16 divider (UART mode only)

Accordingly, when the source clock frequency  $(f_C) = 31.9488$  MHz, the input clock is  $\phi T2$  (f<sub>C</sub>/32), the frequency divider N (BR0CR<BR0S3:0>) = 6, K (BR0ADD<BR0K3:0>) = 8, and BR0CR<BR0ADDE> = 1, the baud rate in UART mode is as follows:

\* Clock condition Clock gear : 1/1 Baud rate =  $\frac{\text{Input clock of baud rate generator}}{\text{Frequency divider for baud rate generator}} \div 16$ =  $\frac{\text{fC}/32}{6 + (16 - 8))} \div 16$ =  $31.9488 \times 10^6 \div 16 \div (6 + \frac{8}{16}) \div 16 = 9600 \text{ (bps)}$ 

Table 3.9.3 show examples of UART mode transfer rates.

Additionally, the external clock input is available in the serial clock. (Serial channels 0 and 1). The method for calculating the baud rate is explained below:

• In UART mode

Baud rate = external clock input frequency ÷ 16

It is necessary to satisfy (External clock input cycle)  $\geq 4/f_{\rm SYS}$ 

• In I/O interface mode

Baud rate = external clock input frequency

It is necessary to satisfy (External clock input cycle)  $\ge 16/f_{SYS}$ 

					Unit (Kops)
f <sub>SYS</sub> [MHz]	Input Clock Frequency Divider	φΤ0 (f <sub>SYS</sub> /4)	φT2 (f <sub>SYS</sub> /16)	фТ8 (f <sub>SYS</sub> /64)	φT32 (f <sub>SYS</sub> /256)

Table 3.9.3 Selection of Transfer Rate (1) (when baud rate generator is used and BR0CR<BR0ADDE> = 0)

Unit (Kbps)

Note: Transfer rates in I/O interface mode are eight times faster than the values given above.

In UART mode, TMRA match detect signal (TA0TRG) can be used for serial transfer clock.

Method for calculating the timer output frequency which is needed when outputting trigger of timer

TA0TRG frequency = Baud rate  $\times$  16

Note: The TMRA0 match detect signal cannot be used as the transfer clock in I/O Interface mode.

(3) Serial clock generation circuit

This circuit generates the basic clock for transmitting and receiving data.

In I/O interface mode

In SCLK output mode with the setting SCOCR < IOC > = 0, the basic clock is generated by dividing the output of the baud rate generator by 2, as described previously.

In SCLK input mode with the setting SCOCR < IOC > = 1, the rising edge or falling edge will be detected according to the setting of the SCOCR < SCLKS > register to generate the basic clock.

• In UART mode

The SC0MOD0<SC1:0> setting determines whether the baud rate generator clock, the internal clock fIO, the match detect signal from TMRA0 or the external clock (SCLK0) is used to generate the basic clock SIOCLK.

(4) Receiving counter

The receiving counter is a 4-bit binary counter used in UART mode, which counts up the pulses of the SIOCLK clock. It takes 16 SIOCLK pulses to receive 1 bit of data; each data bit is sampled three times, on the 7th, 8th and 9th clock cycles.

The value of the data bit is determined from these three samples using the majority rule.

For example, if the data bit is sampled respectively as 1, 0 and 1 on 7th, 8th and 9th clock cycles, the received data bit is taken to be 1. A data bit sampled as 0, 0 and 1 is taken to be 0.

- (5) Receiving control
  - In I/O interface mode

In SCLK output mode with the setting SCOCR < IOC > = 0, the RXD0 signal is sampled on the rising edge or falling of the shift clock, which is output on the SCLK0 pin, according to the SCOCR < SCLKS> setting.

In SCLK input mode with the setting SCOCR < IOC > = 1, the RXD0 signal is sampled on the rising or falling edge of the SCLK0 input, according to the SCOCR < SCLKS> setting.

• In UART mode

The receiving control block has a circuit which detects a start bit using the majority rule. Received bits are sampled three times; when two or more out of three samples are 0, the bit is recognized as the start bit and the receiving operation commences.

The values of the data bits that are received are also determined using the majority rule.

(6) The receiving buffers

To prevent overrun errors, the receiving buffers are arranged in a double buffer structure.

Received data is stored one bit at a time in receiving buffer 1 (which is a shift register). When 7 or 8 bits of data have been stored in receiving buffer 1, the stored data is transferred to receiving buffer 2 (SC0BUF); this causes an INTRX0 interrupt to be generated. The CPU only reads receiving buffer 2 (SC0BUF). Even before the CPU reads receiving buffer 2 (SC0BUF), the received data can be stored in receiving buffer 1. However, unless receiving buffer 2 (SC0BUF) is read before all bits of the next data are received by receiving buffer 1, an overrun error occurs. If an overrun error occurs, the contents of receiving buffer 1 will be lost, although the contents of receiving buffer 2 and SC0CR<RB8> will be preserved.

SCOCR < RB8 > is used to store either the parity bit – added in 8-bit UART mode – or the most significant bit (MSB) – in 9-bit UART mode.

In 9-bit UART mode the wakeup function for the slave controller is enabled by setting SC0MOD0<WU> to 1; in this mode INTRX0 interrupts occur only when the value of SC0CR<RB8> is 1.

SIO interrupt mode is selectable by the register SIMC.

(7) Transmission counter

The transmission counter is a 4-bit binary counter used in UART mode and which, like the receiving counter, counts the SIOCLK clock pulses; a TXDCLK pulse is generated every 16 SIOCLK clock pulses.

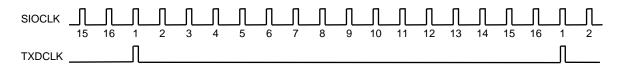

Figure 3.9.4 Generation of the Transmission Clock

- (8) Transmission controller
  - In I/O interface mode

In SCLK output mode with the setting SCOCR < IOC > = 0, the data in the transmission buffer is output one bit at a time to the TXD0 pin on the rising or falling edge of the shift clock which is output on the SCLK0 pin, according to the SCOCR < SCLKS> setting.

In SCLK input mode with the setting SCOCR < IOC > = 1, the data in the transmission buffer is output one bit at a time on the TXD0 pin on the rising or falling edge of the SCLK0 input, according to the SCOCR <SCLKS> setting.

• In UART mode

When transmission data sent from the CPU is written to the transmission buffer, transmission starts on the rising edge of the next TXDCLK, generating a transmission shift clock TXDSFT.

Handshake function

Use of  $\overline{\text{CTS0}}$  pin allows data to be sent in units of one frame; thus, overrun errors can be avoided. The handshake function is enabled or disabled by the SC0MOD<CTSE> setting.

When the  $\overline{\text{CTS0}}$  pin goes high on completion of the current data send, data transmission is halted until the  $\overline{\text{CTS0}}$  pin goes low again. However, the INTTX0 interrupt is generated, and it requests the next data send from the CPU. The next data is written in the transmission buffer and data sending is halted.

Though there is no  $\overline{\text{RTS}}$  pin, a handshake function can be easily configured by setting any port assigned to be the  $\overline{\text{RTS}}$  function. The  $\overline{\text{RTS}}$  should be output "high" to request send data halt after data receive is completed by software in the RXD interrupt routine.

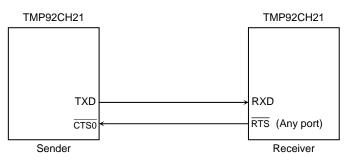

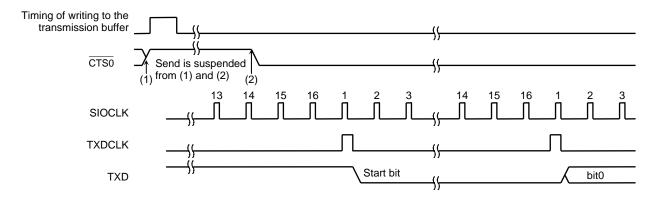

Figure 3.9.5 Handshake Function

Note 1: If the CTS0 signal goes high during transmission, no more data will be sent after completion of the current transmission.

Note 2: Transmission starts on the first falling edge of the TXDCLK clock after the  $\overline{\text{CTS0}}$  signal has fallen.

Figure 3.9.6  $\overline{CTS0}$  (Clear to send) Timing

(9) Transmission buffer

The transmission buffer (SC0BUF) shifts out and sends the transmission data written from the CPU in order from the least significant bit (LSB). When all the bits are shifted out, the transmission buffer becomes empty and generates an INTTX0 interrupt.

(10) Parity control circuit

When SCOCR<PE> in the serial channel control register is set to "1", it is possible to transmit and receive data with parity. However, parity can be added only in 7-bit UART mode or 8-bit UART mode. The SCOCR<EVEN> field in the serial channel control register allows either even or odd parity to be selected.

In the case of transmission, parity is automatically generated when data is written to the transmission buffer SCOBUF. The data is transmitted after the parity bit has been stored in SCOBUF<TB7> in 7-bit UART mode or in SCOMODO<TB8> in 8-bit UART mode. SCOCR<PE> and SCOCR<EVEN> must be set before the transmission data is written to the transmission buffer.

In the case of receiving, data is shifted into receiving buffer 1, and the parity is added after the data has been transferred to receiving buffer 2 (SC0BUF), and then compared with SC0BUF<RB7> in 7-bit UART mode or with SC0CR<RB8> in 8-bit UART mode. If they are not equal, a parity error is generated and the SC0CR<PERR> flag is set.

(11) Error flags

Three error flags are provided to increase the reliability of data reception.

1. Overrun error <OERR>

If all the bits of the next data item have been received in receiving buffer 1 while valid data still remains stored in receiving buffer 2 (SC0BUF), an overrun error is generated.

The below is a recommended flow when the overrun-error is generated.

(INTRX interrupt routine)

- 1) Read receiving buffer
- 2) Read error flag
- 3) If  $\langle OERR \rangle = 1$

then

- a) Set to disable receiving (Write "0" to SC0MOD0<RXE>)
- b) Wait to terminate current frame
- c) Read receiving buffer
- d) Read error flag
- e) Set to enable receiving (Write "1" to SC0MOD0<RXE>)
- f) Request to transmit again
- 4) Other

2. Parity error <PERR>

The parity generated for the data shifted into receiving buffer 2 (SC0BUF) is compared with the parity bit received via the RXD pin. If they are not equal, a parity error is generated.

3. Framing error <FERR>

The stop bit for the received data is sampled three times around the center. If the majority of the samples are 0, a framing error is generated.

## (12) Timing generation

## 1. In UART mode

### Receiving

Mode	9 Bits (Note)	8 Bits + Parity (Note)	8 Bits, 7 Bits + Parity, 7 Bits
Interrupt Timing	Center of last bit (bit8)	Center of last bit (parity bit)	Center of stop bit
Framing Error Timing	Center of stop bit	Center of stop bit	Center of stop bit
Parity Error Timing	_	Center of last bit (parity bit)	Center of stop bit
Overrun Error Timing	Center of last bit (bit8)	Center of last bit (parity bit)	Center of stop bit

Note:

In 9-bit and 8-bit + parity modes, interrupts coincide with the ninth bit pulse.

Thus, when servicing the interrupt, it is necessary to wait for a 1-bit period (to allow the stop bit to be transferred) to allow checking for a framing error.

#### Transmitting

Mode	9 Bits	8 Bits + Parity	8 Bits, 7 Bits + Parity, 7 Bits
Interrupt Timing	Just before stop bit is transmitted	Just before stop bit is transmitted	Just before stop bit is transmitted

### 2. I/O interface

Transmission Interrupt	SCLK output mode	Immediately after last bit data. (See Figure 3.9.19.)
Timing	SCLK input mode	Immediately after rise of last SCLK signal rising mode, or immediately after fall in falling mode. (See Figure 3.9.20.)
Receiving Interrupt	SCLK output mode	Timing used to transfer received to data receive buffer 2 (SC0BUF) (e.g. immediately after last SCLK). (See Figure 3.9.21.)
Timing	SCLK input mode	Timing used to transfer received data to receive buffer 2 (SC0BUF) (e.g. immediately after last SCLK). (See Figure 3.9.22.)

Figure 3.9.16 Serial Mode Control Register 1 (Channel 1, SC1MOD1)

# 3.9.4 Operation in Each Mode

(1) Mode 0 (I/O interface mode)

This mode allows an increase in the number of I/O pins available for transmitting data to or receiving data from an external shift register.

This mode includes the SCLK output mode to output synchronous clock SCLK, and SCLK input mode to input external synchronous clock SCLK.

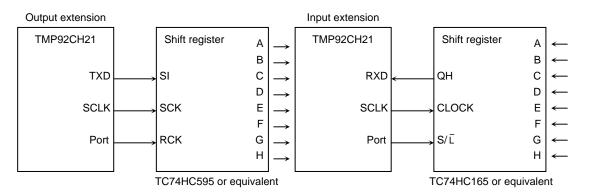

Figure 3.9.17 SCLK Output Mode Connection Example

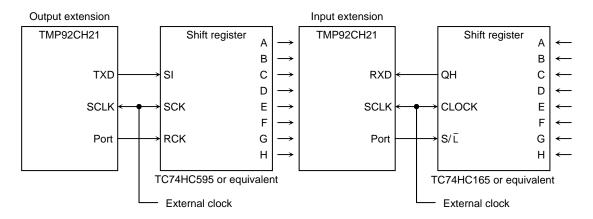

Figure 3.9.18 Example of SCLK Input Mode Connection

1. Transmission

In SCLK output mode 8-bit data and a synchronous clock are output on the TXD0 and SCLK0 pins respectively each time the CPU writes data to the transmission buffer. When all data is output, INTESO<ITX0C> will be set to generate the INTTX0 interrupt.

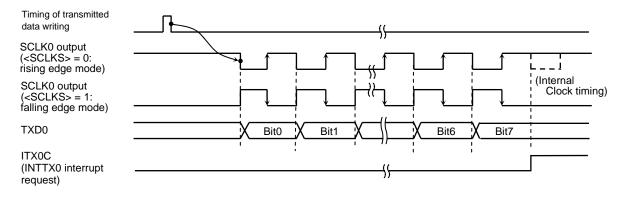

Figure 3.9.19 Transmitting Operation in I/O Interface Mode (SCLK0 output mode) (Channel 0)

In SCLK input mode, 8-bit data is output on the TXD0 pin when the SCLK0 input becomes active after the data has been written to the transmission buffer by the CPU.

When all data is output, INTESO<ITX0C> will be set to generate an INTTX0 interrupt.

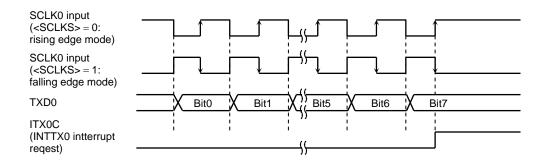

Figure 3.9.20 Transmitting Operation in I/O Interface Mode (SCLK0 input mode) (Channel 0)

2. Receiving

In SCLK output mode the synchronous clock is output on the SCLK0 pin and the data is shifted to receiving buffer 1. This is initiated when the receive interrupt flag INTESO<IRX0C> is cleared as the received data is read. When 8-bit data is received, the data is transferred to receiving buffer 2 (SC0BUF) following the timing shown below and INTESO<IRX0C> is set to 1 again, causing an INTRX0 interrupt to be generated.

Setting SC0MOD0<RXE> to 1 initiates SCLK0 output.

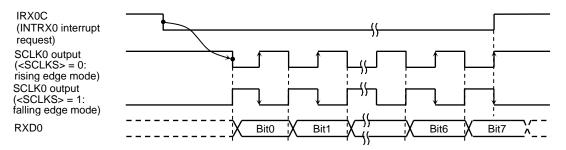

Figure 3.9.21 Receiving Operation in I/O Interface Mode (SCLK0 output mode)

In SCLK input mode the data is shifted to receiving buffer 1 when the SCLK input goes active. The SCLK input goes active when the receive interrupt flag INTESO<IRXOC> is cleared as the received data is read. When 8-bit data is received, the data is shifted to receiving buffer 2 (SCOBUF) following the timing shown below and INTESO<IRXOC> is set to 1 again, causing an INTRXO interrupt to be generated.

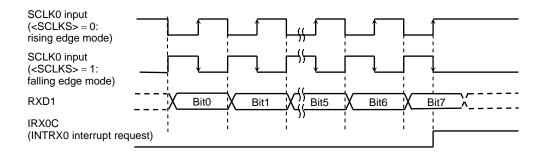

Figure 3.9.22 Receiving Operation in I/O Interface Mode (SCLK0 input mode)

Note: The system must be put in the receive-enable state (SC0MOD0<RXE> = 1) before data can be received.

3. Transmission and receiving (Full duplex mode)

When full duplex mode is used, set the receive interrupt level to 0, and only set the interrupt level (from 1 to 6) of the transmit interrupt. Ensure that the program which transmits the interrupt reads the receiving buffer before setting the next transmit data.

The following is an example of this:

Example:	Channel 0, SCLK output Baud rate = 9600 bps fc = 4.9152 MHz								
				*Cl	ock	c co	ndi	tion:	Clock gear 1/1(fc)
Main routine									
	7	6	5	4	3	2	1	0	
INTES0	Х	0	0	1	Х	0	0	0	Set the INTTX0 level to 1. Set the INTRX0 level to 0.
PFCR	Х	Х	Х	Х	Х	1	0	1	Set PF0, PF1 and PF2 to function as the TXD0,
PFFC	-	Х	Х	Х	Х	1	0	1	RXD0 and SCLK0 pins respectively.
SC0MOD0	-	-	-	-	0	0	-	-	Select I/O interface mode.

SC0BUF	*	*	*	*	*	*	*	*	Set the next transmit data.
X: Don't care, -: I	No c	hang	ge						

(2) Mode 1 (7-bit UART mode)

7-bit UART mode is selected by setting the serial channel mode register SC0MOD0<SM1:0> field to 01.

In this mode a parity bit can be added. Use of a parity bit is enabled or disabled by the setting of the serial channel control register SCOCR<PE> bit; whether even parity or odd parity will be used is determined by the SCOCR<EVEN> setting when SCOCR<PE> is set to 1 (enabled).

Setting example: When transmitting data of the following format, the control registers should be set as described below.

/	Star <del>&lt;</del>	t	Bit0	X Tran	1 Ismi:	ssioi	2 n dir	3 rectio		$\frac{4}{5} \underbrace{6}_{\text{parity}} \underbrace{\text{Stop}}_{\text{Stop}}$ ransmission rate: 2400 bps at f <sub>C</sub> = 39.3216 MHz)
*Clock condition: Clock gear 1/1(fc)										
		7	6	5	4	3	2	1	0	
PFCR	←	Х	Х	Х	Х	Х	_	_	1	
PFFC	←	-	Х	Х	Х	Х	-	-	1	Set PF0 to function as the TXD0 pin.
SC0MOD0	←	-	0	-	-	0	1	0	1	Select 7-bit UART mode.
SC0CR	←	-	1	1	-	-	-	0	0	Add even parity.
BR0CR	←	0	0	1	0	1	0	0	0	Set the transfer rate to 2400 bps.
INTES0	←	Х	1	0	0	_	_	_	-	Enable the INTTX0 interrupt and set it to interrupt level 4.
SC0BUF	←	*	*	*	*	*	*	*	*	Set data for transmission.
X: Don't car	e, -:	No	cha	nge						

#### (3) Mode 2 (8-bit UART mode)

8-bit UART mode is selected by setting SC0MOD0<SM1:0> to 10. In this mode a parity bit can be added (use of a parity bit is enabled or disabled by the setting of SC0CR<PE>); whether even parity or odd parity will be used is determined by the SC0CR<EVEN> setting when SC0CR<PE> is set to 1 (enabled).

Setting example: When receiving data of the following format, the control registers should be set as described below.

------ Transmission direction (Transmission rate: 9600 bps at  $f_C = 39.3216$  MHz)

Main settings	6								
	7	6	5	4	3	2	1	0	
PFCR	← X	Х	Х	Х	Х	-	0	_	Set PF1 to function as the RXD0 pin.
PFFC	$\leftarrow$ -	Х	Х	Х	Х	-	0	_	
SC0MOD0	$\leftarrow$ -	0	1	-	1	0	0	1	Enable receiving in 8-bit UART mode.
SC0CR	$\leftarrow$ -	0	1	-	-	-	0	0	Add odd parity.

if A <sub>CC</sub> ≠ 0 the	en ERRC	DR							
A <sub>CC</sub>	← SC	COBL	JF						Read the received data
X: Don't care,	-: No cł	nang	je						

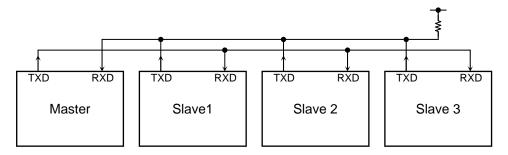

### (4) Mode 3 (9-bit UART mode)

9-bit UART mode is selected by setting SC0MOD0<SM1:0> to 11. In this mode a parity bit cannot be added.

In the case of transmission the MSB (9th bit) is written to SCOMOD0<TB8>. In the case of receiving it is stored in SCOCR<RB8>. When the buffer is written or read, <TB8>or <RB8> is read or written first, before the rest of the SCOBUF data.

#### Wakeup function

In 9-bit UART mode, the wakeup function for slave controllers is enabled by setting SC0MOD0<WU> to 1. The interrupt INTRX0 can only be generated when<RB8> = 1.

Note: The TXD pin of each slave controller must be in open-drain output mode.

Figure 3.9.23 Serial Link Using Wakeup Function

# Protocol

- 1. Select 9-bit UART mode on the master and slave controllers.
- 2. Set the SC0MOD0<WU> bit on each slave controller to 1 to enable data receiving.
- 3. The master controller transmits data one frame at a time. Each frame includes an 8-bit select code which identifies a slave controller. The MSB (bit8) of the data (<TB8>) is set to 1.

- 4. Each slave controller receives the above frame. Each controller checks the above select code against its own select code. The controller whose code matches clears its <WU> bit to 0.
- 5. The master controller transmits data to the specified slave controller (the controller whose SC0MOD0<WU> bit has been cleared to 0). The MSB (bit8) of the data (<TB8>) is cleared to 0.

6. The other slave controllers (whose <WU> bits remain at 1) ignore the received data because their MSBs (bit8 or <RB8>) are set to 0, disabling INTRX0 interrupts. The slave controller whose <WU> bit = 0 can also transmit to the master controller. In this way it can signal the master controller that the data transmission from the master controller has been completed.

Setting example: To link two slave controllers serially with the master controller using the internal clock fIO as the transfer clock.

## 3.9.5 Support for IrDA

SIO0 includes support for the IrDA 1.0 infrared data communication specification. Figure 3.9.24 shows the block diagram.

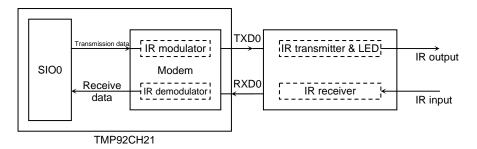

Figure 3.9.24 Block Diagram

(1) Modulation of the transmission data

When the transmit data is 0, the modem outputs 1 to TXD0 pin with either 3/16 or 1/16 times for width of baud rate. The pulse width is selected by the SIRCR<PLSEL>.

When the transmit data is 1, the modem outputs 0.

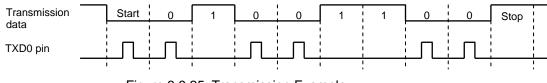

Figure 3.9.25 Transmission Example

(2) Modulation of the receive data

When the receive data has an effective pulse width of "1", the modem outputs "0" to SIO0. Otherwise the modem outputs "1" to SIO0. The effective pulse width is selected by SIRCR<SIRWD3:0>.

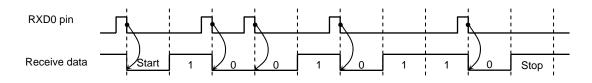

Figure 3.9.26 Receiving Example

(3) Data format

The data format is fixed as follows:

- Data length: 8 bits
- Parity bits: none
- Stop bits: 1 bit
- (4) SFR

Figure 3.9.27 shows the control register SIRCR. Set SIRCR data while SIO0 is stopped. The following example describes how to set this register:

1)	SIO settin ↓	g	;	Set the SIO to UART mode.
	LD LD ↓	(SIRCR), 07H (SIRCR), 37H	, , ,	Set the receive data pulse width to 16×. TXEN, RXEN Enable the transmission and receiving.
4)	Start trans	mission ring for SIO0	;	<ul><li>The modem operates as follows:</li><li>SIO0 starts transmitting.</li></ul>

• IR receiver starts receiving.

- (5) Notes
  - 1. Baud rate for IrDA

When IrDA is operated, set 01 to SC0MOD0<SC1:0> to generate baud rate. Settings other than the above (TA0TRG, f<sub>IO</sub> and SCLK0 input) cannot be used.

2. The pulse width for transmission

The IrDA 1.0 specification is defined in Table 3.9.4.

				•	
Baud Rate	Modulation	Rate Tolerance (% of rate)	Pulse Width (min)	Pulse Width (typ.)	Pulse Width (max)
2.4 Kbps	RZI	±0.87	1.41 μs	78.13 μs	88.55 μs
9.6 Kbps	RZI	±0.87	1.41 μs	19.53 μs	22.13 μs
19.2 Kbps	RZI	±0.87	1.41 μs	9.77 μs	11.07 μs
38.4 Kbps	RZI	±0.87	1.41 μs	4.88 μs	5.96 μs
57.6 Kbps	RZI	±0.87	1.41 μs	3.26 μs	4.34 μs
115.2 Kbps	RZI	±0.87	1.41 μs	1.63 μs	2.23 μs

Table 3.9.4 Baud Rate and Pulse Width Specifications

The pulse width is defined as either baud rate T  $\times$  3/16 or 1.6 µs (1.6 µs is equal to 3/16 pulse width when baud rate is 115.2 Kbps).

The TMP92CH21 has a function which can select the pulse width of transmission as either 3/16 or 1/16. However, 1/16 pulse width can only be selected when the baud rate is equal to or less than 38.4 Kbps.

For the same reason, when using IrDA 115.2 Kbps with USB, the +(16 - K)/16 division function in the baud rate generator of SIO0 cannot be used to generate a 115.2 Kbps baud rate, except under special conditions as explained in (6) below.

The + (16 - K)/16 division function cannot be used also when the baud rate is 38.4 Kbps and the pulse width is 1/16.

	Table 3.9.5	Baud Rate and Pulse	Width for (16 – K	)/16 Division Function
--	-------------	---------------------	-------------------	------------------------

Pulse Width		Baud Rate							
Fuise Width	115.2 Kbps	57.6 Kbps	38.4 Kbps	19.2 Kbps	9.6 Kbps	2.4 Kbps			
T × 3/16	× (Note)	0	0	0	0	0			
T × 1/16	-	-	×	0	0	0			

 $\odot$ : (16 – K)/16 division function can be used.

 $\times$ : (16 – K)/16 division function cannot be used.

-: Cannot be set to 1/16 pulse width.

Note: (16 – K)/16 division function can be used under special

conditions.

(6) Using IrDA 115.2 Kbps with USB

When the system uses USB , set fosch to 9.0 MHz. In this case, the IrDA cannot be 115.2 Kbps without using the (16 – K)/16 division function.

Therefore, only in this case, the following conditions can be used.

(Setting condition)

- $f_{OSCH} = 9.0 \text{ MHz}$ , PLL on  $\rightarrow f_{FPH} = 36 \text{ MHz}$ ,  $f_{USB} = 48 \text{ MHz}$
- Clock for baud rate generator =  $\phi T0$
- Divided value for baud rate generator = 2 + (16 9)/16
- Pulse width = 3/16

(Calculation result)

- Baud rate = 36 MHz/128/(2 + 7/16) = 115.38 KbpsThis baud rate includes a +0.156 % error, but IrDA specification is within  $\pm 0.87$  %.
- Pulse width =  $(1/281.25 \text{ Kbps}) \times (2 \times (1/16) + 3 \times (2/16)) = 1.777 \text{ } \mu\text{s}$ This pulse width is greater than 1.41  $\mu\text{s}$  (IrDA specification).

	7	6	5	4	3		2	1	0
SIRCR Bit symbol	PLSEL	RXSEL	TXEN	RXEN	SIRWE	D3	SIRWD2	SIRWD1	SIRWD0
(1207H) Read/Write				R	/W				
Reset State	0	0	0	0	0		0	0	0
Function	Select transmit pulse width 0: 3/16 1: 1/16	Receive data 0: "H" pulse 1: "L" pulse	Transmit 0: Disable 1: Enable	Receive 0: Disable 1: Enable		ctive pu - 1) + 1 set: 1 t	100 ns to 14	equal to or m	ore than 2x ×
					Formula: x = 1/f <sub>SYS</sub> 0000 0001 to 1110 1111 Receive c 0 1 Transmit 0 1 Select tra 0	Effectives S Canno Equal Equal Canno Operatio Disable Disable Disable Disable Disable	ot be set to or more t ot be set on le (Received e ion le (Input from	th $\ge 2x \times (value)$ han 4x + 100 han 30x + 100 l input is ignor	0 ns

Note: If a pulse width complying with IrDA1.0 standard (1.6

 $\mu s$  min.) can be guaranteed with a low baud rate, setting this bit to "1" will result in reduced power dissipation.

Figure 3.9.27 IrDA Control Register

# 3.10 USB Controller

### 3.10.1 Outline

This USB controller (UDC) is designed to support a variety of serial links in the construction of a USB system.

The outline is as follows:

- (1) Compliant with USB rev1.1
- (2) Full-speed: 12 Mbps (low-speed (1.5 Mbps) not supported)
- (3) Auto bus enumeration with 384-byte descriptor RAM
- (4) Supports 3 kinds of transfer type: Control, interrupt and bulk

Endpoint 0:	Control	$64 \text{ bytes} \times 1\text{-}\mathrm{FIFO}$
Endpoint 1:	BULK (out)	$64 \text{ bytes} \times 2\text{-}\mathrm{FIFO}$
Endpoint 2:	BULK (in)	64 bytes $\times$ 2-FIFO
Endpoint 3:	Interrupt (in)	$8 \text{ bytes} \times 1\text{-}\text{FIFO}$

- (5) Built-in DPLL which generates sampling clock for receive data
- (6) Detecting and generating SOP, EOP, RESUME, RESET and TIMEOUT
- (7) Encoding and decoding NRZI data
- (8) Inserting and discarding stuffed bit
- (9) Detecting and checking CRC
- (10) Generating and decoding packet ID
- (11) Built-in power management function
- (12) dual packet mode supported
- Note1:The TMP92CH21 does not include the pull-up resistor necessary for D+pin. An external pull-up resistor plus software support is required.
- Note2:There are some differences between our specifications and USB 1.1. Refer to "3.10.11 Notice and Restrictions".

## 3.10.1.1 System Configuration

The USB controller (UDC) consists of the following 3 blocks.

- 1. 900/H1 CPU I/F (details given in Section 3.10.2, below).
- 2. UDC core block (DPLL, SIE, IFM and PWM), request controller, descriptor RAM and 4 endpoint FIFO (details given in Section 3.10.3, below).
- 3. USB transceiver

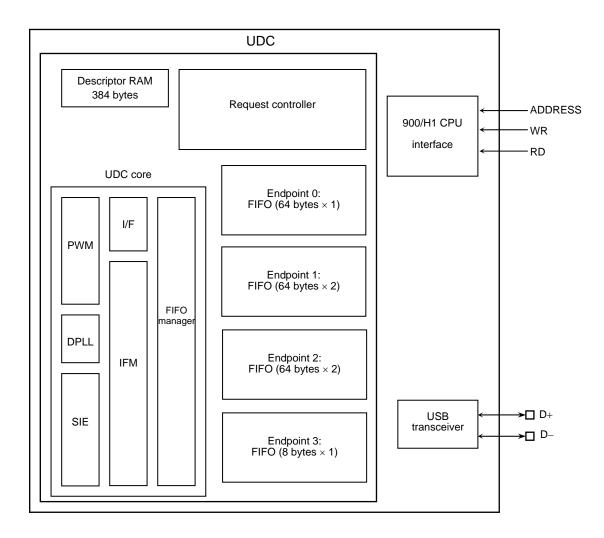

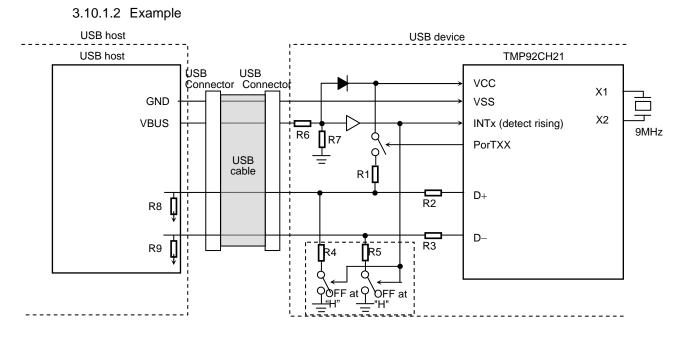

Figure 3.10.1 UDC Block Diagram

The above setting is required when using the TMP92CH21's USB controller.

- 1) Pull-up of D<sup>+</sup> pin
  - In the USB standard, in Full Speed connection, the D<sup>+</sup> pin must be set to pull-up. The ON/OFF control of this pull-up must be by S/W. Recommended value:  $R1=1.5k\Omega$
- 2) Add cascade resistor of D<sup>+</sup>, D<sup>-</sup>signal
  - In the USB standard, for a D+ or D<sup>-</sup> signal, a cascade resistor must be added to each signal. Recommended value :  $R2=27\Omega$ ,  $R3=27\Omega$
- 3) Flow current provision of the Connector connection and D<sup>+</sup> pin, D<sup>-</sup> pin
  - For the D<sup>+</sup> and D<sup>-</sup> pin of the TMP92CH21, the level must be fixed for flow current provision when not in use (when not connected to host). In this case, the connector detection signal is used to control the pull-down resistor which determines the level..

Recommended value: R4=10kΩ, R5=10kΩ

• The example shows use of the connector detection method using VBUS (5V voltage).

Note: Where waveform rise is solw, buffering of waveform is recommended .

Recommended value:  $R6=60k\Omega$ ,  $R7=100k\Omega$ 

(VBUS current consumption when suspended is  ${<}500\mu\text{A})$ 

- 4) Connection of 9MHz oscillator to X1, X2.
  - When using USB with a combination of 9MHz external oscillator and internal PLL, the number of external hub stages which can be used is restricted by the accuracy of the internal PLL (Max 3 stages).
- 5) HOST side pull-down resistor
  - In the USB standard, set pull-down  $D^+$  pin and  $D^-$  signal at USB\_HOST side. Recommended value: R8=15k\Omega, R9=15k\Omega

Note: The above connections and resistor values, etc, are given as examples only. Operation is not guaranteed. Please confirm the latest USB standard specifications and operations on your system.

## 3.10.2 900/H1 CPU I/F

The 900/H1 CPU I/F is a bridge between the 900/H1 CPU and the UDC. Its main functions are as follows:

- INTUSB (interrupt from UDC) generation
- A bridge for SFR
- USB clock control (48 MHz)

## 3.10.2.1 SFRs

The 900/H1 CPU I/F incorporates the following SFRs to control the UDC and USB transceiver.

- USB control USBCR1 (USB control register 1)
- USB interrupt control

USBINTFR1	(USB interrupt flag register 1)
USBINTFR2	(USB interrupt flag register 2)
USBINTFR3	(USB interrupt flag register 3)
USBINTFR4	(USB interrupt flag register 4)
USBINTMR1	(USB interrupt mask register 1)
USBINTMR2	(USB interrupt mask register 2)
USBINTMR3	(USB interrupt mask register 3)
USBINTMR4	(USB interrupt mask register 4)

Address	Read/Write	SFR Symbol
07F0H	R/W	USBINTFR1
07F1H	R/W	USBINTFR2
07F2H	R/W	USBINTFR3
07F3H	R/W	USBINTFR4
07F4H	R/W	USBINTMR1
07F5H	R/W	USBINTMR2
07F6H	R/W	USBINTMR3
07F7H	R/W	USBINTMR4
07F8H	R/W	USBCR1

#### Table 3.10.1 900/H1 CPU I/F SFR

### 3.10.2.2 USBCR1 Register

This register is used to set USB clock enables, transceiver enable etc.

		7	6	5	4	3	2	1	0
USBCR1 (07F8H)	bit Symbol	TRNS_USE	WAKEUP			/	-	SPEED	USBCLKE
	Read/Write	R/W	R/W		/	/	R/W	R/W	R/W
	Reset State	0	0				0	1	0
	Function						Always write "0"		

- TRNS\_USE (Bit7)
  - 0: Disable USB transceiver

1: Enable USB transceiver

- Always set to "1" on the application using USB.
- WAKEUP (Bit6)
  - 0: -
  - 1: Start remote-wakeup function

When the remote-wakeup function is needed, first check Current\_Config<REMOTE WAKEUP>.

If <REMOTE WAKEUP> = "1" (meaning SUSPEND-status), write "1", and "0" to <WAKEUP>. This will initiate the remote-wakeup function.

If the <REMOTE WAKEUP> = "0" or EP0, 1, 2, 3\_STATUS<SUSPEND> = "0", do not write "1" to <WAKEUP>.

- SPEED (Bit1)
  - 1: Full speed (12 MHz)
  - 0: Reserved

This bit selects USB speed.

Always set to "1".

- USBCLKE (Bit0)
  - 0: Disable USB clock
  - 1: Enable USB clock

This bit controls supply of USB clock.

The USB clock ("fusB": 48MHz) is generated by an internal PLL. When the USB is started, write "1" to <USBCLKE> after confirming PLL lock up is terminated.

Also, write "0" to <USBCLKE> before stopping the PLL.

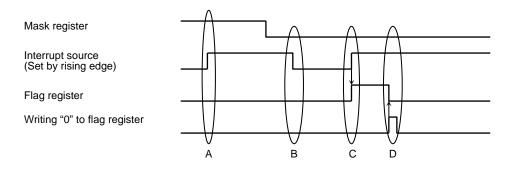

#### 3.10.2.3 USBINTFRn, MRn Register

These SFRs control the INTUSB (only one interrupt to CPU) using the 23 interrupt sources output by the UDC.

The USBINTMRn are mask registers and the USBINTFRn are flag registers. In the INTUSB routine, execute operations according to generated interrupt source after checking USBINTFRn.

The common specification for all MASK and FLAG registers is shown below.

(Common specifications for all mask and flag registers.)

A: The flag register is not set because mask register = "1".

B: The flag register is not set because interrupt souce changes "1"  $\rightarrow$  "0".

C: The flag register is set because mask register = "0" and interrupt souce changes " $0" \rightarrow$  "1".

D: The flag register is reset to "0" by writing "0" to flag register.

Note 1: The "INTUSB generated number" and "bit number which is set to flag register" are not always equal. In the INTUSB interrupt routine, clear FLAG register (USBINTFRn) after checking it. The interrupt request flag, which occurs between the INTUSB interrupt routine and flag register (USBINTFRn) read, is kept in the interrupt controller.

Therefore, after returning from the interrupt routine, the CPU jumps to INTUSB interrupt routine again. Software support is required to avoid ending in an error routine when none of the bits in the flag register (USBINTFRn) is set to "1".

Note 2: Disable INTUSB (write 00H to INTEUSB register) before writing to USBINTMRn or USBINTFRn .

USBINTFR1

(07F0H)	(	(07	F0	H)	
---------	---	-----	----	----	--

	7	6	5	4	3	2	1	0
bit Symbol	INT_URST_STR	INT_URST_END	INT_SUS	INT_RESUME	INT_CLKSTOP	INT_CLKON		
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W		
Reset State	0	0	0	0	0	0		
Function	When read	0: Not generate 1: Generate int	•	: Clear flag : –				

Note: The above interrupts can release Halt state from IDLE2 and IDLE1 mode. (STOP mode cannot be released) \*Those 6 interrupts of all 24 INTUSB sources can release Halt state from IDLE1 mode. Therefore, a low power dissipation system can be built. However, the method of use is limited as below.

Shift to IDLE1 mode :

Execute Halt instruction when the INT\_SUS or INT\_CLKSTOP flag is "1" (SUSPEND state) Release from IDLE1 mode :

> Release Halt state by INT\_RESUME or INT\_CLKON request (request of release SUSPEND) Release Halt state by INT\_URST\_STR or INT\_URST\_END request (request of RESET)

• INT\_URST\_STR (Bit7)

This is the flag register for INT\_URST\_STR ("USB reset" start - interrupt).

This is set to "1" when the UDC starts to receive a "USB reset" signal from a USB-host.

An application program has to initialize the whole UDC with this interrupt.

• INT\_URST\_END (Bit6)

This is the flag register for INT\_URST\_END ("USB reset" end - interrupt).

This is set to "1" when the UDC receives a "USB reset end" signal from a USB-host.

• INT\_SUS (Bit5)

This is the flag register for INT\_SUS (suspend - interrupt).

This is set to "1" when the USB changes to "suspend status".

• INT\_RESUME (Bit4)

This is the flag register for INT\_RESUME (resume - interrupt).

This is set to "1" when the USB changes to "resume status".

• INT\_CLKSTOP (Bit3)

This is the flag register for INT\_CLKSTOP (enables stopping of the clock supply - interrupt).

This is set to "1" after the USB changes to "suspend status". Set USBCR1<USBCLKE> to "0" to stop the clock after detecting this interrupt if needed.

• INT\_CLKON (Bit2)

This is the flag register for INT\_CLKON (enable starting of the clock supply - interrupt).

This is set to "1" after changing to "resume status" or when the UDC started to receive a "USB reset" signal from a USB-host. In case the clock has be stopped, set USBCR1<USBCLKE> to "1" to start the clock after detecting this interrupt if needed.

USBINTFR2

(07F1H)
---------

		7	6	5	4	3	2	1	0

		1: Generate interrupt 1: –								

Note: The above interrupt can release Halt state from IDLE2 mode. (IDLE1 and STOP mode cannot be released.)

		7	6	5	4	3	2	1	0
USBINTFR3	bit Symbol	EP3_FULL_A	EP3_Empty_A						
(07F2H)	Read/Write	R/W	R/W			/			
	Reset State	0	0	/		/			
	Function	When read 0:Not generate interrupt 1:Generate interrupt							
		When write 0: Clear flag 1: -							

Note: The above interrupt can release Halt state from IDLE2 mode. (IDLE1 and STOP mode cannot be released.)

- EPx\_FULL\_A/B:
  - (When transmitting) This is set to "1" when CPU full writes data to FIFO\_A/B. (When receiving) This is set to "1" when UDC full receives data to FIFO\_A/B.
- EPx\_Empty\_A/B:

(When transmitting)

This is set to "1" when FIFO becomes empty after transmission.

(When receiving)

This is set to "1" when FIFO becomes empty after CPU reads all data from FIFO.

Note: The EPx\_FULL\_A/B and EPx\_Empty\_A/B flags are not status flags. Therefore, check DATASET register to determine if FIFO-status is needed.

		7	6	5	4	3	2	1	0	
USBINTFR4	bit Symbol	INT_SETUP	INT_EP0	INT_STAS	INT_STASN	INT_EP1N	INT_EP2N	INT_EP3N	EP2_Empty_B	
(07F3H)	Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	
	Reset State	0	0	0	0	0	0	0	0	
Function When read 0: Not generate interrupt When write 0: Clear flag										
		1: Generate interrupt 1: –								

Note: The above interrupt can release Halt state from IDLE2 mode. (IDLE1 and STOP mode cannot be released.)

### • INT\_SETUP (Bit7)

This is the flag register for INT\_SETUP (setup - interrupt).

This is set to "1" when the UDC receives a request that S/W (software) control is needed from USB host.

Using S/W (INT\_SETUP routine), first read 8-byte device requests from the UDC and execute operation according to each request.

• INT\_EP0 (Bit6)

This is the flag register for INT\_EP0 (received data of the data phase for Control transfer type - interrupt).

This is set to "1" when the UDC receives data of the data phase for Control transfer type. If this interrupt occurs during Control write transfer, data reading from FIFO is needed. If this interrupt occurs during Control read transfer, transmission data writing to FIFO is needed.

In some cases, the host may not assert "ACK" of the last packet in the data stage. In this case, this interrupt cannot be generated. Therefore, ignore this interrupt if it occurs after the last packet data has been written in the data stage because the transmission data number is specified by the host, or it depends on the capacity of the device.

• INT\_STAS (Bit5)

This is the flag register for INT\_STAS (status stage end - interrupt).

This is set to "1" when the status stage ends.

If this interrupt is generated, it means that request ended normally.

If this interrupt is not generated and INT\_SETUP is generated, EP0\_STATUS <STAGE\_ERR> is set to "1", and it means that request did not end normally.

## • INT\_STASN (Bit4)

This is the flag register for INT\_STASN (change host status stage - interrupt).

This is set to "1" when the USB host changes to status stage at the Control read transfer. This interrupt is needed if data length is less than wLength (specified by the host).

• INT\_EPxN (Bit3, 2, 1)

This is the flag register for  $\ensuremath{\text{INT\_EPxN}}$  (NAK acknowledge to the USB host - interrupt).

This is set to "1" when the Endpoint1, 2 and 3 transmit NAK.

Table 3.10.3 UDC CORE SFRs (2/2)

Note: "\*" is not used in the TMP92CH21.

### 3.10.3.2 EPx\_FIFO Register (x: 0 to 3)

This register is prepared for each endpoint independently.

This is the window register from or to FIFO RAM.

In the auto bus enumeration, the request controller in UDC sets the mode, which is defined by the endpoint descriptor, for each endpoint automatically. By this means, each endpoint is automatically set to each direction.

		7	6	5	4	3	2	1	0
Endpoint0	bit Symbol	EP0_DATA7	EP0_DATA6	EP0_DATA5	EP0_DATA4	EP0_DATA3	EP0_DATA2	EP0_DATA1	EP0_DATA0
(0780H)	Read/Write	R/W							
	Reset State	Undefined							
		7	6	5	4	3	2	1	0
Endpoint1	bit Symbol	EP1_DATA7	EP1_DATA6	EP1_DATA5	EP1_DATA4	EP1_DATA3	EP1_DATA2	EP1_DATA1	EP1_DATA0
(0781H)	Read/Write	R/W							
	Reset State	Undefined							
		7	6	5	4	3	2	1	0
Endpoint2	bit Symbol	EP2_DATA7	EP2_DATA6	EP2_DATA5	EP2_DATA4	EP2_DATA3	EP2_DATA2	EP2_DATA1	EP2_DATA0
(0782H)	Read/Write	R/W							
	Reset State	Undefined							
		7	6	5	4	3	2	1	0
Endpoint3	bit Symbol	EP3_DATA7	EP3_DATA6	EP3_DATA5	EP3_DATA4	EP3_DATA3	EP3_DATA2	EP3_DATA1	EP3_DATA0
(0783H)	Read/Write	R/W							
	Reset State	Undefined							

Note1:Read or write to these window registers using 1-byte load instructions only, since each register has only a 1-byte address. Do not use load instructions of 2 bytes or 4 bytes.

Note2: When it is IN-token(except isochronous transfer) and the UDC transmits 1-byte data to the host, if the CPU writes "eop" to the endpoint on a certain timing, a NULL data(0-byte data) may be transmitted.Therefore,

prevent the tramsfer of 1-byte by for example introducing dummy data.

The device request that is received from the USB host is stored in the following 8-byte registers:

bmRequestType, bRequest, wValue\_L, wValue\_H, wIndex\_L, wIndex\_H, wLength\_L and wLength\_H. These are updated whenever a new SETUP token is received from the host.

When the UDC receives without error, INT\_SETUP interrupt is asserted, meaning the new device request has been received.

There is also a request which is operated automatically by the UDC, depending on the request received.

In that case, the UDC does not assert the INT\_SETUP interrupt. Any request which the UDC is currently operating can be checked by reading STANDARD\_REQUEST\_FLAG and REQUEST\_FLAG.

### 3.10.3.3 bmRequestType Register

This register shows the bmRequestType field of the device request.

		7	6	5	4	3	2	1	0			
bmRequestType (07C0H)	bit Symbol	DIRECTION	REQ_TYPE1	REQ_TYPE0	RECIPIENT4	RECIPIENT3	RECIPIENT2	RECIPIENT1	RECIPIENT0

#### 3.10.3.4 bRequest Register

This register shows the bRequest field of the device request.

bRequest (07C1H)	/	7	6	5	4	3	2	1	0
	bit Symbol	REQUEST7	REQUEST6	REQUEST5	REQUEST4	REQUEST3	REQUEST2	REQUEST1	REQUEST0
(0/011)	Read/Write	R	R	R	R	R	R	R	R
	Reset State	0	0	0	0	0	0	0	0

(Standard) 00000000: GET\_STATUS 00000001: CLEAR\_FEATURE 00000010: Reserved 00000101: SET\_FEATURE 00000100: Reserved 00000111: SET\_ADDRESS 00000110: GET\_DESCRIPTOR 000001000: GET\_CONFIGURATION 00001001: SET\_CONFIGURATION 00001010: GET\_INTERFACE 00001011: SET\_INTERFACE 00001100: SYNCH\_FRAME (Printer class) 00000000: GET\_DEVICE\_ID 00000001: GET\_PORT\_STATUS 00000010: SOFT\_RESET

### 3.10.3.5 wValue Register

There are 2 registers; the wValue\_L register and wValue\_H register. wValue\_L shows the lower-byte of the wValue field of the device request, and wValue\_H register shows the upper byte.

		7	6	5	4	3	2	1	0
wValue_L (07C2H)	bit Symbol	VALUE_L7	VALUE_L6	VALUE_L5	VALUE_L4	VALUE_L3	VALUE_L2	VALUE_L1	VALUE_L0
(07 0211)	Read/Write	R	R	R	R	R	R	R	R
	Reset State	0	0	0	0	0	0	0	0
		7	6	5	4	3	2	1	0
wValue_H (07C3H)	bit Symbol	VALUE_H7	VALUE_H6	VALUE_H5	VALUE_H4	VALUE_H3	VALUE_H2	VALUE_H1	VALUE_H0
(070311)	Read/Write	R	R	R	R	R	R	R	R
	Reset State	0	0	0	0	0	0	0	0

### 3.10.3.6 wIndex Register

There are 2 registers, the wIndex\_L register and wIndex\_H register. The wIndex\_L register shows the lower byte of the wIndex field of the device request, and wIndex\_H register shows the upper byte.

These are usually used to transfer index or offset.

0

		7	6	5	4	3	2	1	0
wIndex_L (07C4H)	bit Symbol	INDEX_L7	INDEX_L6	INDEX_L5	INDEX_L4	INDEX_L3	INDEX_L2	INDEX_L1	INDEX_L0
(070411)	Read/Write	R	R	R	R	R	R	R	R
	Reset State	0	0	0	0	0	0	0	0
		7	6	5	4	3	2	1	0
wIndex_H (07C5H)	bit Symbol	INDEX_H7	INDEX_H6	INDEX_H5	INDEX_H4	INDEX_H3	INDEX_H2	INDEX_H1	INDEX_H0
(070011)	Read/Write	R	R	R	R	R	R	R	R

3.10.3.7 WLength Register

0

0

Reset State

There are 2 registers, the wLength\_L register and wLength\_H register. The wLength\_L register shows the lower-byte of the wLength field of the device request, and wLength\_H register shows the upper byte.

0

0

0

0

In the case of data phase, these registers show the byte number to transfer.

0

	/	7	6	5	4	3	2	1	0
wLength_L (07C6H)	bit Symbol	LENGTH_L7	LENGTH_L6	LENGTH_L5	LENGTH_L4	LENGTH_L3	LENGTH_L2	LENGTH_L1	LENGTH_L0
(0/0011)	Read/Write	R	R	R	R	R	R	R	R
	Reset State	0	0	0	0	0	0	0	0
		7	6	5	4	3	2	1	0
wLength_H (07C7H)	bit Symbol	LENGTH_H7	LENGTH_H6	LENGTH_H5	LENGTH_H4	LENGTH_H3	LENGTH_H2	LENGTH_H1	LENGTH_H0
(0/0/11)	Read/Write	R	R	R	R	R	R	R	R
	Reset State	0	0	0	0	0	0	0	0

#### 3.10.3.8 Setup Received Register

This register informs the UDC that an application program has recognized the INT\_SETUP interrupt.

SetupReceived (07C8H)	/	7	6	5	4	3	2	1	0
SetupReceived	bit Symbol	D7	D6	D5	D4	D3	D2	D1	D0
(070011)	Read/Write	W	W	W	W	W	W	W	W
	Reset State	0	0	0	0	0	0	0	0

If this register is accessed by an application program, the UDC disables access to the EPO's FIFO RAM, because the UDC recognizes the device request has been received.

This is to protect data stored in the EPO in the time between the completion of the previous device request and the recognition by the application program of the INT\_SETUP interrupt relating to a new request.

Therefore, write "00H" to this register when the device request in INT\_SETUP routine is recognized.

Note : A recovery time of 2 clocks at 12MHz is needed after writing to this register in order to access EP0\_FIFO.

#### 3.10.3.9 Current\_Config Register

This register shows the present value that is set by SET\_CONFIGURATION and SET\_INTERFACE.

	/	7	6	5	4	3	2	1	0
Current_Config (07C9H)	bit Symbol	REMOTEWAKEUP		ALTERNATE[1]	ALTERNATE[0]	INTERFACE[1]	INTERFACE[0]	CONFIG[1]	CONFIG[0]
(070311)	Read/Write	R		R	R	R	R	R	R
	Reset State	0		0	0	0	0	0	0

#### CONFIG[1:0] (Bit1 to bit0)

00: UNCONFIGURED	Set to UNCONFIGURED by the host.
01: CONFIGURED1	Set to CONFIGURED 1 by the host.
10: CONFIGURED2	Set to CONFIGURED 2 by the host.

### INTERFACE[1:0] (Bit3 to bit2)

00: INTERFACE0	Set to INTERFACE 0 by the host.
01: INTERFACE1	Set to INTERFACE 1 by the host.
10: INTERFACE2	Set to INTERFACE 2 by the host.

#### ALTERNATE[1:0] (Bit5 to bit4)

00: ALTERNATE0	Set to ALTERNATE 0 by the host.
01: ALTERNATE1	Set to ALTERNATE 1 by the host.
10: ALTERNATE2	Set to ALTERNATE 2 by the host.

#### REMOTE WAKEUP (Bit7)

0: Disable	Disabled remote wakeup by the host.
1: Enable	Enabled remote wakeup by the host.

Note1: CONFIG, INTERFACE and ALTERNATE each support 3 kinds (0,1 and 2). Note2: If each request is controlled by S/W, this register is not set.

## 3.10.3.10 Standard Request Register

This register shows the standard request currently being executed. Any bit which is set to "1" shows a request currently being executed.

Standard Request (07CAH)		7	6	5	4	3	2	1	0
	bit Symbol	S_INTERFACE	G_INTERFACE	S_CONFIG	G_CONFIG	G_DESCRIPT	S_FEATURE	C_FEATURE	G_STATUS
	Read/Write	R	R	R	R	R	R	R	R
	Reset State	0	0	0	0	0	0	0	0
	S_INTI	ERFACE	(Bit 7) : S	SET_INTE	RFACE				

S_INTERFACE	(Bit 7) · SET_INTERFACE
G_INTERFACE	(Bit 6) : GET_INTERFACE
S_CONFIG	(Bit 5) : SET_CONFIGRATION
G_CONFIG	(Bit 4) : GET_CONFIGRATION
G_DESCRIPT	(Bit 3) : GET_DESCRIPTOR
S_FEATURE	(Bit 2) : SET_FEATURE
C_FEATURE	(Bit 1) : CLEAR_FEATURE
G_STATUS	(Bit 0) : GET_STATUS

### 3.10.3.11 Request Register

This register shows the device request currently being executed.

Any bit which is set to "1" shows a request currently being executed.

Request (07CBH)		7	6	5	4	3	2	1	0
	bit Symbol		SOFT_RESET	G_PORT_STS	G_DEVICE_ID	VENDOR	CLASS	ExSTANDARD	STANDARD
	Read/Write		R	R	R	R	R	R	R
	Reset State	/	0	0	0	0	0	0	0

SOFT_RESET	$(Bit 6)$ : SOFT_RESET
G_PORT_STS	(Bit 5) : GET_PORT_STATUS
G_DEVICE_ID	(Bit 4) : GET_DEVICE_ID
VENDOR	(Bit 3) : Vendor class request
CLASS	(Bit 2) : Class request
ExSTANDARD	(Bit 1) : Auto Bus Enumeration not supported
	(SET_DESCRIPTOR, SYNCH_FRAME)
STANDARD	(Bit 0) : Standard request

**Reset State** 

### 3.10.3.12 DATASET Register

This register shows whether FIFO contains data or not.

The application program can access this register to check whether FIFO contains data or not.

In receive status, when a valid data transfer from the USB host has finished, the bit which corresponds to the applicable endpoint is set to "1" and an interrupt generated. And, when the application reads the 1-packet data, this bit is cleared to "0". In transmit status, when it has completed the 1-packet data transfer to FIFO, this bit is set to "1". And when valid data is transferred to the USB host, this bit is cleared to "0" and an interrupt generated.

DATASET1 (07CCH)		7	6	5	4	3	2	1	0
	bit Symbol	EP3_DSET_B	EP3_DSET_A	EP2_DSET_B	EP2_DSET_A	EP1_DSET_B	EP1_DSET_A		EP0_DSET_A
	Read/Write	R	R	R	R	R	R		R
	Reset State	0	0	0	0	0	0		0
		7	6	5	4	3	2	1	0
(07CDH)	bit Symbol	EP7_DSET_B	EP7_DSET_A	EP6_DSET_B	EP6_DSET_A	EP5_DSET_B	EP5_DSET_A	EP4_DSET_B	EP4_DSET_A
	Read/Write	R	R	R	R	R	R	R	R

Note: DATASET1<EP3\_DSET\_B>, DATASET2 registers are not used in the TMP92CH21.

0

Single packet mode

0

0

(DATASET1: Bit0, bit2, bit4 and bit6 DATASET2: Bit0, bit2, bit4 and bit6)

0

0

0

0

0

These bits show whether FIFO of the corresponding endpoint has data or not.

In receive mode endpoint, if the corresponding endpoint bit is "1", FIFO contains data to be read. Access EPx\_SIZE register, determine the size of the data that should be read, and read data of this size. When this bit is "0", there is no data to be read.

In transmit mode endpoint, if the corresponding endpoint bit is "0", the CPU can transfer data under the FIFO payload. If this bit is "1", because FIFO has transfer data waiting, transfer data to FIFO from UDC after the corresponding bit has been cleared to "0". When a short-packet is transferred, access EOP register after writing transmission data to the corresponding endpoint.

- Dual packet mode
  - (DATASET1: Bit3, bit5 and bit7 DATASET2: Bit1, bit3 bit5 and bit7)

These bits become effective in the dual packet mode. FIFO has 2-packets in this mode.

Each packet (packet-A and packet-B) has its own DATASET-bit.

Unlike as in the case above, in isochronous transfer, this shows the packet that can access the current frame. In this case, whether bit A or B is set to "1", it is renewed according to the shifting frame.

- Note1:In receive mode, if the endpoint bits corresponding to packet-A or packet-Bare "1", read the required packet-number data after checking EPx\_SIZE<PKT\_ACTIVE>.
- Note2: In transmit mode, if both A and B bits are not "1", this means there is space in FIFO. So, write data of payload or less to FIFO. If the transmission is short-packet, write "0" to EOP<EPn\_EOPB> after writing data to the FIFO. The maximum size that can be written to A or B packet is the same as the maximum payload size. If both A and B bits are "0", continuous writing of double maximum payload size is available.
- Note3: In dual packet transmit mode, if both A and B packet are empty and EOP<EPn\_EOPB> is written "0", the NULL-data is set to FIFO. In single mode, the NULL-data is also set to FIFO if the above operation is executed when packet-A contains no data.
- Note4:No data is set in this register when NULL-packet (0Length-packet) is received.

# 3.10.3.13 EPx\_STATUS Register (x: 0 to 7)

These registers are status registers for each endpoint. The <SUSPEND> is common all endpoints.

Note: EP4, 5, 6 and 7\_STATUS registers are not used in the TMP92CH21.

TOGGLE Bit (Bit6) 0: TOGGLE Bit0 1: TOGGLE Bit1

SUSPEND (Bit5) 0: RESUME

1: SUSPEND

This bit shows status of toggle sequence bit.

This bit shows status of UDC power management. In the SUSPEND status, access to UDC is limited. For details, refer to 3.10.9.

STATUS [2:0]		These bits show status of UDC endpoint.
(Bit4 to bit2)		The status shows whether transfer is possible or not, and the
		results of the transfer. These depend on transfer type.
		(For the Isochronous transfer type, refer to 3.10.6.)
000: READY	Receiving:	Device can be received.
		In endpoints 1 to 7, this register is initialized to "READY" by setting transfer type at SET_CONFIGURATION.
		In endpoint 0, this register is initialized to "READY" by detecting USB reset from the host.
		This is initialized to "READY" by terminating the status stage without error.
	Transmitting:	Basically, the same as "Receiving".
		But in transmitting, when data for transmission is set to FIFO and answer to token from host and transfer data to host collect and received ACK, status register does not change, and it remains "READY". In this case, EPx_Empty_A or EPx_Empty_B interrupt terminate the transfer correctly.
001: DATAIN		UDC set to DATAIN and generates EPx_FULL_A or EPx_FULL_B interrupt when data is received from the host without error.
010: FULL		Refer to 3.10.8 (2) Details for the STATUS register.
011: TX_ERR		After transfer of data to IN token from host, UDC sets TX-ER to status register when "ACK" is not received from host. In this case, an interrupt is not generated. The hosts re-try IN token transfer.
100: RX_ERR		UDC sets RX_ERR to status register without transmitting "ACK" to host when an error (such as a CRC-error) is detected in data of received token. In this case, an interrupt is not generated. The hosts re-try IN token transfer.
101: BUSY		This status is used only for the control transfer type and it is set when a status-stage token is received from the host after a terminated data-stage.
		When status-stage can be finished, terminates correctly and returns to READY. This is not used in the Bulk and interrupts transfer type.
110: STALL		This status shows that the corresponding endpoint is in STALL status.
		In this status, STALL-handshake returns, except for SETUP-token. The control endpoint returns to READY from stall condition when SETUP-token is received.
		Other endpoints return to READY when initialization command of FIFO is received.
		(Note) With Automatic Set_Interface request answer, requests to interface 4 to 6 may not become request errors. If this is a problem, in Set_Interface request answer, set Standard Request Mode <s_interface> to "1" and use software.</s_interface>
111: INVALID		This status shows that the corresponding endpoint is in UNCONFIGURED status.
		In this status, the UDC has no effect when a token is received from the host.
		On reset, all endpoints are set to INVALID status. Only endpoint 0 returns to READY on receiving USB-reset. Corresponding endpoints return to READY according to configuration.

FIFO_DISABLE (Bit1) 0: FIFO enabled 1: FIFO disabled	This bit symbol shows FIFO status, except for EP0. If the FIFO is set to disabled, the UDC transmits NAK handshake for all transfers. Disabled or enabled status is set by the COMMAND register. This bit is cleared to "0" when transfer type is changed.
STAGE_ERROR (Bit0) 0: SUCCESS 1: ERROR	This bit symbol shows that the status stage has not been terminated correctly. ERROR is set when a status stage is not terminated correctly and a new SETUP token is received. When this bit is "1", this bit is cleared to "0" by read EP0_STATUS register. This bit is not cleared even if normal control transfer or other transfer is executed after it. To clear, read this bit. When software transaction is finished and UDC writes EOP register, UDC shifts to status register and waits for termination of status stage. In this case, if software is needed to confirm that the status stage has been terminated correctly, when

a new request flag is received, it is possible to confirm whether or not the last request was terminated correctly. It can also be confirmed, when a new request flag is asserted, whether or nor

the last request was cancelled before completion.

## 3.10.3.14 EPx\_SIZE Register (x: 0 to 7)

These registers have the following functions.

- a) In receive mode, showing the 1-packet data number which was received correctly.
- b) In transmit mode, showing payload size. Showing length value when short packet is transferred.

It is not necessary to read this register when it is transmitting.

c) Showing dual packet mode and currently effective packet.

Each endpoint has an H (High)-register that shows upper bit 9 to bit7 of data size, and an L (Low) register which shows lower bit 6 to bit0 and control bit of FIFO. Each H/L register also has 2-set for dual-packet mode.

Note: EP3,4,5,6,7\_SIZE\_H\_B registers are not used in the TMP92CH21.

DATASIZE[9:7] (H register: Bit2 to bit0) DATASIZE[6:0] (L register: Bit6 to bit0)

In receiving, the data number of the 1 packet received from the host is shown. This is renewed when data from the host is received with no error.

By setting EPx\_MODE register, these bits are initialized to MAX pay load size in bulk/interrupt transfer, and "0" in isochronous transfer.

PKT\_ACTIVE (L register: Bit7) 1: OUT\_ENABLE 0: OUT\_DISABLE When dual-packet mode is selected, this bit shows the packet that can be accessed. In this case, the UDC accesses packets that divide FIFO (Packet A and Packet B) mutually. When FIFO in UDC is accessed by CPU, refer to this bit. If receiving endpoint, start reading from that packet that this bit is "1". In single-packet mode, this bit has no effect because packet-A is always used.

## 3.10.3.15 FRAME Register

This register shows the frame number which is issued with SOF token from the host and is used for Isochronous transfer type.

Each HIGH and LOW register shows upper and lower bits.

		7	6	5	4	3	2	1	0
FRAME_L (07E1H)	bit Symbol	_	T[6]	T[5]	T[4]	T[3]	T[2]	T[1]	T[0]
(07210)	Read/Write	R	R	R	R	R	R	R	R

#### 3.10.3.16 ADDRESS Register

This register shows the device address which is specified by the host in bus enumeration.

		7	6	5	4	3	2	1	0
ADDRESS (07E3H)	bit Symbol		A6	A5	A4	A3	A2	A1	A0
(07E3H)	Read/Write		R	R	R	R	R	R	R
	Reset State		0	0	0	0	0	0	0

By reading this register, the present address can be confirmed.

ADDRESS [6:0] (Bit6 to bit0)

The UDC compares this registers and address in all packet ID, and UDC judges whether it is an effective transaction or not.

This is initialized to "00H" by USB reset.

## 3.10.3.17 EOP Register

This register is used when a control transfer type dataphase terminates or when a short packet is transmitting bulk-IN or interrupt-IN.

		7	6	5	4	3	2	1	0
EOP (07CFH)	bit Symbol	EP7_EOPB	EP6_EOPB	EP5_EOPB	EP4_EOPB	EP3_EOPB	EP2_EOPB	EP1_EOPB	EP0_EOPB
(0/011)	Read/Write	W	W	W	W	W	W	W	W
	Reset State	1	1	1	1	1	1	1	1

Note1: EOP<EP7\_EOPB, EP6\_EOPB, EP5\_EOPB, EP4\_EOPB> registers are not used in the TMP92CH21.

Note2: When writing to this register, a recovery time of 5clocks at 12MHz is needed. After writing this register, insert dummy instruction of 420 ns or longer.

In a control transfer type dataphase, write "0" to <EP0\_EOPB> when all transmission data is written to the FIFO, or read all receiving data from the FIFO. The UDC terminates its status stage on this signal.

When a short packet is transmitted by using bulk-IN or interrupt-IN endpoint, use this to terminate writing of transmission data. In this case, write "0" to <EP0\_EOPB> of writing endpoint. Write "1" to other bits.

## 3.10.3.18 Port Status Register

This register is used when a printer class request is received.

In the case of a GET\_PORT\_STATUS request, the UDC operates automatically using this data.

		7	6	5	4	3	2	1	0
Port Status	bit Symbol	Reserved7	Reserved6	PaperError	Select	NotError	Reserved2	Reserved1	Reserved0
(07E0H)	Read/Write	W	W	W	W	W	W	W	W
	Reset State	0	0	0	1	1	0	0	0

Note: The TMP92CH21 does not use this register since it does not support printer-class.

The data should be written before receiving request. Write "0" to the <Reserved> bit of this register. This register is initialized to "18H" on reset.

#### 3.10.3.19 Standard Request Mode Register

This register sets the answer for Standard Request, either answering automatically in hardware, or by control through software. Each bit represents a kind of request.

When the relevant bit in this register is set to "0", the answer is executed automatically by hardware. When the relevant bit in this register is set to "1", the answer is controlled by software. If a request is received during hardware control, the interrupt signal (INT\_SETUP, INT\_ENDPOINTO, INT\_STATUS, INT\_STATUSNAK) is set to disable. If a request is received during software control, the interrupt signal is asserted, and it is controlled by software.

Note: With Automatic Set\_Interface request answer, requests to interface 4 to 6 may not become request errors. If this is a problem, in Set\_Interface request answer, set Standard Request Mode <S\_INTERFACE> to "1" and use software.

		7	6	5	4	3	2	1	0
Standard Request Mode	bit Symbol	S_Interface	G_Interface	S_Config	G_Config	G_Descript	S_Feature	C_Feature	G_Status
(07D8H)	Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
	Reset State	0	0	0	0	0	0	0	0

S_Intetface G_Interface S_Config G_Config G_Descript S_Feature C_Feature	(Bit 7): SET_INTERFACE (Bit 6): GET_INTERFACE (Bit 5): SET_CONFIGRATION (Bit 4): GET_CONFIGRATION (Bit 3): GET_DESCRIPTOR (Bit 2): SET_FEATURE (Bit 1): CLEAR_FEATURE
G_Status	$(Bit 0)$ : GET_STATUS

## 3.10.3.20 Request Mode Register

This register sets the answer for Class Request either automatically in hardware or by control through software. Each bit represents a kind of request.

When relevant bit in this register is set to "0", the answer is executed automatically by hardware. When relevant bit in this register is set to "1", the answer is controlled by software. If a request is received during hardware control, the interrupt signal (INT\_SETUP, INT\_ENDPOINTO, INT\_STATUS, INT\_STATUSNAK) is set to disable. If a request is received during software control, the interrupt signal is asserted, and it is controlled by software.

		7	6	5	4	3	2	1	0
Request Mode	bit Symbol		Soft_Reset	G_Port_Sts	G_DeviceId				
(07D9H)	Read/Write		R/W	R/W	R/W				
	Reset State		0	0	0				

Note: The TMP92CH21 does not use this register since it does not support printer-class.

_	(Bit 7)	: Reserved
Soft_Reset	(Bit 6)	: SOFT_RESET
G_Port_Sts	(Bit 5)	: GET_PORT_STATUS
G_Config	(Bit 4)	: GET_DEVICE_ID
G_Descript	(Bit 3 to 0)	): Reserved

Note1: SET\_ADDRESS request is supported only by auto-answer .

Note2: SET\_DESCRIPTOR and SYNCH\_FRAME are controlled only by software .

Note3: Vendor Request and Class Request (Printer Class and so on) are controlled only by software.

Note4: INT\_SETUP, ENDPOINTO, STATUS and STATUSNAK interrupts assert only when it is software-control.

## 3.10.3.21 COMMAND Register

This register sets COMMAND at each endpoint. This register can be set to select endpoint in bit6 to bit4 and kind of COMMAND in bit3 to bit0. COMMAND for endpoint that is supported is ignored.

COMMAND	
(07D0H)	

		7	6	5	4	3	2	1	0	
MAND DOH)	bit Symbol		EP[2]	EP[1]	EP[0]	Command[3]	Command[2]	Command[1]	Command[0]	
JUN)	Read/Write		W	W	W	W	W	W	W	
	Reset State		0	0	0	0	0	0	0	

Note: When writing to this register, a recovery time of 5clocks at 12MHz is needed. After writing this register, insert dummy instruction of 420 ns or longer.

## EP [2:0] (Bit6 to bit4)

- 000: Select endpoint 0
  - 001: Select endpoint 1
  - 010: Select endpoint 2
  - 011: Select endpoint 3

## COMMAND [3:0] (Bit3 to bit0)

0000: Reserved 0001: Reserved	
0010: SET_DATA0	This COMMAND clear toggle sequence bit of corresponding endpoint (EP0 to EP3). If this COMMAND is input, it sets toggle sequence bit of the corresponding endpoint to "0". Data toggle for transfer is renewed automatically by UDC. However, this COMMAND execution is required if setting toggle sequence bit of endpoint to "0",. If control transfer type and Isochronous transfer type, execution of this COMMAND is not required because of hardware control.
0011: RESET	<ul> <li>This COMMAND resets the corresponding endpoint (EP0 to EP3).</li> <li>If this COMMAND is input, the corresponding endpoint is initialized. CLEAR_FEATURE request stalls endpoint. When this stall is cleared, execute this COMMAND. (This command does not affect transfer mode.)</li> <li>This command initializes the following:.</li> <li>Clear toggle sequence bit of corresponding endpoint.</li> <li>Clear STALL of corresponding endpoint.</li> <li>Set to FIFO_ENABLE condition.</li> <li>Clear the data in FIFO</li> </ul>
0100: STALL	This COMMAND sets corresponding endpoint to STALL (EP0 to EP3). If STALL handshake must be return as answer for device request, execute this command.
0101: INVALID	<ul> <li>This COMMAND sets condition to prohibition of use of corresponding endpoint (EP1 to EP3).</li> <li>If UDC detects USB_RESET signal from USB host, it sets all endpoints (except endpoint 0) to prohibition using it automatically. If Config and Interface are changed by device request, set endpoint that is not used to prohibit use.</li> <li>Note: If setting endpoint that is set to Isochronous transfer mode to "no use", after change to Isochronous mode, set to "no use" by COMMAND register.</li> </ul>
0110: CREATE_SOF	This COMMAND sets quasi-SOF generation function to enable (EP0). Default is set to disable, it must be used for Isochronous transfer.
0111: FIFO_DISABLE	This COMMAND sets FIFO of corresponding endpoint to disable (EP1 to EP3). If this command is set externally, all transfers for corresponding endpoint return NAK. When it is set externally while receiving packet, this becomes valid from next token. This command does not affect the packet that is transferring.

1000: FIFO_ENABLE	This COMMAND sets FIFO of corresponding endpoint to enable (EP1 to EP3). If FIFO is set to disable by FIFO_DISABLE COMMAND, this command is used for release of disable condition. If set while receiving packet, this becomes valid from next token. If USB_RESET is detected from host and RESET COMMAND execute and transfer mode is set by using SET_CONFIG and SET_INTERFACE request, the corresponding endpoint enters FIFO_ENABLE condition.
1001: INIT_DESCRIPTOR	This COMMAND is used if descriptor RAM is rewritten during system operation (EP0). If UDC detects USB_RESET from host controller, it reads content of descriptor RAM automatically, and it performs relevant settings. If descriptor RAM is changed during system operation, it must read setting again. Therefore, execute this command. When connected to USB host, this function starts reading automatically. Therefore, in this case, it is not necessary to execute this command.
1010: FIFO_CLEAR	<ul> <li>This COMMAND initializes FIFO of corresponding endpoint (EP1 to EP3).</li> <li>However, EPx_STATUS<toggle> is not initialized.</toggle></li> <li>If resetting by software, execute this COMMAND.</li> <li>This command ilnitializes the following: <ul> <li>Clear STALL of relevant endpoint.</li> <li>Set to FIFO_ENABLE condition.</li> <li>Clear the data in FIFO</li> </ul> </li> </ul>
1011: STAL_CLEAR	This COMMAND clear STALL of corresponding endpoint (EP1 to EP3). If clearing only STALL of endpoint, execute this COMMAND.

## 3.10.3.22 INT\_Control Register

INT\_STATUS\_NAK interrupt is disabled and enabled by the value that is written to this register.

This is initialized to disable by external reset. When setup packet is received, it becomes disabled.

		7	6	5	4	3	2	1	0
INT_Control (07D6H)	bit Symbol								Status_nak
(07066)	Read/Write								R/W
	Reset State	/							0

In control read transfer, if the host terminates a dataphase with small data length (smaller than the data length that is specified by the host as wLength), the device side and stage management cannot be synchronized. Therefore, INT\_STATUSNAK interrupt signals this shift to status stage. If needed, set to "1" after receiving setup packet.

#### STATUS\_NAK (Bit0)

0: INT\_STATUS\_NAK interrupt disable 1: INT\_STATUS\_NAK interrupt enable

#### 3.10.3.23 USB STATE Register

This register shows the current device state for connection with USB host.

		7	6	5	4	3	2	1	0
USB STATE	bit Symbol					/	Configured	Addressed	Default
(07CEH)	Read/Write					/	R/W	R	R
	Reset State	/				/	0	0	1

Note: When writing to this register, a recovery time of 5clocks at 12MHz is needed. After writing this register, insert dummy instruction of 420 ns or longer.

Inside the UDC, the answer for each Device Request is managed by referring to these bits (Configured, Addressed and Default). If transaction for SET\_CONFIG request is executed using software, write the present state to this register. If host appointconfig is 0, this becomes Unconfigured, and it is necessary to return to Addressed state. Therefore, if host appoint config is 0, write "0" to bit2.

When Configured bit (Bit2) is written "0", Addressed bit (bit 1) is set automatically by hardware. When host appoint config value that supported by device, the device must execute mode setting for each endpoint by using the value that is appointed by endpoint-descriptor in the config-descriptor. After finish mode setting, set Configured bit (Bit2) to "1" before accessing EOP register. When this bit is set to "1", Addressed bit (Bit1) is set to "0" automatically.

Bit2 to bit0 000: Default 010: Addressed 100: Configured

#### 3.10.3.24 EPx\_MODE Register (x: 1 to 3)

This register sets transfer mode of endpoint (EP1 to EP3).

If SET\_CONFIG and SET\_INTERFACE processing is set to software control, this control must use appointed config or interface. Access this register to set mode.

		7	6	5	4	3	2	1	0
EP1_MODE (0789H)	bit Symbol		/	Payload[2]	Payload[1]	Payload[0]	Mode[1]	Mode[0]	Direction
	Read/Write			R/W	R/W	R/W	R/W	R/W	R/W
	Reset State			0	0	0	0	0	0
		7	6	5	4	3	2	1	0
EP2_MODE (078AH)	bit Symbol			Payload[2]	Payload[1]	Payload[0]	Mode[1]	Mode[0]	Direction
	Read/Write			R/W	R/W	R/W	R/W	R/W	R/W
	Reset State			0	0	0	0	0	0
		7	6	5	4	3	2	1	0
EP3_MODE (078BH)	bit Symbol			Payload[2]	Payload[1]	Payload[0]	Mode[1]	Mode[0]	Direction
	Read/Write			R/W	R/W	R/W	R/W	R/W	R/W
	Reset State			0	0	0	0	0	0

There is a limitation to the timing that can be written.

If SET\_CONFIG and SET\_INTERFACE processing is set to software control, after INT\_SETUP interrupt is received, finish writing before accessing EOP register. This register prohibits writing when it is timing, and it is ignored.

Note1: When writing to this register, a recovery time of 5clocks at 12MHz is needed. After writing this register, insert dummy instruction of 420 ns or longer.

Note2: When writing to this register, endpoint is initialized same as RESET of COMMAND register.

#### DIRECTION (Bit0)

0: OUT Direction from host to device

1: IN Direction from device to host

## MODE [1:0] (Bit1 and bit2)

- 00: Control transfer type
- 01: Isochronous transfer type
- 10: Bulk transfer type or interrupt transfer type
- 11: Interrupt (No toggle)

Note: If setting endpoint that is set to Isochronous transfer mode to "no use", after changing to Isochronous mode, set to "no use" by COMMAND register.

#### PAYLOAD [2:0] (Bit3, bit4 and bit5)

000:	8 bytes
001:	16 bytes
010:	32 bytes
011:	64 bytes
0100:	128 bytes
0101:	256 bytes
0110:	512 bytes
0111:	1023 bytes (Note1, 2)

Note3:Max packet size of Isochronous transfer type is 1023 bytes.

Note4:IfwMaxPacketSize of descriptor was set to other than 8, 16, ..., 1023, Payload more than descriptor value is set by auto-answer of Set\_Configration and Set\_Interface.

Others (Bit6 and bit7) Reserved

#### 3.10.3.25 EPx\_SINGLE Register

This register sets mode of FIFO in each endpoint (SINGLE/DUAL).

		7	6	5	4	3	2	1	0
EPx_SINGLE1 (07D1H)	bit Symbol	EP3_SELECT	EP2_SELECT	EP1_SELECT		EP3_SINGLE	EP2_SINGLE	EP1_SINGLE	
(070111)	Read/Write	R/W	R/W	R/W		R/W	R/W	R/W	
	Reset State	0	0	0		0	0	0	

Note: Endpoint 3 supports only SINGLE mode in the TMP92CH21.

```
Bit number
    0: No use
    1: EP1_SINGLE
    2: EP2_SINGLE
    3: EP3_SINGLE
    4: No use
    5: EP1_SELECT
    6: EP2_SELECT
    7: EP3_SELECT
    When EPx_SELECT bit is "1", EPx_SINGLE bit becomes valid in the following content.
                   0: DUAL mode 1: SINGLE mode
    If setting content of EPx_SINGLE bit to valid, set EPx_SELECT bit to "1".
                                   1: Valid
                   0: Invalid
```

## 3.10.3.26 EPx\_BCS Register

This register sets mode of access to FIFO in each endpoint.

EPx_BCS1 (07D3H)		7	6	5	4	3	2	1	0
	bit Symbol	EP3_SELECT	EP2_SELECT	EP1_SELECT		EP3_BCS	EP2_BCS	EP1_BCS	
	Read/Write	R/W	R/W	R/W		R/W	R/W	R/W	
	Reset State	0	0	0		0	0	0	

Bit number

0: No use 1: EP1\_BCS 2: EP2\_BCS 3: EP3\_BCS 4: No use 5: EP1\_SELECT 6: EP2\_SELECT 7: EP3\_SELECT Always write "1" to EPx\_BCS bit regardless of whether endpoint is used or not. 0: Reserved 1: CPU access If setting content of EPx\_BCS bit to valid, set EPx\_SELECT bit to "1". 0: Invalid

1: Valid

## 3.10.3.27 USBREADY Register

This register informs finishing writing data to descriptor RAM on UDC. After assigned data to descriptor RAM, write "0" to bit0.

		7	6	5	4	3	2	1	0
USBREADY	bit Symbol								USBREADY
(07E6H)	Read/Write								R/W
	Reset State								0

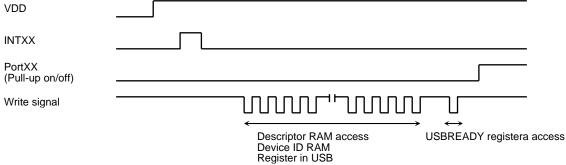

#### USBREADY (Bit0)

0: Writing to descriptor RAM has finished.

1: Writing to descriptor RAM is enabled.

(However, writing to descriptor RAM is prohibited when connected to host.)

Detect level of VDD signal from USB cable, and execute initialize sequence. In this case, UDC disable detecting USB\_RESET signal until USBREADY register is written "0" after release of USB\_RESET.

If the pull-up resistor on D+ signal is controlled by control signal, when pull-up resistor is connected to host in OFF condition, this condition is equivalent condition with USB\_RESET signal by pull-down resistor on the host side. Therefore UDC is not detected in USB\_RESET until "0" is written to USBREADY register

Note1: External pull-up resistor and control switch are needed with the TMP92CH21.

Note2: The above setting is an example for communication. A specific circuit is required to prevent current flow at connector detection , no-use, and no connection.

### 3.10.3.28 Set Descriptor STALL Register

This register sets whether returns STALL automatically in data stage or status stage for Set Descriptor Request.

	/	7	6	5	4	3	2	1	0
Set Descriptor STALL (07E8H)	bit Symbol								S_D_STALL
(** = ** *)	Read/Write	/	/					/	W
	Reset State	/							0

Bit0: S\_D\_STALL

0: Software control (Default)

1: Automatically STALL

3.10.3.29 Descriptor RAM

This register is used for store descriptor to RAM. The size of the descriptor is 384 bytes. However, when storing descriptor, write according to descriptor RAM structure sample.

Descriptor RAM (0500H) ≀		7	6	5	4	3	2	1	0
	bit Symbol	D7	D6	D5	D4	D3	D2	D1	D0
	Read/Write	R/W							
(067FH)	Reset State	Undefined							

Read/Write timing is only possible before detection of USB\_RESET or during processing of SET\_DESCRIPTOR request.

SET\_DESCRIPTOR request processes from INT\_SETUP assert until access of EOP register.

If there is rewriting request of descriptor in SET\_DESCRIPTOR, process the request in the following sequence.

- 1) Read every packet of the descriptor that is transferred by SET\_DESCRIPTOR.
- 2) When reading descriptor number of last packet finished, write all descriptors to RAM for descriptor.
- 3) When writing is completed, execute INIT\_DESCRIPTOR of COMMAND register.
- 4) When all the process is completed, access EOP register, and finish status stage.
- 5) When INT\_STATUS is received, it shows normal finish of status stage.

If USB\_RESET is detected, it starts reading automatically. Therefore, when it connects to the host, executing INIT\_DESCRIPTOR command is not necessary.

# 3.10.4 Descriptor RAM

This area stores the descriptor that is defined in USB. Device, Config, Interface, Endpoint and String descriptor must set to RAM using the following format.

Device descriptor	18 bytes
Config 1 descriptor (Interfaces, endpoints)	
	255 bytes or less
Config 2 descriptor (Interfaces, ENDPOINT)	
(	255 bytes or less
String0 length	1 byte
String1 length	1 byte
String2 length	1 byte
String3 length	1 byte
String0 descriptor	
	63 bytes or less
String1 descriptor	
	63 bytes or less
String2 descriptor	
	63 bytes or less
String3 descriptor	
	63 bytes or less

- Note 1: If String Descriptor is supported, set StringxLength area to size0. No support String Dedcriptor is returned STALL.
- Note 2: Config Descriptior refers to descriptor sample.
- Note 3: Sequencer in UDC determines Config number, Interface number and Endpoint number. Therefore, if supporting Endpoint number is small, assign address according to priority.
- Note 4: This function become effective only in case of store descriptor as RAM.
- Note 5: RAM size is total 384 bytes.
- Note 6: Possible timing in RD/WR of descriptor RAM is only before detection of USB\_RESET and processing of SET\_DESCRIPTOR request. (Prohibit access other than this timing.)

Writing must finish before connection to USB host and processing of SET\_DESCRIPTOR request.

SET\_DESCRIPTOR request processes from INT\_SETUP assert until access of EOP register.

Note 7:The class descriptor, and the vender descriptors, etc except a standard descriptor cannnot be supported by an auto bus enumeration.

## 3.10.5 Device Request

3.10.5.1 Standard request

UDC support automatically answers in standard request.

(1) GET\_STATUS Request

This request automatically returns to status that is determined by receive side.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
10000000B 10000001B 10000010B	GET_STATUS	0	0 Interface endpoint	2	Device, interface or endpoint status

Request to device returns according to priority of little endian as follows.

D7	D6	D5	D4	D3	D2	D1	D0
0	0	0	0	0	0	Remote wakeup	Self power
D15	D14	D13	D12	D11	D10	D9	D8
0	0	0	0	0	0	0	0

- Remote wakeup Reinstates current remote wakeup setting. This bit is set or reset by SET\_FEATURE or CLEAR\_FEATURE request. Default is "0".
- Self power Reinstates current power supply setting. This bit returns Self or BusPower according to value that is set to bmAttributes field in Config descriptor.

Request to interface returns 00H of 2 bytes.

Request to endpoint returns according to priority of little endian as follows.

D7	D6	D5	D4	D3	D2	D1	D0
0	0	0	0	0	0	0	HALT
D15	D14	D13	D12	D11	D10	D9	D8
0	0	0	0	0	0	0	0

• HALT

Returns to halt status of selected endpoint.

## (2) CLEAR\_FEATURE request

This request clears or disables the relevant function.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
00000000B 00000001B 00000010B	CLEAR_ FEATURE	Feature selector	0 Interface endpoint	0	None

- Reception side device
  - Feature selector: 1 Present remote wakeup setting is disabled.
  - Feature selector: except 1 STALL state
- Reception side interface
  - STALL state
- Reception side end point
  - Feature selector: 0 Halt of relevant endpoint is cleared.
    - Note: When cleared HALT state, following is set.
      - Initialize FIFO
      - ·Clear the toggle sequence bit
    - ·Clear STALL state

Feature selector: except 0 STALL state

Note: Stalls if request is to non-existent endpoint.

# (3) SET\_FEATURE request

This request sets or enables the relevant function.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
00000000B 00000001B 00000010B	SET_ FEATURE	Feature selector	0 Interface endpoint	0	None

- Reception side device Feature selector: 1 Present remote wakeup setting is disabled. Feature selector: except 1 STALL state
   Reception side interface
- Reception side interface STALL state
- Reception side end point Feature selector: 0 Halt of relevant endpoint Feature selector: except 0 STALL state

Note: Stalls if request is to non-existent endpoint.

(4) SET\_ADDRESS request

This request sets the device address. Answer subsequent requests using this device address.

Answer requests using the current device address until the status stage of this request is terminated normally.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
0000000B	SET_ADDRESS	Device Address	0	0	None

## (5) GET\_DESCRIPTOR request

This request transmits appointed descriptor.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
1000000B	GET_ DESCRIPTOR	Descriptor type and Descriptor index	0 or Language ID	Descriptor length	Descriptor

- Device Device transmits device descriptor that is stored in descriptor RAM. There is an IdProductm bcdDevice field as register in this device. When descriptor ROM is used, if the descriptor data is determined as ROM, this area only can be rewritten. Access this register before connecting to USB host.
- Config Config transmits config descriptor that is stored in descriptor RAM. At this point, it transmits not only config descriptor but also interface and endpoint descriptor.
- String String transmits string descriptor of index that is specified by lower byte of wValue field.
- Note: Descriptor of short data length in wLength and descriptor length is automatically transmitted by answer of Get\_Descriptor.

## (6) SET\_DESCRIPTOR request

bmRequestType	bRequest	wValue	wIndex	wLength	Data
0000000B	SET_	Descriptor type	0	Descriptor	Descriptor
	Descriptor	and	or	length	
		Descriptor index	Language ID		

This request sets or enables the relevant function.

Automatic answer of this request is not supported.

According to INT\_SETUP interrupt, if the request received was identified as a SET\_DESCRIPTOR request, take back data after confirming EP0\_DSET\_A bit of DATASET register is "1". When completed, access EOP register, and write "0" to EP0\_EOPB bit, so status stage is finished. The process is the same for a vendor request.

Please refer to vendor request section.

(7) GET\_CONFIGURATION request

This request returns configuration value of present device.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
1000000B	GET_ CONFIG	0	0	1	Configuration value

If it is not configured, it returns "0". Otherwise, it returns the configuration value.

## (8) SET\_CONFIGURATION request

This request sets device configuration.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
0000000B	SET_ CONFIG	Configuration value	0	0	None

If is the configuration value is that specified using lower byte of wValue field. When this value is "0", it is not configured.

#### (9) GET\_INTERFACE request

This request returns AlternateSetting value that is set by specified interface.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
10000001B	GET_ INTERFACE	0	Interface	1	Alternate setting

If there is no specified interface, it enters STALL state.

Note: If the descriptor is configured no endpoint in interface, use the software answer since automatic answer of GET\_INTERFACE request by hardware is not supported.

#### (10) SET\_INTERFACE request

#### This request selects AlternateSetting in specified interface.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
00000001B	SET_ INTERFACE	Alternate setting	Interface	0	None

If there is no specified interface, it enters STALL state.

Note: If the descriptor is configured no endpoint in interface, use the software answer since automatic answer of SET\_INTERFACE request by hardware is not supported.

## (11) SYNCH\_FRAME request

This request transmits synchronous frame of endpoint.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
10000010B	SYNCH_FRAME	0	Endpoint	2	Frame No.

Automatic answer of this request is not supported.

According to INT\_SETUP interrupt, if request received was identified as a SYNCH\_FRAME request, write 2byte data in Frame No after confirming EP0\_DSET\_A bit of DATASET register is "0". When completed, access EOP register, and write "0" to EP0\_EOPB bit, so status stage is finished. This can be used only where the endpoint supports isochronous transfer type and supports this request. The process is the same for a vendor request.

Please refer to vendor request section.

## 3.10.5.2 Printer Class Request

UDC does not support "Automatic answer" of printer class request. Processing of Class requests is the same as for vendor requests when answering INT\_SETUP interrupts.

(1) GET\_PORT\_STATUS request

This request transmits Port Status to host.

bmRequestType	bRequest	wValue	WIndex	wLength	Data
10100001B	GET_ PORT_STATUS	0	Interface	1	Port status

UDC has an internal Port\_STATUS register. Therefore, write port information to this register. When this request is received, data of Port\_Status register is transmitted. Set port information to Port\_Status register using application before setting register. Port information of only 1 type can be transmitted, so wIndex value is ignored.

D7	D6	D5	D4	D3	D2	D1	D0
Reserved	Reserved	Paper error	Select	Not error	Reserved	Reserved	Reserved

(2) SOFT\_RESET request

This request receives soft reset.

bmRequestType	bRequest	wValue	WIndex	wLength	Data
00100011B	SOFT_RESET	0	Interface	0	None

When soft reset is received, SOFT\_RESET flag is set. When status stage is finished, SOFT\_RESET flag is reset. This request receive flag is of only 1 type, so wIndex field value is ignored.

(3) Vendor request (Class request)

UDC does not support "Automatic answer" of Vendor requests.

According to INT\_SETUP interrupt, access the register in which the device request is stored, and identify the request. If this request is a Vendor request, control the UDC externally, and process the Vendor request.

Below is an explanation for the case where data phase is transmitting (Control read), and for the case where data phase is receiving (Control write).

(a) Control request

bmRequestType	bRequest	wValue	wIndex	wLength	Data
110000xxB	Vendor specific	Vendor specific	Vendor specific	Vendor specific (Expire 0)	Vendor data

When INT\_SETUP is received, identify contents of request by bmRequestType, bRequest, wValue, wIndex and wLength registers and process each request. According to application, access Setup\_Received register after request has been identified. UDC must also be informed that INT\_SETUP interrupt has been recognized.

After transmitting data prepared in application, access DATASET register, and confirm EP0\_DSET\_A bit is "0". After confirming, write data FIFO of endpoint 0. If transmitting data is more than payload, write data after it confirming whether EP0\_DSET\_A bit in DATASET register is "0". (INT\_ENDPOINT0 interrupt can be used.) If writing all data is finished, write "0" to EP0 bit of EOP register. When UDC receives this, the status stage finishes automatically.

INT\_STATUS interrupt is asserted when UDC finishes status stage normally. If finishing status stage normally is recognized by external application, manage this stage by using this interrupt signal. If status stage cannot be finished normally and during status stage, a new SETUP token may be received. In this case, when INT\_SETUP interrupt signal is asserted, "1" is set to STAGE\_ERROR bit of EP0\_STATUS register informing externally that the status stage cannot be finished normally.

The dataphase may have finished on a data number that is shorter than the value showed to wLength by protocol of control read transfer type in USB. If the application program is configured using only the wLength value, processing cannot be carried out when the host shifts status stage without arriving at the expected data number. At this point, shifting to status stage can be confirmed by using INT\_STATUSNAK interrupt signal. (However, releasing mask of STATUS\_NAK bit by using interrupt control register is needed.) In Vendor Request, this problem will not occur because the receiving buffer size is set to host controller by driver. (In every host, data (data that is transmitted from device by payload of 8 bytes) may be taken to be short packet until confirmation of payload size on device side. Therefore, exercise care if controlling standard requests by software.)

# (b) Control write/request

## There is no dataphase

bmRequestType	bRequest	wValue	wIndex	wLength	Data
010000xxB	Vendor specific	Vendor specific	Vendor specific	0	None

When INT\_SETUP is received, identify contents of request by bmRequestType, bRequest, wValue, wIndex, wLength registers, and process each request. According to application, access Setup\_Received register after request has been identified. UDC must also be informed that the INT\_SETUP interrupt has been recognized. If application processing is finished, write "0" to EP0 bit of EOP register. When UDC receives this, the status stage finishes automatically.

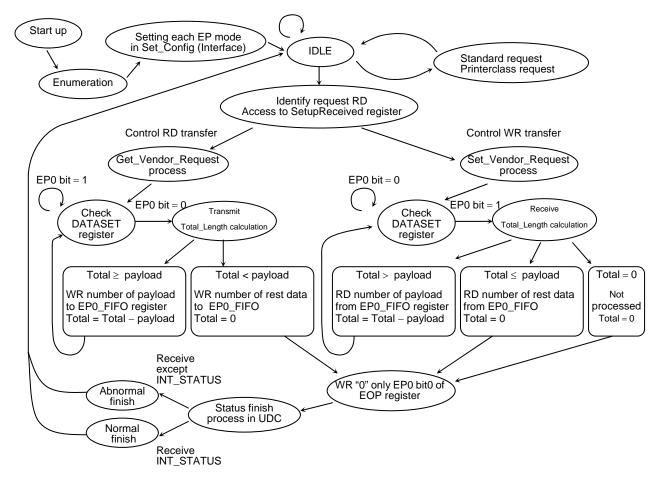

## There is dataphase

bmRequestType	bRequest	wValue	wIndex	wLength	Data
010000xxB	Vendor specific	Vendor specific	Vendor specific	Vendor specific (Except for 0)	Vendor data

When INT\_SETUP is received, identify contents of device request by bmRequestType, bRequest, wValue, wIndex, wLength registers, and process each request. According to application, access Setup\_Received register after request has been identified. UDC must also be informed that the INT\_SETUP interrupt has been recognized.

After receiving data prepared in application, access DATASET register, and confirm EP0\_DSET is "1". After confirming, read data FIFO of endpoint 0. If data is more than payload, write data after it confirming whether the EP0\_DSET\_A bit in DATASET register is "1". (INT\_ENDPOINT0 interrupt can be used.) If reading all data is finished, write "0" to EP0 bit of EOP register. When UDC receives this, the status stage finishes automatically.

INT\_STATUS interrupt is asserted when UDC finishes status stage normally. If finishing status stage normally is recognized by external application, manage this stage by using this interrupt signal. If status stage cannot be finished normally and during status stage, a new SETUP token may be received. In this case, when INT\_SETUP interrupt signal is asserted, "1" is set to STAGE\_ERROR bit of EP0\_STATUS registerinforming externally that the status stage cannot be finished normally.

Below is control flow in UDC as seen from application.

Figure 3.10.2 Control Flow in UDC as seen from Application

Note : This chart does not cover special cases such as overlap receive SETUP packet. Please refer to chapter of 3.10.6 (2) (c)Control transfer type.

# 3.10.6 Transfer mode and Protocol Transaction

The UDC performs the following automatically in hardware;

- Receive packet
- Determine address endpoint transfer mode
- Error process
- Confirm toggle bit CRC of data receiving packet
- Generate toggle bit CRC of data transmitting packet, etc
- Handshake answer
- (1) Protocol outline

Format of USB packet is shown below. This is processed during transmission and receiving by hardware into the UDC.

• SYNC field

This field always comes first in each packet, and input data and internal CLK is synchronized in the UDC.

• Packet identification field (PID)

This field follows SYNC field in every USB packet. The UDC distinguishes the PID type and determines the transfer type by decoding this code.

• Address field

The UDC uses this field to confirm whether or not this function was specified by the host. The UDC compares the address with that set to the ADDRESS register. If the address accords with it, the UDC continues the process. If the address does not accord, the UDC ignores this token.

• Endpoint field

If sub-channels of more than two are needed in fields of 4 bits, it decides the function. The UDC can support a maximum of seven endpoints, excluding the control endpoint. Tokens for endpoints that are not permitted are ignored.

• Frame number field

A field of 11 bits is added by the host at each frame. This field follows the SOF token that is transmitted first in each frame, and the frame number is specified. The UDC reads the content of this field when the SOF token is received, and sets the frame number to the FRAME register.

• Data field

This field is data of unit byte in bytes 0 to 1023. When receiving it, the UDC transfers only part of this data to FIFO, and after CRC is confirmed, an interrupt signal is asserted and the UDC informs FIFO that data transfer is completed. When transmitting, following IN token, FIFO data is transferred. Finally, data CRC field is attached.

• CRC function

5 bits CRC is attached to the token, and 15 bits CRC to the data. The UDC automatically compares the CRC of the received data with the attached CRC. When transmitting, CRC is generated automatically and is transmitted. This function may be compared by various transfer modes.

(2) Transfer mode

UDC supports FULL speed transfer mode.

• FULL speed device

Control transfer type

Interrupt transfer type

Bulk transfer type

Isochronous transfer type

The following is an explanation of UDC operation in each transfer mode.

The explanation is of data flow up until FIFO.

(a) Bulk transfer type

Bulk transfer type warrants transferring no error between host and function by using detect error and retry. Basically, 3 phases are used - token, data and handshake. However, with flow control and a STALL condition, data phase is changed to hand shake phase, and it become to 2 phases. The UDC holds status of each endpoint, and flow control is controlled in hardware. Each endpoint condition can be confirmed using EPx\_STATUS register.

(a-1) Transmission bulk mode

Below is the transaction format for bulk transfer during transmitting.

- Token: IN
- Data: DATA0/DATA1, NAK, STALL
- Handshake: ACK

Control flow

Below is the control-flow when the UDC receives an IN token.

- 1. The token packet is received and the address endpoint number error is confirmed, and it checks whether the relevant endpoint transfer mode corresponds with the IN token. If it does not correspond, the state returns to IDLE.
- 2. Condition of EPx\_STATUS register is confirmed.
  - INVALID condition: State returns to IDLE.
  - STALL condition: Stall handshake is returned and state returns to IDLE.

FIFO condition is confirmed, if data number of 1 packet is not prepared, NAK handshake is returned, and state returns to IDLE.

If data number of 1 packet is prepared to FIFO, it shifts to 3.

3. Data packet is generated.

Data packet generated by using toggle bit register in UDC.

Next, data is transferred from FIFO of internal UDC to SIE, and data packet is generated. At this point, the transferred data number is confirmed. And if there is more than the maximum payload size of each endpoint, bit stuff error is generated, transfer is finished, and STATUS becomes STALL.

- 4. CRC bit (counted transfer data of FIFO from first to last) is attached to last.
- 5. When ACK handshake from host is received,
  - Clear FIFO.
  - Clear DATASET register.
  - Renew toggle bit, and prepare for next.
  - Set STATUS to READY.

UDC finishes normally. FIFO can receive the next data.

If a time out occurs without receiving ACK from host,

- Set STATUS to TX\_ERR.
- Return FIFO address pointer.

Execute above setting. And wait next retry keeping FIFO data.

This flow is shown in Figure 3.10.3.

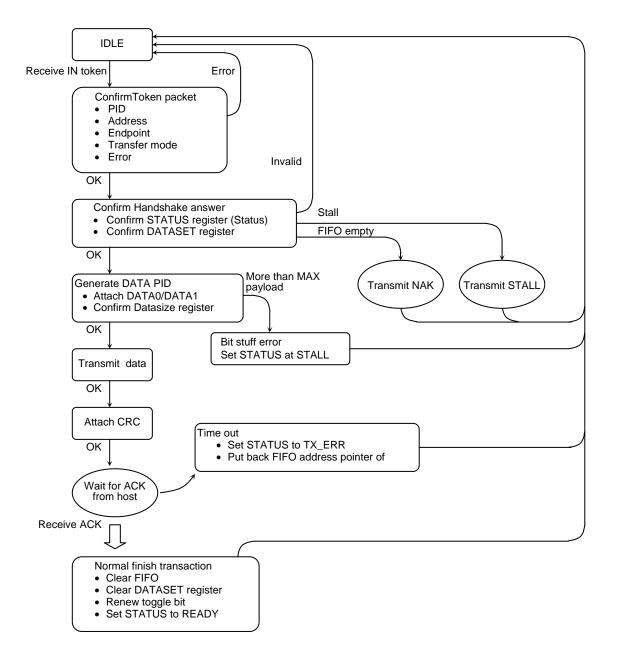

Figure 3.10.3 Control Flow in UDC (Bulk transfer type (transmission)/Interrupt transfer type (transmission))

(a-2) Receiving bulk mode

Below is the transaction format for receiving bulk transfer type.

- Token: OUT
- Data: DATA0/DATA1
- Handshake: ACK, NAK, STALL

## Control flow

Below is the control-flow when the UDC receives an IN token.

- 1. The token packet is received and the address endpoint number error is confirmed, and it checks whether the relevant endpoint transfer mode corresponds with the OUT token. If it does not correspond, the state returns to IDLE.
- 2. Condition of status register is confirmed.
  - INVALID condition: State returns to IDLE.
  - STALL condition: When dataphase finishes, stall handshake is returned,

the state returns to IDLE, and data is canceled.

FIFO condition is confirmed, if data number of 1 packet is not prepared, present transferred data is canceled, NAK handshake is returned after dataphase, and the state returns to IDLE.

3. Data packet is received.

Data is transferred from SIE of internal UDC to FIFO. At this point, it confirms transferred data number, and if there is more than the maximum payload size of each endpoint, STATUS becomes STALL and the state returns to IDLE. ACK handshake does not return.

4. After last data is transferred, the counted CRC is compared with the transferred CRC. If they do not correspond, STATUS is set to RX\_ERR and the state returns to IDLE. At this point ACK is not returned.

After retry, when next data is received normally, STATUS changes to DATIN. If the data toggle does not correspond, it is judged not to have taken ACK in the last loading, the current loading is regarded as a retry of the last loading and data is canceled. Set STATUS as RX\_ERR, return to host and return to IDLE. FIFO address pointer returns, and the next data can be received.

5. If CRC is compared with toggle and it finishes normally, ACK handshake is returned.

Below is the process in the UDC.

- Set transfer data number to DATASIZE register.
- Set DATASET register.
- Renew toggle bit, and prepare for next.
- Set STATUS to READY.

UDC finishes normally.

This flow is shown in Figure 3.10.4.

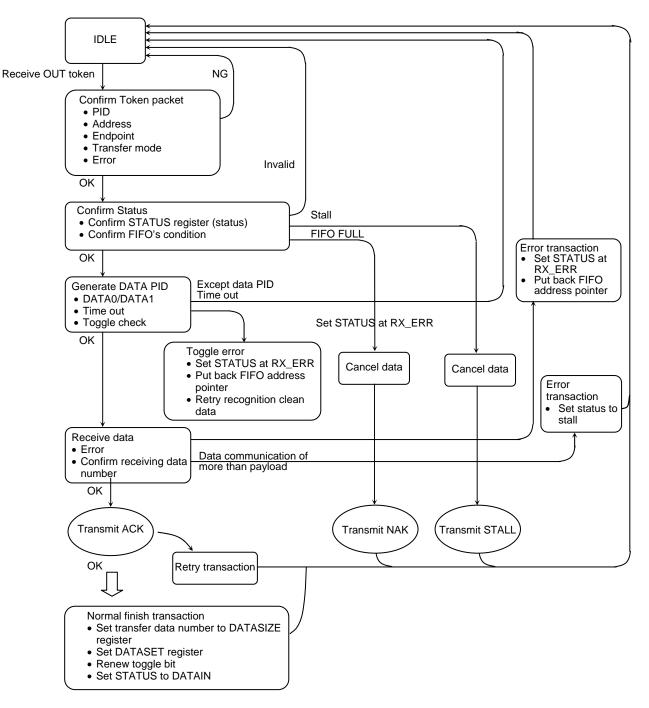

Figure 3.10.4 Control Flow in UDC (Bulk transfer type (Receiving))

(b) Interrupt transfer type

Interrupt transfer type uses the same transaction format as transmission bulk transfer.

For transmission using toggle bit, hardware setting and answer in the UDC are the same as for transmission bulk transfer. Interrupt transfer can be transferred without using toggle bit. In this case, if ACK handshake from host is not received, toggle bit is renewed, and finish is normal. The UDC clears FIFO for next transfer.

(b-1) Interrupt transmitting mode (Toggle mode)

UDC operation is same as in bulk transmission mode. Please refer to section (a).

(b-2) Interrupt transmission mode (Not toggle mode)

This is basically the same as bulk transmission mode. However, if ACK handshake from host is not received, transaction is different.

When ACK handshake from host is received after transmission of data packet, Clear FIFO.

- Clear DATASET register.
- Renew toggle bit and prepare for next.
- Set STATUS to READY.

UDC finishes normally by above transaction. FIFO can receive next data.

If a time out occurs without receiving ACK from host,

- Clear FIFO.
- Clear DATASET register.
- Renew toggle bit and prepare for next.
- Set STATUS to TX\_ERR.

Execute above setting. This setting is the same except for STATUS changes.

(c) Control transfer type

Control transfer type is configured in the three stages below.

- Setup stage
- Data stage
- Status stage

Data stage is sometimes skipped. Each stage is configured in one or several transactions. The UDC executes each transaction while managing three stages in hardware. Control transfer has the 3 types given below depending on whether there is data stage or not, and on direction.

- Control read transfer type
- Control write transfer type
- Control write transfer type (No data stage)

The 3 transfer sequences are shown in Figure 3.10.6, Figure 3.10.7 and Figure 3.10.8.

The UDC automatically answers standard requests in hardware. Class request and vendor request must have an intervening CPU controlling the UDC.

Below is the control flow in the UDC and the control flow in the intervening CPU.

#### (c-1) Setup stage

Setup stage is the same as transmission bulk transaction except that token ID becomes SETUP.

However, control flow in the UDC is different.

- Token: SETUP
- Data: DATA 0
- Handshake: ACK

#### Control flow

Below is the control flow in the UDC when SETUP token is received.

- 1. SETUP token packet is received and address, endpoint number and error are confirmed. It also checks whether the relevant endpoint is in control transfer mode.
- 2. STATUS register state is confirmed.

State returns to IDLE only if it is INVALID state.

In bulk transfer mode, receiving data is enabled by STATUS registers value and FIFO condition. However, in SETUP stage, STATUS is returned to READY and accessing from the CPU to FIFO is always prohibited, and internal FIFO of endpoint 0 is cleared. It also prepares for following dataphase.

If the CPU accesses Setup Received registers in the UDC, it recognizes Device request as received, and accessing from the CPU to EPO is enabled.

This function is for receiving a new request when the current device request has not finished normally.

3. Data packet is received.

Device request of 8 bytes from SIE in UDC is transferred to the request register below.

- bmRequestType register
- bmRequest register
- wValue register
- wIndex register
- wLength register
- 4. After last data is transferred, counted CRC is compared with transferred CRC. If they do not correspond, STATUS is set to RX\_ERR and the state returns to IDLE. At this point it does not return ACK, and host retries.
- 5. If CRC corresponds with toggle and it finishes normally, ACK handshake is returned to host. The process in the UDC is shown below.
  - Receiving device request is judged whether software control or hardware control. If the request needs control in software, INT\_SETUP interrupt is asserted. If hardware is used, INT\_SETUP interrupt is not asserted.
  - According to stage control flow, prepare for next stage.
  - Set STATUS to DATAIN.
  - Set toggle bit to "1".

The Setup stage is completed by the above.

This flow is shown in Figure 3.10.5.

8-byte data that is transferred by this SETUP stage is device request.

The CPU must process corresponding to device request.

The UDC detects the following contents only from data of 8 bytes, and it manages stage in hardware.

- Whether there is data stage or not
- Data stage direction

These are used to determine control read transfer type, control write transfer type, and control write transfer type (no data phase).

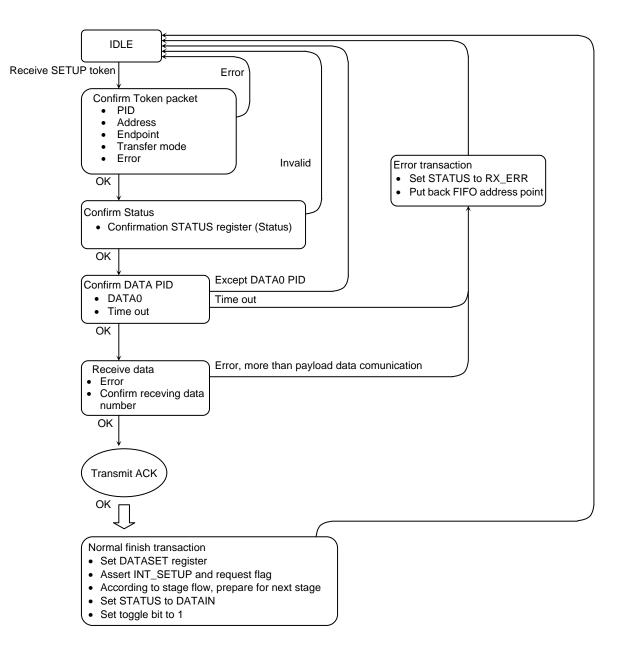

Figure 3.10.5 Control Flow in UDC (Setup stage)

(c-2) Data stage

Data stage is configured by one or several transactions based on toggle sequence.

The transaction is the same as for format transmission or receiving bulk transaction except for the following differences:

- Toggle bit starts from "1" by SETUP stage.
- It determines whether right or not by comparing IN and OUT token with direction bit of device request. If a token of the opposite direction is received, it is recognized as status stage.
- INT\_ENDPOINT0 interrupt is asserted.

#### (c-3) Status stage

Status stage is configured 0-data-length packet with DATA1's PID and handshake IN or OUT token. It uses a transaction in the opposite direction to the preceding stage.

The combination is given below.

- Control read transfer type: OUT
- Control write transfer type: IN
- Control write transfer type (not dataphase): IN

UDC processes status stage base of control flow in control transfer type. At this point, CPU must write "0" to EPO bit of EOP register in last transaction for status stage to finish normally.

Details of status stage are given below.

#### (c-3-1) IN status stage

IN status stage transaction format is given below.

- Token: IN
- Data: DATA1 (0 data length), NAK, STALL
- Handshake: ACK

#### Control flow

The transaction flow of IN status stage in UDC is given below.

- 1. Token packet is received and address, endpoint number and error are confirmed. If it does not corrspond, the state returns to IDLE. If status stage is enabled based on stage control flow in the UDC, advance to next stage.
- 2. STATUS register state is confirmed.
  - INVALID condition: State returns to IDLE.
  - STALL condition: Stall handshake is returned and state returns to IDLE.

Confirmation of whether EOP register is accessed or not is carried out externally. If it is not accessing, NAK handshake is returned to continue control transfer, and state returns to IDLE.

3. If EOP register access is confirmed, 0-data-length data packet and CRC are transmitted.

- 4. If ACK handshake from host is received,
  - Set STATU to READY.
  - Assert INT\_STATUS interrupt.

It finishes normally by the above transaction.

If a time out occurs without receiving ACK from host,

• Set STATUS register to TX\_ERR and state returns to IDLE, and wait for restring status stage.

At this point, if new SETUP stage is started without status stage finishing normally, the UDC sets error to STATUS register.

#### (c-3-2) OUT status stage

The transaction format for OUT status stage is given below.

- Token: OUT
- Data: DATA1 (0 data length)
- Handshake: ACK, NAK, STALL

#### Control flow

The transaction flow for OUT status stage in the UDC is given below.

- 1. Token packet is received and address, endpoint number and error are confirmed. If they do not correspond, the state returns to IDLE. If status stage is enabled based on stage control flow in the UDC, advance to next stage.
- 2. STATUS register state is confirmed.
  - INVALID condition: State returns to IDLE.
  - STALL condition: Data is cleared, stall handshake is returned, and state returns to IDLE.

Whether EOP register is accessed or not is confirmed externally. If it is not accessed, NAK handshake is returned to continue control transfer, and state returns to IDLE.

- 3. If EOP register access is confirmed, 0-data-length data packet and CRC are received.
- 4. If there is no error in data, ACK handshake is transmitted to host.
  - Set STATUS to READY.
  - Assert INT\_STATUS interrupt.

It finishes normally by the above transaction.

If there is an error in data, ACK handshake is not returned.

• Set RX\_ERR to STATUS register and return to IDLE. It waits to retry status stage.

At this point, if new SETUP stage is started without status stage finishing normally, the UDC sets error to STATUS register. For sequence of this protocol, refer to section supplement.

(c-4) Stage management

The UDC manages each stage of control transfer by hardware.

Each stage is changed by receiving token from USB host, or CPU accesses register. Each stage in control transfer type has to process combination software. UDC detects the following contents from 8-byte data in SETUP stage. The stage is managed by determining control transfer type.

- Whether there is data stage or not
- Data stage direction

Based on these it is determined to be either control read transfer type, control write transfer type, or control write transfer type (No data stage).

Various conditions for changing stage in control transfer are given below.

If receiving token for next stage from host before switching to next stage from state of internal UDC, NAK handshake is returned and BUSY is informed to USB host. In all control transfer types, if SETUP token is received from host, present transaction is stopped, and it switches to SETUP stage in the UDC. The CPU receives new INT\_SETUP even if it is processing previous control transfer.

Stage change condition of control read transfer type

- 1. Receive SETUP token from host
  - Start setup stage in UDC.
  - Receive data in request normally and judge. And assert INT\_SETUP interrupt externally.
  - Change data stage in the UDC.
- 2. Receive IN token from host
  - The CPU receives a request from the request register every INT\_SETUP interrupt.
  - Judge request and access Setup Received register to inform the UDC that INT\_SETUP interrupt has been recognized .
  - According to Device request, monitor EP0 bit of DATASET register, and write data to FIFO.
  - If the UDC is set data of payload to FIFO or CPU set short packet transfer in EOP register, EPO bit of DATASET register is set.
  - The UDC transfers data that is set to FIFO to host by IN token interrupts.
  - When the CPU finishes transaction, it writes "0" to EP0 bit of EOP register.
  - Change status stage in the UDC.
- 3. Receive OUT token from host.
  - Return ACK to OUT token and change state to IDLE in the UDC.
  - Assert INT\_STATUS interrupt externally.

These changing conditions are shown in Figure 3.10.6.

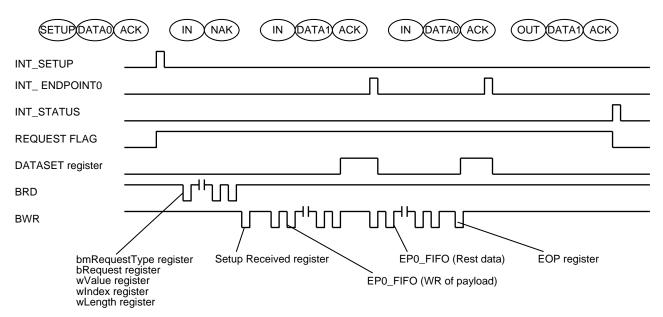

Figure 3.10.6 The Control Flow in UDC (Control Read Transfer Type)

Stage change condition of control writes transfer type

- 1. Receive SETUP token from host.
  - Start setup stage in the UDC.
  - Receive data in request normally and judge. And assert INT\_SETUP interrupt externally.
  - Change data stage in the UDC.
- 2. Receive OUT token from host.
  - CPU receives a request from the request register every INT\_SETUP interrupt.
  - Judge request and access Setup Received register for inform the UDC that INT\_SETUP interrupt has been recognized.
  - Receive dataphase data normally, and set EP0 bit of DATASET register.
  - The CPU receives data in FIFO by setting DATASET.
  - The CPU processes receiving data by device request.
  - When the CPU finishes transaction, it writes "0" to EP0 bit of EOP register.
  - Change status stage in the UDC.
- 3. Receive IN token from host.
  - Return data packet of 0 data to IN token and change state to IDLE in the UDC.
  - Assert INT\_STATUS interrupt externally when ACK for 0 data packet is received.

These changing conditions are shown in Figure 3.10.7.

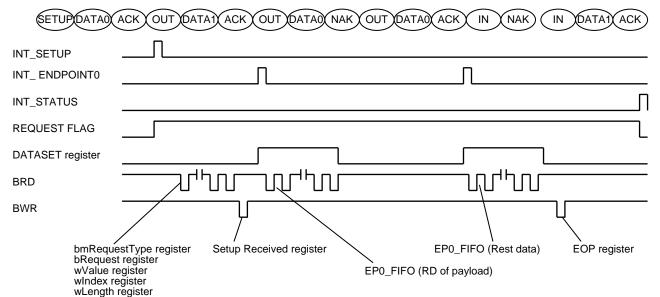

Figure 3.10.7 The Control Flow in UDC (Control Write Transfer Type)

In control read transfer type, transaction number of data stage does not always correspond with the data number specified by the device request. The CPU can therefore process using INT\_STATUSNAK interrupt. However, when class and vendor request is used, wLength value corresponds to data transfer number in data phase. With this setting, using this interrupt is not need. Data stage data can be confirmed by accessing DATASIZE register.

Stage change condition of control write (no data stage) transfer type

- 1. Receive SETUP token from host
  - Start setup stage in UDC.
  - Receive data in request normally and judge. And assert INT\_SETUP interrupt externally.
  - Change data stage in the UDC.
- 2. Receive IN token from host
  - CPU receives a request from the request register every INT\_SETUP interrupt.
  - Judge request and access Setup Received register to inform the UDC that INT\_SETUP interrupt has been recognized.
  - The CPU processes receiving data by device request.
  - When the CPU finishes transaction, it writes "0" to EP0 bit of EOP register.
  - Change status stage in the UDC.
  - Return data packet of 0 data to IN token and change state to IDLE in the UDC.
  - Assert INT\_STATUS interrupt externally when ACK for 0 data packet is received.

These change condition is Figure 3.10.8.

SETUPDA	TAO ACK	INNAK	IN DATA1 ACK	
INT_SETUP	го			
INT_STATUS			Γ	
REQUEST FLAC	3			
DATASET regist	er			
BRD		<u> </u>		
BWR		J		
wVa wIN	RequestType register equest register alue register Idex register ength register	Setup Received register	EOP register	

(d) Isochronous transfer type

Isochronous transfer type is guaranteed transfer by data number that is limited to each frame.

However, this transfer does not retry when an error occurs. Therefore, Isochronous transfer type transfer only 2 phases (token, data) and it does not use handshake phase. And data PID for data phase is always DATA0 because this transaction does not support toggle sequence. Therefore, UDC does not confirm when data PID is in receiving mode.

Isochronous transfer type processes data every frame. Therefore, all transactions for completed transfers use receiving SOF token. The UDC uses FIFO that is divided into two in Isochronous transfer type.

#### (d-1) Isochronous transmission mode

The transaction format for Isochronous transfer type format in transmitting is given below.

- Token: IN
- Data: DATA0

## Control flow

Isochronous transfer type is frame management. And data that is written to FIFO in endpoint is transmitted by IN token in the next frame.

Below are two conditions in FIFO of Isochronous transmission mode transferring.

- X. FIFO for storing data that transmits to host in present frame (DATASET register bit = 1)
- Y. FIFO for storing data for transmitting host in next frame (DATASET register bit = 0)

FIFO that is divided into two (packet A and packet B) conditions is whether X condition or Y condition. The flow below is explained as X Condition (packet A), Y Condition (packet B) in present frame.

X and Y conditions change one after the other by receiving SOF.

Control flow in the UDC when receiving IN token is shown below.

- 1. Token packet is received and address endpoint number error is confirmed, and it checks whether the relevant endpoint transfer mode corresponds with the IN token. If it does not correspond, the state returns to IDLE.
- 2. Condition of status register is confirmed.
  - INVALID condition: State returns to IDLE.
- 3. Data packet is generated.

Data packet is generated. At this point, data PID is always attached to DATA0. Next, data is transferred from FIFO (X condition) of packet A in UDC to SIE, and DATA packet is generated.

4. CRC bit (counted transfer data of FIFO from first to last) is attached to last.

- 5. Below is transaction when SOF token is received from host.
  - Change the packet A's FIFO from X Condition to Y Condition, and clear data.
  - Change the packet B from Y Condition to X Condition.
  - Set frame number to frame register.
  - Assert SOF and inform externally that frame is incremented.
  - DATASET register clears packet A bit and it sets packet B bit arrangement loading in present frame.
  - Set STATUS to READY.

The UDC finishes normally by above transaction.

Packet A's FIFO can be received with next data.

In renewed frame, Packet A's FIFO interchanges with packet B's FIFO, and transaction uses same flow.

If SOF token is not received by error and so on, this data is lost because frame is not renewed. There is no problem in receiving PID if frame data is received with CRC error, USB sets LOST to STATUS on FRAME register, and exact frame number is unknown. However, in this case, SOF is asserted and FIFO condition is renewed. If SOF token is received without transmit and transfer Isochronous in frame, UDC clears FIFO (X Condition) and sets STATUS to FULL.

Note1: In IN transfer, data ("LSB (bit0) of last byte in data" ="1" and "last 5 bits of result that CRC counted" = "1") is transmitted to USB host, that data is transmitted correctly.

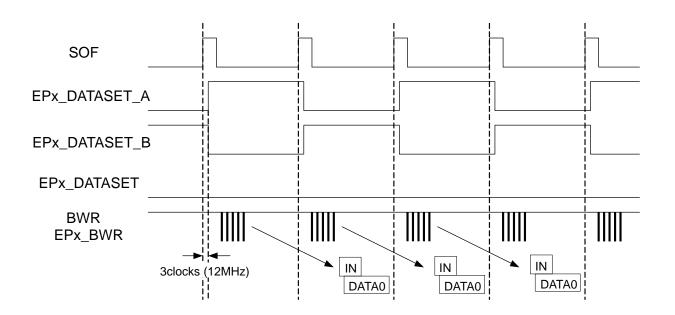

However, CRC error is recognized. In transfer other than Isochronous IN transfer, the following handshake packet from USB host is recognized correctly because of data, is transmitted to USB host correctly, and transfer returns to normal.

However, in Isochronous transfer, token packet is transmitted to it. Therefore, it ignores token packet when CRC error is recognized.

Therefore, for isochronous transfer, execute the following.

- Transmit data that last bit of data field is "0".
- Attach data that last bit of data field is "0".
- After Isochronous IN transfer is executed, execute dummy transfer 1 time before receiving next SOF.

Note2: When using the Isochronous IN transfer, do not use other endpoints simultaneously.

Note: EPx\_DATASETA,B change at 3 clocks of 12MHz after receiving SOF. Write data to FIFO after EPx\_DATASETA,B are changing.

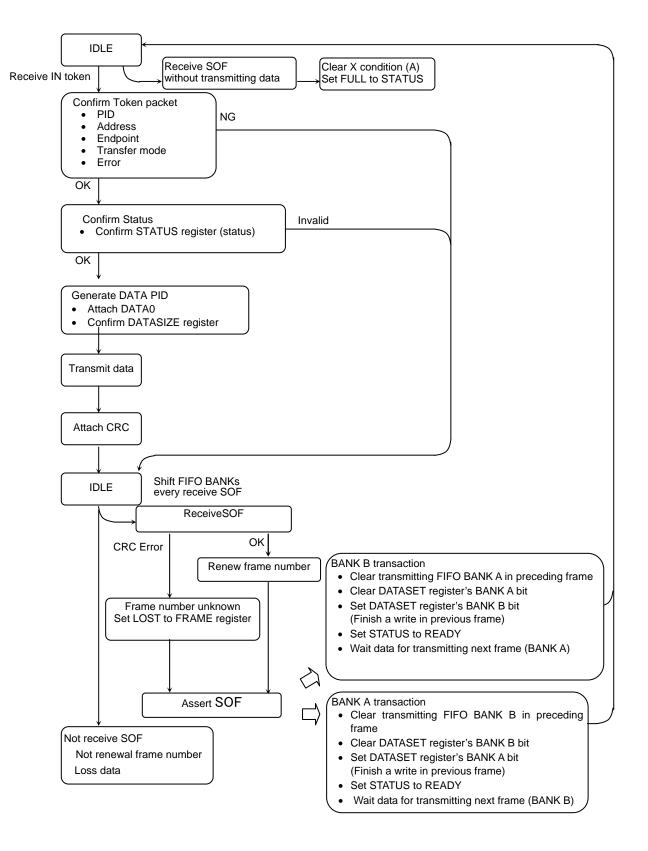

Figure 3.10.10 Control Flow in UDC (Isochronous transfer type (Transmission))

(d-2) Isochronous receiving mode

Transaction format for Isochronous transfer type in receiving is given below.

- Token: OUT
- Data: DATA0

## Control flow

Isochronous transfer type is frame management. And data that is written to FIFO by OUT token is received to the CPU in the next frame.

- Below are two conditions in FIFO of Isochronous receiving mode transferring
- X. FIFO for storing data received from host in present frame (DATASET register bit = 0)
- Y. FIFO for storing data for transmitting host in previous frame (DATASET register bit = 1)

FIFO that is divided into two (packet A and packet B) conditions is whether X condition or Y condition. The flow below explains X Condition (packet A) and Y Condition (packet B) in present frame.

X and Y conditions change one after the other by receiving SOF.

Below is control flow in the UDC when receiving OUT token.

The whole transaction is processed by hardware.

- 1. Token packet is received and address endpoint number error is confirmed, and it checks whether the relevant endpoint transfer mode corresponds with the OUT token. If it does not correspond, the state returns to IDLE.
- 2. Condition of status register is confirmed.
  - INVALID condition: State returns to IDLE.
- 3. Data packet is received.

Data is transferred from SIE into the UDC to packet A's FIFO (X Condition).

- 4. After last data was transferred, and counted CRC is compared with transferred CRC. When transfer is finished, the result is reflected to STATUS. However, data is stored FIFO, data number that packet A is received is set to DATASIZE register of packet A.
- 5. The transaction when SOF token from host is received is given below.
  - Change packet A's FIFO from X Condition to Y Condition.
  - Change packet B from Y Condition to X Condition, and clear data. Prepare for next transfer.
  - Set frame number to frame register.
  - Assert SOF and inform externally that frame is incremented.
  - DATASET register set packet A bit and clear packet B bit arrangement loading in present frame.
  - If CRC comparison result agrees, DATAIN is set to STATUS. If result does not agree, RX\_ERR is set to STATUS.

The UDC finishes normally by the above transaction.

The CPU takes back packet A's data.

In renewed frame, Packet A's FIFO interchanges with packet B's FIFO, and the transaction uses the same flow.

If SOF token is not received by error and so on, this data is lost because the frame is not renewed. There is no problem in receiving PID and if frame data is received with CRC error, USB sets LOST to STATUS on FRAME register, and exact frame number is unknown. However, in this case, SOF is asserted and FIFO condition is renewed. If SOF token is received without transmit and transfer Isochronous in frame, UDC clears FIFO (X Condition) and sets STATUS to FULL.

These are shown in Figure 3.10.12.

Note: EPx\_DATASET changes at 2 clocks of 12MHz after receiving SOF. Read data from FIFO after EPx\_DATASET is rising.

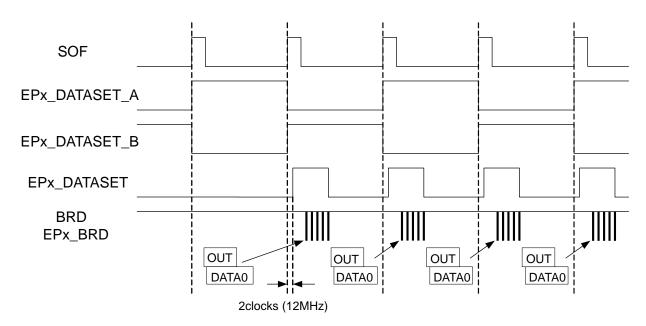

Figure 3.10.11 Isochronous Receiving mode

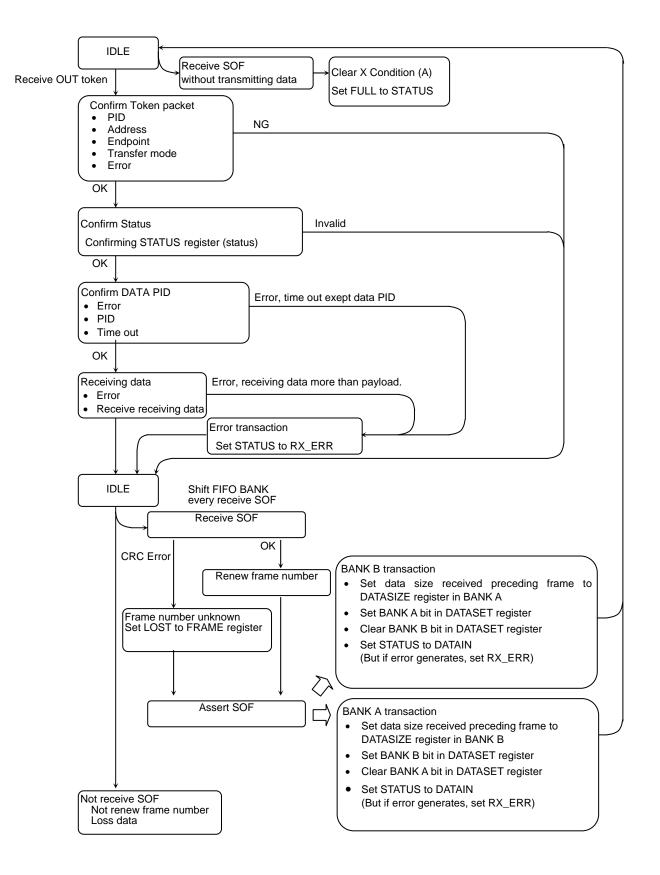

Figure 3.10.12 Control Flow in UDC (Isochronous transfer type (Receiving))

## 3.10.7 Bus Interface and Access to FIFO

## (1) CPU bus interface

The UDC prepares two types of FIFO access, single packet and dual packet. In single packet mode, FIFO capacity that is implemented by hardware is used as large FIFO. In dual packet mode, FIFO capacity is divided into two and used as two FIFOs. It is also used as an independent FIFO. Even if the UDC is transmitting and receiving to USB host, it can be used as an efficient bus by possible load to FIFO.

But control transfer type receives only single packet mode.

Epx\_SINGLE signal in dual packet mode must be fixed to "0". If this signal is fixed to "0", FIFO register runs in single mode.

Sample: Where endpoint 1 is used to dual packet of payload 64 bytes.

EP1_FIFO size	:	Prepare 128 bytes
EP1_SINGLE signal	:	Hold 0
EP1 Descriptor setting		
Direction	:	Optional
Max payload size	:	64 bytes
Transfer mode	:	Optional

(a) Single packet mode

This is data sequence of single packet mode when CPU bus interface is used. Figure 3.10.13 is receiving sequence. Figure 3.10.14 is transmitting sequence. This chapter focuses on access to FIFO. For Data sequence with USB host refer to chapter 5.

Endpoint 0 cannot be changed to exclusive single packet mode. Endpoints 1 to 3 can be changed between single packet and dual packet by setting Epx\_SINGLE register. Do not change packet when transferring.

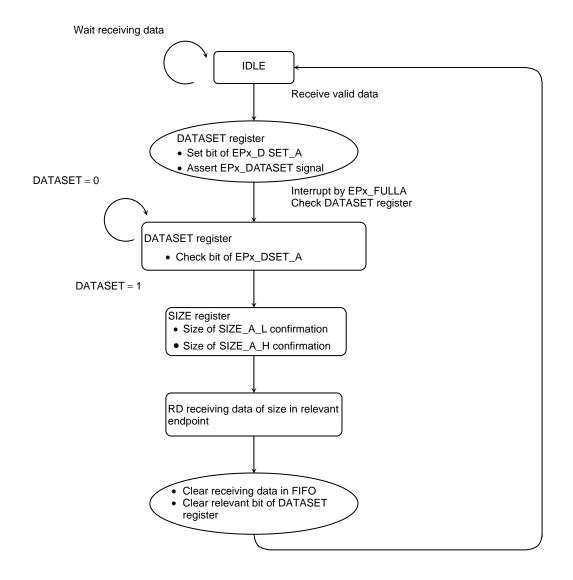

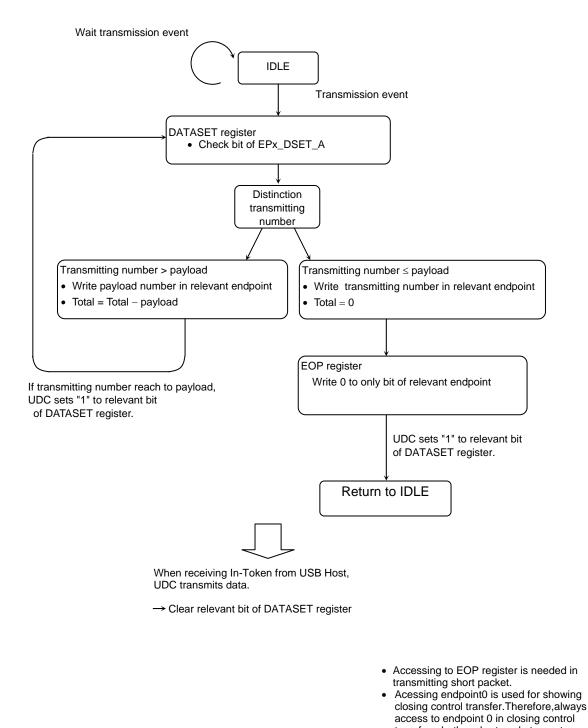

Figure 3.10.13 Receiving Sequence in Single Packet Mode

Below is the transmitting sequence in single packet mode.

Figure 3.10.14 Transmitting Sequence in Single Packet Mode

transfer whether short packet or not.

(b) Dual packet mode

In dual packet mode, FIFO is divided into A and B packet, and is controlled according to priority in hardware. It can be performed at once, transmitting and receiving data to USB host and exchanges to external of UDC. When it reads out data from FIFO for receiving, confirm condition of two packets, and consider the order of priority. If it has received data to two packets, the UDC outputs from first receiving data by FIFO that can be accessed are common in two packets. EPx\_SIZE register is prepared for both packet A and packet B. First, the CPU must recognize the data number of first receiving packet by PKT\_ACTIVE bit. If PKT\_ACTIVE bit was set to 1, that packet is received first. Packet A and packet B set data turn about always.

This sequence is shown below.

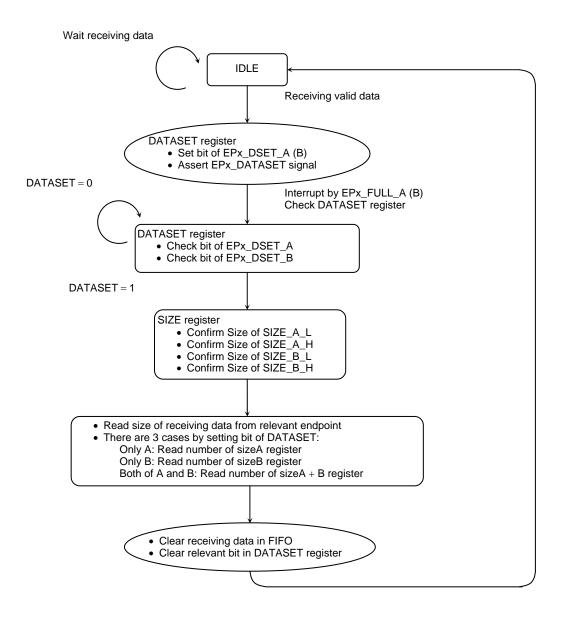

Figure 3.10.15 Receiving Sequence in Dual Packet Mode

Data can be set to available FIFO when transmitting regardless of packet A or B.

Below is the Transmitting Sequence in Dual Packet Mode.

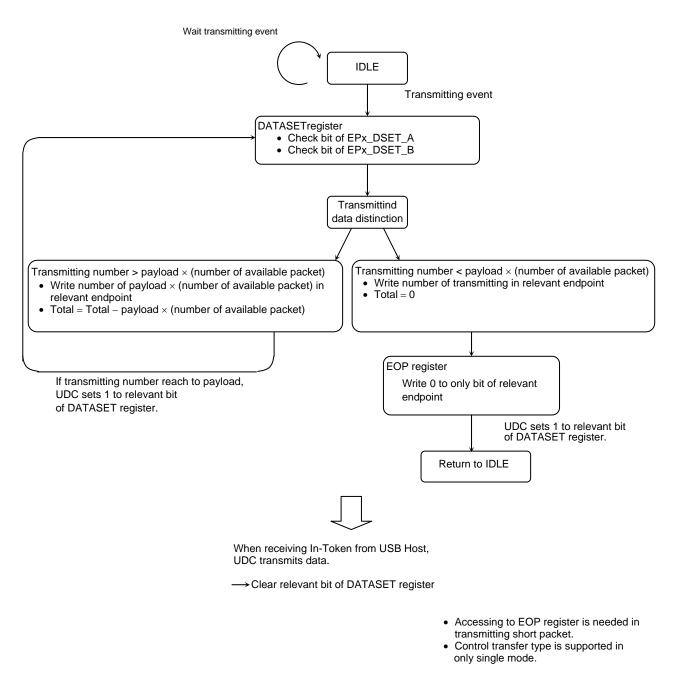

Figure 3.10.16 Transmitting Sequence in Dual Packet Mode

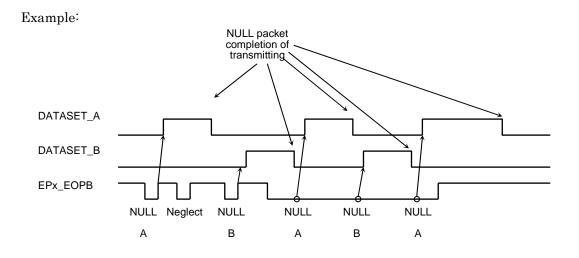

(c) Issuance of NULL packet

If transmitting NULL packet, by input L pulse from EPx\_EOPB signal, data of 0 length is set to FIFO, and NULL packet can be transferred to IN token.

But if NULL data is set to FIFO, it is valid only in the case where SET signal is L level condition (where FIFO is empty). If it answers to receiving IN token by using NULL packet in a certain period, it is answered by keeping EPx\_EOPB signal to L level.

However, if mode is dual packet mode, EPx\_DATASET signal assert L level for showing space of data. Therefore, data condition (whether either has data or not) cannot be confirmed externally.

Note: NULL packet can also be set by accessing EOP register.

(2) Interrupt control

Interrupt signal is prepared. This function uses adept system. For detail refer to 3.10.2 900/H1 CPU I/F.

## 3.10.8 USB Device answer

The USB controller (UDC) sets various registers and initialization in the UDC in detecting of hardware reset, detecting of USB bus reset, and enumeration answer. Each condition is explained below.

(1) Bus reset detect condition.

When the UDC detects a bus reset on the USB signal line, it initializes internal register, and it prepares enumeration operation from USB host. After detecting a USB reset, the UDC sets ENDPOINT0 to control transfer type 8-byte payload and default address for using default pipe. Any endpoint other than this is prohibited.

Register name		Initial value
ENDPOINT STATUS	EP0	00H
	Except for EP0	1CH

(2) Detail of STATUS register

Status register that was prepared for each endpoint shows the condition of each endpoint in the UDC.

Each condition affects the various USB transfers. Refer to chapter 5 for the changing conditions for each transfer type.

EPx\_STATUS register value is 0 to 3, and its conditions are shown below. 0 to 4 are the results of various transfers. It can be confirmed previous result that is transferred to endpoint by confirming from external of UDC.

- 0 READY
- 1 DATAIN
- 2 FULL
- 3 TX\_ERR
- 4 RX\_ERR

These conditions mean that the endpoint is operating normally. The meaning that is showed is different for each transfer mode. Therefore, please refer to each transfer mode column below. ISO transfer mode

Below is the transfer condition for the previous frame. Receiving SOF renews this.

	OUT (RX)	IN (TX)	
Initial	READY	READY	
Not transfer	READY	FULL	
Finish normally	DATAIN	READY	
Detect anerror	RXERR	TXERR	

Transfer modes other than ISO transfer

This is the result of the previous transfer. When transfer is finished, this is renewed.

	OUT, SETUP	IN
Initial	READY	READY
Transfer finish normally	DATAIN	READY
Status stage finish	READY	READY
Transfer error	RXERR	TXERR

"Initial" is that renew RESET, USB reset, Current\_Config register. In detect error, it does not generate EPx\_DATASET except in toggle transfer mode and Isochronous transfer mode of interrupt.

5 to 7 show the status register means that the endpoint is in special condition.

- 5 BUSY BUSY is generated only at endpoint of control transfer. If UDC transfer in control writes transfer, when CPU has not finished enumeration transaction, and if it receives ID of status stage from USB host, BUSY is set. STATUS is BUSY until CPU finishes enumeration transaction and EP0 bit of EOP register is written 0 in UDC. If CPU enumeration transaction finishes and EP0 bit of EOP register is written 0 and status stage from USB host finishes normally, it displays READY.
- 6 STALL Shows that endpoint is in STALL condition. This condition is generated if it violates protocol or error in bus enumeration. To return endpoint to normal transfer condition, USB device request is needed. This request returns to normal condition. But control endpoint returns to normal condition by receiving SETUP token. And it becomes SETUP stage.
- 7 INVALID This condition shows condition that endpoint cannot be used. UDC sets condition that isn't designated in ENDPOINT to INVALID condition, and it ignores all tokens for this endpoint. In initializing, this condition is always generated. When UDC detects hardware reset, it sets all endpoints to INVALID condition. Next, if USB reset is received, endpoint 0 only is renewed to READY. Other endpoints that are defined on disruptor are renewed if SET\_CONFIG request finishes normally.

## 3.10.9 Power Management

USB controller (UDC) can be switched from optional resume condition (turn on the power supply condition) to suspend (Suspension) condition, and it can be returned from suspend condition to turn on the power supply condition.

This function can be set to low electricity consumption by operating CLK supplying for UDC.

## (1) Switch to suspend condition

The USB host can set the USB device to suspend condition by maintaining IDLE state. The UDC switches to suspend condition by the following process.

- UDC switches to suspend condition if it detects IDLE state of more than 3 ms (about 3.07ms) on USB signal. At this point, UDC sets SUSPEND bit of STATUS register to "1".
- UDC renews USBINTFR1<INT\_SUS> and <INT\_CLKSTOP> from "0" to "1" if it detects IDLE state of more than 5 ms (about 5.46ms) on USB signal. Afterward reset USBCR1<USBCLKE> to "0" to stop USB clock.
- In this condition, all register values in the UDC are kept. However, external access is not possible except for reading of STATUS register, Current\_Config register, and USBINTFR1, USBINTFR2, USBINTMR1, USBINTMR2 and USBCR1.
- (2) Return from suspend condition by host resume

When activity of bus on USB signal is restored by resume condition output from USB host, the UDC releases SUSPEND condition, and it resets SUSPEND bit of STATUS register to "0". The system is thereby resumed. The resume condition output from the host is maintained for at least 20 ms. Therefore effective protocol occurs on USB signal line after this time has elapsed.

(3) Return from suspend condition by remote wakeup

Remote wakeup is system for prompt resume from suspended USB device to USB host. Some applications do not support remote wakeup. Remote wakeup is also limited using from USB host by bus enumeration.

UDC remote wakeup function can be used when it is permitted.

Setting remote wakeup by bus can be confirmed by bit7 of Current\_Config register. When this bit is "1", remote wakeup can be used. Remote wakeup is not disabled by this bit. Therefore, if this bit shows disabled, remote wakeup must not be set. If it fills the conditions, output resumes condition output to USB host by writing USBCR1<WAKEUP> from "1" to "0" of UDC in suspend condition. And it prompts resume from UDC to host. After UDC changes to suspend condition, WAKEUP input is ignored for 2 ms. Therefore, remote wakeup becomes effective when USBINTFR1<INT\_SUS> is set to "1".

(4) Low power consumption by control of CLK input signal

When the UDC switches to suspend condition, it stops CLK and switches to low power consumption condition. But as system, this function enables low power consumption by stopping source of CLK. CLK that is supplied to the UDC can be controlled by using USBINTFR1<INT\_SUS>, <INT\_CLKSTOP> and USBCR1<USBCLKE>.

If UDC switches to suspend condition, USBINTFR1<INT\_SUS> is set to "1", and <INT\_CLKSTOP> is set to "1". After confirmation, stop CLK supply (USBCLK) by setting "0" to USBCR1<USBCLKE>. If SUSPEND condition is released by resuming from host, supply normal CLK to UDC within 3 ms.

When remote wakeup is used, it is necessary to supply a stable CLK to the UDC before use. When doubler circuit is used as generation source, the above control is needed.

• Return from suspend condition by USB reset (by INT\_CLKON interrupt)

When UDC stops CLK in suspend condition, UDC can not detect USB reset and control CLK in suspend condition as above mentioned.

In case CLK is stopped in suspend condition, UDC can detect USB reset and return from suspend condition by supplying CLK (USBCR1<USBCLKE>=1) after detecting INT\_CLKON interrupt.

## (2) Register initial value

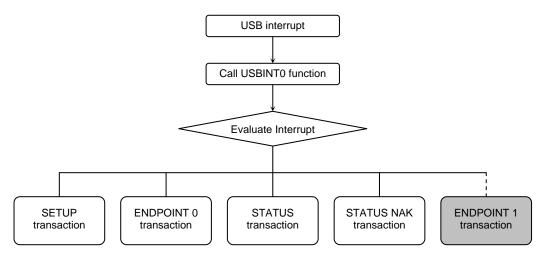

Note 1: The above initial value is the value that is initialized by external reset, USB\_RESET. This value may differ from that displayed depending on conditions.

Please refer to register configure in chapter 2.

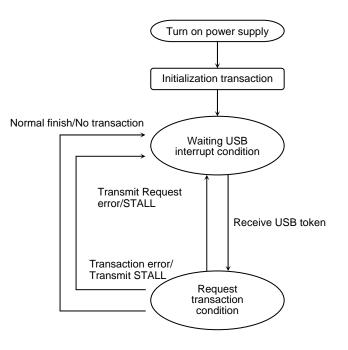

Note 2: EP0\_STATUS register is initialized to 0x00 after USB\_RESET is received.

Note 3: Initial value of ID\_STATE register is initialized by external reset, BRESET. When USB\_RESET signal is received from host, it is initialized to 0x00.

(c-26) Getting descriptor information (related to standard request)

## 3.10.11 Notice and Restrictions

1. Limitation of writing to COMMAND register in special timing

When "STALL" command is issued, ENDPOINT status might shift to "INVALID". To avoid this problem, follow the routine below.

a. BULK (IN/OUT)

When issuing a STALL command to endpoint in BULK transfer, be sure to issue STALL command after stopping RD/WR access to endpoint; that is UDC returns NAK in response to token from host. INT\_EPxNAK should be used to detect NAK transmit.

b. CONTROL OUT with data stage (software response)

If STALL needs to be set for endpoint 0 judging from request after receiving INT\_SETUP interrupt, access SetupReceived register. After that, issue STALL command after detecting INT\_ENDPOINT0 interrupt.

c. CONTROL OUT without data stage (software response)

If STALL needs to be set for endpoint 0 judging from request after receiving INT\_SETUP interrupt, issue STALL command before access to eop register.

d. CONTROL IN(software response)

If STALL needs to be set for endpoint 0 judging from request after receiving INT\_SETUP interrupt, issue STALL command before setting the first transmit data to host.

2. Limitation of EPx\_STATUS<STATUS2:0> when executing USB\_RESET command EPx\_STATUS<STATUS2:0> may indicate different condition, if aUSB\_RESET command is executed to the endpoint processing the token. To avoid this phenomenon, do not RESET the endpoint while transferring. (It is available when processing a request that needs USB\_RESET to that endpoint.)

- 3. When generating toggle error of device controller
  - a. UDC operation

If USB host fails to receive ACK transmitted from the UDC in OUT transfer, the USB host transmits the same data to the UDC again. When the FIFO is available to receive, the UDC detects toggle error because of detecting the same data(having the same toggle as the data which is received just before) and returns ACK. The UDC rejects it because the data have already been received normally. Meanwhile, if FIFO is not available, the UDC returns NAK and informs the USB host that it is unable to receive.

## b. USB1.1 Standard (from USB1.0 Standard description)

The priority of each process in USB1.0 and USB1.1 standard is explained as follows in chapter "8.4.5.3 Function Response to an OUT Transaction". It shows the priority of ACK response by toggle error (SequenceBitsMatch=No) is higher than that of NAK response.

Data Packet Corrupted	Receiver Halt Feature	Sequence Bits Match	Function Can Accept Data	Handshake Returned by Function
Yes	N/A	N/A	N/A	None
No	Set	N/A	N/A	STALL
No	Not set	No	N/A	ACK
No	Not set	Yes	Yes	ACK
No	Not set	Yes	No	NAK

Table 3.10.4 Function Responses to OUT Transactions in Order of Precedence

Since the UDC gives priority to detecting FIFO condition over toggle error, the UDC returns NAK in the response to USB host when FIFO is not available because it is full. This is shown in the flow chart "3.10.6(a-2) Receiving bulk mode". Thus, the UDC operates differently from USB standard under conditions where FIFO is not available.

For that reason, the UDC may generate the retry process several times in case of toggle error, while USB standard finishes it after the first time.

That is, the UDC returns NAK if it receives the data including toggle error with FIFO full. However, after FIFO becomes available, the UDC returns ACK to the USB host and finishes the retry process.

- 4. When using the USB device controller in the TMP92CH21, a crystal oscillator is recommended (USB standard  $\leq$  9 MHz $\pm$ 2500ppm). In this case, a maximum of 3 stages of external hub can be used due to the precision of this USB device controller and the internal clock.
- 5. Limitation of using the Isochronous IN transfer

When using the Isochronous IN transfer, do not use other endpoints simultaneously.

# 3.11 Analog/Digital Converter

The TMP92CH21 incorporates a 10-bit successive approximation type analog/digital converter (AD converter) with 4-channel analog input.

Figure 3.11.1 is a block diagram of the AD converter. The 4-channel analog input pins (AN0 to AN3) are shared with the input only port G so they can be used as an input port.

Note: When IDLE2, IDLE1 or STOP mode is selected, in order to reduce power consumption, the system may enter a stand-by mode with some timings even though the internal comparator is still enabled. Therefore be sure to check that AD converter operations are halted before a HALT instruction is executed.

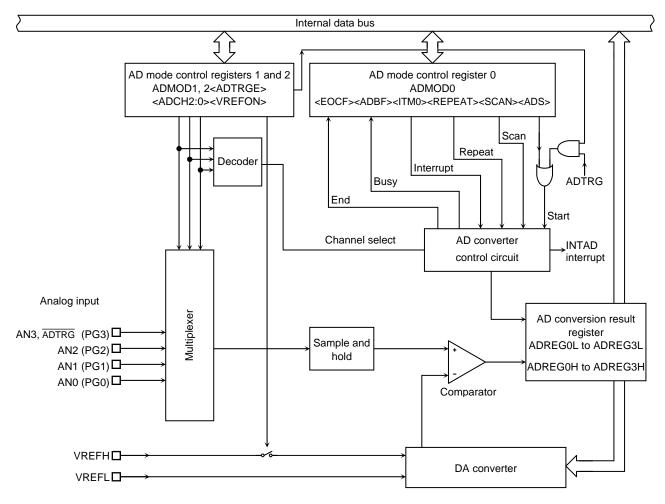

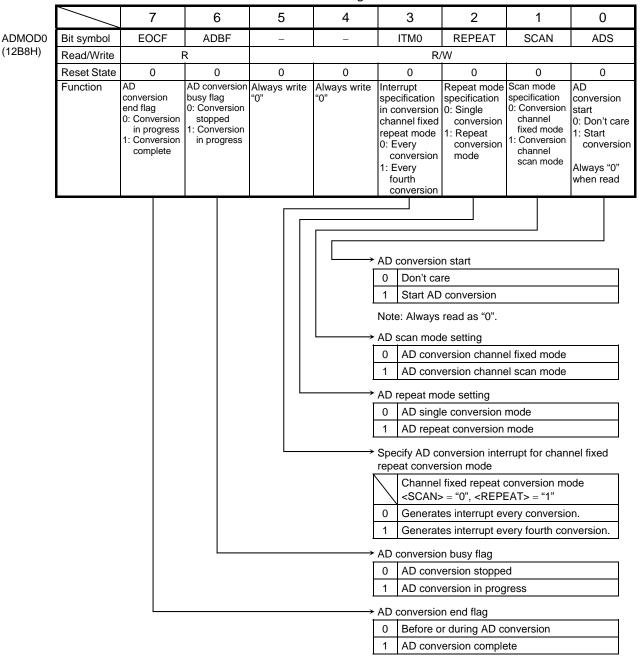

Figure 3.11.1 Block Diagram of AD Converter

## 3.11.1 Analog/Digital Converter Registers

The AD converter is controlled by the three AD mode control registers: ADMOD0, ADMOD1 and ADMOD2. The four AD conversion data result registers (ADREG0H/L to ADREG3H/L) store the results of AD conversion.

Figure 3.11.2 shows the registers related to the AD converter.

Figure 3.11.5 AD Converter Related Registers

read, the flag is cleared to 0.

- 3.11.2 Description of Operation
  - (1) Analog reference voltage

A high level analog reference voltage is applied to the VREFH pin; a low level analog reference voltage is applied to the VREFL pin. To perform AD conversion, the reference voltage, the difference between VREFH and VREFL, is divided by 1024 using string resistance. The result of the division is then compared with the analog input voltage.

To turn off the switch between VREFH and VREFL, write a 0 to ADMOD1  $\langle$ VREFON> in AD mode control register 1. To start AD conversion in the OFF state, first write a 1 to ADMOD1 $\langle$ VREFON>, wait 3 µs until the internal reference voltage stabilizes (this is not related to fc), then set ADMOD0 $\langle$ ADS> to 1.

(2) Analog input channel selection

The analog input channel selection varies depending on the operation mode of the AD converter.

- In analog input channel fixed mode (ADMOD0<SCAN> = 0)
   Setting ADMOD1<ADCH1:0> selects one of the input pins AN0 to AN3 as the input channel.
- In analog input channel scan mode (ADMOD0<SCAN> = 1) Setting ADMOD1<ADCH1:0> selects one of the four scan modes.

Table 3.11.1 illustrates analog input channel selection in each operation mode.

On a reset, ADMOD0<SCAN> is set to 0 and ADMOD1<ADCH1:0> is initialized to 00. Thus pin AN0 is selected as the fixed input channel. Pins not used as analog input channels can be used as standard input port pins.

	=	-
<adch1:0></adch1:0>	Channel Fixed <scan> = "0"</scan>	Channel Scan <scan> = "1"</scan>
00	AN0	ANO
01	AN1	$AN0 \rightarrow AN1$
10	AN2	$AN0 \rightarrow AN1 \rightarrow AN2$
11	AN3	$AN0 \rightarrow AN1 \rightarrow AN2 \rightarrow AN3$

Table 3.11.1 Analog Input Channel Selection

(3) Starting AD conversion

To start AD conversion, write a 1 to ADMODO<ADS> in AD mode control register "0" or ADMOD2<ADTRGE> in AD mode control register 2, and input falling edge on ADTRG pin. When AD conversion starts, the AD conversion busy flag ADMOD0<ADBF> will be set to 1, indicating that AD conversion is in progress.

During AD conversion, a falling edge input on the  $\overline{\text{ADTRG}}$  pin will be ignored.

(4) AD conversion modes and the AD conversion end interrupt

The four AD conversion modes are:

- Channel fixed single conversion mode
- Channel scan single conversion mode
- Channel fixed repeat conversion mode
- Channel scan repeat conversion mode

The ADMOD0<REPEAT> and ADMOD0<SCAN> settings in AD mode control register 0 determine the AD mode setting.

Completion of AD conversion triggers an INTAD AD conversion end interrupt request. Also, ADMOD0<EOCF> will be set to 1 to indicate that AD conversion has been completed.

1. Channel fixed single conversion mode

Setting ADMOD0<REPEAT> and ADMOD0<SCAN> to 00 selects conversion channel fixed single conversion mode.

In this mode, data on one specified channel is converted once only. When the conversion has been completed, the ADMOD0<EOCF> flag is set to 1, ADMOD0<ADBF> is cleared to 0, and an INTAD interrupt request is generated.

2. Channel scan single conversion mode

Setting ADMOD0<REPEAT> and ADMOD0<SCAN> to 01 selects conversion channel scan single conversion mode.

In this mode, data on the specified scan channels is converted once only. When scan conversion has been completed, ADMOD0<EOCF> is set to 1, ADMOD0<ADBF> is cleared to 0, and an INTAD interrupt request is generated.

3. Channel fixed repeat conversion mode

Setting ADMOD0<REPEAT> and ADMOD0<SCAN> to 10 selects conversion channel fixed repeat conversion mode.

In this mode, data on one specified channel is converted repeatedly. When conversion has been completed, ADMOD0<EOCF> is set to 1 and ADMOD0<ADBF> is not cleared to 0 but held at 1. INTAD interrupt request generation timing is determined by the setting of ADMOD0<ITM0>.

Setting <ITM0> to 0 generates an interrupt request every time an AD conversion is completed.

Setting  $<\!\!\text{ITM0}\!\!>$  to 1 generates an interrupt request on completion of every fourth conversion.

4. Channel scan repeat conversion mode

Setting ADMOD0<REPEAT> and ADMOD0<SCAN> to 11 selects conversion channel scan repeat conversion mode.

In this mode, data on the specified scan channels is converted repeatedly. When each scan conversion has been completed, ADMOD0<EOCF> is set to 1 and an INTAD interrupt request is generated. ADMOD0<ADBF> is not cleared to 0 but held at 1.

To stop conversion in a repeat conversion mode (e.g., in cases 3. and 4.), write a 0 to ADMOD0<REPEAT>. After the current conversion has been completed, the repeat conversion mode terminates and ADMOD0<ADBF> is cleared to 0.

Switching to a halt state (IDLE2 mode with ADMOD1<I2AD> cleared to 0, IDLE1 mode or STOP mode) immediately stops operation of the AD converter even when AD conversion is still in progress. In repeat conversion modes (e.g., in cases 3. and 4.), when the halt is released, conversion restarts from the beginning. In single conversion modes (e.g., in cases 1. and 2.), conversion does not restart when the halt is released (the converter remains stopped).

Table 3.11.2 shows the relationship between the AD conversion modes and interrupt requests.

Mode	Interrupt Request		ADMOD0	
Mode	Generation	<itm0></itm0>	<repeat></repeat>	<scan></scan>
Channel fixed single conversion mode	After completion of conversion	х	0	0
Channel scan single conversion mode	After completion of scan conversion	х	0	1
Channel fixed repeat	Every conversion	0	1	0
conversion mode	Every fourth conversion	1	Ι	0
Channel scan repeat conversion mode	After completion of every scan conversion	х	1	1

Table 3.11.2 Relationship between AD Conversion Modes and Interrupt Requests

X: Don't care

#### (5) AD conversion time

132 states (6.6  $\mu s$  at fSys = 20 MHz) are required for the AD conversion of one channel.

(6) Storing and reading the results of AD conversion

The AD conversion data upper and lower registers (ADREG0H/L to ADREG3H/L) store the results of AD conversion. (ADREG0H/L to ADREG3H/L are read-only registers.)

In channel fixed repeat conversion mode, the conversion results are stored successively in registers ADREG0H/L to ADREG3H/L. In other modes the AN0, AN1, AN2, AN3 and AN4 conversion results are stored in ADREG0H/L, ADREG1H/L, ADREG2H/L and ADREG3H/L respectively.

Table 3.11.3 shows the correspondence between the analog input channels and the registers which are used to hold the results of AD conversion.

Table 3.11.3 Correspondence between Analog Input Channels and AD Conversion Result Registers

	AD Conversion	n Result Register
Analog Input Channel (Port G)	Conversion Modes Other than at Right	Channel Fixed Repeat Conversion Mode (ADMOD0 <itm0 1="" =="">)</itm0>
AN0	ADREG0H/L	ADREG0H/L ←
AN1	ADREG1H/L	↓ ADREG1H/L
AN2	ADREG2H/L	ADREG2H/L
AN3	ADREG3H/L	↓ ADREG3H/L —

<ADRxRF>, bit0 of the AD conversion data lower register, is used as the AD conversion data storage flag. The storage flag indicates whether the AD conversion result register has been read or not. When a conversion result is stored in the AD conversion result register, the flag is set to 1. When either of the AD conversion result registers (ADREGxH or ADREGxL) is read, the flag is cleared to 0.

Reading the AD conversion result also clears the AD conversion end flag ADMOD0<EOCF> to 0.

Setting example:

1. Convert the analog input voltage on the AN3 pin and write the result to memory address 2800H using the AD interrupt (INTAD) processing routine.

Main routine:

		7	6	5	4	3	2	1	0	
INTE0AD	→ 0	1	1	0	0	_	_	-	-	Enable INTAD and set it to interrupt level 4.
ADMOD	1 ←	1	1	0	0	0	0	1	1	Set pin AN3 to be the analog input channel.
ADMOD	→ C	Х	Х	0	0	0	0	0	1	Start conversion in channel fixed single conversion mode.
- Interrupt	routine p	oroc	essir	ng ex	am	ole:				
WA	~	AE	RE	G3						Read value of ADREG3L and ADREG3H into 16-bits general-purpose register WA.
WA	~	>:	> 6							Shift contents read into WA six times to right and zero fill upper bits.
(2800H)	←	W	4							Write contents of WA to memory address 2800H.

2. This example repeatedly converts the analog input voltages on the three pins AN0, AN1 and AN2, using channel scan repeat conversion mode.

-	INTE0AD	←	1	0	0	0	-	-	-	_	Disable INTAD.
	ADMOD1	←	1	1	0	0	0	0	1	0	Set pins AN0 to AN2 to be the analog input channels.
_	ADMOD0	←	Х	Х	0	0	0	1	1	1	Start conversion in channel scan repeat conversion mode.
-	X: Don't care,	-: N	o ch	nang	е						

# 3.12 Watchdog Timer (Runaway detection timer)

The TMP92CH21 contains a watchdog timer of runaway detecting.

The watchdog timer (WDT) is used to return the CPU to the normal state when it detects that the CPU has started to malfunction (runaway) due to causes such as noise. When the watchdog timer detects a malfunction, it generates a non-maskable interrupt INTWD to notify the CPU of the malfunction.

Connecting the watchdog timer output to the reset pin internally forces a reset. (The level of external RESET pin is not changed.)

#### 3.12.1 Configuration

Figure 3.12.1 is a block diagram of the watchdog timer (WDT).

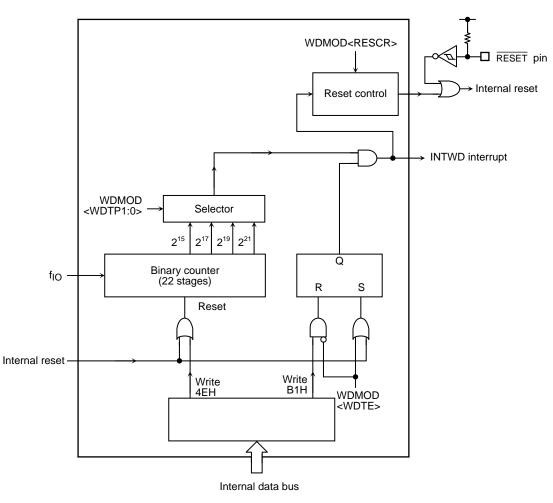

Figure 3.12.1 Block Diagram of Watchdog Timer

Note: Care must be exercised in the overall design of the apparatus since the watchdog timer may fail to function correctly due to external noise, etc.

### 3.12.2 Operation

The watchdog timer generates an INTWD interrupt when the detection time set in the WDMOD<WDTP1:0> has elapsed. The watchdog timer must be cleared to zero in software before an INTWD interrupt will be generated. If the CPU malfunctions (e.g., if runaway occurs) due to causes such as noise, but does not execute the instruction used to clear the binary counter, the binary counter will overflow and an INTWD interrupt will be generated. The CPU will detect malfunction (runaway) due to the INTWD interrupt, and in this case it is possible to return the CPU to normal operation by means of an anti-malfunction program.

The watchdog timer begins operating immediately on release of the watchdog timer reset.

The watchdog timer is reset and halted in IDLE1 or STOP mode. The watchdog timer counter continues counting during bus release (when  $\overline{\text{BUSAK}}$  goes low).

When the device is in IDLE2 mode, the operation of the WDT depends on the WDMOD<I2WDT> setting. Ensure that WDMOD<I2WDT> is set before the device enters IDLE2 mode.

The watchdog timer consists of a 22-stage binary counter which uses the clock  $\phi$  (2/fIO) as the input clock. The binary counter can output 2<sup>15</sup>/fIO, 2<sup>17</sup>/fIO, 2<sup>19</sup>/fIO and 2<sup>21</sup>/fIO.

WDT counter	n	χ	Overflow	_X	<u>}}</u>		0
WDT interrupt					···		
				Write	clear code —		_
WDT clear (Software)						_	

Figure 3.12.2 Normal Mode

The runaway detection result can also be connected to the reset pin internally.

In this case, the reset time will be between 22 and 29 system clocks (35.2 to  $46.4 \,\mu s$  at fosch = 40 MHz) as shown in Figure 3.12.3. After a reset, the fIO clock is fFPH/4, where fFPH is generated by dividing the high-speed oscillator clock (fosch) by sixteen through the clock gear function.

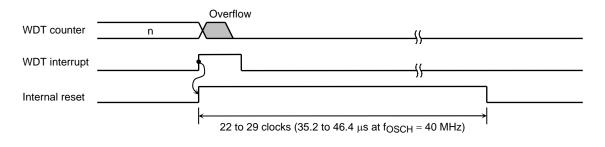

Figure 3.12.3 Reset Mode

## 3.12.3 Control Registers

The watchdog timer (WDT) is controlled by two control registers WDMOD and WDCR.

- (1) Watchdog timer mode register (WDMOD)
  - 1. Setting the detection time for the watchdog timer in <WDTP1:0>

This 2-bit register is used for setting the watchdog timer interrupt time used when detecting runaway.

On a reset this register is initialized to WDMOD < WDTP1:0 > = 00.

The detection time for WDT is  $2^{15}/f_{\rm IO}$  [s]. (The number of system clocks is approximately 65,536.)

2. Watchdog timer enable/disable control register <WDTE>

At reset, the WDMOD<WDTE> is initialized to 1, enabling the watchdog timer.

To disable the watchdog timer, it is necessary to set this bit to 0 and to write the disable code (B1H) to the watchdog timer control register (WDCR). This makes it difficult for the watchdog timer to be disabled by runaway.

However, it is possible to return the watchdog timer from the disabled state to the enabled state merely by setting <WDTE> to 1.

3. Watchdog timer out reset connection <RESCR>

This register is used to connect the output of the watchdog timer with the RESET terminal internally. Since WDMOD<RESCR> is initialized to 0 at reset, a reset by the watchdog timer will not be performed.

(2) Watchdog timer control register (WDCR)

This register is used to disable and clear the binary counter for the watchdog timer.

• Disable control

The watchdog timer can be disabled by clearing WDMOD<WDTE> to 0 and then writing the disable code (B1H) to the WDCR register.

WDCR	•	<u> </u>	0	1	0	0	1	1	1	0	Write the clear code (4EH).
WDMOD	+	<u></u>	0	_	_	Х	0	-	_	0	Clear WDMOD <wdte> to 0.</wdte>
WDCR	+	<u></u>	1	0	1	1	0	0	0	1	Write the disable code (B1H).

• Enable control

Set WDMOD<WDTE> to 1.

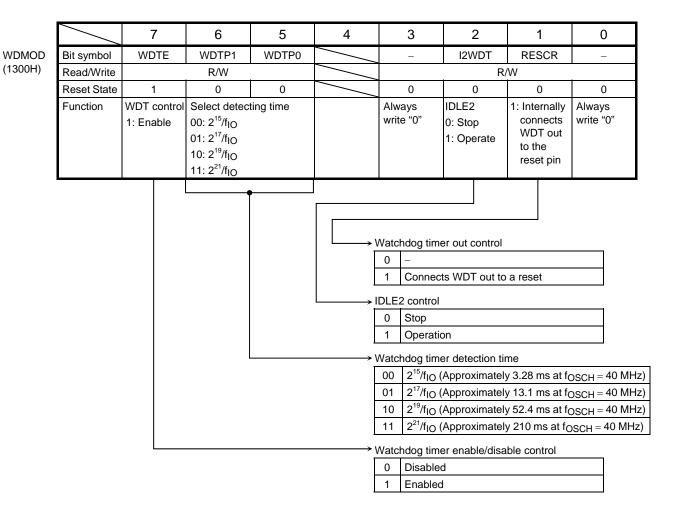

• Watchdog timer clear control

To clear the binary counter and cause counting to resume, write the clear code (4EH) to the WDCR register.

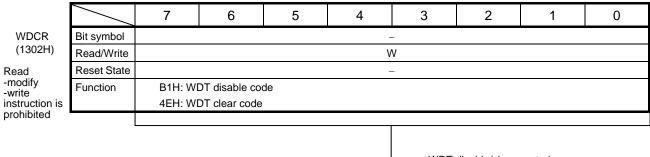

WDCR  $\leftarrow$  0 1 0 0 1 1 1 0 Write the clear code (4EH).

Note1: If the disable control is used, set the disable code (B1H) to WDCR after writing the clear code (4EH) once. (Please refer to setting example.)

Note2: If the watchdog timer setting is changed, change setting after setting to disable condition once.

-	WDT disable/clear control							
I	B1H	Disable code						
	4EH	Clear code						
	Others	Don't care						

Figure 3.12.5 Watchdog Timer Control Register

- 3.13 Real Time Clock (RTC)
  - 3.13.1 Function Description for RTC
    - 1) Clock function (hour, minute, second)
    - 2) Calendar function (month and day, day of the week, and leap year)
    - 3) 24- or 12-hour (AM/PM) clock function
    - 4) +/-30 s adjustment function (by software)
    - 5) Alarm function (alarm output)
    - 6) Alarm interrupt generate

#### 3.13.2 Block Diagram

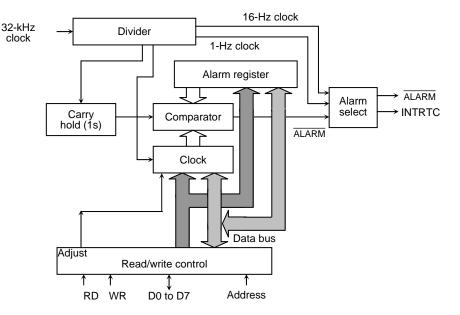

Figure 3.13.1 RTC Block Diagram

Note 1: Western calendar year column:

This product uses only the final two digits of the year. Therefore, the year following 99 is 00 years. In use, please take into account the first two digits when handling years in the western calendar.

Note 2: Leap year:

A leap year is divisible by 4, but the exception is any leap year which is divisible by 100; this is not considered a leap year. However, any year which is divisible by 400, is a leap year. This product does not take into account the above exceptions. Since this product accounts only for leap years divisible by 4, please adjust the system for any problems.

### 3.13.5 Operational description

### (1) Reading clock data

1. Using 1Hz interrupt

1Hz interrupt and the count up of internal data synchronize. Therefore, data can read correctly if reading data after 1Hz interrupt occurred.

2. Using two times reading

There is a possibility of incorrect clock data reading when the internal counter carries over. To ensure correct data reading, please read twice, as follows:

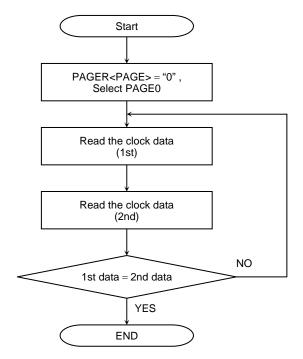

Figure 3.13.2 Flowchart of clock data read

### (2) Writing clock data

When a carry over occurs during a write operation, the data cannot be written correctly. Please use the following method to ensure data is written correctly.

1. Using 1Hz interrupt

1Hz interrupt and the count up of internal data synchronize. Therefore, data can write correctly if writing data after 1Hz interrupt occurred.

2. Resetting a counter

There are 15-stage counter inside the RTC, which generate a 1Hz clock from 32,768 kHz. The data is written after reset this counter.

However, if clearing the counter, it is counted up only first writing at half of the setting time, first writing only. Therefore, if setting the clock counter correctly, after clearing the counter, set the 1Hz-interrupt to enable. And set the time after the first interrupt (occurs at 0.5s) is occurred.

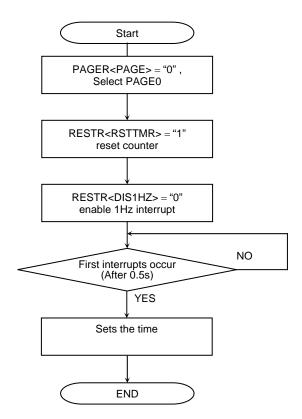

Figure 3.13.3 Flowchart of data write

2. Disabling the clock

A clock carry over is prohibited when "0" is written to PAGER<ENATMR> in order to prevent malfunction caused by the Carry hold circuit. While the clock is prohibited, the Carry hold circuit holds a one sec. carry signal from a divider. When the clock becomes enabled, the carry signal is output to the clock, the time is revised and operation continues. However, the clock is delayed when clock-disabled state continues for one second or more. Note that at this time system power is down while the clock is disabled. In this case the clock is stopped and clock is delayed.

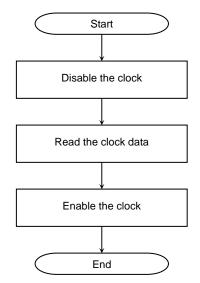

Figure 3.13.4 Flowchart of Clock disable

3.13.6 Explanation of the interrupt signal and alarm signal

The alarm function used by setting the PAGE1 register and outputting either of the following three signals from  $\overline{\text{ALARM}}$  pin by writing "1" to PAGER<PAGE>. INTRTC outputs a 1-shot pulse when the falling edge is detected. RTC is not initialized by RESET. Therefore, when the clock or alarm function is used, clear interrupt request flag in INTC (interrupt controller).

- (1) When the alarm register and the clock correspond, output "0".
- (2) 1Hz Output clock.
- (3) 16Hz Output clock.
- (1) When the alarm register and the clock correspond, output "0"

When PAGER<ENAALM>= "1", and the value of PAGE0 clock corresponds with PAGE1 alarm register, output "0" to  $\overline{\text{ALARM}}$  pin and generate INTRTC.

The methods for using the alarm are as follows:

Initialization of alarm is done by writing "1" to RESTR<RSTALM>. All alarm settings become Don't care. In this case, the alarm always corresponds with value of the clock, and if PAGER<ENAALM> is "1", INTRTC interrupt request is generated.

Setting alarm min., alarm hour, alarm date and alarm day is done by writing data to the relevant PAGE1 register.

When all setting contents correspond, RTC generates an INTRTC interrupt if PAGER<INTENA><ENAALM> is "1". However, contents which have not been set up (don't care state) are always considered to correspond.

Contents which have already been set up, cannot be returned independently to the Don't care state. In this case, the alarm must be initialized and alarm register reset.

The following is an example program for outputting an alarm from ALARM pin at noon (PM12:00) every day.

D	(PAGER), 09H	;	Alarm disable, setting PAGE1
D	(RESTR), D0H	;	Alarm initialize
D	(DAYR), 01H	;	W0
D	(DATER),01H		1 day
D	(HOURR), 12H	;	Setting 12 o'clock
D	(MINR), 00H	;	Setting 00 min
		;	Set up time 31 µs (Note)
D	(PAGER), 0CH	;	Alarm enable
D	(PAGER), 8CH	;	Interrupt enable )
	_D _D _D _D _D _D _D _D	LD (RESTR), D0H LD (DAYR), 01H LD (DATER),01H LD (HOURR), 12H LD (MINR), 00H LD (PAGER), 0CH	LD (RESTR), D0H ; LD (DAYR), 01H ; LD (DATER),01H ; LD (HOURR), 12H ; LD (MINR), 00H ; LD (PAGER), 0CH ;

When the CPU is operating at high frequency oscillation, it may take a maximum of one clock at 32 kHz (about 30us) for the time register setting to become valid. In the above example, it is necessary to set 31us of set up time between setting the time register and enabling the alarm register.

Note: This set up time is unnecessary when you use only internal interruption.

(2) With 1Hz output clock

RTC outputs a clock of 1Hz to ALARM pin by setting up PAGER<ENAALM>= "0", RESTR<DIS1HZ>= "0", <DIS16HZ>= "1". RTC also generates an INTRTC interrupt on the falling edge of the clock.

(3) With 16Hz output clock

RTC outputs a clock of 16Hz to ALARM pin by setting up PAGER<ENAALM>= "0", RESTR<DIS1HZ>= "1", <DIS16HZ>= "0". RTC also generates INTRTC an interrupt on the falling edge of the clock.

## 3.14 LCD Controller

This LSI incorporates two types of liquid crystal display driving circuit for controlling LCDs. One circuit supports an internal RAM LCD driver that can store display data in the LCD driver itself, and the other circuit supports a shift-register type LCD driver that must serially transfer the display data to the LCD driver for each display picture.

Software-programmable screen size supported.

This LCDC supports 2 bpp (bit per pixel: 4 grayscales), 3 bpp (8 grayscales), 4 bpp (16 grayscales) 8 bpp, (256 colors) and 12 bpp (4096 colors) for dot matrix panels. In passive matrix STN mode, it supports 8 bpp (256 colors) out of a palette of 4096 colors. And in active matrix TFT mode, it supports 8 bpp (256 colors) and 12 bpp (4096 colors).

Data bus width for 8- or 12-bit TFT panels is supported, and 8- and 4-bit wide LCD panel data bus for STN panels, plus hardware panning (soft horizontal and vertical scrolling).

### 1) Shift register type LCD driver control mode (SR mode)

This mode is for monochrome STN or color STN panels. Before setting start register, set the mode of operation, the start address of source data save memory and LCD size to control register.

After setting start register, the LCDC outputs a bus release request to the CPU and reads data from source memory.

The LCDC then transmits LCD size data to the external LCD driver through the special LCDC data bus (LD11 to LD0). At this time, the control signals connected to the LCD driver output the specified waveform which is synchronized with the data transmission. After display data reading from RAM is completed, the LCDC cancels the bus release request and the CPU will re-start.

In the TMP92CH21, SRAM and SDRAM burst mode can be used for the external display RAM. 16-Kbytes of internal RAM are available for use as display RAM. As internal RAM access is very fast (32-bit bus width, 1 SYSCLK read/write), it is possible to reduce CPU load to a minimum, enabling LCDC DMA.

2) Color display mode for TFT panel

The data transmission process is as above in SR mode. LD11 to LD0; 8 bpp RGB (R: 3, G: 3, B: 2) and 12 bpp RGB (R: 4, G: 4, B: 4), LCP0, LFR, LLP and LDIV: invert data line control the TFT source driver. And besides signals LCP1 and LBCD, OE can also control details of output timing for control of TFT gate driver.

### 3) Internal RAM LCD driver control mode (RAM mode)

Data transmission to the LCD driver is executed CPU command. After setting operation mode to control register, when CPU command is executed the LCDC outputs chip select signal to the LCD driver connected externally by control pin (LCP0 etc.). Therefore control of data transmission numbers corresponding to LCD size is controlled by CPU command.

# 3.14.1 LCDC features by Mode

The various features and pin operations of are as follows.

Table 3 14 1	LCDC features by	v Mode (eva	mole T6C13B	T6B664 hv	(Toshiha)
					10311104)

		-	pe LCD Driver Control Mode	RAM Built-in Type
	LCD driver	TFT	STN	LCD Driver Control

LCDMODE0 Register

Note: Only "burst 1clk access" SDRAM access is supported

## LCDMODE1 Register

	/	7	6	5	4	3	2	1	0
LCDMODE1	Bit symbol			LLPMODE	LDINV	AUTOINV	INTMODE	LDO1	LDO0
(0281H)	Read/Write			R/W	R/W	R/W	R/W	R/W	R/W
	Reset State			0	0	0	0	0	0
	Function			LLP mode	LD bus	Auto LD bus	Interrupt	LD bus width	o control
					inversion	inversion	select	00: 4-bit widt	h A type
					(Note 1)	0: Disable	0: LP	01: 4-bit widt	h B type
				0: Mode 1	0: Normal	1: Enable	1: BCD	10: 8-bit widt	h A type
				1: Mode 2	1: Inversion	(Valid in		11: 8-bit widt	h B type
						TFT mode)			

When using TFT mode, LD bus width is fixed below setting. Set "10" to <LDO1:0> for 256-color. For 4096-color, setting <LDO1:0> is not needed, but bus-width becomes 12-bit automatically.

Note: When setting  $\langle LDINV \rangle = 1$ , auto LD bus inversion function does not work.

<LDINV> = 0 must be set if you want to use auto LD bus inversion function.

LCD Size Setting Register

Note 1: Maximum size in color mode (STN,TFT) is  $320 \times 320$ .

When internal SRAM is set as display RAM, the maximum size is as below.

1 bpp (Monochrome):	$640\times200$
2 bpp (4 grayscales):	$320\times200$
4 bpp (16 grayscales):	$256\times128$
8 bpp (256 colors):	$128\times128$
12 bpp (4096 colors):	128  imes 64

Note 2: This LSI does not support 240-segment size, but if a cascade type segment driver is selected, it can used by setting for 256-segment size. In this case, a 256-segment display area must be prepared.

### 3.14.3 Shift Register Type LCD Driver Control Mode (SR mode and STN color)

3.14.3.1 Description of Operation

Set the mode of operation, start address of source data save memory, grayscale level and LCD size to control registers before setting start register.

After setting start register, the LCDC outputs a bus release request to the CPU and reads data from source memory. After data reading from source data is completed, the LCDC cancels the bus release request and the CPU will restart. The LCDC then transmits LCD size data to the external LCD driver through the LD bus (special data bus only for LCD driver). At this time, the control signals (LCP0 etc.) connected to the LCD driver output the specified waveform which is synchronized with the data transmission.

The LCD controller generates control signals (LFR, LBCD, LLP etc.) from base clock LCDSCC. LCDSCC is the base clock for the LCD controller, which is generated by system clock fSYS.

This LSI has a special clock generator for the LCDC. Details of LCD frame refresh rate can be set using this special generator. This generator is made from an 8-bit counter and 1/16 speed clock from the system clock.

- Note 1: During data read from source memory (during DMA operation), the CPU is stopped by the internal BUSREQ signal. When using SR mode LCDC, programmers must monitor CPU performance.
- Note 2: This LSI has a 16-Kbyte SRAM, this internal RAM is available for use as display RAM. Internal RAM access is very fast (32-bit bus width, 1 SYSCLK read/write), it is possible to reduce CPU load to a minimum, enabling LCDC DMA.

This LCDC supports monochrome, 2 bpp (4 grayscales), 3 bpp (8 grayscales), 4 bpp (16 grayscales), 8 bpp (256 colors) and 12 bpp (4096 colors). Display RAM is supported by external SDRAM, SRAM and internal RAM (16 Kbytes).

It is automatically set to suitable condition data correction against interference between pixels in panels. Special adjustment is not required.

In passive matrix STN mode, 8 bpp (256 colors) is supported out of a palette of 4096 colors. Support is also given for 4096 colors out of a pallet of 4096 colors.

Data output width is selectable between 4 bits or 8 bits, and data output sequence selectable between 2 modes.

SR type LCD control setting is described below.

### 3.14.3.2 Memory Space (Common spec. SR mode and TFT mode)

The LCDC can display an LCD panel image which is divided horizontally into 3 parts; upper, middle and lower. Each area is called A area, B area and C area with the characteristics shown below.

The Start/End address of each area in the physical memory space can be defined in the LCD start/end address registers. C area can be defined only in start address.

A and B areas can be displayed by program and set to enable or not in Start Address register and Row Number register. When the Row Number registers of A and B areas are set to 0, C area takes over all panel space.

When the size of A or B area is greater than the LCD panel, the area of the panel is all C area because the displaying priority is A > B > C. If the A area is set to enable while the panel area is defined as all C area (A and B areas are disabled), C area is shifted below the LCD panel and A area is inserted from the top of the LCD panel. Similarly if the B area is set to enable while the panel area is defined as all C area, B area is inserted from the bottom of the C area overlapping.

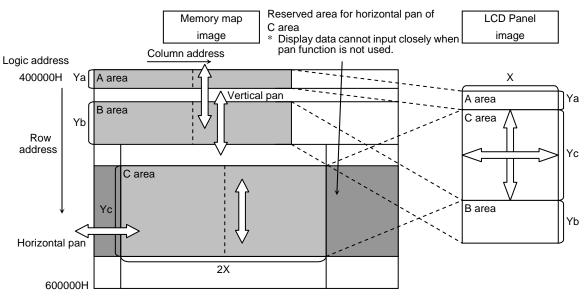

Figure 3.14.1 Memory Mapping from Physical Memory to LCD Panel

3.14.3.3 Display Memory Mapping and Panning Function (Common spec. SR mode and TFT mode)

The LCDC can only change the panel window if you change each start address of A, B and C areas. The display area can be panned vertically and horizontally by changing the row address and column address.

This LCDC can select many display modes: 1 bpp (monochrome), 2 bpp (4 grayscales), 3 bpp (8 grayscales), 4 bpp (16 grayscales), 8 bpp (256 colors) and 12 bpp (4096 colors) and 1-line (row). Data volume is different for each display mode. When using the panning function, care must be exercised in calculating the address for each display mode. For details, refer to Figure 3.14.2 to Figure 3.14.5, "Relation of memory map image and output data". This LCDC can also support external SDRAM, SRAM and internal SRAM for display RAM.

When using SDRAM for display RAM, data from one line to the next line cannot be input continuously in display RAM, even if the panning function is not used. One row address of display SDRAM corresponds to the first line of the display panel. Second line display data cannot now be set within the first row address of the display RAM even if the necessary data for the size you want to display does not fill the capacity of first row address of the display SDRAM. Adding one line to the display panel is equal to adding one address to the row address of the display SDRAM. In other words, when using SDRAM for display RAM, address calculation for panning is simple.

When using SRAM for display RAM, data from one line to the next line must be input continuously to the display RAM. However, address calculation for panning is complex and horizontal panning function is not supported.

### 3.14.3.4 Data Transmission

This LSI has an LD bus (LD7 to LD0): a special data bus for LCD driver. Bus width of 4-or 8-bits can be supported, and 2 formats selected for each bus width . The 2 formats of 8-bit bus width can support only STN color mode (256, 4096 colors). The 12-bit bus width supports only TFT mode.

LD bus data invert function is also supported. By setting LCDMODE2<LDINV> = 1, all LD bus data is inverted. There is <AUTOINV> bit in this LCDMODE2 register, but this automatic data invert function is only for TFT mode.

Figure 3.14.5 Relation of Memory Map Image and Output Data (4)

### 3.14.3.5 Refresh Rate Setting

Frame cycle (refresh rate) is generated from setting of LSCC (LCDSCC<SCC7:0>) and FP [9:0] (LCDCTL0<FP9, 8>, LCDFFP<FP7:0>). The LBCD terminal outputs one pulse every cycle and the LFR normally outputs an inverted signal every cycle. But when the DIVIDE FRAME function is used, the LFR signal changes to a special signal for high quality display.

(1) Basic clock setting

This LSI has a special clock generator for basic source clock used in the LCD controller. This generator can set details of the refresh rate for the LCDC.

This generator is made by dividing the system clock by 16 and an 8-bit counter.

The following shows the method of setting and calculation.

f<sub>BCD</sub>[Hz]: Frame rate (Refresh rate: Frequency of LBCD signal) FP: FP [9:0] setting value of FFP register SCC: <SCC7:0> setting value of LSCC register

 $f_{BCD}$  [Hz] =  $f_{SYS}$  [Hz] / ((SCC+1) × 16 × FP)

Example:

 $f_{\mbox{SYS}}\left[\mbox{Hz}\right]$  = 20MHz, 480COM (FP = 480), target refresh rate = 140Hz

140 [Hz] = 20000000 [Hz]/((SCC+1)  $\times$  16  $\times$  480)

(SCC+1) = 20000000/(140 ×16 × 480) = 18.60

Value of setting to register is only integer, SCC = 17. The floating value is disregarded.

In this case, the refresh rate comes to 144.6 [Hz]

						- 3								
		7	6	5	4	3	2	1	0					
LCDSCC (0287H)	Bit symbol	SCC7	SCC6	SCC5	SCC4	SCC3	SCC2	SCC1	SCC0					
	Read/Write	R/W												
	Reset State	0	0	0	0	0	0	0	0					
	Function	LCDC Source Clock Counter bit7 to bit0												

\* Data should be written from 1-hex to FFFF-hex in the above register. It cancannot operate if set to "0".

\* If the refresh rate is set too fast, it may not be in time with the display data. t<sub>LP</sub> time is determined by SCC.

 $t_{LP}[s] = (1/f_{SYS}[Hz]) \times 16 \times (SCC + 1)$ 

 $t_{LP}$  is shown in 1-line (ROW) display time. 1-line data transmission must be completed during  $t_{LP}$  cycle time. AboutRefer to "Data transmission and bus occupation" for details of data transmission time.

(2) Refresh rate adjust function (Correct function)

In this function, the LBCD frequency: refresh rate is generated by setting LCDSCC<SCC7:0> and FP [9:0] register. The FFP value is normally set at the same value as the ROW number, but this value can be used for correction of BCD frequency: refresh rate.

This function always uses a value greater than the ROW number, set to slower frequency. The LCDC cannot operate correctly if a value smaller than the ROW number is set.

The following is an example of settings:.

Example:

```
\label{eq:sys} \begin{array}{l} f_{SYS} \ [Hz] = 20 \ MHz, \ 480 \ COM \ ( \ FP = 480 \ ), \ Target \ refresh \ rate = 140 \ Hz \\ 140 \ [Hz] = 20000000 \ [Hz]/((SCC+1) \times 16 \times 480) \\ (SCC+1) = 2000000/(140 \times 16 \times 480) = 18.60 \end{array}
```

Value of setting to register is only integer, SCC = 17. The floating value is disregarded.

In this case, refresh rate comes to 144.6 [Hz]  $f_{BCD} \text{ [Hz]} = f_{SYS} \text{ [Hz]}/((\text{SCC+1}) \times 16 \times \text{FP})$ 

FP value is adjusted to set SCC=17 in above equation again.

140 [Hz] = 20000000/(18  $\times$  16  $\times$  FP) FP = 496.03

Value of setting to register is only integer, FP = 496.

In this case, refresh rate comes to 140.0 [Hz]

	Function	Setting bit7 to bit0 for fFP												

### LCD f<sub>FP</sub> Register

Reference) We recommend refresh rate values in the region of:... Monochrome: 70 [Hz]

4, 8, 16 grayscales and color: 140 to 200 [Hz]

(3) Divide frame adjust function

The DIVIDE FRAME function allows for adjustments to reduce uneven display in large LCD panels.

When this function is enabled by setting  $\langle FRMON \rangle = 1$ , the LFR signal alternates between high and low level with each LLP cycle for the LCDDVM register values given below.

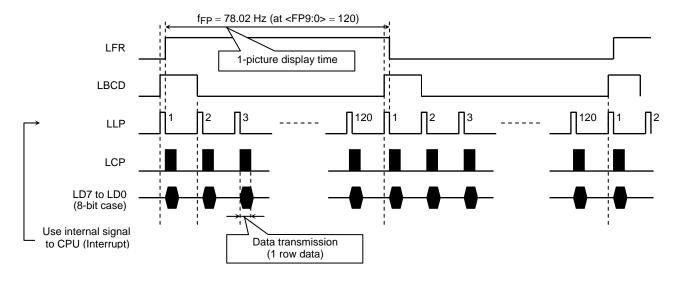

When this function is disabled by setting  $\langle FRMON \rangle = 0$ , the LFR signal alternates between high and low level with each LBCD cycle. This function is not affected by the LBCD timing.

Note: Availability of this function depends on the actual LCD driver or LCD panel used. We recommend checking that register's value when used in the proposed environment.

	Function Setting DVM bit7 to bit0													

#### Divide Frame Register

(Reference) In general, prime numbers (3, 5, 7, 11, 13 ...) are best for the value of the LCDDVM register.

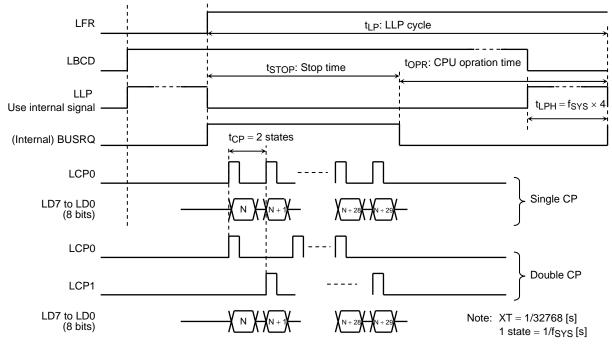

Figure 3.14.7 Detailed Timing Diagram of SR Mode

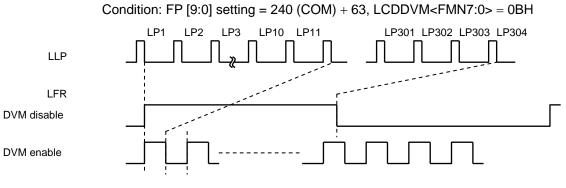

Figure 3.14.8 Waveform of LLP, LFR

### 3.14.3.6 LCD Data Transmission Speed and Data Bus Occupation Rate

After setting start register, the LCDC outputs a bus release request to the CPU and reads data from source memory. The LCDC then transmits LCD size data to the external LCD driver through the special LCDC data bus (LD11 to LD0). At this time, the control signals connected to the LCD driver output the specified waveform which is synchronized with the data transmission. After data reading from RAM for display is completed, the LCDC cancels the bus release request and the CPU will restart.

During data read from source memory (during DMA operation), the CPU is stopped by the internal BUSREQ signal. When using SR mode LCDC, programmers must monitor CPU performance. The occupation rate of the data bus depends on data size, transmission speed (CPU clock speed) and display RAM type used.

Display RAM	Bus Width	Valid Data Reading Time (f <sub>SYS</sub> Clock/Byte)	Valid Data Reading Time t <sub>LRD</sub> (ns/Byte) at f <sub>SYS</sub> = 20 MHz
External SRAM	16 bits	2/2	50
	32 bits	2/4	25
Internal RAM	32 bits	1/4	12.5
External SDRAM	16 bits	*1/2	*25
	32 bits	*1/4	*12.5

Note: When using SDRAM for display RAM, overhead time (+ 8 clocks) is required for every 1 row data reading.

t<sub>STOP</sub> refers to the CPU stoppage time during transmission of 1 row data. t<sub>STOP</sub> is calculated by the equation below for each display mode.

t <sub>STOP</sub> = (S	SegNum × K/8) × $t_{LRD}$		; Except SDRAM use
SegNum	: Number of segmen	t	
К	: bit number per pixe	l (bpp)	
	Monochrome	K = 1	
	4 Grayscales	K = 2	
	8/16 Grayscales	K = 4	
	256 colors	K = 8	
	4096 colors	K = 12	
	used, more overhead tir	•	
t <sub>STOP</sub> = (S	SegNum × K/8) × t <sub>LRD</sub> +	((1/f <sub>SYS</sub> ) × 8)	; SDRAM use

Data bus occupation rate equals the percentage of  $t_{\text{STOP}}$  time in  $t_{\text{LP}}$  time.

Data bus occupation rate =  $t_{STOP}/t_{LP}$ 

Wh

Note: For t<sub>LP</sub> time, refer to "refresh rate setting".

### 3.14.3.7 Timing Diagram of LD Bus

The TMP92CH21 can select to display RAM for external SRAM: Available to set WAIT, internal SRAM and external SDRAM: 16, 32, 64, 128, 256 and 512 Mbits.

As a 480-byte FIFO buffer is built into this LCDC, the LD bus speed can be controlled.

The speed can be selected from 3 kinds of cycle: (fSYS/2, fSYS/4, and fSYS/8)

LD bus data: LD11 to LD0 is out at rising edge of LCP0, LCD driver receives at falling edge of LCP0.

Note: If the LCP cycle is too slow it may not transfer correctly.

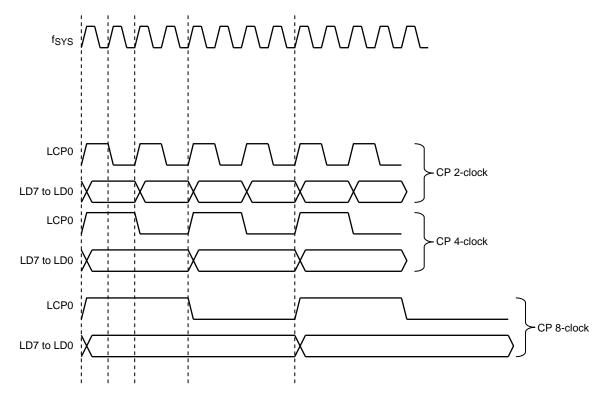

Figure 3.14.9 Selection of LCP Cycle

If LCP cycle is not set at a suitable speed with respect to the refresh rate, LD bus data will not transfer correctly. tLP time is shown in the equation below.

 $t_{LP} [s] = (1/f_{SYS} [Hz]) \times 16 \times (SCC+1)$ 

Data transmission must finish in  $t_{LP}$  time. Set SCC clock and LCP0 speed to be less than  $t_{LP}$  time. For setting of SCC, refer to "basic clock setting" of "refresh rate setting".

The kind of display memory and display mode determine LCP speed. In other words, when the setting is too fast, there will be not enough transmission data in FIFO, and LCD data will not transfer correctly.

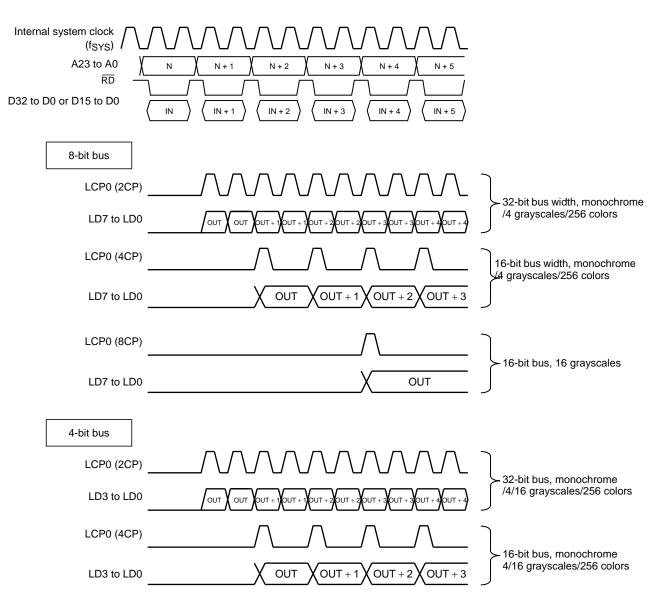

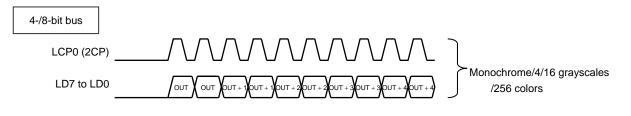

Figure 3.14.10 Fastest Timing Diagram for External SRAM, 0 waits

\* When using internal SRAM, always select 32-bit bus width and 0 waits, 1 clocks access.

Figure 3.14.11 Timing Diagram for Internal SRAM

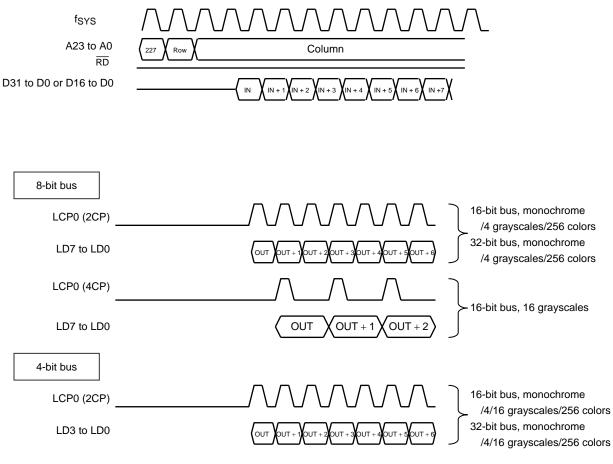

Figure 3.14.12 Timing Diagram of SDRAM Burst Run

### 3.14.3.8 Setting of Color Palette

This LSI can support monochrome, 4-, 8-, 16-level grayscales and color STN panels, and color TFT panels. The following shows the settings for each mode.

• Monochrome

No need for special setting, simply select monochrome mode by LCDMODE1<MODE3:0> register.

• 4, 8, 16 grayscales

No need for special setting, as with monochrome mode, simply select monochrome mode by LCDMODE1<MODE3:0> register.

For 8- and 16-level grayscale modes, both settings need 4-bit data per 1 pixel. Even if set to 8 grayscales mode, the LSB bit of the display data is invalid.

• 256 colors STN

Firstly, select STN256 color mode by LCDMODE1<MODE3:0> and next set the detail contrast adjustment. In 256STN color mode, 8-bit display data is divided into 3 bits (red), 3 bits (green) and 2 bits (blue). Red and green are 8-level contrast and blue is 4 level contrast. Each level can be adjusted from 16-level contrast.

Red contrast level can be selected by LCDRP10, LCDRP32, LCDRP54 and LCDRP76registers, green by LCDGP10, LCDGP32, LCDGP54 and LCDGP76, and blue by LCDBP10, and LCDBP32.

As a result, support is given for for 8 bpp: 256 colors out of a palette of 4096 colors.

# 3.14.4 TFT Color Display Mode

#### 3.14.4.1 Description of Operation

This is basically the same setting as for SR mode.

Set the mode of operation, start address of source data save memory, color level and LCD size to control registers before setting start register.

After setting start register, the LCDC outputs a bus release request to the CPU and reads data from source memory. After data reading from source data is completed, the LCDC cancels the bus release request and the CPU will restart. The LCDC then transmits LCD size data to the external LCD driver through the LD bus (the special data bus only for LCD driver). At this time, the control signals (LCP0 etc.) connected to the LCD driver output the specified waveform which is synchronized with the data transmission.

In TFT mode LCDC, the CPU is stopped by the internal BUSREQ signal during data read from source memory (during DMA operation).

The LCD controller generates control signals (LFR, LBCD, LLP etc.) from base clock LCDSCC. LCDSCC is the base clock for the LCD controller, which is generated by system clock fSYS.

For TFT source driver, the following signals are supported: 8-bit RGB or 4-bit × RGB special data bus and LCP0, LFR, LLP and LDIV.

And for TFT gate driver control, LCP1, LBCD and LGOE2 to LGOE0.

#### 3.14.4.2 Memory Space

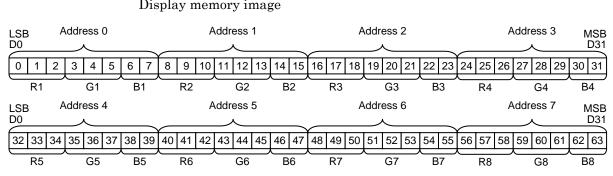

Memory space setting is the same as for SR mode. Refer to SR mode section.

#### 3.14.4.3 Mapping of Display Memory and Panning Function

Panning function and display memory mapping are the same as for SR mode. Refer to SR mode section.

#### 3.14.4.4 Data Transmission

This LSI outputs display data form special bus for LCD driver. The LCD driver input width can be selected. 8-bit and 12-bit widths are supported.

# Relation of memory map image and output data

• 256 colors (8 bpp; R: 3 bits, G: 3 bits, B: 2 bits) Display memory image

#### LD bus output sequence

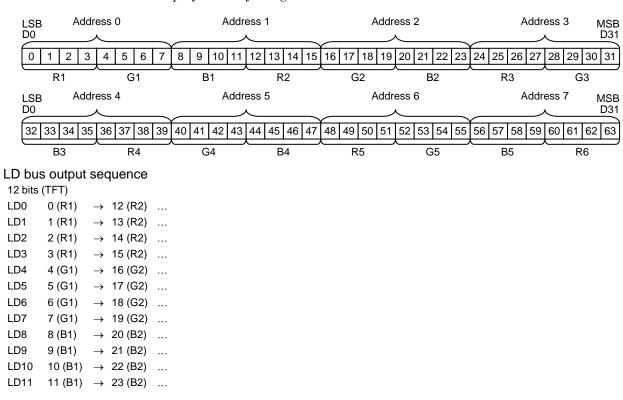

8 bits (TFT) LD0  $0\;(\mathsf{R1})\;\;\rightarrow\;\;8\;(\mathsf{R2})$ ...  $1~(\text{R1})~\rightarrow~9~(\text{R2})$ LD1 ... LD2 2 (R1) → 10 (R2) ... LD3  $3 (G1) \rightarrow 11 (G2)$ ... LD4  $4~(\text{G1})~\rightarrow~12~(\text{G2})~\dots$ LD5  $5 (G1) \rightarrow 13 (G2) \dots$ LD6  $6 (B1) \rightarrow 14 (B2) \dots$ LD7  $7 (B1) \rightarrow 15 (B2) \dots$ 

\* When using 256-color TFT mode, 8-bit LD bus width must be used.

LD8, LD9, LD10 and LD11 terminals are available for use as general ports.

#### 3.14.4.5 Setting Each Control Signals

The TFT source driver is controlled by base clock (LCP0), data start clock (LFR) and load pulse (LLP). Special data bus LD11 to LD0 uses 8 bits or 12 bits for suitable LCD driver.

The timing of each signal can be finely adjusted using the relevant control register.

When using the TFT driver a large amount of data is required. So, when using wide bus and high speed transmission, some noise may be generated. This LSI has an LDIV function. This function automatically sets the minimum data change method, from inverting data and LDIV signal, to comparing current data with the previous data. If the TFT LCD driver supports the data inverting function, it is possible to decrease the noise.

The following shows basic timings.

Figure 3.14.17 Timing Diagram of TFT Driver Control

		7	6	5	4	3	2	1	0
	Bit symbol						PCPV2	PCPV1	PCPV0
(0288H)	Read/Write	/					R/W	R/W	R/W
	Reset State	/					0	0	0
	Function						Pre LCP1 CLK: LCP1 pulse number		
							Dummy clock number until valid clock of gate driver LCP1		

LCD Clock Counter Register 0

Delay control 1 is set by LCDCCR0<PCPV2:0>. Delay of Dummy clock is controlled by pulse number derived by subtracting common number and <PCPV2:0> from LCDFFP<FP9:0> (refer to SR mode section).

LCD Clock Counter Register 1

	/	7	6	5	4	3	2	1	0	
LCDCCR1	Bit symbol				TLDE4	TLDE3	TLDE2	TLDE1	TLDE0	
(0289H)	Read/Write				R/W	R/W	R/W	R/W	R/W	
	Reset State				0	0	0	0	0	
	Function				LLP_Set-up time: f <sub>SYS</sub> pulse × 8					
					Set up time for TFT source driver LLP signal					
						(Offset	of f <sub>SYS</sub> 14~16	i pulse)		

Set up time of LLP (horizontal front porch) is set in LCDCCR1<TLDE4:0>. This is called "Delay control 2". 1 pulse of this set up time in LCDCCR1 register is equal to 8 times of fsys regardless of LCP0 and LCP1. The set up time has offset time; fsys\*14 to 16(f<sub>SYS</sub> × 14.5 or more). If "0" is written in LCDCCR1 register, fsys\*14 to 16 of time is delayed. This offset time changes according to the setting conditions. The cycle of LCP1 is determined by (the value of LCDSCC register +1) \* fsys \* 16, thus horizontal back porch is the time when offset time and set up time are subtracted from the cycle of LCP1.

LCDCCR2 (028AH)		7	6	5	4	3	2	1	0
	Bit symbol	LLPSU7	LLPSU6	LLPSU5	LLPSU4	LLPSU3	LLPSU2	LLPSU1	LLPSU0
	Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
	Reset State	0	0	0	0	0	0	0	0
Function TFT source driver, LLP_Enable signal: f <sub>SYS</sub> × 8									
				Н	ligh width time	e for LLP signa	al		

LCD Clock Counter Register 2

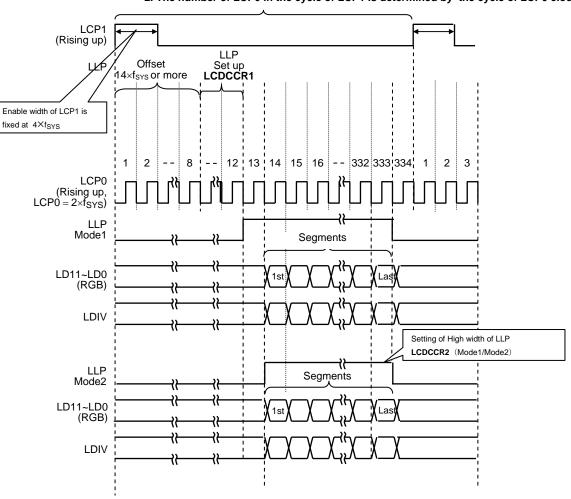

The pulse number of LCP0 in LCDCCR2 means enable time of LLP. This register determines "High width" time as mentioned above. 1 pulse of this time in LCDCCR2 register is equal to 8 times of fsys regardless of LCP0 and LCP1. If "0" is written in LCDCCR2 register, High level is output during the period that the valid data is output from LD bus.

(In Mode1, high level is kept during one more LCP0 than valid data.)

# 3.14.5 Source Driver Control

Data shift clock; LCP0, Data; LD11 to LD0 and LLP signals become valid after the time (offset time + set up time set in (LCDCCR1)) from LCP1.

LLP signal has 2 modes; Mode1 (LLP rises 1 LCP0 clock before valid data) and Mode2 (LLP rises at the same time as valid data)

1. The cycle of LCP1 is determined by (LCDSCC+1)  $\times$  f<sub>SYS</sub>  $\times$  16 2. The number of LCP0 in the cycle of LCP1 is determined by the cycle of LCP0 clock.

\* Condition: Segment = 320, LCDCCR1 = 1, LCP0 =  $2 \times f_{SYS}$ , LCDSCC = 41

Figure 3.14.18 Timing Example for TFT Driver

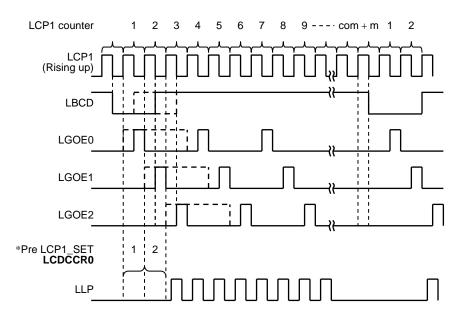

Note: The above figure and explanation are under the following condition. <LCDCTL2> CPHP = 1, CPVP = 0

When <LCDCTL2> CPHP = 0, CPVP = 1, the alignment of LCP0/LCP1 inverts.

#### 3.14.5.1 Gate Driver Control

The TFT gate driver is controlled bybase clock LCP1and vertical shift data signal LBCD. This LSI has 3-bit output enable signals LGOE2 to LGOE0which can be controlled individually. The TFT gate driver's output can be controlled by this timing and is available for blanking adjustment and zoom function.

The LBCD signal begins output from rising of LCP1 and the TFT gate driver recognizes the start point of the vertical direction. LGOE0 then outputs from rising of LCP1 and repeats. LGOE1 outputs one LCP1 clock delayed. LGOE2 delay one LCP1 clock from LGOE1. By LCDCTL1<LBCDW1:0> setting, the width of LBCD can be selected from 1, 2, or 3 clocks of LCP1.

# 1. The cycle of LBCD is determined by the setting of (LCDFFP) register. 2. Enable width of LBCD is selectable from (1×LCP1) to (3×LCP1).

Note 1: LCP1 counter (LCDFFP) : 1024 clocks maximum

Note 2: Pre\_LCP1\_SET (LCDCCR0) : 8 clocks (3bits) of LCP1 maximum

Figure 3.14.19 Example of TFT Gate Driver Timing Control

(Notes on settings)

- 1. LCP0 cycle: LCP0=fsys × n (n=2, 4, 8: transmission speed of LD bus) LCP0 cycle is generated by system clock and value of LCDMODE0<SCPW1:0>
- 2. LCP1 cycle: LCP1= f<sub>SYS</sub> × 16 × (SCC + 1) LCP1 cycle is generated by value of LCDSCC register. High level width of LCP1 is fixed to f<sub>SYS</sub> × 4 times. (Positive edge)

As indicated above, the cycles of LCP0 and LCP1 are able to set each other. There are some limitations to settings of LD bus speed and LCDSCC.

Segment	Transmission	Minimum		
Size	Speed of	LCDSCC		
	LD bus	value		
	2	9		
64	4	17		
	8	33		
	2	17		
128	4	33		
	8	65		
	2	21		
160	4	41		
	8	81		
	2	33		
256	4	65		
	8	129		
	2	41		
320	4	81		
	8	161		

High level width of LLP is adjusted every  $f_{SYS} \times 8$  cycle. However, LLP is adjusted every 2-clock of LLP when transmission speed of the LD bus is set to 2-Clock. LLP is also adjusted every 4-clock of LLP when transmission speed of the LD bus is set to 4-clock of LCP0.

Setting method is the same as in the STN case, following the calculation below.

f <sub>BCD</sub> [Hz]	: Frame frequency (Refresh rate: LBCD cycle)
FP	: FP [9:0] FFP register setting value
SCC	: SCC [7:0] LSCC register setting value

 $f_{BCD}$  [Hz] =  $f_{SYS}$  [Hz] / ((SCC+1) × 16 × FP)

Frame correction function is the same as in the STN case.

3. LCP1 Setting: Vertical front porch is determined by LCDCCR0.

Vertical front porch is determined by the above 3bits; LCDCCR0<PCPV2:0>. Vertical back porch is controlled by the pulse number which is <PCPV2:0> subtracted from LCDFFP<FP9:0> as explained in the SR mode section.

4. LLP Setting: Set up time is determined by LCDCCR1.

Set up time of LLP (horizontal front porch) is set in LCDCCR1 register. This is called "Delay control 2". 1 pulse of this set up time in LCDCCR1 register is equal to 8 times of fsys regardless of LCP0 and LCP1. The set up time has offset time; fsys×14 or more. If "0" is written in LCDCCR1 register, fsys×14.5 or more of time is delayed. This offset time changes according to the setting conditions. The cycle of LCP1 is determined by (the value of LCDSCC register +1) × fsys × 16, thus horizontal back porch is the time where offset time and set up time are subtracted from the cycle of LCP1.

5. LLP High width: High width of LLP is determined by LCDCCR2.

The pulse number of LCP0 in LCDCCR2 means enable time of LLP. This register determines "High width" time as mentioned above. 1 pulse of this time in LCDCCR2 register is equal to 8 times of fsys regardless of LCP0 and LCP1. If "0" is written in LCDCCR2 register, High level is output during the period that the valid data is output from the LD bus.

(In Mode1, high level is kept during one more LCP0 than valid data.)

6. LDIV: Enable/disable of Auto Invert function is determined by LCDMODE1<AUTOINV>.

If "1" is written in LCDMODE1<AUTOINV> bit, the LCD controller monitors the status of the LD bus. The LCDC compares the value of previous data with the data supposed to be sent. If more than a majority of all the LD bus change, LDIV outputs "1" and the LCDC inverts the LD bus value that was supposed to be sent.

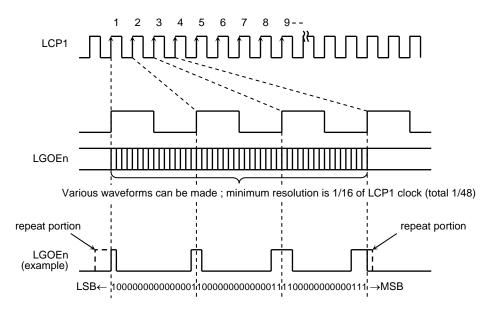

This is effective in reducing noise or power consumption where the LCD driver has an LDIV pin.

7. LGOE0 to 2: Programmable waveform

LGOE0 is output on the rising edge of the first LCP1 and repeats every 3 pulses of LCP1. LGOE1 is the 2nd LCP1 and LGOE2 the 3rd, and they also repeat every 3 pulses of LCP1.

LGOE0 to LGOE2 can be generated by 1/16 clocks of LCP1 cycle set in control registers (48bits  $\times$  3) respectively.

These signals can finely adjust the gate output signal and this will enables fine adjustment of gate bias (the setting of blanking) or zoom function without modification of data etc.

Various waveforms can be generated by writing LCDOEn5 to LCDOEn0 registers (48bits for each signal). (When "1" is written, output is High level. When "0" is written, output is Low level. The direction of data is from LSB to MSB.)

Figure 3.14.20 Details of waveform of LGOEn for gate driver

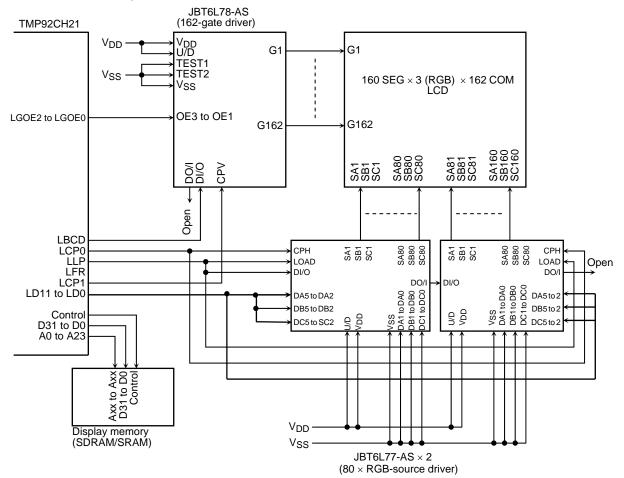

Note1) The above explanation and figures are given for the setting below. Condition: <LCDCTL2>CPHP = 1, CPVP = 0

For CPHP = 0, CPVP = 1 setting, LCP0 and LCP1 phases are inverted.

Note2) The minimum resolution of LGOEn is 1/16 of LCP1 cycle.

LCP1= (LCDSCC+1)  $\times$  f<sub>SYS</sub>  $\times$ 16

Thus, the minimum resolution of LGOEn is (LCDSCC +1)  $\times$   $f_{SYS}.$ 

3.14.5.2 Example of TFT LCD driver connection

Note: Other circuit is required for power supply for driving LCD driver.

# 3.14.6 Built-in RAM Type LCD driver Mode

3.14.6.1 Description of Operation

Data transmission to the LCD driver is executed by a transmit instruction from the CPU.

After setting operation mode of to the control register, when a CPU transmit instruction is executed the LCDC outputs a chip select signal to the LCD driver connected externally by the control pin (LCP0...). Therefore control of data transmission numbers corresponding to LCD size is controlled by CPU instruction. There are 2 kinds of LCD driver address in this case, which are selected by the LCDCTL<MMULCD> register.

#### 3.14.6.2 Random Access Type

This corresponds to address direct writing type LCD driver when  $\langle MMULCD \rangle = "1"$ . The transmission address can also assign the memory area 3C0000H - 3FFFFF, the four areas each being 64 Kbytes.

Interface and access timing are the same as for normal memory. Refer to the memory access timing section.

Address	Function	Chip Enable Terminal						
3C0000H to 3CFFFFH	Built-in RAM LCDD1	LCP0						
3D0000H to 3DFFFFH	Built-in RAM LCDD2	LLP						
3E0000H to 3EFFFFH	Built-in RAM LCDD3	LFR						
3F0000H to 3FFFFFH	Built-in RAM LCDD4	LBCD						

Table 3.14.2 Racdom Access Type Built-in RAM Type LCD driver

#### 3.14.6.3 Sequential Access Type

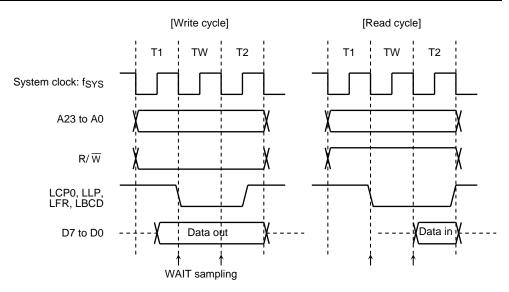

Data transmission to the LCD driver is executed by a transmit instruction from the CPU.

After setting operation mode to the control register, when a CPU transmit instruction is executed the LCDC outputs a chip select signal to the LCD driver connected externally by the control pin (LCP0...). Therefore control of data transmission numbers corresponding to LCD size is controlled by CPU instruction. There are 2 kinds of LCD driver address in this case, which are selected by the LCDCTL<MMULCD> register.

This corresponds to a LCD driver which has each 1 byte of instruction register and display data register in LCD driver when  $\langle MMULCD \rangle = "0"$ . Please select the transmission address at this time from 1FE0H to 1FE7H.

# 3.15 Melody/Alarm Generator (MLD)

The TMP92CH21 contains a melody function and alarm function, both of which are output from the MLDALM pin. Five kinds of fixed cycle interrupt are generated using a 15-bit counter for use as the alarm generator.

The features are as follows.

1) Melody generator

The Melody function generates signals of any frequency (4 Hz to 5461 Hz) based on a low-speed clock (32.768 kHz), and outputs the signals from the MLDALM pin.

The melody tone can easily be heard by connecting an external loudspeaker.

2) Alarm generator

The alarm function generates eight kinds of alarm waveform having a modulation frequency (4096 Hz) determined by the low-speed clock (32.768 kHz). This waveform can be inverted by setting a value to a register.

The alarm tone can easily be heard by connecting an external loudspeaker.

Five kinds of fixed cycle interrupts are generated (1 Hz, 2 Hz, 64 Hz, 512 Hz, and 8192 Hz) by using a counter which is used for the alarm generator.

This section is constituted as follows.

#### 3.15.3 Operational description

```
3.15.3.1 Melody Generator
```

The Melody function generates signals of any frequency (4 Hz to 5461 Hz) based on a low-speed clock (32.768 kHz) and outputs the signals from the MLDALM pin.

The melody tone can easily be heard by connecting an external loud speaker.

#### (Operation)

MELALMC<MELALM> must first be set as 1 in order to select the melody waveform to be output from MLDALM. The melody output frequency must then be set to 12-bit registers MELFH and MELFL.

The following are examples of settings and calculations of melody output frequency.

(Formula for calculating melody waveform frequency)

	at fs = 32.768 [kHz]
Melody output waveform	$f_{MLD} [Hz] = 32768/(2 \times N + 4)$
Setting value for melody	$N = (16384/ f_{MLD}) - 2$
(Note: N = 1 to 4095 (001H to FF	FH), 0 is not acceptable.)

#### (Example program)

When outputting an "A" musical note	(440 Hz)
in a macroal nete	(=)

LD	(MELALMC),XXXXX1B	; Select melody waveform
LD	(MELFL), 23H	; $N = 16384/440 - 2 = 35.2 = 023H$
LD	(MELFH), 80H	; Start to generate waveform

Reference) Basic musical scale setting table

Scale	Frequency [Hz]	Register Value: N
С	264	03CH
D	297	035H
E	330	030H
F	352	02DH
G	396	027H
А	440	023H
В	495	01FH
С	528	01DH

#### 3.15.3.2 Alarm Generator

The alarm function generates eight kinds of alarm waveform having a modulation frequency of 4096 Hz determined by the low-speed clock (32.768 kHz). This waveform is reversible by setting a value to a register.

The alarm tone can easily be heard by connecting an external loud speaker.

Five kinds of fixed cycle (interrupts can be generated 1 Hz, 2 Hz, 64 Hz, 512 Hz, 8 192 Hz) by using a counter which is used for the alarm generator.

#### (Operation)

MELALMC<MELALM> must first be set as 0 in order to select the alarm waveform to be output from MLDALMC. The "10" must be set on the MELALMC <FC1:0> register, and clear internal counter. Alarm pattern must then be set on the 8-bit register of ALM. If it is inverted output-data, set <ALMINV> as invert.

Then set the MELAMC<FC1:0> to "11" to start the free-run counter.

To stop the alarm output, write "00H" to the ALM register.

The following are examples of program, setting value of alarm pattern and waveform of each setting value.

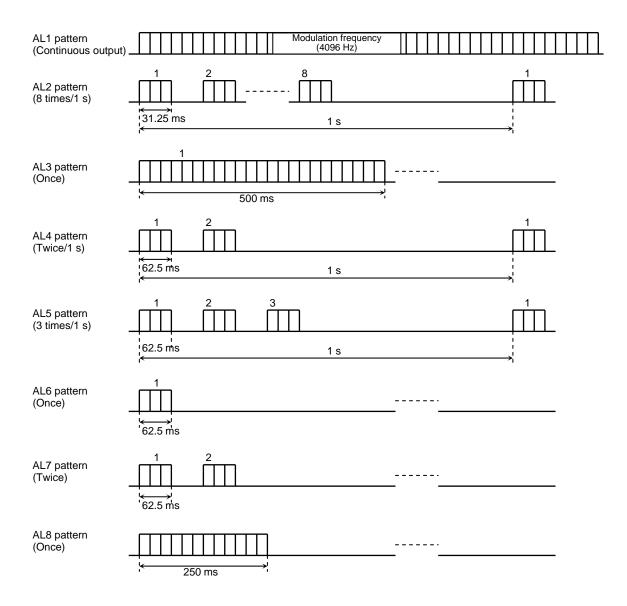

#### (Setting value of alarm pattern)

Setting Value for ALM Register	Alarm Waveform
00H	Write "0"
01H	AL1 pattern
02H	AL2 pattern
04H	AL3 pattern
08H	AL4 pattern
10H	AL5 pattern
20H	AL6 pattern
40H	AL7 pattern
80H	AL8 pattern
Others	Undefined
	(Do not set)

#### (Example program)

When outputting AL2 pattern (31.25 ms/8 times/1 s)

- LD (MELALMC), 80H
- LD (ALM), 02H LD
- ; Clear counter, set output alarm waveform
- (MELALMC), COH
- ; Set AL2 pattern ; Free-run counter start

## Example: Waveform of alarm pattern for each setting value (Not inverted)

# 3.16 SDRAM Controller (SDRAMC)

The TMP92CH21 includes an SDRAM controller which supports SDRAM access by CPU/LCDC.

- The features are as follows.
- (1) Support SDRAM

Data rate type:	Only SDR (Single data rate) type
Bulk of memory:	16/64/128/256/512 Mbits
Number of banks:	2/4 banks
Width of data bus:	16/32
Read burst length:	1 word/full page
Write mode:	Single/burst

#### (2) Initialize function

All banks precharge command 8 times auto refresh command Set the mode register command

#### (3) Access mode

	CPU Access	LCDC Access
Read burst length	1 word/full page selectable	Full page
Addressing mode	Sequential	Sequential
CAS latency (clock)	2	2
Write mode	Single/burst selectable	-

#### (4) Access cycle

CPU Access (Read/write)

Read cycle:	1 word– 4 states/full page – 1 state
Write cycle:	Single – 3 states/burst – 1 state
Access data width:	8 bits/16 bits/32 bits

LCDC Burst Access (Read only)

Read cycle:	1 word (50 ns at $f_{SYS} = 20 \text{ MHz}$ )
Over head:	4 states (200 ns at $f_{SYS} = 20 \text{ MHz}$ )
Access data width:	16 bits/32 bits

(5) Refresh cycle auto generate

Auto-refresh is generated while another area is being accessed.

Refresh interval is programmable.

Self-refresh is supported

- Note 1: Display data for LCDC must be set from the head of each page.
- Note 2: Condition of SDRAM's area set by CS1 or CS2 setting of memory controller.

# 3.16.1 Control Registers

Figure 3.16.1 shows the SDRAMC control registers. Setting these registers controls the operation of SDRAMC.

#### SDRAM Command Register

Note 1: <SCMM2:0> is automatically cleared to "000" after the specified command is issued. Before writing the next command, make sure that <SCMM2:0> is "000". In the case of the Self Refresh Entry command, however, <SCMM2:0> is not cleared to "000" by execution of this command. Thus, this register can be used as a flag for checking whether or not Self Refresh is being performed.

Note 2: The Self Refresh Exit command can only be specified while Self Refresh is being performed.

Figure 3.16.1 SDRAM Control Registers

# 3.16.2 Operation Description

(1) Memory access control

SDRAM controller is enabled when SDACR1<SMAC> = 1. And then SDRAM control signals ( $\overline{\text{SDCS}}$ ,  $\overline{\text{SDRAS}}$ ,  $\overline{\text{SDCAS}}$ ,  $\overline{\text{SDWE}}$ , SDLLDQM, SDLUDQM, SDULDQM, SDUUDQM, SDCLK and SDCKE) are operating during the time CPU or LCDC accesses CS1 or CS2 area.

## 1. Address multiplex function

In the access cycle, outputs row/column address through A0 to A15 pin. And multiplex width is decided by setting SDACR2<SMUXW0:1> of use memory size. The relation between multiplex width and Row/Column address is shown in Table 3.16.3.

		Ad	dress of SDRA	M Accessing Cycle				
TMP92CH21		Row Address		Column Address				
Pin Name	TypeA <smuxw> "00"</smuxw>	TypeB <smuxw> "01"</smuxw>	TypeC <smuxw> "10"</smuxw>	16-Bit Data Bus Width B1CSH <bnbus> = "01"</bnbus>	32-Bit Data Bus Width B1CSH <bnbus> = "10"</bnbus>			
A0	A9	A10	A11	A1	A2			
A1	A10	A11	A12	A2	A3			
A2	A11	A12	A13	A3	A4

A14	A23	EA24	EA25					
A15	EA24	EA25	EA26					

Table 3.16.1 Address Multiplex

\* AP: Auto Precharge

#### 2. Burst length

When the CPU accesses the SDRAM, the burst length is fixed to 1-word read/single write. When the LCDC accesses the SDRAM, the burst length is fixed to full page.

SDRAM access cycle is shown in Figure 3.16.2 and Figure 3.16.3.

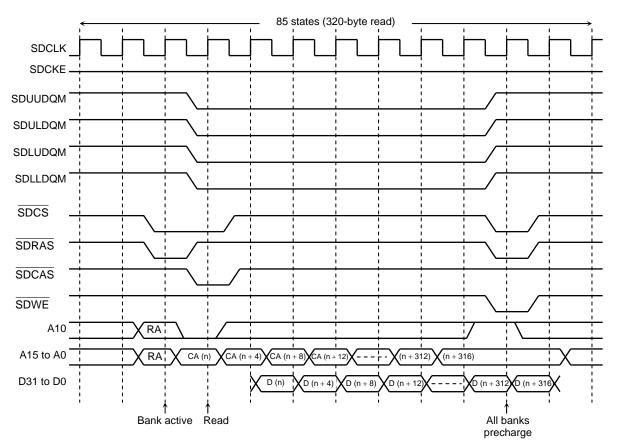

SDRAM access cycle number does not depend on the settings of B1CSL and B2CSL registers. In the full page burst read cycle, a mode register set cycle and a precharge cycle are automatically inserted at the beginning and end of a cycle.

## (2) Instruction executing on SDRAM

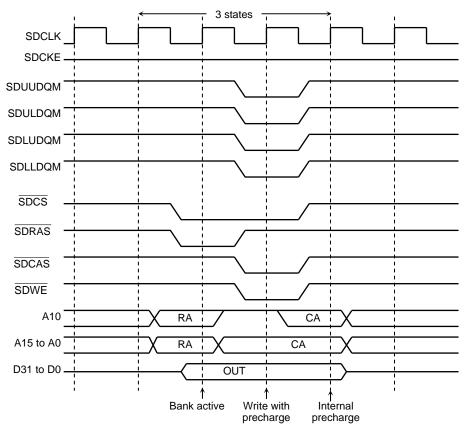

The CPU can execute instructions on SDRAM. However, the following functions do not operate.

- a) Executing HALT instruction
- b) Execute instructions that write to SDCMM register

These operations must be executed by another memory such as the built-in RAM.

#### (3) Refresh control

This LSI supports two refresh commands: auto-refresh and self-refresh.

(a) Auto-refresh

The auto-refresh command is automatically generated at intervals set by SDRCR<SRS2:0> by setting SDRCR<SRC> to "1". The generation interval can be set from between 47 to 312 states (2.4  $\mu$ s to 15.6  $\mu$ s at f<sub>SYS</sub> = 20 MHz).

CPU operation (instruction fetch and execution) stops while performing the auto-refresh command. The auto-refresh cycle is shown in Figure 3.16.4 and the auto-refresh generation interval is shown in Table 3.16.2. The Auto-Refresh function cannot be used in IDLE1 and STOP modes. In these modes, use the Self-Refresh function to be explained next.

Note: A system reset disables the Auto-Refresh function.

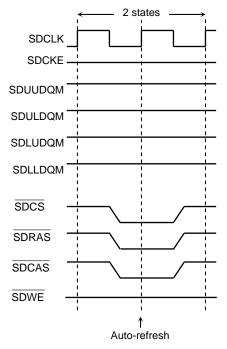

Figure 3.16.4 Timing of Auto-Refresh Cycle

(Unit: μs)

SDR	CR <srs< th=""><th>2:0&gt;</th><th>Insertion</th><th></th><th colspan="6">f<sub>SYS</sub> Frequency (System clock)</th></srs<>	2:0>	Insertion		f <sub>SYS</sub> Frequency (System clock)					
SRS2	SRS1	SRS0	Interval (State)	6 MHz	10 MHz	12.5 MHz	15 MHz	17.5 MHz	20 MHz	
0	0	0	47	7.8	4.7	3.8	3.1	2.7	2.4	
0	0	1	78	13.0	7.8	6.2	5.2	4.5	3.9	
0	1	0	97	16.2	9.7	7.8	6.5	5.5	4.9	
0	1	1	124	20.7	12.4	9.9	8.3	7.1	6.2	
1	0	0	156	26.0	15.6	12.5	10.4	8.9	7.8	
1	0	1	195	32.5	19.5	15.6	13.0	11.1	9.8	
1	1	0	249	41.5	24.9	19.9	16.6	14.2	12.4	
1	1	1	312	52.0	31.2	25.0	20.8	17.8	15.6	

(b) Self-refresh

The self-refresh ENTRY command is generated by setting SDCMM<SCMM2:0> to "101". The self-refresh cycle is shown in Figure 3.16.5. During self-refresh Entry, refresh is performed within the SDRAM (an auto-refresh command is not needed).

The auto-refresh command is automatically executed once when self-refresh is released, following which, refresh is executed according to the setting of the autorefresh command.

Note 1: When standby mode is released by a system reset, the I/O registers are initialized and the Self Refresh state is exited. Note that the Auto Refresh function is also disabled at this time.

Note 2: The SDRAM cannot be accessed while it is in the Self Refresh state.

Note 3: To execute the HALT instruction after the Self Refresh Entry command, insert at least 10 bytes of NOP or other instructions between the instruction to set SDCMM<SCMM2:0> to "101" and the HALT instruction.

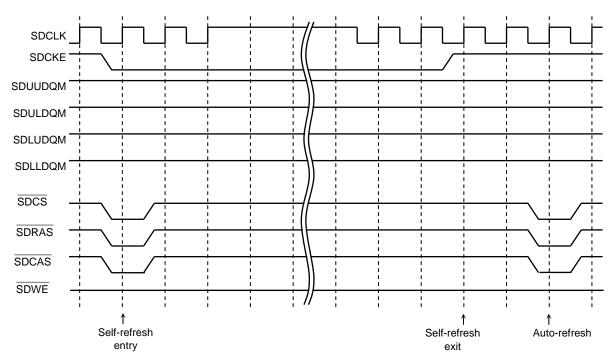

Figure 3.16.5 Timing of Self-Refresh Cycle

# (4) SDRAM initialize

This LSI can generate the following SDRAM initialize routine after introduction of power supply to SDRAM. The command is shown in Figure 3.16.6.

- 1. Precharge all commnad
- 2. Eight Auto Refresh commands
- 3. Mode Register set command

The above commands are issued by setting SDCMM<SCMM2:0> to "001".

While these commands are issued, the CPU operation (an instruction fetch, command execution) is halted.

Before executing the initialization sequence, appropriate port settings must be made to enable the SDRAM control signals and address signals (A0 to A15).

After the initialization sequence is completed, SDCMM < SCMM2:0> is automatically cleared to "000".

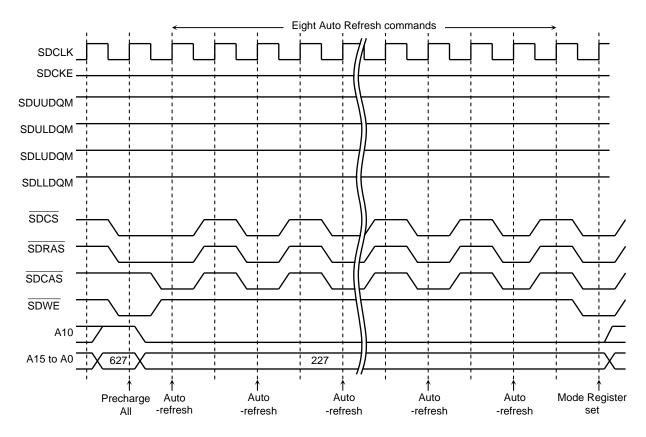

Figure 3.16.6 Timing of Initialization command

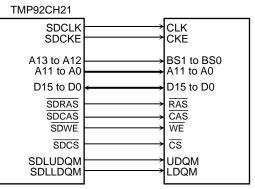

(5) Connection example

Figure 3.14.7-Figure 3.14.10 shows an example of connections between the TMP92CH21 and SDRAM

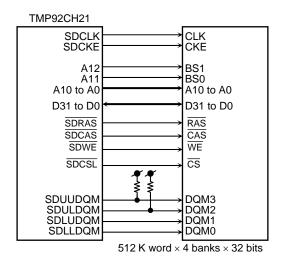

Figure 3.16.9 Connection with SDRAM (512 K word  $\times$  32 bits)

#### 3.16.3 Limitations arising when using SDRAM

Take care to note the following points when using SDRAMC.

1. WAIT access

When using SDRAM, some limitation is added when accessing memory other than SDRAM. In WAIT-pin input setting of the Memory Controller, if the setting time is inserted as an external WAIT, set a time less than the Auto-Refresh cycle  $\times$  14 (Auto-Refresh function controlled by SDRAM controller).

2. Execution of SDRAM command before HALT instruction (SR (Self refresh)-Entry, Initialize, Mode-set)

When a SDRAM controller command (SR-Entry, Initialize and Mode-set) is issued, several states are required for execution time after the SDCMM register is set.

Therefore, when a HALT instruction is executed after the SDRAM command, please insert a NOP of more than 10 bytes or 10 other instructions before executing the HALT instruction.

3. AR (Auto-Refresh) interval time

When using SDRAM, set the system clock frequency to satisfy the minimum operation frequency for the SDRAM and minimum refresh cycle.

In a system in which SDRAM is used and the clock is geared up and down, exercise care in AR cycle for SDRAM.

When AR cycle is changed, set to disable by writing "0" to SDRCR<SRC>.

The AR cycle may also not correspond to the SDRAM A.C specification when stopping Auto-Refresh. Therefore, set Auto-Refresh cycle after adding 10 states to distibuted Auto-Refresh cycle.

(Example of calculation) Condition: fSYS=12MHz, SDRAM specification of distributed Auto-Refresh interval time =4096times/64ms

64ms/ 4096times = 15.625us/1time = 187.5<br/>state/1time 187.5 – 10 = 177.5<br/>state/less than 1 time is needed  $\rightarrow$  156 state is needed

4. Self-Refresh ENTRY method

In order to prevent a conflict between a Self-Refresh ENTRY command and an Auto-Refresh, please stop Auto-Refresh once.

A) Disable Auto Refresh before writing Self Refresh ENTRY command.B) Enable Auto Refresh after writing Self Refresh ENTRY command.

Because the above instruction should be executed continuously, a 16-bit instruction must be used as below.

Note : \* When using SDRAM as a stack pointer, it is necessary to disable SDRAM access by, for example, a "DI" instruction.

5. Note when changing access mode

If changing access mode from "full page read" to "1 word read", execute the following program. This program must not be executed on the SDRAM.

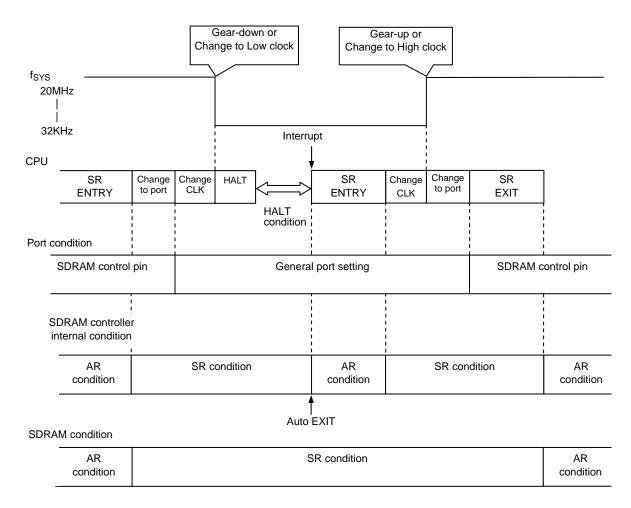

di		; Interrupt Disable (Added)
ld	a,(optional external memory address)	; Dummy read instruction (Added)
ld	(sdacr1),00001101b	; Change to "1-word read"
ld	(sdcmm),0x04	; Execute MRS (mode register setting)
ei		; Interrupt enable (Added)

6. "Auto Exit" problem when exiting from SDRAM Self-Refresh Mode

The SDRAM specification may not be satisfied when using the Self-Refresh function together with CPU stand-by function or changing clock, because when the CPU releases HALT mode, the Self-Refresh Auto Exit function automatically operates.

The following figure shows an example of how to avoid this problem using S/W.

#### (Control Outline)

\*The target ports to change are SDCKE pin and SDCS pin.

\*The method of Self-refresh Entry includes the condition 4).

\* SR : Self-refresh , AR : Auto-refresh

# 3.17 NAND-Flash Controller

### 3.17.1 Characteristics

The NAND-Flash controller (NDFC) is provided with dedicated pins for connecting with NAND-Flash memory. The NDFC also has an ECC calculation function for error correction.

Although the NDFC has two channels (channel 0, channel 1), all pins except for Chip Enable are shared between the two channels. Only the operation of channel 0 is explained here.

The NDFC has the following features:

- 1) Controlled NAND-Flash interface by setting registers.
- 2) ECC calculating circuits. (for SCL-type)
- Note 1: The WP (Write Protect) pin of NAND Flash is not supported. If this function is needed, prepare it on an external circuit.

Note 2: The two channels cannot be accessed simultaneously. It is necessary to switch between the two channels.

# 3.17.2 Block Diagram

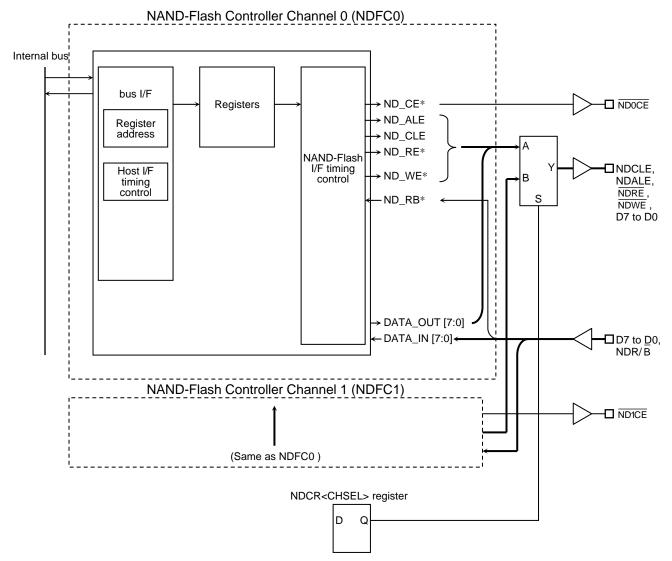

Figure 3.17.1 NAND-Flash Controller Block Diagram

- 3.17.3 Operation Description
  - 3.17.3.1 Accessing NAND-Flash Memory

The NDFC accesses data on NAND Flash memory indirectly through its internal registers. It also contains the ECC calculating circuits. Please see 3.17.3.2 for details of the ECC. This section explains the operations for accessing the NAND Flash.

Basically, set the command in ND0FMCR and then read or write to ND0FDTR. The read cycle for ND0FDTR is completed after the external read cycle for the NAND-Flash is finished. Likewise, the write cycle for ND0FDTR is completed after the external write cycle for the NAND-Flash is finished.

1) Initialize

The initialize sequence is as follows.

- (1) ND0FSPR: Set the low pulse width.
- (2) ND0FIMR: Set 0x81 if interrupt is required.(Release interrupt mask)
- 2) Write

The write sequence is as follows.

(1) ND0FMCR: Set 0x7C for ECC data reset.

(2)	Write 512 bytes	
	ND0FMCR:	Set 0x9D for NDCLE signal enable and command mode.
	ND0FDTR:	Set 0x80 for the serial data input command.
	ND0FMCR:	Set 0x9E for NDALE signal enable and address mode.
	ND0FDTR:	Write address. Set A [7:0], A [16:9], and A [24:17]. If it is
		required, set A [25].
	ND0FMCR:	Set 0xBC for the data mode.
	ND0FDTR:	Write 512 bytes data.
(3)	Read ECC data	
	ND0FMCR:	Set 0xDC for the ECC data read mode.
	NDECCRD:	Read 6 bytes ECC data.
	First data:	LPR [7:0]
	Second dat	a: LPR [15:8]
	Third data	: CPR [5:0], 2'b11
	Fourth dat	a: LPR [23:16]
	Fifth data:	LPR [31:24]
	Sixth data	CPR [11:6], 2'b11

(4) Write 16-byte redundant data Set 0x9C for the data mode without ECC calculation. ND0FMCR: Write 16-byte redundant data. ND0FDTR: D520: LPR [23:16] LPR [31:24] D521: D522: CPR [11:6], 2'b11 LPR [7:0] D525: D526: LPR [15:8] D527: CPR [5:0], 2'b11 (5) Run page program ND0FMCR: Set 0x9D for NDCLE signal enable and command mode. ND0FDTR: Set 0x10 for the page program command. ND0FMCR: Set 0x1C for NDALE signal disable. Wait several states (e.g., "NOP"  $\times$  10) ND0FSR: Check BUSY flag. If it is 0, go to the next. If it is 1, wait until it becomes 0. (6) Read status ND0FMCR: Set 0x1D for NDCLE signal and command mode. ND0FDTR: Set 0x70 for Status read command. Set 0x1C for NDCLE signal disable. ND0FMCR: ND0FDTR: Read the Status data from the NAND-Flash.

(7) Repeat 1 to 6 for all other pages if required.

3) Read

The read sequence is as follows.

(1)	ND0FMCR:	Set 0x7C for ECC data reset.
(2)	Read 512 bytes	
	ND0FMCR:	Set $0x1D$ for NDCLE signal enable and command mode.
	ND0FDTR:	Set 0x00 for the read command.
	ND0FMCR:	Set 0x1E for NDALE signal enable and address mode.
	ND0FDTR:	Set A [7:0], A [16:9], and A [24:17]. If it is required, set A [25].
	ND0FMCR:	Set 0x1C for NDALE signal disable.

Wait several states (e.g., "NOP"  $\times \, 10)$ 

ND0FSR:	Check BUSY flag. If it is 0, go to the next.	
	If it is 1, wait until it becomes 0.	
ND0FMCR:	Set $0x3C$ for the data mode with ECC calculation.	
ND0FDTR:	Read 512-byte data.	
ND0FMCR:	Set $0x1C$ for the data mode without ECC calculation.	
ND0FDTR:	Read 16-byte redundant data.	

(3) Read ECC data

ND0FMCR: Se	t 0x5C for the ECC data read mode.
NDECCRD: Re	ad 6-byte ECC data.
First data:	LPR [7:0]
Second data:	LPR [15:8]
Third data:	CPR [5:0], 2'b11
Fourth data:	LPR [23:16]
Fifth data:	LPR [31:24]
Sixth data:	CPR [11:6], 2'b11

(4) Software routine: Compare ECC data and red

Compare ECC data and redundant data, run the error routine if error is generated.

(5) Read other pages

ND0FMCR:	Set 0x1C.
ND0FSR:	Check BUSY flag. If it is 0, go to the next.
	If it is 1, wait until it becomes 0.

# 4) ID read

The ID read sequence is as follows.

- (1) ND0FMCR: Set 0x1D for NDCLE signal enable and command mode.
- (2) ND0FDTR: Set 0x90 for the ID Read command.
- (3) ND0FMCR: Set 0x1E for NDALE signal enable and the address mode.
- (4) ND0FDTR: Set 0x00.
- (5) ND0FMCR: Set 0x1C for the data mode without ECC calculation.
- (6) ND0FDTR: Read Maker code.
- (7) ND0FDTR: Read Device code.

### 3.17.3.2 ECC Control

The NDFC contains the ECC calculating circuits. The circuits are controlled by ND0FMCR. This circuit executes ECC data calculation. However, ECC comparison and error correction is not executed. This must be executed using software.

The calculated ECC data can be read from the NDECCRD register when ND0FMCR is 0xD0 (write mode) or 0x50 (read mode). This is 6-byte data, and six NDECCRD read operations are required. The order of the data is as follows.

First data:	LPR [7:0]
Second data:	LPR [15:8]
Third data:	CPR [5:0], 2'b11
Fourth data:	LPR [23:16]
Fifth data:	LPR [31:24]
Sixth data:	CPR [11:6], 2'b11

# Table 3.17.3 NAND-Flash Control Registers

Address	Register	Register Name
01C0H	NDCR	NAND-Flash control register

### 3.17.4.1 NAND-Flash Data Transfer Register (ND0FDTR and ND1FDTR)

Bit (s)	Mnemonic	Field Name	Description
7:0	DATA	DATA	NAND-Flash data. Read: Read the data that was read from the NAND-Flash. Write: Write data to the NAND-Flash.

Note 1: This register has a 512-address window from 1D00H to 1EFFH since a NAND-Flash page size is either 256 or 512 bytes.

When the CPU reads from or writes to the NAND-Flash , and if the block transfer instruction ("LDIR" instruction) is used, the following restriction applies to the 900/H1 CPU.

[Restriction for using the block transfer instruction]

1) The source address for "LDIR" instruction should be set to (1F00H - read (or write) byte number)

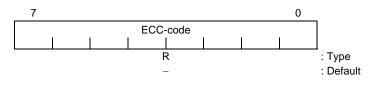

Example 1) In case of 512-byte read

	-			
	ld	bc, 512	;	512 bytes
	ld	xix, 2000H	;	dst = 2000H
	ld	xiy, 1D00H	;	src = (1F00H - 512) = 1D00H
	ldir	(xix + ), (xiy + )	;	Block transfer instruction
Exar	nple 2) Iı	n case of 16-byte r	ea	d
	ld	bc, 16	;	16 bytes
	ld	xix, 2000H	;	dst = 2000H
	ld	xiy, 1EF0H	;	src = (1F00H - 16) = 1EF0H
	ldir	(xix + ), (xiy + )	;	Block transfer instruction

Note 2: Both ND0FDTR and ND1FDTR are assigned to the same address. The NDCR<CHSEL> register determines which channel is accessed.

Figure 3.17.2 NAND-Flash Data Transfer Register (ND0FDTR and ND1FDTR)

3.17.4.2 NAND-Flash ECC-code Read Register (ND0ECCRD and ND1ECCRD)

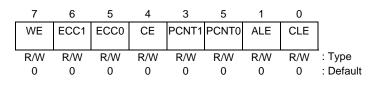

Bit (s)	Mnemonic	Field Name	Description
7:0	ECC-code	ECC-code	Read calculated ECC data.

Note 1: Both ND0ECCRD and ND1ECCRD are assigned to the same address. The NDCR<CHSEL> register determines which channel is accessed.

Figure 3.17.3 NAND-Flash ECC-code Read Register (ND0ECCRD and ND1ECCRD)

## 3.17.4.3 NAND-Flash Mode Control Register (ND0FMCR and ND1FMCR)

Bits	Mnemonic	Field Name	Description	
7	WE	Write enable	<ul> <li>Write enable (Default: 0)</li> <li>This bit enables the data write operation. When writing the data to the NAND-Flash, set this bit to "1".</li> <li>When writing command or address, this bit need not be set to "1".</li> <li>0: Disable write operation</li> <li>1: Enable write operation</li> </ul>	
6	ECC1	ECC control	https://doi.org/10.1011/2014       ECC control (Default: 00)         Control the ECC calculating circuits with <ce> (bit4) register.         11 (at<ce> = X): Reset ECC circuits         00 (at<ce> = 1): ECC circuits are disabled.</ce></ce></ce>	
5	ECC0		<ul> <li>01 (at<ce> = 1): ECC circuits are enabled.</ce></li> <li>10 (at<ce> = 1): Read ECC data calculated by NDFC</ce></li> <li>10 (at<ce> = 0): Read ID data</ce></li> </ul>	
4	CE	Chip enable	Chip enable (Default: 0) Enable NAND-Flash access. Set "1" to this bit when accessing the NAND-Flash. 0: Disable (NDCE is High.) 1: Enable (NDCE is Low.)	
3	PCNT1	Power control	Power control (Default: 00)	
2	PCNT0		Always write "11"	
1	ALE	Address latch enable	Address latch enable (Default: 0) This bit specifies the value of the NDALE signal. 0: Low 1: High	
0	CLE	Command latch enable	Command latch enable (Default: 0) This bit specifies the value of the NDCLE signal. 0: Low 1: High	

Figure 3.17.4 NAND-Flash Mode Control Register (ND0FMCR and ND1FMCR)

### 3.17.4.4 NAND-Flash Status Register (ND0FSR and ND1FSR)

Bits	Mnemonic	Field Name	Description
7	BUSY	BUSY	BUSY (Default: Undefined)
			This bit shows the status of the NAND-Flash.
			0: Ready
			1: Busy
6:0	-	-	Reserved

Note: A noise-filter for some states is built into the NDFC, so when the NDR/ $\overline{B}$  pin changes, a <BUSY> flag is not renewed at the same time. Therefore, insert several delays (e.g., "NOP" instruction × 10) using software before starting this flag check.

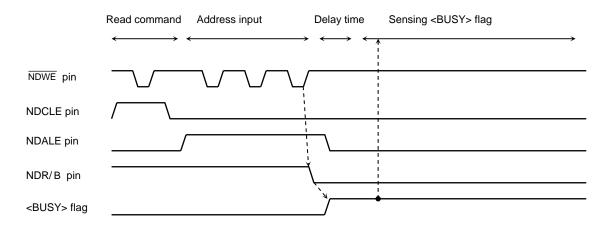

Figure 3.17.5 NAND-Flash Status Register (ND0FSR and ND1FSR)

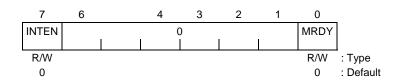

### 3.17.4.5 NAND-Flash Interrupt Status Register (ND0FISR and ND1FISR)

Bits	Mnemonic	Field Name	Description
7:1	-	—	Reserved
0	RDY	Ready	Ready (Default: 0)
			When NDR/ $\overline{B}$ signal changes from low (BUSY) to High (
			READY) and NDFIMR <mrdy> is "1", this bit is set to "1". By writing "1", this bit is cleared to 0.</mrdy>
			Read:
			0: None
			1: Change NDR/ $\overline{B}$ signal from BUSY to READY.
			Write:
			0: No change
			1: Clear to "0"

Figure 3.17.6 NAND-Flash Interrupt Status Register (ND0FISR and ND1FISR)

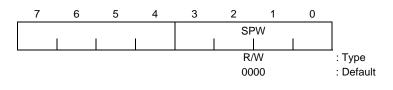

### 3.17.4.6 NAND-Flash Interrupt Mask Register (ND0FIMR and ND1FIMR)

Bits	Mnemonic	Field Name	Description
7	INTEN	Interrupt enable	Interrupt enable (Default: 0) When <inten> and <mrdy> are set "1" and NDFISR<rdy> becomes "1", INTNDFC occurs. 0: Disable 1: Enable</rdy></mrdy></inten>
6:1	-	-	Reserved
0	MRDY	Mask RDY interrupt	Mask RDY interrupt (Default: 0) This bit masks the NDFISR <rdy>. If <mrdy> is "1" and NDR/<math>\overline{B}</math> signal changes from Low to High, NDFISR<rdy> is set to "1". 0: Disable to set NDFISR<rdy> 1: Enable to set NDFISR<rdy></rdy></rdy></rdy></mrdy></rdy>

Figure 3.17.7 NAND-Flash Interrupt Mask Register (ND0FIMR and ND1FIMR)

### 3.17.4.7 NAND-Flash Strobe Pulse Width Register (ND0FSPR and ND1FSPR)

Bits	Mnemonic	Field Name	Description	
7:4	-	—	Reserved	
3:0	SPW	Strobe pulse	Strobe pulse width (Default: 0000)	
		width	These bits set the Low pulse width of the $\overline{\text{NDRE}}$ and $\overline{\text{NDWE}}$ signals.	
			The Low pulse width is ((value set to SPW) +1 )× $f_{\mbox{SYS}}$ clock	

Figure 3.17.8 NAND-Flash Strobe Pulse Width Register (ND0FSPR and ND1FSPR)

### 3.17.4.8 NAND-Flash Reset Register (ND0FRSTR and ND1FRSTR)

Bits	Mnemonic	Field Name	Description
7:1	-	-	Reserved
0	RST	Reset	Reset (Default: 0)
			By setting this bit, reset the NDFC (except NDCR <chsel> register).</chsel>
			By reset, this bit is automatically cleared to "0".
			0: Don't care
			1: Reset

Note: After writing <RST> register, several waits are required (about 10 states) before accessing the NDFC.

# 3.17.5 Timing Diagrams

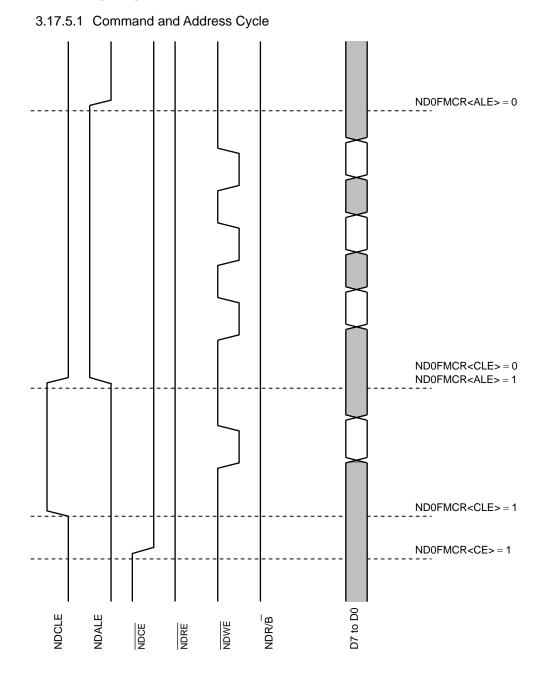

Figure 3.17.10 Command and Address Cycle

### 3.17.5.2 Data Read Cycle

Figure 3.17.11 shows a timing chart example for a Data Read cycle from the NAND-Flash at ND0FSPR = 02H.

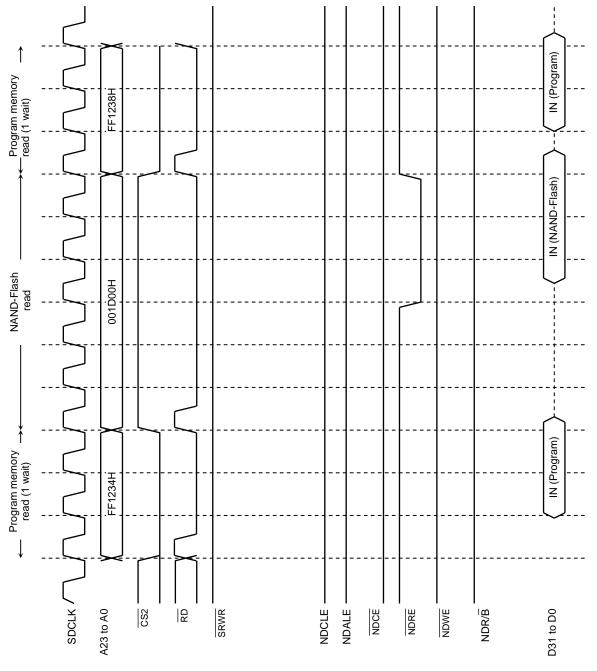

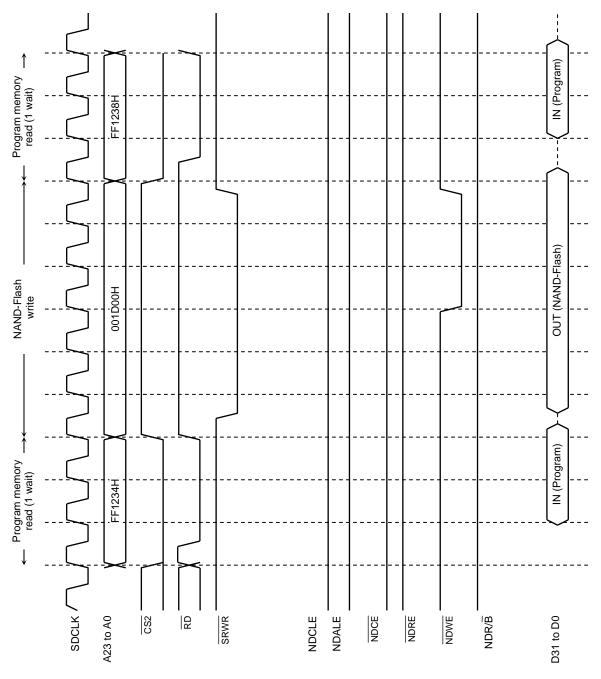

Figure 3.17.11 Data Read Cycle Example (ND0FSPR = 02H)

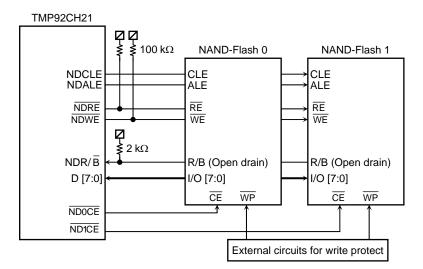

### 3.17.5.3 Data Write Cycle

Figure 3.17.12 shows a timing chart example for a Data Write cycle to the NAND-Flash at ND0FSPR = 02H.

### 3.17.6 Example of NAND-Flash Use

Note 1: By reset, both NDRE and NDWE pins become input ports (Port 71 and Port 72) And so require pull-up resistors.

Note 2: Use the NAND-Flash memory and board capacitance to set the correct value for the NDR/ $\overline{B}$  pin pull-up resistor . 2 k $\Omega$  is a typical value.

Note 3: The NAND-Flash WP (write protect) pin is not supported by the TMP92CH21. It must be provided by an external circuit if required.

Figure 3.17.13 Example of NAND-Flash Connection

# 3.18 16-Bit Timer/Event Counters (TMRB0)

The TMP92CH21 incorporates one multifunctional 16-bit timer/event counter (TMRB0) which has the following operation modes:

- 16-bit interval timer mode
- 16-bit event counter mode
- 16-bit programmable pulse generation (PPG) mode

The timer/event counter consists of a 16-bit up counter, two 16-bit timer registers (one of them with a double buffer structure), a 16-bit capture register, two comparators, a capture input controller, a timer flip-flop and a control circuit.

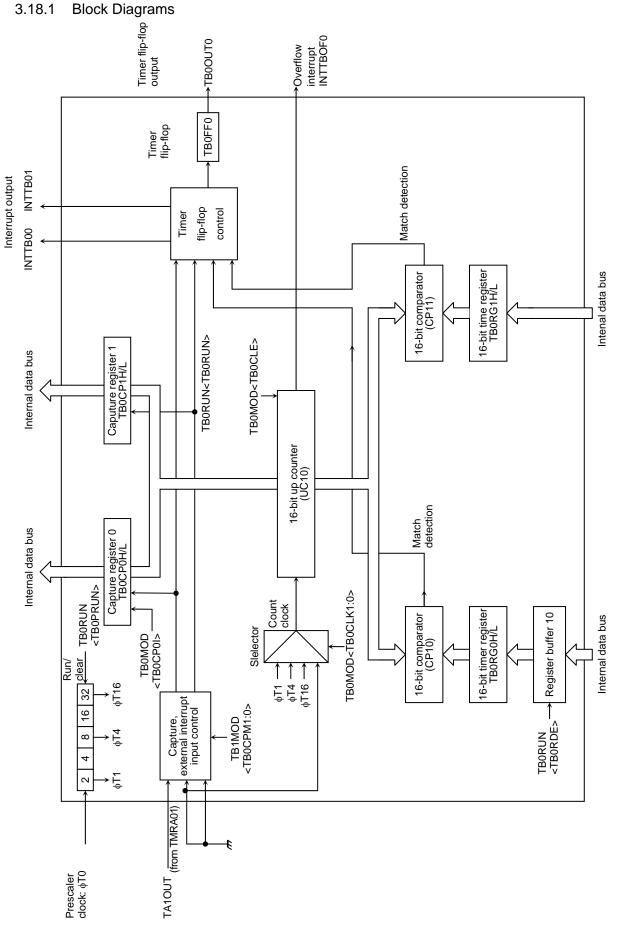

The timer/event counter is controlled by an 11-byte control SFR.

This chapter includes the following sections:

- 3.18.1 Block Diagrams
- 3.18.2 Operation of Each Block
- 3.18.3 SFRs
- 3.18.4 Operation in Each Mode
  - (1) 16-bit interval timer mode
  - (2) 16-bit programmable pulse generation (PPG) output mode

	Channel	TMRB0
Spec.		TWINDO
External	External clock/capture trigger input pins	None
pins	Timer flip-flop output pins	TB0OUT0 (also used as PC2)
	Timer run register	TB0RUN (1180H)
	Timer mode register	TB0MOD (1182H)
	Timer flip-flop control register	TB0FFCR (1183H)
		TB0RG0L (1188H)

		TB0CP1H (118FH)

Table 3.18.1 Pins and SFR of TMRB0

# 3.18.2 Operation of Each Block

### (1) Prescaler

The 5-bit prescaler generates the source clock for timer 0. The prescaler clock ( $\phi$ T0) is a divided clock (divided by 8) from the f<sub>FPH</sub>.

This prescaler can be started or stopped using TB0RUN<TB0PRUN>. Counting starts when <TB0PRUN> is set to 1; the prescaler is cleared to 0 and stops operation when <TB0PRUN> is cleared to 0.

System clock selection SYSCR1	Clock gear selection SYSCR1	_	r	r counter input IMRB prescale MOD <tb0clk< th=""><th>r</th></tb0clk<>	r

Table 3.18.2 Prescaler Clock Resolution

### (2) Up counter (UC10)

UC10 is a 16-bit binary counter which counts up pulses input from the clock specified by TB0MOD<TB0CLK1:0>.

Any one of the prescaler internal clocks  $\phi T1$ ,  $\phi T4$  and  $\phi T16$  can be selected as the input clock. Counting or stopping and clearing of the counter is controlled by TB0RUN<TB0RUN>.

When clearing is enabled, the up counter UC10 will be cleared to 0 each time its value matches the value in the timer register TB0RG1H/L. If clearing is disabled, the counter operates as a free-running counter.

Clearing can be enabled or disabled using TB0MOD<TB0CLE>.

A timer overflow interrupt (INTTBOF0) is generated when UC10 overflow occurs.

(3) Timer registers (TB0RG0H/L and TB0RG1H/L)

These 16-bit registers are used to set the interval time. When the value in the up counter UC10 matches the value set in this timer register, the comparator match detect signal will go active.

Setting data for both Upper and Lower timer registers is always needed. For example, either using a 2-byte data transfer instruction or using a 1-byte data transfer instruction twice for the lower 8 bits and upper 8 bits in order.

The TB0RG0H/L timer register has a double-buffer structure, which is paired with a register buffer. The value set in TB0RUN<TB0RDE> determines whether the double-buffer structure is enabled or disabled: it is disabled when  $\langle TB0RDE \rangle = 0$ , and enabled when  $\langle TB0RDE \rangle = 1$ .

When the double buffer is enabled, data is transferred from the register buffer to the timer register when the values in the up counter (UC10) and the timer register TB0RG1H/L match.

After a reset, TB0RG0H/L and TB0RG1H/L are undefined. If the 16-bit timer is to be used after a reset, data should be written to it beforehand.

On a reset <TB0RDE> is initialized to 0, disabling the double buffer. To use the double buffer, write data to the timer register, set <TB0RDE> to 1, then write data to the register buffer as shown below.

TB0RG0H/L and the register buffer both have the same memory addresses (001188H and 001189H) allocated to them. If  $\langle TB0RDE \rangle = 0$ , the value is written to both the timer register and the register buffer. If  $\langle TB0RDE \rangle = 1$ , the value is written to the register buffer only.

The addresses of the timer registers are as follows:

· TMRBC			 		
	TB0R0	G0H/L	TB0R	G1H/L	
Upper (TB0R		Lower 8 bits (TB0RG0L)	Upper 8 bits (TB0RG1H)	Lower 8 bits (TB0RG1L)	
0011	89H	001188H	00118BH	00118AH	

The timer registers are write-only registers and thus cannot be read.

### (4) Capture registers (TB0CP0H/L and TB0CP1H/L)

These 16-bit registers are used to latch the values in the up counters.

All 16 bits of data in the capture registers should be read. For example, using a 2-byte data load instruction or two 1-byte data load instructions. The least significant byte is read first, followed by the most significant byte.

The addresses of the capture registers are as follows:

P0H/L	TB0C	P1H/L
Lower 8 bits (TB0CP0L)	Upper 8 bits (TB0CP1H)	Lower 8 bits (TB0CP1L)
00118CH	00118FH	00118EH
	(TB0CP0L)	Lower 8 bits (TB0CP0L) Upper 8 bits (TB0CP1H)

The capture registers are read-only registers and thus cannot be written to.

#### (5) Capture input control

This circuit controls the timing to latch the value of the up counter UC10 into TB0CP0H/L and TB0CP1H/L.

The value in the up counter can be loaded into a capture register by software. Whenever 0 is programmed to TB0MOD<TB0CP0I>, the current value in the up counter is loaded into capture register TB0CP0H/L. It is necessary to keep the prescaler in run mode (i.e., TB0RUN<TB0PRUN> must be held at a value of 1).

#### (6) Comparators (CP10 and CP11)

CP10 and CP11 are 16-bit comparators which compare the value in the up counter UC10 with the value set in TB0RG0H/L or TB0RG1H/L respectively, in order to detect a match. If a match is detected, the comparator generates an interrupt (INTTB00 or INTTB01 respectively).

#### (7) Timer flip-flops (TB0FF0)

These flip-flops are inverted by the match detect signals from the comparators and the latch signals to the capture registers. Inversion can be enabled and disabled for each element using TB0FFCR<TB0C1T1, TB0C0T1, TB0E1T1 and TB0E0T1>.

After a reset the value of TB0FF0 is undefined. If "00" is programmed to TB0FFCR <TB0FF0C1:0>, TB0FF0 will be inverted. If "01" is programmed to the capture registers, the value of TB0FF0 will be set to "1". If "10" is programmed to the capture registers, the value of TB0FF0 will be cleared to "0".

The values of TB0FF0 can be output via the timer output pin TB0OUT0 (which is shared with PC6). Timer output should be specified using the port B function register.

	X: Don't care,	-: No	o cha	ange	Э						

(2) 16-bit programmable pulse generation (PPG) output mode

Square wave pulses can be generated at any frequency and duty ratio. The output pulse may be either low active or high active.

The PPG mode is obtained by inversion of the timer flip-flop TB0FF0 that is enabled by the match of the up counter UC10 with timer register TB0RG0H/L or TB0RG1H/L and is output to TB0OUT0. In this mode the following conditions must be satisfied.

(Value set in TB0RG0H/L) < (Value set in TB0RG1H/L)

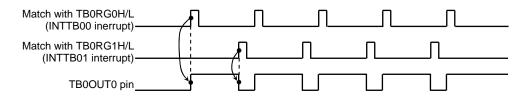

Figure 3.18.6 Programmable Pulse Generation (PPG) Output Waveforms

When the TB0RG0H/L double buffer is enabled in this mode, the value of register buffer 10 will be shifted into TB0RG0H/L at match with TB0RG1H/L. This feature facilitates the handling of low duty waves.

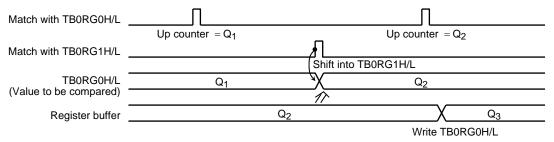

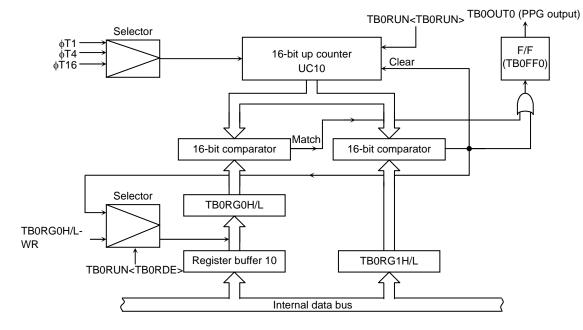

Figure 3.18.7 Operation of Register Buffer

The following block diagram illustrates this mode.

Figure 3.18.8 Block Diagram of 16-Bit Mode

The following example shows how to set 16-bit PPG output mode:

			7	6	5	4	3	2	1	0

# 3.19 Touch Screen Interface (TSI)

The TMP92CH21 has an interface for a 4-terminal resistor network touch screen. This interface supports two procedures: an X/Y position measurement and touch detection. Each procedure is executed by setting the TSI control register (TSICR0 and TSICR1) and using an internal AD converter.

### 3.19.1 Touch Screen Interface Module Internal/External Connection

			"N"	"N" is the number of bits between bit6 and bit0 which are set to "1". Note2)									

Note1: Since an internal clock is used for the debounce circuit, when IDLE1, STOP mode, the de-bounce circuit don't operate and also interrupt which through this circuit is not generated. When IDLE1, STOP mode, set this circuit to disable (Write "0" to TSICR1<DBC7>) before entering HALT state.

Note2: Ex:

 $TSICR1=95H \rightarrow N = 64 + 4 + 1 = 69$ 

### 3.19.3 Touch Detection Procedure

The Touch detection procedure shows procedure until a pen is touched by the screen and it is detected.

By touching, TSI generates interrupt (INT4) and this procedure terminates. After an X/Y position measuring procedure is terminated, return to this procedure and wait for the next touch.

When the waiting state, make ON only the SPY switch ON and OFF the other 3 switches (SMY, SPX and SMX).

The pull-down resistor that is connected to the P96/INT4/PX pin is ON when the SPX switch is OFF.

During this waiting state, P96/INT4/PX pin's level is L because the internal Pull-down resistors (PXD) between the X and Y directions in the touch screen are not connected and INT4 is not generated.

When the pen touches the screen, P96/INT4/PX pin's level is H because the internal resistors between the X and Y directions in the touch screen are connected and INT4 is generated.

In order to avoid the generation of several interrupts from one touch, a debounce circuit is used, as below.

This can ignore the pulse under the time which is set to TSICR1 register.

The circuit detects the rising of signal, counts-up the time of the counter which is set, after count, receive the signal internal. During counting, when the signal is set to Low, counter is cleared. And the state become to state of waiting a rising edge.

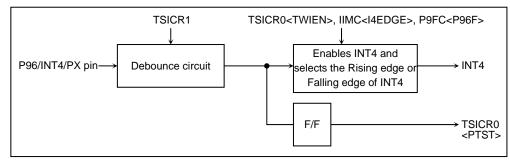

Figure 3.19.3 Block Diagram of Debounce Circuit

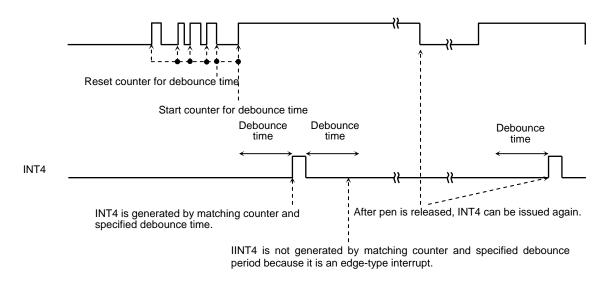

Figure 3.19.4 Timing Diagram of Debounce Circuit

### 3.19.4 X/Y Position Measuring Procedure

During the INT4 routine, execute an X/Y position measuring procedure as below.

<X position measurement>

Make both the SPX and SMX switches ON, and the SPY and SMY switches OFF.

With this setting, an analog voltage which shows the X position will be input to the PG3/MY/AN3 pin. The X position can be measured by converting this voltage to digital code using the AD converter.

<Y position measurement>

Next, make both the SPY and SMY switches ON and the SPX and SMX switches OFF.

With this setting, an analog voltage which shows the Y position will be input to the PG2/MX/AN2 pin. The Y position can be measured by converting this voltage to digital code using the AD converter.

The above analog voltage which is inputted to AN3 or AN2 pin can be calculated as follows.

It is the ratio between the resistance value in the TMP92CH21F and the resistance value in the touch screen as shown in Figure 3.19.5.

Therefore, if the pen touches an area on the touch screen, the analog voltage will be neither 3.3 V nor 0.0 V.

Please remember to take into consideration the variation in the rate of resistance.

It is also recommended that an average taken from several AD conversions be adopted as the correct code.

# 3.20 I<sup>2</sup>S (Inter-IC Sound)

An I<sup>2</sup>S format compatible serial output circuit is built-in.

This product can be used in digital audio system applications by connecting LSI for sound generation (e.g., a DA converter).

This circuit has both  $I^2\!S$  mode and general SIO mode. But both modes have only clock output and data transmitting functions.

Figure 3.20.1 shows an outline for each mode.

	I <sup>2</sup> S mode	SIO mode

Figure 3.20.4 Whole Timing Diagram

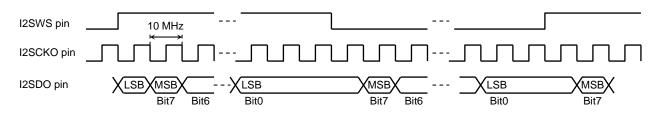

Figure 3.20.5 Detail Timing Diagram

- (3) Notes
  - 1) INTI2S timing

INTI2S is generated after the last data of FIFO is loaded to the internal shifter. FIFO is now empty and it is possible to write the next data.

2) I2SCTL0<TXE>

A transmission is started by programming "1" to the  $\langle TXE \rangle$  register and stopped by writing "0".

After<TXE> is programmed "1" once, the transmission is repeated automatically from right to left in order, alternately.

If a transmission should be stopped, program "0" to  $\langle TXE \rangle$  after  $\langle BUSY \rangle$  changes to "0" in the INTI2S interrupt routine.

When  $\langle TXE \rangle$  is programmed "0" during transmitting, transmitting stops immediately.

3) FIFO size

A 16-byte FIFO is provided for both right and left channels. It is not necessary to use all data, but please use the even numbers  $(2, 4 \dots 16)$ .

4) I2SCTL0<I2SFSEL>

Write "1" to  $\leq$ I2SFSEL> and use the right channel FIFO for monaural.

It is not necessary to write data to the left channel FIFO. Channel transmission data is fixed at "0".

5) Address for I2SBUFR and I2SBUFL

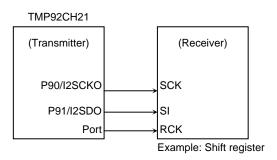

If writing data to I2SBUFR or I2SBUFL, use "word or long word data load instruction". A "byte data load instruction" cannot be used.

The address of I2SBUFR selectable from 0800H to 0803H, and I2SBUFL is selectable from 0808H to 080BH.

#### 3.20.4 Explanation of SIO Mode

(1) Connection example

Figure 3.20.6 shows an example with external LSI.

Note: Since P90 to P91 become high impedance by reset, connect a pull-up or pull-down resistor if necessary.

#### Figure 3.20.6 Example with External LSI

(2) Procedure

A 32-byte FIFO is built-in. If the FIFO's data becomes empty, an INTI2S interrupt is generated.

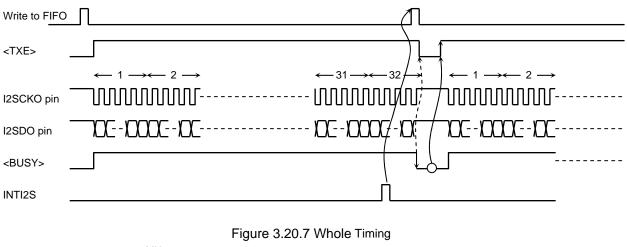

In the interrupt routine, write the next transmission data to the FIFO.

The following shows a setting example and timing diagram.

# (Setting example) Transmitting by SIO mode, I2SCKO = 10 MHz, synchronous with rising edge (at $f_{SYS}$ = 20 MHz)

(Main routine)									
	7	6	5	4	3	2	1	0	
INTE5I2S	Х	0	0	1	Х	_	_	_	Set interrupts level.
P9CR	-	_	_	_	_	_	0	0	Set pins to P90 (I2SCKO) and P91 (I2SDO).
P9FC	-	-	-	-	-	-	1	1	
I2SCTL0	0	1	-	1	0	0	1	-	Set SIO mode, LSB first, 8 bits, f <sub>SYS</sub> /2 clocks.
	-	1	_	1	0	0	0	1	Set rising edge.
I2SBUFR	**	**	**	**	**	**	**	**	Write 32-byte data to FIFO (16 times).
I2SCTL0	1	1	-	1	0	0	1	-	Start transmitting.
	-	1	-	1	0	0	0	1	
(INTI2S interrupt r	outin	ie)							
I2SBUFR	**	**	**	**	**	**	**	**	Write 32-byte data to FIFO (16 times).
lf <busy></busy>	> = "1	l" th	en V	VAIT	l els	e NI	EXT		Confirm termination of the 32-byte data transfer.
I2SCTL0	1	1	-	1	0	0	1	-	Start transmitting.
	-	1	-	1	0	0	0	1	
X: Don't care, -: N	o ch	ange	е						

## TOSHIBA

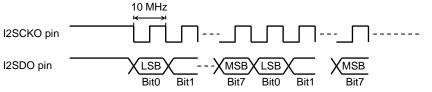

Figure 3.20.8 Detail Timing

- (3) Notes
  - 1) INTI2S timing

INTI2S is generated after the last data of FIFO is loaded to the internal shifter. FIFO is now empty and it is possible to write the next data.

2) I2SCTL0 <TXE>

A transmission is started by programming "1" to the <TXE> register and stopped by programming "0".

<TXE> register is cleared to "0" when <BUSY> changes from "1" to "0".

When  $<\!\!\text{TXE}\!\!>$  is programmed "0" during transmitting, transmitting stops immediately.

3) FIFO size

A 32-byte FIFO is provided for SIO mode. It is not necessary to use all data but please use even numbers (2, 4 ... 32).

The <BUSY> will be changed to "0" and <TXE> will be cleared to "0" automatically after transmitting all programmed data to FIFO. In case of continuous transmitting, program "1" to <TXE> after programming data to FIFO.

The number of data programmed to FIFO is counted automatically and held by programming "1" to <TXE>.

4) Address for I2SBUFR and I2SBUFL

If writing data to I2SBUFR (I2SBUFL cannot be written), use "word or long word data load instruction". A "byte data load instruction" cannot be used.

The address of I2SBUFR is selectable from 0800H to 0803H.

### 3.21 Boot ROM

A boot ROM is built-in to download user's boot program. Three downloading methods are supported.

#### 3.21.1 Operation Mode

There are 2 operation modes: MULTI mode and BOOT mode. Each mode is set according to the status of the AM1 and AM0 pins when  $\overline{\text{RESET}}$  is asserted.

- (1) MULTI mode: After reset, the CPU fetches and executes instructions from an external memory.
- (2) BOOT mode: After reset, the CPU fetches and executes instructions from the internal boot ROM. A user program which executes programming to on-board memory (e.g., NOR flash) is loaded from either NAND flash, UART or USB to internal RAM, and then branched to the internal RAM. This operation will initiate a user program boot.

Table 3.21.2 shows an outline of boot operation.

Mode	Setting P	ins	On	eration Mode					
RESET	AM1	AM0	Ορ						
1	0	1	MULTI	Start from external 16-bit bus memory					
	1	0	NOLT	Start from external 32-bit bus memory					
	1	1	BOOT (Start from internal boot ROM)						
	0	0	TEST (Disabled to set)						

Table 3.21.1 Operation Mod	Table 3.21	.1	Operation	Mode
----------------------------	------------	----	-----------	------

Name	Order of		Loading		Operation after
Name	Setting	Source	l/F	Destination	Loading
(a)	1	NAND flash	Data bus		Branch to
(b)	2	PC	UART	Internal RAM	Branch to internal RAM
(c)	3	PC	USB		internal train

#### 3.21.2 Hardware Specification for Internal Boot ROM

#### (1) Memory map

Figure 3.21.1 shows a memory map of BOOT mode.

An 8-Kbyte ROM is built-in and it is mapped to address 3FE000H to 3FFFFFH.

In MULTI mode, the boot ROM is not mapped and its area is mapped as an external area.

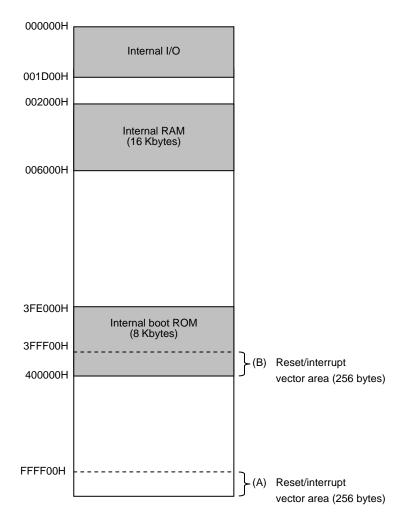

Figure 3.21.1 Memory Map of BOOT Mode

(2) Reset/interrupt address conversion circuit

A reset/interrupt vector address conversion circuit is included.

This function allows for individual reset/interrupt vector areas. For details, refer to section 3.6.5, Internal Boot ROM Control.

(3) Clearing boot ROM

After boot sequence in BOOT mode, the application system program may continue to run without reset asserting. In this case, any external memory which is mapped to address 3FE000H to 3FFFFFH cannot be accessed because the boot ROM is assigned here.

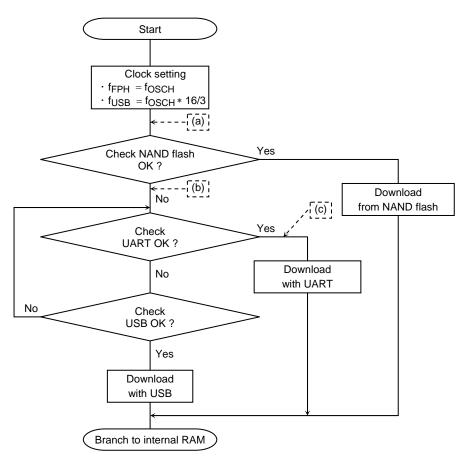

So, an internal boot ROM can be cleared by setting BROMCR<ROMLESS> to "1". For the details, refer to section 3.6.5, Internal Boot ROM Control.

#### 3.21.3 Outline of Boot Operation

There are 3 downloading methods: NAND flash, UART and USB.

After reset, a boot program in the boot ROM operates as shown in the Figure 3.21.2 flow chart.

Internal RAM use is the same regardless of downloading method, and is shown in Figure 3.21.3.

- Note 1: When USB downloading is used, a special USB device driver and application software are needed on the PC.
- Note 2: When UART downloading is used, special application software is needed on the PC.
- Note 3: (a), (b) and (c) on the flow chart show the points at which external port pins are set. Refer to Table 3.21.3 for details.

Figure 3.21.2 Flow Chart Outline of Internal Boot ROM

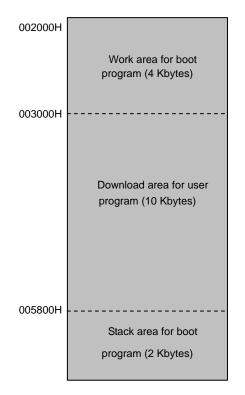

Figure 3.21.3 Internal RAM Use

#### (1) Port setting

The boot program port settings are shown in Table 3.21.3, and Table 3.21.4 shows PCB design. These port settings must be carefully noted when designing an application system.

The remaining ports are not set, so they maintain their status after reset.

Po	rt	Function	I/O	Po	ort Setting by Boot Progra	m
FC			1/0	(a)	(b)	(c)
NAND	P71	NDRE	Output			
flash	P72	NDWE	Output			
	P75	NDR/B	Input	Set to the function pin shown	No change from (a)	No change from (a)
	P84	ND0CE	Output	left	No change nom (a)	No change nom (a)
	PJ5	NDALE	Output			
	PJ6	NDCLE	Output			
	-	D7 to D0	I/O		No change	
UART	PF0	TXD1	Output	No change to input port status after reset	No change from (a)	Set to the TXD1 output pin
	PF1	RXD1	Input	Set to the RXD1 input pin		No change from (a)
USB	-	D +	I/O		No change	
	_	D –	I/O		no change	
	PC6	PUCTL	Output	No change to input port status after reset	Set to the output port pin	No change from (b)

Table 3.21.3 Port Setting

Port		Function	I/O	Boot Method						
		Function	1/0	NAND flash	UART	USB				
NAND			Not affected by UART boot.	Not affected by USB boot.						
flash			because this pin is changed to	If the NAND flash is not used in the system, ensure no conflict with the I/O direction shown	in the system, ensure no conflict with the I/O direction					
	P75	NDR/B	Input	Connect to NAND flash and pull-up by 2 k $\Omega$ resistor because R/B pin of NAND flash has open-drain output buffer.	l left.	shown left.				
	P84	ND0CE	Output	Connect to NAND flash.						
	PJ5	NDALE	Output							
	PJ6	NDCLE	Output							
	-	D7 to D0	I/O							
UART	PF0	TXD1	Output	Not affected by NAND flash	Connect to level shifter.	Not affected by USB boot.				
	PF1	RXD1	Input	boot.		Pull-up by 100 k $\Omega$ to avoid UART executing.				
USB	_	D +	I/O	Not affected NAND flash boot.	Not affected by UART boot.	Connect to USB connector, add dumping resistor (27 $\Omega$ ) and 1.5 k $\Omega$ pull-up which can be switched ON/OFF.				
	_	D –	I/O			Connect to USB connector and add dumping resistor $(27\Omega)$ .				
	PC6	PUCTL	Output			Used to control ON/OFF pull-up resistor of D + pin. The switch should be ON by "1". As this pin changes to input port by reset, add100 k $\Omega$ pull-down.				

Table 3.21.4 How to Design PCE	3
	<u> </u>

Note 1: When booting method is either NAND flash or UART and USB is used in the system, ensure the D + pin pull-up resistor is not on in the BOOT mode.

Note 2: When booting method is USB, do not start UART application software on the PC.

Note 3: When booting method is UART, do not connect the USB connector.

(2) I/O registers setting by boot program

Table 3.21.5 shows I/O register setting by boot program.

Take particular note of these set values when using an application system program which continues to run without asserting a reset after a boot sequence is executed .

Also take note of the status of the CPU registers and internal RAM following execution of a boot sequence.

Symbol	Set Value	Set Content			
WDMOD	00H	Stop watchdog timer.			
WDCR	B1H	Disable watchdog timer.			
SYSCR0	80H	Set system clock.			
SYSCR1	00H	Set system clock.			
SYSCR2	2CH	Set system clock.			
PLLCR0 40H		Where USB is used for boot, set to use PLL			
		output clock for f <sub>FPH</sub> .			
	00H	Where USB is not used for boot, set not to use PLL			
		output clock for f <sub>FPH</sub> .			
PLLCR1	80H	Set to PLL ON. Not affected by boot method.			
INTEUSB	04H	Set USB interrupt level.			
INTETC01	44H	Set INTTC interrupt level.			

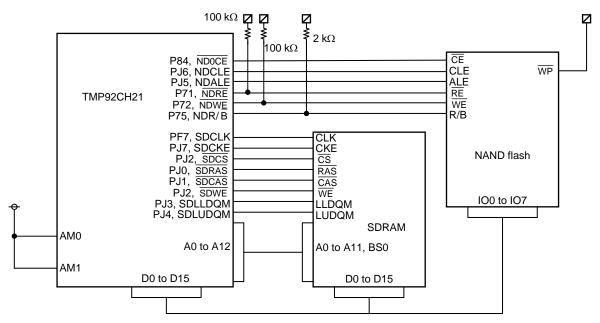

Table 3.21.5 I/O Register Setting by Boot Program

Note: The setting values for NAND flash, UART and USB are not shown. Set each register where these functions are used in the system.

#### 3.21.4 Download from NAND flash

#### (1) Connection example

Figure 3.21.4 shows an example of NAND flash. (A 16-bit SDRAM is used as program memory).

- Note 1: The values of the pull-up resistors are recommended values.
- Note 2: The WP (Write protect) pin of NAND flash is not supported by the TMP92CH21. If necessary, it must be prepared on an external circuit.

#### Figure 3.21.4 Example of NAND Flash Connection

(2) Supported NAND flash

The boot program is designed based on SmartMedia<sup>™</sup> physical format specification Ver1.20. Table 3.21.6 shows supported memory devices and device codes.

Memory Size [Mbyte]	NAND Flash 3.3 V Model	Masked ROM 3.3 V Model			
1 2	Not supported				
4	OK (E3H)	OK (D5H)			
8	OK (E6H)	OK (D6H)			
16	OK (73H)	OK (57H)			
32	OK (75H)	OK (58H)			
64	OK (76H)	OK (D9H)			
128	OK (79H)	OK (DAH)			

(3) Data format

The download data consists of the boot identification code (4 bytes), user program size (2 bytes) and user program (max 10 Kbytes). These should be assigned (programmed) to NAND flash as shown in Figure 3.21.5. Also program the ECC code in the redundant area of the NAND flash, the block status area and thedata status area.

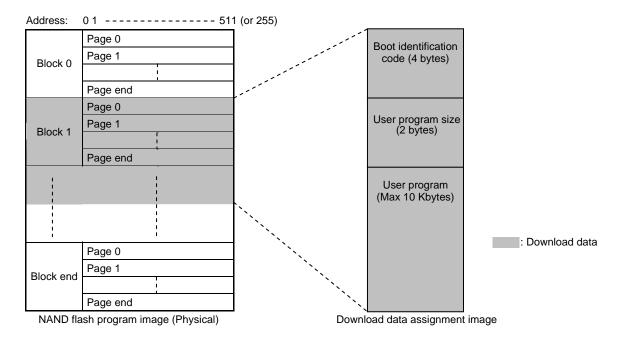

Figure 3.21.5 Download Data Image

a) Boot identification code (4 bytes)

The boot program initially checks the boot identification code. If the boot characters in ASCII code are read from the first 4 bytes in page 0, block 1 of the NAND flash, the boot program will recognize the boot method as NAND flash.

42H ("B")
4FH ("O")
4FH ("O")
54H ("T")

Figure 3.21.6 Boot Identification Code

b) User program size (2 bytes)

The program size should be programmed to the next 2 bytes. The first byte is the lower 8 bits and the second is the upper 8 bits. This size indicates only the user program size; it does not include the boot identification code (4 bytes) and user program size (2 bytes).

This must be less than or equal to 10 Kbytes. So, the maximum number is 2800H.

Size (Lower 8 bits)
Size (Upper 8 bits)

Figure 3.21.7 User Program Size

c) User program (max 10 Kbytes)

This refers to a user program that is loaded to internal RAM.

When creating a user program, note the following points.

- Set start address to 3000H
  - Beforehand, program (write) the user program to NAND flash in binary format.

An example explaining how to make a binary format file is given below.

Example: How to convert from Intel Hex format file to binary format file

- The following is an example of display in text editor when an Intel Hex format file is opened. : 10300000607F100030000F201030000B1F16010B7
  - :0000001FF
- In fact, their data are as below because ASCII code is used for Intel Hex format files. 3A313033303030303030363037463130303030303030304632303130333030303 423146313630313042370D0A3A30303030303030303146460D0A

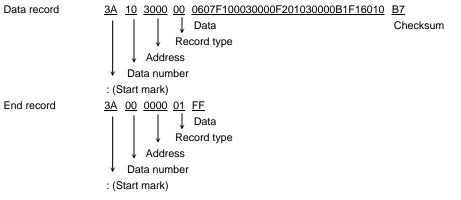

So, first convert the above data to binary format using the table below.

Before (ASCII)	After (Binary)				
ЗA	3A (Only 3A should not be converted.)				
30 to 39	0 to 9				
41 or 61	A				
42 or 62	В				
43 or 63	С				
44 or 64	D				
45 or 65	E				
46 or 66	F				
0D0A	Delete				

Next, delete characters other than data

(Start mark, data number, address, record type and checksum).

The Intel Hex format and its meaning are given below.

(4) Error check item

The items checked by the boot program are given below.

If an error occurs in any check, the boot program will cancel downloading from NAND flash and skip to the next operation (recognizing UART or USB).

a) Supported NAND flash

The boot program reads a device code from NAND flash and checks whether it is supported or not.

- b) Boot identification code
- c) User program size

The boot program checks whether it is less than or equal to 10 Kbytes.

d) Block status area

The boot program checks whether each block is normal or not. If the block status area on first page of any block has 2-bit or more "0" data, it is an error.

e) Data status area

The boot program checks whether each data status is correct or not. If the data status area has 4-bit or more "0" data, it is an error.

f) ECC error

The boot program reads both calculated code from NDFC and ECC code in NAND flash and checks whether they are correctable or not.

g) NAND flash R/B

The boot program checks whether NDR/B pin is normal or not in each action.

If the busy status is longer than 70  $[\mu s]$  at fFPH = 40 MHz, it is an error.

#### (5) ECC error check

a) Calculation ECC code

The NDFC (NAND flash controller) is used for calculation of ECC code.

b) ECC code correction

The boot program operates as below.

- 1. Compares both calculated ECC code from NDFC and ECC code in NAND flash.
- 2. Evaluates and corrects according to the following cases.

Case (a): No data error	$\rightarrow$ (OK) Next operation
Case (b): 1-bit data error	$\rightarrow$ (OK) Error correction
	and next operation
Case (c): 2-bit or more data error	$\rightarrow$ (Error) Termination
Case (d): ECC code 1-bit error	$\rightarrow$ (OK) Next operation
Case (e): ECC code 2-bit or more en	$rror \rightarrow (Error)$ Termination

For reference, details of calculation flow are given below.

1) Make XOR data by calculating exclusive OR after both ECC code from NDFC and NAND flash are placed to 4-byte data as below.

Lower 2 bytes: Line parity Upper 2 bytes: Column parity

(Valid data of column parity is lower 6-bit in upper 2 bytes)

- 2) If XOR data equals "0", it will terminate normally because the ECC code is the same, but if not, they are checked as to whether they are correctable or not.
- 3) If XOR data does not have 2-bit or more "1" data, it will terminate normally because of the ECC code 1-bit error.
- 4) If the effective data (2-bit width from bit0 to bit21 in XOR data) equals either 01B or 10B, it corrects data because they are correctable.

If the effective data has either 00B or 11B, it terminates abnormally because they are not correctable.

- 5) Data correcting takes error line information from line parity in XOR data and error bit information from column parity and inverts the bit.
  - Example: If the XOR data equals 0026A65AH, line parity is shown below in binary. 10 10 01 10 01 01 10 10B If 10B is converted to 1B and 01B is converted to 0B, they become 1 1 0 1 0 0 1 1B and meaning the 212th byte. In the same manner, error bit information becomes bit5. As a result, it inverts bit5 of 212th byte.

#### 3.21.5 Download with UART

(1) Connection example

Figure 3.21.8 shows an example of UART. (A 16-bit NOR flash is used as program memory.)

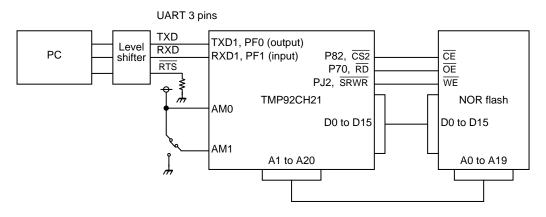

Figure 3.21.8 Example of UART

(2) UART interface specification

SIO channel 1 is used to download.

The following shows the UART communication format in BOOT mode.

Before booting, the PC side must also be setup in the same way.

The default baud rate is 9600 bps, but it can be changed to other values as shown in Table 3.21.9.

Serial transfer mode	:	UART (Asynchronous communication) mode, full duplex communication
Data length	:	8 bits
Parity bit	:	None
STOP bit	:	1 bit
Handshake	:	None
Baud rate (Default)	:	9600 bps

(3) UART data transfer format

Table 3.21.7 to Table 3.21.12 show the supported frequency, data transfer format, baud rate modification commands, operation commands, version management information, and frequency measurement result with data storing location, respectively.

Please also refer to the description of boot program operation in the following pages.

Table 3.21.7 Supported Frequency (f<sub>OSCH</sub>)

_							2 (	00011/				
6.0	0 8	.00	9.00	10.00	16.00	20.00	22.579	25.00	32.00	33.868	36.00	40.00
MH	z M	lHz	MHz	MHz	MHz	MHz	MHz	MHz	MHz	MHz	MHz	MHz

Note: Internal PLL (Clock multiplier) is not used.

	Byte Number to Transfer	Transfer Data from PC to TMP92CH21	Baud Rate	Transfer Data from TMP92CH21 to PC
Boot ROM	1st byte	Matching data (5AH)	9600 bps	<ul> <li>– (Frequency measurement and baud rate auto set)</li> </ul>
_	2nd byte	_		OK: Echo back data (5AH)
	-			Error: Nothing transmitted
	3rd byte	-		Version management information
	to			(Refer to Table 3.21.11)
	6th byte			
	7th byte	-		Frequency information
				(Refer to Table 3.21.12)
	8th byte	Baud rate modification command		-
	9th byte	(Refer to Table 3.21.9)		OK: Echo back data
		-		Error: Error code × 3
	10th byte	User program	New	Error: Stop operation by checksum error
	to	Intel Hex format (binary)	baud rate	
	n'th – 4 byte			
	n'th – 3 byte	-		OK: SUM (High)
				(Refer (6) – c)
	n'th – 2 byte	-		OK: SUM (Low)
	n'th – 1 byte	User program start command (C0H)		-
		(Refer to Table 3.21.10)		OK: Echo back data (C0H)
				Error: Error code × 3
	n'th byte	-		
RAM	-	Branch to user program start address		

"Error code  $\times$  3" means sending error code 3 times. For example, when error code is 62H,

TMP92CH21 sends 62H 3 times. (For error code, refer to (4)-b.)

Table 3.21.9	Baud Rate Modification Command
--------------	--------------------------------

Baud Rate (bps)	9600	19200	38400	57600	115200
Modification Command	28H	18H	07H	06H	03H

Note 1:If f<sub>OSCH</sub> is either 16.0, 20.0, 20.58 or 25.0 MHz, 115200 bps is not supported.

Note 2: If f<sub>OSCH</sub> is 10.0 MHz, both 57600 and 115200 bps are not supported.

Note 3: If f<sub>OSCH</sub> is 6.00, 8.00 or 9.00 MHz, then 38400, 57600 and 115200 bps are not supported.

Table 3.21.10 Operation Command

Operation Command	Operation
СОН	Start user program

Table 3.21.11 Version Management Information

Version Information	ASCII Code

	02H	03H	04H	05H	06H	07H

#### (4) Description of UART boot program operation

The boot program receives data that is sent from the PC by UART, and loads it to internal RAM.

If the transferring terminates normally, it calculates SUM and sends the result to the PC before staring to execute the user program. The starting address to execute is the address received first . This boot program enables user's own on-board programming.

- a) Operation procedure
  - 1. Connect the serial cable . Make sure to perform connection before resetting the micro controller.
  - 2. Set both AM1 and AM0 pins to "1" and reset the micro controller.
  - 3. The receive data in the first byte is the matching data. When the boot program starts, it goes to a state in which it waits for the matching data to be received. Upon receiving the matching data, it automatically adjusts the serial channels' initial baud rate to 9600 bps. The matching data is 5AH.
  - 4. The second byte is used to echo back 5AH to the PC upon completion of the automatic baud rate setting in the first byte. If the device fails in automatic baud rate setting, it goes to an idle state.
  - 5. The third through sixth bytes are used to send the boot program's version management information in ASCII code. The PC should check that the correct version of the boot program is used.

- 6. The seventh byte is used to send information of the measured frequency. The PC should check that the frequency of the resonator is measured correctly.
- 7. The receive data in the eighth byte is the baud rate modification data. The five kinds of baud rate modification data shown in Table 3.21.9 are available. Even when you do not change the baud rate, be sure to send the initial baud rate data (28H: 9600 bps). Baud rate modification becomes effective after the echo back transmission is completed.
- 8. The ninth byte is used to echo back the received data to the PC when the data received in the eighth byte is one of the baud rate modification data corresponding to the device's operating frequency. Then the baud rate is changed. If the received baud rate data does not correspond to the device's operating frequency, the device goes to an idle state after sending 3 bytes of baud rate modification error code (62H).
- 9. The receive data in the 10th byte through n'th 4 bytes is received as binary data in Intel Hex format. No received data is echoed back to the PC.

The boot program processing routine ignores the received data until it receives the start mark (3AH for ":") in Intel Hex format. Nor does it send error code to the PC. After receiving the start mark, the routine receives a range of data from the data length to checksum and writes the received data to the specified RAM addresses successively.

After receiving one record of data from start mark to checksum, the routine goes to a start mark waiting state again.

If a receive error or checksum error of Intel Hex format occurs, the device goes to an IDLE state without returning error code to the PC.

Because the boot program processing routine executes a SUM calculation routine upon detecting the end record, the controller should be placed in a SUM waiting state after sending the end record to the device.

- 10. The n'th 3 bytes and the n'th 2 bytes are the SUM value that is sent to the PC in order of upper byte and lower byte. For details on how to calculate the SUM, refer to "notes on SUM" in the latter pages of this manual. The SUM calculation is performed only when no write error, receive error, or Intel Hex format error has been encountered after detecting the end record. Soon after calculation of SUM, the device sends the SUM data to the PC. The PC should determine whether writing to the RAM has terminated normally depending on whether the SUM value is received after sending the end record to the device.
- 11. After sending the SUM, the device goes to a state waiting for the user program start code. If the SUM value is correct, the PC should send the user program start command to the n'th 1 byte. The user program start command is C0H.
- 12. The n'th byte is used to echo back the user program start code to the PC. After sending the echo back to the PC, the stack pointer is set to 5FFFH and the boot program jumps to the 1st address that is received as data in Intel Hex format.
- 13. If the user program start code is wrong or a receive error occurs, the device goes to an idle state after returning 3 bytes of error code to the PC.

b) Error code

The boot program sends the processing status to the PC using various codes. The error codes are listed in the table below.

Error Code	Meaning of Error Code	
62H	Baud rate modification error occurred.	
64H	Operation command error occurred.	
A1H	Framing error in received data occurred.	
A3H	Overrun error in received data occurred	

Table 3.21.13 Error Codes

Note 1: When a receive error occurs when receiving the user program, the device does not send the error code to the PC.

Note 2: After sending the error code, the device goes to an IDLE state.

- c) Notes on SUM
  - 1. Calculation method

SUM consists of byte + byte... + byte, the sum of which is returned in words as the result. Namely, data is read out in bytes, the sum of which is calculated, with the result returned in words.

Example:

	If the data to be calculated consists of the 4 bytes
A1H	above to the left. SLIM of the data is:
	shown to the left, SUM of the data is:
B2H	A1H + B2H + C3H + D4H = 02EAH
СЗН	SUM (HIGH) = 02H
D4H	SUM (LOW) = EAH

2. Calculation data

The data from which SUM is calculated is the RAM data from the first address received to the last address received.

The received RAM write data is not the only data to be calculated for SUM. Even when the received addresses are noncontiguous and there are some unwritten areas, data in the entire memory area is calculated. The user program should not contain unwritten gaps.

- d) Notes on Intel Hex format (Binary)
  - 1. After receiving the checksum of a record, the device waits for the start mark (3AH for ":") of the next record. Therefore, the device ignores all data received between records during that time unless the data is 3AH.
  - 2. Make sure that once the PC program has finished sending the checksum of the end record, it does not send anything and waits for 2 bytes of data to be received (upper and lower bytes of SUM). This is because after receiving the checksum of the end record, the boot program calculates the SUM and returns the calculated SUM in 2 bytes to the PC.
  - 3. Writing to areas outside the device's internal RAM causes incorrect operation. Therefore, when an extended record is transmitted, be sure to set a paragraph address to 0000H.
  - 4. Always make sure the first record type is an extended record, because the initial value of the address pointer is 00H.
  - 5. The user program is assigned to the address from 3000H to 57FFH and it should be within 10 Kbytes.
  - 6. Transmit a user program not by the ASCII code but by binary. An example explaining how to make binary format file is given below.

Example: How to convert from Intel Hex format file to binary format file.

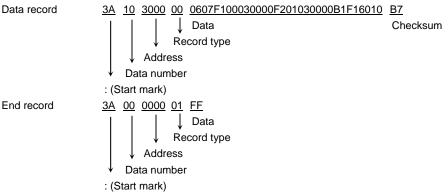

The following is an example of display in text editor where an Intel Hex format file is opened.

- : 10300000607F100030000F201030000B1F16010B7
- : 00000001FF
- In fact, their data are as below because ASCII code is used for Intel Hex format files. 3A31303330303030303036303746313030303330303046323031303330303030 423146313630313042370D0A3A30303030303030303146460D0A

30,	mst	COnven	uie	abuve	uala	ιυ	Dinary	ionnai	using	uie	lable	DEIOW.

Before (ASCII)	After (Binary)
3A	3A (Only 3A should not be converted.)
30 to 39	0 to 9
41 or 61	A
42 or 62	В
43 or 63	С
44 or 64	D
45 or 65	E
46 or 66	F
0D0A	Delete it

The Intel Hex format and its meaning are given below.

e) Error when receiving user program

If the following errors occur in Intel Hex format when receiving the user program, the device goes to an idle state. When the record type is not 00H, 01H, and 02H

when the record type is not obil, offi, and

When a checksum error occurs

f) Error between frequency measurement and baud rate

The boot program measures the resonator frequency when receiving matching data. If the error is under 3%, the boot program decides on that frequency. Since there is an overlap between the margin of 3% for 32.000 MHz and 33.868 MHz, the boundary is set at the intermediate value between the two. The baud rate is set based on the measured frequency. Each baud rate includes a set error shown in Table 3.21.14. For example, in the case of 20.000 MHz and 9600 bps, the baud rate is actually set at 9615.38 bps with an error of 0.2%. To establish communication, the sum of the baud rate set error shown in Table 3.21.14 and frequency error must be under 3%.

	9600 bps	19200 bps	38400 bps	57600 bps	115200 bps
6.000 MHz	0.2	0.2	-	-	-
8.000 MHz	0.2	0.2	-	-	-
9.000 MHz	0.2	-0.7	-	-	—
10.000 MHz	0.2	0.2	-1.4	-	—
16.000 MHz	0.2	0.2	0.2	-0.8	—
20.000 MHz	0.2	0.2	0.2	1.0	—
22.579 MHz	-0.7	-0.7	-0.7	0.1	-
25.000 MHz	0.5	-0.8	0.5	0.5	-
32.000 MHz	0.2	0.2	0.2	0.7	-0.8
33.868 MHz	0.3	0.3	0.3	-0.7	-0.7
36.000 MHz	0.2	-0.7	0.2	0.2	0.2
40.000 MHz	0.2	0.2	0.2	-0.3	1.0

Table 3.21.14 Setting Error of Each Baud Rate (%)

-: Not supported

- (5) Further notes
  - a) Handshake function The TMP92CH21 has a  $\overline{\text{CTS}}$  pin, but boot programs do not use it.
  - b) RS-232C connector

When the boot program is running, do not connect or disconnect an RS-232C connector.

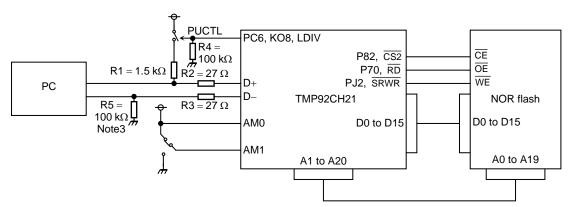

c) Software on PC

Special application software is needed on the PC.

#### 3.21.6 Download with USB

#### (1) Connection example

Figure 3.21.9 shows an example of USB. (16-bit NOR flash is used as program memory.)

Note 1: The values of pull-up / pull-down resistors are recommended values.

Note 2: The PC6 (KO8, LDIV) pin is assigned as PUCTL (Control to pull-up) for USB. So, note whether it is used as KO8 or LDIV.

Note 3: Pull-down resistor R2 is used only to fix the level for the flow current. If there is no ON/ OFF control by port for example, confirm operation by actual setting, and set the value to ensure the USB connection is not cut.

Figure 3.21.9 USB Connecting Example

(2) USB interface specification outline

For USB booting, make sure the oscillator is 9 MHz.

The baud rate is fixed at full speed (12 MHz).

The boot function is employed using the following 2 transfer types.

Table 3.21.15 Trai	nsfer Types Used	by Boot Program
--------------------	------------------	-----------------

Transfer Type	Purpose
Control	Used as transmitting for standard request or vendor request
Bulk	Used as transmitting for vendor request or user program

An outline flowchart is given below.

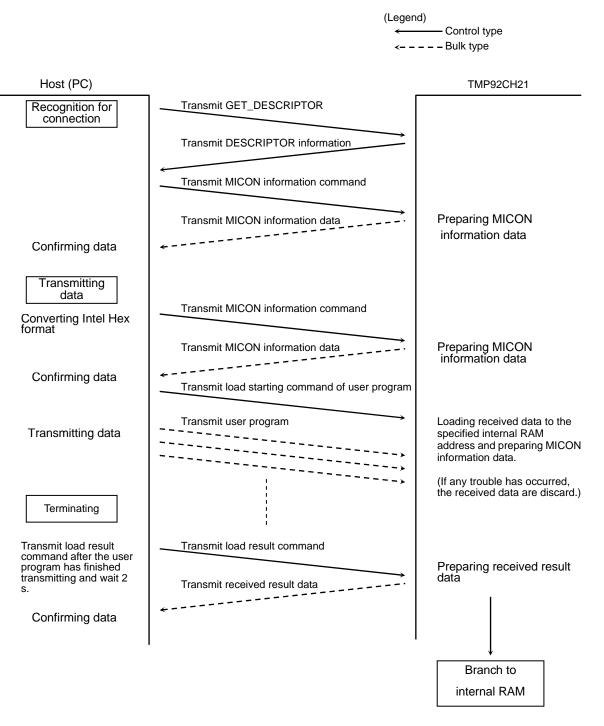

Figure 3.21.10 Outline Flowchart

The vendor request command table is shown below.

Command Name	Value of Request	Outline	Notes
MICON (Microcomputer) information command	00H	Transmit microcomputer information	This is transmitted after a setup stage is terminated by bulk in transfer type.
Load starting command of user program	02H	Receive user program	Substitute size of user program to wIndex. The user program should be received after a setup stage is terminated by bulk out transfer type.
Transmit result command	04H	Transmit the result	This is transmitted after a setup stage is terminated by bulk in transfer type.

#### **Device Descriptor**

Field Name	Value	Meaning
Blength	12H	18 bytes
BdescriptorType	01H	Device descriptor
BcdUSB	0110H	USB Version 1.1
BdeviceClass	00H	Device class is not used
BdeviceSubClass	00H	Sub command is not used
BdeviceProtocol	00H	Protocol is not used
BmaxPacketSize0	40H	EP0 max packet size 64 bytes
IdVendor	0930H	Vendor ID
IdProduct	6504H	Product ID (0)
BcdDevice	0001H	Device version (v 0.1)
Imanufacturer	00H	Index value of string descriptor in which producer is shown
Iproduct	00H	Index value of string descriptor in which product name is shown
IserialNumber	00H	Index value of string descriptor in which product number is shown
BnumConfigurations	01H	Configuration is 1

## Configuration Descriptor

Field Name	Value	Meaning
bLength	09H	9 bytes
bDescriptorType	02H	Configuration descriptor
wTotalLength	0020H	Total length (32 bytes) in which each descriptor of configuration descriptor, interface and endpoint is added.
bNumInterfaces	01H	Interface is 1
bConfigurationValue	01H	Configuration number 1
iConfiguration	00H	Index value of string descriptor in which this configuration name is shown (Not used).
bmAttributes	80H	Bus power
MaxPower	31H	Maximum power consumption (49 mA)

## Interface Descriptor

Field Name	Value	Meaning
bLength	09H	9 bytes
bDescriptorType	04H	Interface descriptor
bInterfaceNumber	00H	Interface number 0
bAlternateSetting	00H	Alternate setting number 0
bNumEndpoints	02H	Endpoint is 2
bInterfaceClass	FFH	Specified device
bInterfaceSubClass	00H	
bInterfaceProtocol	50H	Bulk only protocol
ilinterface	00H	Index value of string descriptor in which this interface name is shown (Not used).

## Endpoint Descriptor

Field Name	Value	Meaning
<endpoint 1=""></endpoint>		
blength	07H	7 bytes
bDescriptorType	05H	Endpoint descriptor
bEndpointAddress	01H	EP1 is OUT
bmAttributes	02H	Bulk transfer
wMaxPacketSize	0040H	Payload 64 bytes
bInterval	00H	(Ignored for bulk transfer)
<endpoint 2=""></endpoint>		
bLength	07H	7 bytes
bDescriptor	05H	Endpoint descriptor
bEndpointAddress	82H	EP2 is IN
bmAttributes	02H	Bulk transfer
wMaxPacketSize	0040H	Payload 64 bytes
bInterval	00H	(Ignored for bulk transfer)

The information transmitted by the MICON information command is shown below.

Table 3.21.20 Information	Transmitted by	MICON Information Command
	Than to the to a b	

Micon Information	ASCII Code
"TMP92CH21FG"	54H, 4DH, 50H, 39H, 32H, 43H, 48H, 32H, 31H, 46H, 47H, 20H, 20H, 20H, 20H

The information transmitted by the result information command is shown below.

Result	Value	Error Condition	
No error	00H		
Not received user program error	02H	When a user program is received without receiving user program starting command.	
Received except Intel Hex format error	04H	When the first data of the user program is not ":" (3AH).	
Over user program size error	06H	When more than the value of wIndex is received.	
Received incorrect address error	08H	When the user program address is incorrect. When the user program size is over 10 Kbytes	
Protocol error or other error	0AH	<ul> <li>When start or result of user program is received first.</li> <li>When check SUM is incorrect in Intel Hex file.</li> <li>When record type is incorrect in Intel Hex file.</li> <li>When address length is more than 2 in Intel Hex file.</li> <li>When end record length is not 0 in Intel Hex file.</li> </ul>	

Table 3.21.21 Information Transmitted by Result Information Command

(3) Description of USB boot program operation

The boot program provides the following RAM loader function.

The data, which is transmitted by the PC in Intel Hex format, is loaded to the internal RAM.

After loading normally, the user program will begin to execute. The first received address is set as the starting address.

By this function, this boot program enables the user's own on-board programming.

- a. Operational procedure
  - 1. Connect the USB cable.
  - 2. Set both AM1 and AM0 pin to "1" and reset the micro controller.
  - 3. On the PC side, recognize USB connection and confirm sub information by GET\_DISCRIPTOR.
  - 4. On the PC side, transmit MICON information command by vendor request and confirm MICON information data by Bulk IN after a setup stage is finished.
  - 5. The boot program prepares MICON information in ASCII code after MICON information command is received.
  - 6. On the PC side, convert user program into binary format.
  - 7. On the PC side, transmit load-starting command by vendor request and transmit user program by Bulk OUT after a setup stage is finished.
  - 8. On the PC side, wait 2 seconds and transmit load result command by vendor request. Confirm the result by bulk in after a setup stage is finished.
  - 9. The boot program prepares the result after load result command is received.
  - 10. If the result is not normal, the boot program cannot be returned normally. In this case, terminate device driver on the PC and retry from step 2.

- b. Notes on user program format (Binary)
  - 1. After receiving the checksum of a record, the device waits for the start mark (3AH for ":") of the next record. The device therefore ignores all data received between records during that time unless the data is 3AH.
  - 2. The first record type is not needed as an address record because the initial value of the address pointer is 00H.
  - 3. The user program is assigned to the address from 3000H to 57FFH and it should be within 10 Kbytes.
  - 4. In the user program, change the Intel Hex format file (usually ASCII code) to binary format and transfer it. The example below explains how to make a binary format file. (This is the same as with UART.)

Make sure that the maximum data number of 1 record is FAH for the user program.

Example: Transfer data case of writing 16 bytes data from address 3000H by Intel Hex format file.

The following is an example of display in text editor where an Intel Hex format file is opened. : 10300000607F100030000F201030000B1F16010B7

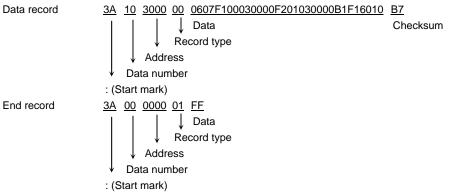

: 00000001FF

In fact, their data are as below because ASCII code is used for Intel Hex format files. 3A313033303030303030363037463130303030303030304632303130333030303 423146313630313042370D0A3A303030303030303146460D0A

Before (ASCII)	After (Binary)	
3A	3A (Only 3A should not be converted.)	
30 to 39	0 to 9	
41 or 61	A	
42 or 62	В	
43 or 63	С	
44 or 64	D	
45 or 65	E	
46 or 66	F	
0D0A	Delete it	

So, first convert the above data to binary format using the table below.

The Intel Hex format and its meaning are given below.

- (4) Further notes
  - a) USB connector

When the boot program is running, do not connect or disconnect the USB connector.

b) Software on PC

Special USB device driver and application software is needed on the PC.

## 4. Electrical Characteristics

## 4.1 Absolute Maximum Ratings

Parameter	Symbol	Rating	Unit
Power Supply Voltage	V <sub>CC</sub>	-0.5 to 4.0	V
Input Voltage	VIN	-0.5 to VCC + 0.5	V
Output Current	I <sub>OL</sub>	2	mA
Output Current (MX, MY pin)	I <sub>OL</sub>	15	mA
Output Current	I <sub>OH</sub>	-2	mA
Output Current (PX, PY pin)	I <sub>OH</sub>	–15	mA
Output Current (Total)	$\Sigma I_{OL}$	80	mA
Output Current (Total)	ΣΙΟΗ	-80	mA
Power Dissipation (Ta = 85°C)	PD	600	mW
Soldering Temperature (10 s)	T <sub>SOLDER</sub>	260	°C
Storage Temperature	T <sub>STG</sub>	-65 to 150	°C
Operation Temperature	T <sub>OPR</sub>	-20 to 70	°C

Note: The absolute maximum ratings are rated values which must not be exceeded during operation, even for an instant. Any one of the ratings must not be exceeded. If any absolute maximum rating is exceeded, the device may break down or its performance may be degraded, causing it to catch fire or explode resulting in injury to the user. Thus, when designing products which include this device, ensure that no absolute maximum rating value will ever be exceeded.

#### Solderability

Test parameter	Test condition	Note
parameter		
Solderability	(1) Use of Sn-37Pb solder Bath	Pass:
	Solder bath temperature =230°C, Dipping time = 5 seconds	solderability rate until forming $\ge 95\%$
	The number of times = one, Use of R-type flux	
	(2) Use of Sn-3.0Ag-0.5Cu solder bath	
	Solder bath temperature =245°C, Dipping time = 5 seconds	
	The number of times = one, Use of R-type flux

AC measuring conditions

• Output level: High = 0.7 VCC, Low = 0.3 VCC,  $C_L$  = 10 pF

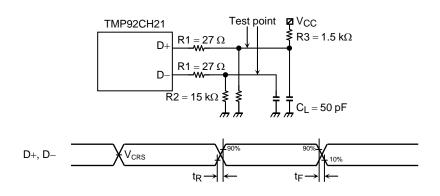

## 4.3.9 USB Timing (Full-speed)

 $V_{CC}=3.3\pm0.3$  V/f\_{USB}=48 MHz/Ta = -20 to 70°C

Parameter	Symbol	Min	Max	Unit
Rising time for D+, D-	t <sub>R</sub>	4	20	ns
Falling time for D+, D-	tF	4	20	115
Output signal crossover voltage	VCRS	1.3	2.0	V

AC measuring conditions

# 4.4 AD Conversion Characteristics

Parameter	Symbol	Min	Тур.	Max	Unit
Analog reference voltage (+)	V <sub>REFH</sub>	V <sub>CC</sub> - 0.2	V <sub>CC</sub>	V <sub>CC</sub>	
Analog reference voltage (-)	V <sub>REFL</sub>	V <sub>SS</sub>	V <sub>SS</sub>	V <sub>SS</sub> + 0.2	
AD converter power supply voltage	AV <sub>CC</sub>	V <sub>CC</sub>	V <sub>CC</sub>	V <sub>CC</sub>	V
AD converter ground	AV <sub>SS</sub>	V <sub>SS</sub>	V <sub>SS</sub>	V <sub>SS</sub>	
Analog input voltage	AVIN	V <sub>REFL</sub>		V <sub>REFH</sub>	
Analog current for analog reference voltage <vrefon> = 1</vrefon>	I <sub>REF</sub>		0.8	1.35	mA
Analog current for analog reference voltage <vrefon> = 0</vrefon>	IREF		0.02	5.0	μΑ
Total error (Quantize error of $\pm$ 0.5 LSB is included.)	ET		±1.0	±4.0	LSB

Note 1: 1LSB = (VREFH - VREFL) / 1024 [V]

Note 2: Minimum frequency for operation

AD converter operation is guaranteed only when using fc (high-frequency oscillator). fs is not guaranteed.

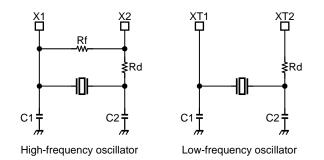

However, operation is guaranteed if the clock frequency selected by the clock gear is over 4MHz.

Note 3: The value for Icc includes the current which flows through the  $\mathsf{AV}_{\mathsf{CC}}$  pin.

## 4.5 Recommended Oscillation Circuit

The TMP92CH21 has been evaluated by the oscillator vender below. Use this information when selecting external parts.

- Note: The total load value of the oscillator is the sum of external loads (C1 and C2) and the floating load of the actual assembled board. There is a possibility of operating error when using C1 and C2 values in the table below. When designing the board, design the minimum length pattern around the oscillator. We also recommend that oscillator evaluation be carried out using the actual board.
- (1) Connection example

#### (2) TMP92CH21FG Recommended ceramic oscillator

The TMP92CH21FG recommend the high-frequency oscillators by Murata Manufacturing Co., Ltd and TDK Corporation.

Please refer to the following URL;

•Murata Manufacturing Co., Ltd http://www.murata.com/

•TDK Corporation http://www.tdk.co.jp/tetop01/

# 5. Table of Special function registers (SFRs)

The SFRs include the I/O ports and peripheral control registers allocated to the 4-Kbyte address space from 000000H to 001FFFH.

- (1) I/O Port
- (2) Interrupt control
- (3) Memory controller
- (4) MMU
- (5) Clock gear, PLL
- (6) LCD controller
- (7) Touch screen I/F
- (8) SDRAM controller
- (9) 8-bit timer
- (10) 16-bit timer
- Table layout

- (11) UART/serial channel
- (12) USB controller
- (13) AD converter
- (14) Watchdog timer
- (15) RTC (Real time clock)
- (16) Melody/alarm generator
- (17) NAND flash controller
- (18) I<sup>2</sup>S

					-				
Symbol	Name	Address	7	6		[	1	0	
									—→Bit symbol
									—→Read/Write
									→Initial value after reset
									→ Remarks

Note: "Prohibit RMW" in the table means that you cannot use RMW instructions on these registers.

Example: When setting bit0 only of the register P0CR, the instruction "SET 0, (PxCR)" cannot be used. The LD (transfer) instruction must be used to write all eight bits.

#### Read/Write

R/W:	Both read and write are possible.
R:	Only read is possible.
W:	Only write is possible.
W*:	Both read and write are possible (when this bit is read as1)
Prohibit RMW:	Read-modify-write instructions are prohibited. (The EX, ADD, ADC, BUS, SBC, INC, DEC, AND, OR, XOR, STCF, RES, SET, CHG, TSET, RLC, RRC, RL, RR, SLA, SRA, SLL, SRL, RLD and RRD instructions are read-modify-write instructions.)
R/W*:	Read-modify-write is prohibited when controlling the pull-up resistor.

# 6. Points of Note and Restrictions

## 6.1 Notation

- (1) The notation for built-in I/O registers is as follows: Register symbol <Bit symbol> Example: TA01RUN<TA0RUN> denotes bit TA0RUN of register TA01RUN.
- (2) Read-modify-write instructions (RMW)

An instruction in which the CPU reads data from memory and writes the data to the same memory location in one instruction.

Example 1: SET 3, (TA01RUN); Set bit3 of TA01RUN.

Example 2: INC 1, (100H); Increment the data at 100H.

- Examples of read-modify-write instructions on the TLCS-900:
  - Exchange instruction

EX (mem), R

Arithmetic operations

ADD (mem), R/#	ADC	(mem), R/#
SUB (mem), R/#	SBC	(mem), R/#
INC #3, (mem)	DEC	#3, (mem)

Logic operations

AND (mem), R/#	OR	(mem), R/#
XOR (mem), R/#		

Bit manipulation operations

STCF#3/A, (mem)	RES	#3, (mem)
SET #3, (mem)	CHG	#3, (mem)
TSET#3, (mem)		

Rotate and shift operations

RLC	(mem)	RRC	(mem)
$\operatorname{RL}$	(mem)	RR	(mem)
SLA	(mem)	SRA	(mem)
$\operatorname{SLL}$	(mem)	$\operatorname{SRL}$	(mem)
RLD	(mem)	RRD	(mem)

### (3) fOSCH, fc, fFPH, fSYS, fIO and one state

The clock frequency input on pins X1 and 2 is referred to as for the clock selected by PLLCR0<FCSEL> is referred to as fc.

The clock selected by SYSCR1<SYSCK> is referred to as fFPH. The clock frequency give by fFPH divided by 2 is referred to as system clock fSYS. The clock frequency given by fSYS divided by 2 is referred to as fIO.

One cycle of fSYS is referred to as one state.

## 6.2 Notes

#### (1) AM0 and AM1 pins

These pins are connected to the  $V_{CC}$  (Power supply level) or the  $V_{SS}$  (Grand level) pin. Do not alter the level when the pin is active.

(2) Reserved address areas

The 16 bytes area (FFFFF0H ~ FFFFFH) cannot be used since it is reserved for use as internal area. If using an emulator, an optional 64 Kbytes of the 16M bytes area is used for emulator control. Therefore, if using an emulator, this area cannot be used.

(3) Standby mode (IDLE1)

When the HALT instruction is executed in IDLE1 mode (in which only the oscillator operates), RTC (Real-time-clock) and MLD (Melody-alarm-generator) operate. When necessary, stop the circuit before the HALT instruction is executed.

(4) Warm-up counter

The warm-up counter operates when STOP mode is released, even if the system is using an external oscillator. As a result, a time equivalent to the warm-up time elapses between input of the release request and output of the system clock.

(5) Watchdog timer

The watchdog timer starts operation immediately after a reset is released. Disable the watchdog timer when it is not to be used.

(6) AD converter

The string resistor between the VREFH and VREFL pins can be cut by program so as to reduce power consumption. When STOP mode is used, disable the resistor using the program before the HALT instruction is executed.

(7) CPU (Micro DMA)

Only the "LDC cr, r" and "LDC r, cr" instructions can be used to access the control registers in the CPU (e.g., the transfer source address register (DMASn).).

### (8) Undefined SFR

The value of an undefined bit in an SFR is undefined when read.

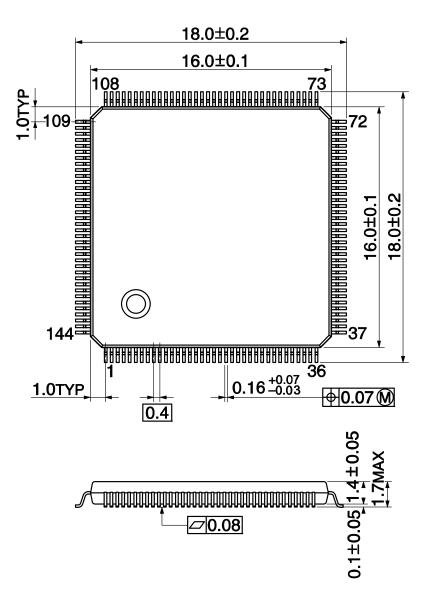

### (9) POP SR instruction

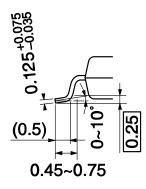

Please execute the POP SR instruction during DI condition.

7. Package Dimensions

Package Name: LQFP144-P-1616-0.40C

Unit: mm

Note: Palladium plating

# **RESTRICTIONS ON PRODUCT USE**

- Toshiba Corporation, and its subsidiaries and affiliates (collectively "TOSHIBA"), reserve the right to make changes to the information in this document, and related hardware, software and systems (collectively "Product") without notice.
- This document and any information herein may not be reproduced without prior written permission from TOSHIBA. Even with TOSHIBA's written permission, reproduction is permissible only if reproduction is without alteration/omission.
- Though TOSHIBA works continually to improve Product's quality and reliability, Product can malfunction or fail. Customers are responsible for complying with safety standards and for providing adequate designs and safeguards for their hardware, software and systems which minimize risk and avoid situations in which a malfunction or failure of Product could cause loss of human life, bodily injury or damage to property, including data loss or corruption. Before creating and producing designs and using, customers must also refer to and comply with (a) the latest versions of all relevant TOSHIBA information, including without limitation, this document, the specifications, the data sheets and application notes for Product and the precautions and conditions set forth in the "TOSHIBA Semiconductor Reliability Handbook" and (b) the instructions for the application that Product will be used with or for. Customers are solely responsible for all aspects of their own product design or applications; (b) evaluating and determining the appropriateness of the use of this Product in such design or applications; (b) evaluating and determining the applicability of any information contained in this document, or in charts, diagrams, programs, algorithms, sample application circuits, or any other referenced documents; and (c) validating all operating parameters for such designs and applications. TOSHIBA ASSUMES NO LIABILITY FOR CUSTOMERS' PRODUCT DESIGN OR APPLICATIONS.
- Product is intended for use in general electronics applications (e.g., computers, personal equipment, office equipment, measuring
  equipment, industrial robots and home electronics appliances) or for specific applications as expressly stated in this document. Product
  is neither intended nor warranted for use in equipment or systems that require extraordinarily high levels of quality and/or reliability
  and/or a malfunction or failure of which may cause loss of human life, bodily injury, serious property damage or serious public impact
  ("Unintended Use"). Unintended Use includes, without limitation, equipment used in nuclear facilities, equipment used in the aerospace
  industry, medical equipment, equipment used for automobiles, trains, ships and other transportation, traffic signaling equipment,
  equipment used to control combustions or explosions, safety devices, elevators and escalators, devices related to electric power, and
  equipment used in finance-related fields. Do not use Product for Unintended Use unless specifically permitted in this document.
- · Do not disassemble, analyze, reverse-engineer, alter, modify, translate or copy Product, whether in whole or in part.
- Product shall not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable laws or regulations.
- The information contained herein is presented only as guidance for Product use. No responsibility is assumed by TOSHIBA for any infringement of patents or any other intellectual property rights of third parties that may result from the use of Product. No license to any intellectual property right is granted by this document, whether express or implied, by estoppel or otherwise.
- ABSENT A WRITTEN SIGNED AGREEMENT, EXCEPT AS PROVIDED IN THE RELEVANT TERMS AND CONDITIONS OF SALE FOR PRODUCT, AND TO THE MAXIMUM EXTENT ALLOWABLE BY LAW, TOSHIBA (1) ASSUMES NO LIABILITY WHATSOEVER, INCLUDING WITHOUT LIMITATION, INDIRECT, CONSEQUENTIAL, SPECIAL, OR INCIDENTAL DAMAGES OR LOSS, INCLUDING WITHOUT LIMITATION, LOSS OF PROFITS, LOSS OF OPPORTUNITIES, BUSINESS INTERRUPTION AND LOSS OF DATA, AND (2) DISCLAIMS ANY AND ALL EXPRESS OR IMPLIED WARRANTIES AND CONDITIONS RELATED TO SALE, USE OF PRODUCT, OR INFORMATION, INCLUDING WARRANTIES OR CONDITIONS OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, ACCURACY OF INFORMATION, OR NONINFRINGEMENT.
- Do not use or otherwise make available Product or related software or technology for any military purposes, including without limitation, for the design, development, use, stockpiling or manufacturing of nuclear, chemical, or biological weapons or missile technology products (mass destruction weapons). Product and related software and technology may be controlled under the Japanese Foreign Exchange and Foreign Trade Law and the U.S. Export Administration Regulations. Export and re-export of Product or related software or technology are strictly prohibited except in compliance with all applicable export laws and regulations.
- Please contact your TOSHIBA sales representative for details as to environmental matters such as the RoHS compatibility of Product. Please use Product in compliance with all applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive. TOSHIBA assumes no liability for damages or losses occurring as a result of noncompliance with applicable laws and regulations.
