The RF MOSFET Line **RF Power Field-Effect Transistor** N-Channel Enhancement-Mode

Designed for broadband commercial and industrial applications at frequencies to 54 MHz. The high gain, broadband performance and linear characterization of this device makes it ideal for large–signal, common source amplifier applications in 12.5 Volt mobile and base station equipment.

- Guaranteed Performance at 54 MHz, 12.5 Volts Output Power — 55 Watts PEP Power Gain — 13 dB Min Two-Tone IMD — -25 dBc Max Efficiency — 40% Min, Two-Tone Test
- Characterized with Series Equivalent Large–Signal Impedance Parameters
- Excellent Thermal Stability
- All Gold Metal for Ultra Reliability
- Aluminum Nitride Package Electrical Insulator
- Circuit Board Photomaster Available by Ordering Document MRF255PHT/D from Motorola Literature Distribution.

55 W, 12.5 Vdc, 54 MHz N–CHANNEL BROADBAND RF POWER FET

 $I_D = 1 A$

DESIGN CONSIDERATIONS

The MRF255 is a common-surce, RF power, N-channel enhancement mode Metal-Oxide Semiconductor Field-Effect Transistor (MOSFET). Motorola RF MOSFETs feature a vertical structure with a planar design.

Motorola Application Note AN211A, FETs in Theory and Practice, is suggested reading for those not familiar with the construction and characteristics of FETs.

This device was designed primarily for HF 12.5 V mobile linear power amplifier applications. The major advantages of RF power MOSFETs include high gain, simple bias systems, relative immunity from thermal runaway, and the ability to withstand severely mismatched loads without suffering damage.

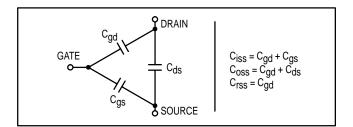

MOSFET CAPACITANCES

The physical structure of a MOSFET results in capacitors between all three terminals. The metal oxide gate structure determines the capacitors from gate-to-drain (C_{ad}), and gate-to-source (Cqs). The PN junction formed during fabrication of the RF MOSFET results in a junction capacitance from drain-to-source (Cds).

These capacitances are characterized as input (Ciss), output (C_{OSS}) and reverse transfer (C_{rss}) capacitances on data sheets. The relationships between the inter-terminal capacitances and those given on data sheets are shown below. The Ciss can be specified in two ways:

- 1. Drain shorted to source and positive voltage at the gate.
- 2. Positive voltage of the drain in respect to source and zero volts at the gate.

In the latter case the numbers are lower. However, neither method represents the actual operating conditions in RF applications.

DRAIN CHARACTERISTICS

One critical figure of merit for a FET is its static resistance in the full-on condition. This on-resistance, RDS(on), occurs in the linear region of the output characteristic and is specified at a specific gate-source voltage and drain current. The drain-source voltage under these conditions is termed VDS(on), For MOSFETs, VDS(on) has a positive temperature coefficient at high temperatures because it contributes to the power dissipation within the device.

GATE CHARACTERISTICS

The gate of the RF MOSFET is a polysilicon material, and is electrically isolated from the source by a layer of oxide. The input resistance is very high — on the order of 10^9 ohms — resulting in a leakage current of a few nanoamperes.

Gate control is achieved by applying a positive voltage to the gate greater than the gate-to-source threshold voltage, VGS(th).

Gate Voltage Rating — Never exceed the gate voltage rating. Exceeding the rated V_{GS} can result in permanent damage to the oxide layer in the gate region.

Gate Termination — The gates of these devices are essentially capacitors. Circuits that leave the gate opencircuited or floating should be avoided. These conditions can result in turn-on of the devices due to voltage build-up on the input capacitor due to leakage currents or pickup.

Gate Protection — These devices do not have an internal monolithic zener diode from gate—to—source. If gate protection is required, an external zener diode is recommended.

Using a resistor to keep the gate-to-source impedance low also helps damp transients and serves another important function. Voltage transients on the drain can be coupled to the gate through the parasitic gate-drain capacitance. If the gate-to-source impedance and the rate of voltage change on the drain are both high, then the signal coupled to the gate may be large enough to exceed the gate-threshold voltage and turn the device on.

DC BIAS

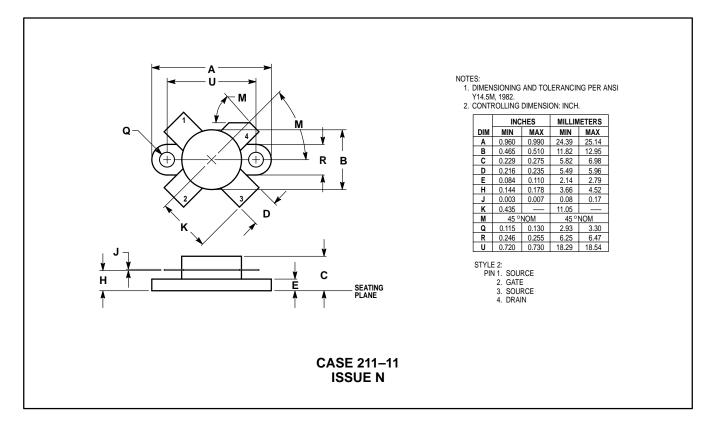

Since the MRF255 is an enhancement mode FET, drain current flows only when the gate is at a higher potential than the source. See Figure 8 for a typial plot of drain current versus gate voltage. RF power FETs operate optimally with a quiescent drain current (IDQ), whose value is application dependent. The MRF255 was characterized for linear and CW operation at IDQ = 400 mA, which is the suggested value of bias current for typical applications.

The gate is a dc open circuit and draws essentially no current. Therefore, the gate bias circuit may generally be just a simple resistive divider network. Some applications may require a more elaborate bias sytem.

GAIN CONTROL

For CW applications, power output of the MRF255 may be controlled to some degree with a low power dc control signal applied to the gate, thus facilitating applications such as manual gain control, AGC/ALC and modulation systems. The characteristic is very dependent on frequency and load line.

PACKAGE DIMENSIONS

Motorola reserves the right to make changes without further notice to any products herein. Motorola makes no warranty, representation or guarantee regarding the suitability of its products for any particular purpose, nor does Motorola assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation consequential or incidental damages.
