## APPLICATIONS

Mechanical potentiometer and trimmer replacements LCD backlight, contrast, and brightness controls Digital volume control
Portable device-level adjustments
Electronic front panel-level controls
Programmable power supply

## GENERAL DESCRIPTION

The AD5228 is Analog Devices' latest 32-step-up/step-down control digital potentiometer emulating mechanical potentiometer operation ${ }^{1}$. Its simple up/down control interface allows manual control with just two external pushbutton tactile switches. The AD5228 is designed with a built-in adaptive debouncer that ignores invalid bounces due to contact bounce commonly found in mechanical switches. The debouncer is adaptive, accommodating a variety of pushbutton tactile switches that generally have less than 10 ms of bounce time during contact closures. When choosing the switch, the user should consult the timing specification of the switch to ensure its suitability in an AD5228 application.
${ }^{1}$ The terms digital potentiometer and RDAC are used interchangeably.

Rev. 0
Information furnished by Analog Devices is believed to be accurate and reliable. However, no responsibility is assumed by Analog Devices for its use, nor for any infringements of patents or other rights of third parties that may result from its use. Specifications subject to change without notice. No license is granted by implication or otherwise under any patent or patent rights of Analog Devices. FUNCTIONAL BLOCK DIAGRAM

Figure 1.
The AD5228 can increment or decrement the resistance in discrete steps or in autoscan mode. When the $\overline{\mathrm{PU}}$ or $\overline{\mathrm{PD}}$ button is pressed briefly (no longer than 0.6 s ), the resistance of the AD5228 changes by one step. When the $\overline{\mathrm{PU}}$ or $\overline{\mathrm{PD}}$ button is held continuously for more than a second, the device activates the autoscan mode and changes four resistance steps per second.

The AD5228 can also be controlled digitally; its up/down features simplify microcontroller usage. The AD5228 is available in a compact thin SOT-23-8 (TSOT-8) package. The part is guaranteed to operate over the automotive temperature range of $-40^{\circ} \mathrm{C}$ to $+105^{\circ} \mathrm{C}$.

The AD5228's simple interface, small footprint, and very low cost enable it to replace mechanical potentiometers and trimmers with typically $3 \times$ improved resolution, solid-state reliability, and faster adjustment, resulting in considerable cost saving in end users' systems.

Users who consider EEMEM potentiometers should refer to the recommendations in the Applications section.

${ }^{1}$ Typicals represent average readings at $25^{\circ} \mathrm{C}, \mathrm{V}_{\mathrm{DD}}=5 \mathrm{~V}$.
${ }^{2}$ Resistor position nonlinearity error, $\mathrm{R}-\mathrm{INL}$, is the deviation from an ideal value measured between the maximum resistance and the minimum resistance wiper positions. R-DNL measures the relative step change from ideal between successive tap positions. Parts are guaranteed monotonic.
${ }^{3} I N L$ and DNL are measured at $\mathrm{V}_{\mathrm{W}}$ with the RDAC configured as a potentiometer divider similar to a voltage output $\mathrm{D} / \mathrm{A}$ converter. $\mathrm{V}_{\mathrm{A}}=\mathrm{V}_{\mathrm{DD}}$ and $\mathrm{V}_{\mathrm{B}}=0 \mathrm{~V}$.
${ }^{4}$ Guaranteed by design and not subject to production test.
${ }^{5}$ DNL specification limits of $\pm 1$ LSB maximum are guaranteed monotonic operating conditions.
${ }^{6}$ Resistor Terminals $\mathrm{A}, \mathrm{B}$, and W have no limitations on polarity with respect to each other.
$7 \overline{\mathrm{PU}}$ and $\overline{\mathrm{PD}}$ have $100 \mathrm{k} \Omega$ internal pull-up resistors, $\mathrm{l}_{\mathrm{DD}} \mathrm{ACT}=\mathrm{V}_{\mathrm{DD}} / 100 \mathrm{k} \Omega+\operatorname{losc}$ (internal oscillator operating current) when $\overline{\mathrm{PU}}$ or $\overline{\mathrm{PD}}$ is connected to ground.
 dissipation.
${ }^{9}$ Bandwidth, noise, and settling time are dependent on the terminal resistance value chosen. The lowest $R$ value results in the fastest settling time and highest bandwidth. The highest R value results in the minimum overall power consumption.
${ }^{10}$ All dynamic characteristics use $\mathrm{V}_{\mathrm{DD}}=5 \mathrm{~V}$.
${ }^{11}$ Note that all input control voltages are specified with $t_{R}=t_{F}=1 \mathrm{~ns}\left(10 \%\right.$ to $90 \%$ of $\left.V_{D D}\right)$ and timed from a voltage level of 1.6 V . Switching characteristics are measured using $\mathrm{V}_{\mathrm{DD}}=5 \mathrm{~V}$.
${ }^{12}$ The debouncer keeps monitoring the logic-low level once $\overline{\mathrm{PU}}$ is connected to ground. Once the signal lasts longer than 11 ms, the debouncer assumes the last bounce is met and allows the AD5228 to increment by one step. If the $\overline{\mathrm{PU}}$ signal remains at low and reaches $\mathrm{t}_{\text {AS_staRt, }}$, the AD5528 increments again, see Figure 7 . Similar characteristics apply to $\overline{\mathrm{PD}}$ operation.

## ABSOLUTE MAXIMUM RATINGS

Table 3.

| Parameter | Rating |
| :---: | :---: |
| $V_{\text {DD }}$ to GND | -0.3 V, +7 V |
| $\mathrm{V}_{\mathrm{A}}, \mathrm{V}_{\mathrm{B}}, \mathrm{V}_{\mathrm{W}}$ to GND | $0 \mathrm{~V}, \mathrm{~V}_{\mathrm{DD}}$ |
| $\overline{\text { PU, }}$, $\overline{\mathrm{PD}}, \mathrm{PRE}$ Voltage to GND | $0 \mathrm{~V}, \mathrm{~V}_{\mathrm{DD}}$ |
| Maximum Current |  |
| $I_{\text {we, }} I_{\text {wa }}$ Pulsed | $\pm 20 \mathrm{~mA}$ |
| $\mathrm{I}_{\text {wB }}$ Continuous ( $\mathrm{Rww}^{\text {}} \leq 5 \mathrm{k} \Omega$, A open) $)^{1}$ | $\pm 1 \mathrm{~mA}$ |
| Iwa Continuous ( $\mathrm{Rwa} \leq 5 \mathrm{k} \Omega$, B open) ${ }^{1}$ | $\pm 1 \mathrm{~mA}$ |
| $\mathrm{I}_{\mathrm{AB}}$ Continuous $\left(\mathrm{R}_{\mathrm{AB}}=10 \mathrm{k} \Omega / 50 \mathrm{k} \Omega / 100 \mathrm{k} \Omega\right)^{1}$ | $\begin{aligned} & \pm 500 \mu \mathrm{~A} / \pm 100 \mu \mathrm{~A} / \\ & \pm 50 \mu \mathrm{~A} \end{aligned}$ |
| Operating Temperature Range | $-40^{\circ} \mathrm{C}$ to $+105^{\circ} \mathrm{C}$ |
| Maximum Junction Temperature <br> (Tرmax) | $150^{\circ} \mathrm{C}$ |
| Storage Temperature | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Lead Temperature <br> (Soldering, $10 \mathrm{~s}-30 \mathrm{~s}$ ) | $245^{\circ} \mathrm{C}$ |
| Thermal Resistance ${ }^{2} \theta_{\text {JA }}$ | $230^{\circ} \mathrm{C} / \mathrm{W}$ |

${ }^{1}$ Maximum terminal current is bounded by the maximum applied voltage across any two of the $A, B$, and $W$ terminals at a given resistance, the maximum current handling of the switches, and the maximum power dissipation of the package. $\mathrm{V}_{\mathrm{DD}}=5 \mathrm{~V}$.
${ }^{2}$ Package power dissipation $=\left(\mathrm{T}_{\mathrm{m}} \max -\mathrm{T}_{\mathrm{A}}\right) / \theta_{\mathrm{JA}}$.

## ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 6. SOT-23-8 Pin Configuration

Table 4. Pin Function Descriptions

| Pin No. | Mnemonic | Description |
| :---: | :---: | :---: |
| 1 | $\overline{\mathrm{PU}}$ | Push-Up Pin. |
|  |  | Connect to the external pushbutton. Active low. $\mathrm{A} 100 \mathrm{k} \Omega$ pull-up resistor is connected to V VD . |
| 2 | $\overline{P D}$ | Push-Down Pin. |
|  |  | Connect to the external pushbutton. Active low. $\mathrm{A} 100 \mathrm{k} \Omega$ pull-up resistor is connected to $\mathrm{V}_{\mathrm{DD}}$. |
| 3 | A | Resistor Terminal A. GND $\leq \mathrm{V}_{\mathrm{A}} \leq \mathrm{V}_{\mathrm{DD}}$. |
| 4 | GND | Common Ground. |
| 5 | W | Wiper Terminal W. GND $\leq \mathrm{V}_{\mathrm{W}} \leq \mathrm{V}_{\mathrm{DD}}$. |
| 6 | B | Resistor Terminal B. GND $\leq \mathrm{V}_{\mathrm{B}} \leq \mathrm{V}_{\mathrm{DD}}$. |
| 7 | PRE | Power-On Preset. Output = midscale if PRE = GND; output $=$ zero scale if $P R E=V_{D D}$. Do not let the PRE pin float. No pull-up resistor is needed. |
| 8 | $V_{D D}$ | Positive Power Supply, 2.7 V to 5.5 V . |

## THEORY OF OPERATION

The AD5228 is a 32 -position manual up/down digitally controlled potentiometer with selectable power-on preset. The AD5228 presets to midscale when the PRE pin is tied to ground and to zero-scale when PRE is tied to $V_{D D}$. Floating the PRE pin is not allowed. The step-up and step-down operations require the activation of the $\overline{\mathrm{PU}}$ (push-up) and $\overline{\mathrm{PD}}$ (push-down) pins. These pins have $100 \mathrm{k} \Omega$ internal pull-up resistors that the $\overline{\mathrm{PU}}$ and $\overline{\mathrm{PD}}$ activate at logic low. The common practice is to apply external pushbuttons (tactile switches) as shown in Figure 30.

Figure 30. Typical Pushbutton Interface
Because of the bounce mechanism commonly found in the switches during contact closures, a single pushbutton press usually generates numerous bounces during contact closure. Note that the term pushbutton refers specifically to a pushbutton tactile switch or a similar switch that has 10 ms or less bounce time during contact closure. Figure 31 shows the characteristics of one such switch, the KRS-3550 tactile switch. Figure 32 and Figure 33 show close ups of the initial bounces and end bounces, respectively.

Figure 31. Typical Tactile Switch Characteristics

Figure 32. Close-Up of Initial Bounces

Figure 33. Close-Up of Final Bounces
The following paragraphs describes the $\overline{\mathrm{PU}}$ incrementing operation. Similar characteristics apply to the $\overline{\mathrm{PD}}$ decrementing operation.

The AD5228 features an adaptive debouncer that monitors the duration of the logic-low level of $\overline{\mathrm{PU}}$ signal between bounces. If the $\overline{\mathrm{PU}}$ logic-low level signal duration is shorter than 7 ms , the debouncer ignores it as an invalid incrementing command. Whenever the logic-low level of $\overline{\mathrm{PU}}$ signal lasts longer than 11 ms , the debouncer assumes that the last bounce is met and therefore increments Rwв by one step.
Repeatedly pressing the $\overline{\text { PU }}$ button for fast adjustment without missing steps is allowed, provided that each press is not shorter than tpu, which is 12 ms (see Figure 2). As a point of reference, an advanced video game player can press a pushbutton switch in 40 ms .

If the $\overline{\mathrm{PU}}$ button is held for longer than 1 second, continuously holding it activates autoscan mode such that the AD5228 increments by four $\mathrm{R}_{\mathrm{wb}}$ steps per second (see Figure 3).

Whenever the maximum $\mathrm{R}_{\mathrm{WB}}\left(=\mathrm{R}_{A B}\right)$ is reached, $\mathrm{R}_{\mathrm{WB}}$ stops incrementing regardless of the state of the $\overline{\mathrm{PU}}$ pin. Any continuous holding of the $\overline{\mathrm{PU}}$ pin to logic-low simply elevates the supply current.

When both $\overline{\mathrm{PU}}$ and $\overline{\mathrm{PD}}$ buttons are pressed, $\mathrm{R}_{\mathrm{WB}}$ decrements until it stops at zero scale.

All the preceding descriptions apply to $\overline{\mathrm{PD}}$ operation. Due to the tolerance of the internal RC oscillator, all the timing information given previously is based on the typical values, which can vary $\pm 30 \%$.

The AD5228 debouncer is carefully designed to handle common pushbutton tactile switches. Other switches that have excessive bounces and duration are not suitable to use in conjunction with the AD5228.

Figure 34. AD5228 Equivalent RDAC Circuit

## PROGRAMMING THE DIGITAL POTENTIOMETERS Rheostat Operation

If only the W -to- B or W -to-A terminals are used as variable resistors, the unused terminal can be opened or shorted with W. Such operation is called rheostat mode and is shown in Figure 35.

Figure 35. Rheostat Mode Configuration

The end-to-end resistance, $\mathrm{R}_{A B}$, has 32 contact points accessed by the wiper terminal, plus the $B$ terminal contact if $R_{\text {wB }}$ is used. Pushing the $\overline{\mathrm{PU}}$ pin discretely increments $\mathrm{R}_{w B}$ by one step. The total resistance becomes $\mathrm{R}_{\mathrm{s}}+\mathrm{R}_{\mathrm{w}}$ as shown in Figure 34. The change of $R_{w B}$ can be determined by the number of discrete $\overline{\mathrm{PU}}$ executions provided that its maximum setting is not reached during operation. $\Delta \mathrm{R}_{\mathrm{WB}}$ can, therefore, be approximated as

$$
\begin{align*}
& \Delta R_{W B}=+\left(\overline{P U} \frac{R_{A B}}{32}+R_{W}\right)  \tag{1}\\
& \Delta R_{W B}=-\left(\overline{P D} \frac{R_{A B}}{32}+R_{W}\right) \tag{2}
\end{align*}
$$

where:
$\overline{P U}$ is the number of push-up executions.
$\overline{P D}$ is the number of push-down executions.
$R_{A B}$ is the end-to-end resistance.
$R_{W}$ is the wiper resistance contributed by the on-resistance of the internal switch.
Similar to the mechanical potentiometer, the resistance of the RDAC between the Wiper W and Terminal A also produces a complementary resistance, $\mathrm{R}_{\mathrm{w}}$. When these terminals are used, the $B$ terminal can be opened or shorted to $W$. Rwa can also be approximated if its maximum and minimum settings are not reached.

$$
\begin{align*}
& \Delta R_{W A}=-\left((32-\overline{P U}) \frac{R_{A B}}{32}+R_{W}\right) \\
& \Delta R_{W A}=+\left((32-\overline{P D}) \frac{R_{A B}}{32}+R_{W}\right) \tag{4}
\end{align*}
$$

Note that Equations 1 to 4 do not apply when $\overline{\mathrm{PU}}$ and $\overline{\mathrm{PD}}=0$ execution.

Because in the lowest end of the resistor string, a finite wiper resistance is present, care should be taken to limit the current flow between W and B in this state to a maximum pulse current of no more than 20 mA . Otherwise, degradation or possible destruction of the internal switches can occur.

The typical distribution of the resistance tolerance from device to device is process lot dependent, and $\pm 20 \%$ tolerance is possible.

## Potentiometer Mode Operation

If all three terminals are used, the operation is called potentiometer mode. The most common configuration is the voltage divider operation as shown in Figure 36.

Figure 36. Potentiometer Mode Configuration
The change of $\mathrm{V}_{\mathrm{wb}}$ is known provided that the AD5228 maximum or minimum scale has not been reached during operation. If the effect of wiper resistance is ignored, the transfer functions can be simplified as

$$
\begin{align*}
\Delta V_{W B} & =+\frac{\overline{P U}}{32} V_{A}  \tag{5}\\
\Delta V_{W B} & =+\frac{\overline{P D}}{32} V_{A} \tag{6}
\end{align*}
$$

Unlike in rheostat mode operation where the absolute tolerance is high, potentiometer mode operation yields an almost ratiometric function of $\overline{\mathrm{PU}} / 32$ or $\overline{\mathrm{PD}} / 32$ with a relatively small error contributed by the $\mathrm{R}_{\mathrm{w}}$ term. The tolerance effect is, therefore, almost canceled. Although the thin film step resistor $\mathrm{R}_{\mathrm{s}}$ and CMOS switch resistance, $\mathrm{R}_{\mathrm{w}}$, have very different temperature coefficients, the ratiometric adjustment also reduces the overall temperature coefficient effect to $5 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$ except at low value codes where $\mathrm{R}_{\mathrm{w}}$ dominates.

Potentiometer mode operations include an op amp input and feedback resistors network and other voltage scaling applications. The A, W, and B terminals can be input or output terminals and have no polarity constraint provided that $\left|\mathrm{V}_{\mathrm{AB}}\right|,\left|\mathrm{V}_{\mathrm{WA}}\right|$, and $\left|\mathrm{V}_{\mathrm{WB}}\right|$ do not exceed $V_{\text {DD }}$-to-GND.

## CONTROLLING INPUTS

All $\overline{\mathrm{PU}}$ and $\overline{\mathrm{PD}}$ inputs are protected with a Zener ESD structure as shown in Figure 37.

Figure 37. Equivalent ESD Protection in $\overline{P U}$ and $\overline{P D}$ Pins
$\overline{\mathrm{PU}}$ and $\overline{\mathrm{PD}}$ pins are usually connected to pushbutton tactile switches for manual operation, but the AD5228 can also be controlled digitally. It is recommended to add external MOSFETs or transistors that simplify the logic controls.

Figure 38. Digital Control with External MOSFETs

## TERMINAL VOLTAGE OPERATION RANGE

The AD5228 is designed with internal ESD diodes for protection. These diodes also set the voltage boundary of the terminal operating voltages. Positive signals present on Terminal A, B, or W that exceed $V_{D D}$ are clamped by the forward-biased diode. There is no polarity constraint between $V_{A}, V_{W}$, and $V_{B}$, but they cannot be higher than $V_{D D}$ or lower than GND.

Figure 39. Maximum Terminal Voltages Set by $V_{D D}$ and GND

## POWER-UP AND POWER-DOWN SEQUENCES

Because of the ESD protection diodes that limit the voltage compliance at Terminals A, B, and W (Figure 39), it is important to power on $V_{D D}$ before applying any voltage to Terminals $\mathrm{A}, \mathrm{B}$, and W. Otherwise, the diodes are forward-biased such that $V_{D D}$ is powered on unintentionally and can affect other parts of the circuit. Similarly, VDD should be powered down last. The ideal power-on sequence is in the following order: GND, $\mathrm{V}_{\mathrm{DD}}$, and $\mathrm{V}_{\mathrm{A} / \mathrm{B} / \mathrm{W}}$. The order of powering $\mathrm{V}_{\mathrm{A}}, \mathrm{V}_{\mathrm{B}}$, and $\mathrm{V}_{\mathrm{w}}$ is not important as long as they are powered on after $\mathrm{V}_{\mathrm{DD}}$. The states of the $\overline{\mathrm{PU}}$ and $\overline{\mathrm{PD}}$ pins can be logic high or floating, but they should not be logic low during power-on.

## LAYOUT AND POWER SUPPLY BIASING

It is always a good practice to use compact, minimum lead length layout design. The leads to the input should be as direct as possible with a minimum conductor length. Ground paths should have low resistance and low inductance. It is also good practice to bypass the power supplies with quality capacitors. Low ESR (equivalent series resistance) $1 \mu \mathrm{~F}$ to $10 \mu \mathrm{~F}$ tantalum or electrolytic capacitors should be applied at the supplies to minimize any transient disturbance and to filter low frequency ripple. Figure 39 illustrates the basic supply bypassing configuration for the AD5228.

## APPLICATIONS

## MANUAL ADJUSTABLE LED DRIVER

The AD5228 can be used in many electronics-level adjustments such as LED drivers for LCD panel backlight controls. Figure 41 shows a manually adjustable LED driver. The AD5228 sets the voltage across the white LED D1 for the brightness control. Since U2 handles up to 250 mA , a typical white LED with $\mathrm{V}_{\mathrm{F}}$ of 3.5 V requires a resistor, R 1 , to limit U 2 current. This circuit is simple but not power efficient. The U2 shutdown pin can be toggled with a PWM signal to conserve power.

Figure 41. Low Cost Adjustable LED Driver

## ADJUSTABLE CURRENT SOURCE FOR LED DRIVER

Because LED brightness is a function of current rather than of forward voltage, an adjustable current source is preferred as shown in Figure 42. The load current can be found as the $\mathrm{V}_{\mathrm{wB}}$ of the AD5228 divided by Rset.

$$
\begin{equation*}
I_{D 1}=\frac{V_{W B}}{R_{S E T}} \tag{7}
\end{equation*}
$$

The U1 ADP3333ARM-1.5 is a 1.5 V LDO that is lifted above or lowered below 0 V . When $\mathrm{V}_{\mathrm{wb}}$ of the AD5228 is at its minimum, there is no current through D1, so the GND pin of U1 is at -1.5 V if U3 is biased with the dual supplies. As a result, some of the U2 low resistance steps have no effect on the output until the U1 GND pin is lifted above 0 V . When $\mathrm{V}_{\mathrm{WB}}$ of the AD5228 is at its maximum, $\mathrm{V}_{\text {out }}$ becomes $\mathrm{VL}+\mathrm{V}_{\mathrm{AB}}$, so the U 1 supply voltage must be biased with adequate headroom. Similarly, PWM signal can be applied at the U1 shutdown pin for power efficiency.

Figure 42. Adjustable Current Source for LED Driver

## ADJUSTABLE HIGH POWER LED DRIVER

The previous circuit works well for a single LED. Figure 43 shows a circuit that can drive three to four high power LEDs. The ADP1610 is an adjustable boost regulator that provides the voltage headroom and current for the LEDs. The AD5228 and the op amp form an average gain of 12 feedback network that servos the R Ret voltage and the ADP1610 FB pin 1.2 V band gap reference voltage. As the loop is set, the voltage across $\mathrm{R}_{\text {SEt }}$ is regulated around 0.1 V and adjusted by the digital potentiometer.

$$
\begin{equation*}
I_{L E D}=\frac{V_{R_{\text {SIF }}}}{R_{\text {SET }}} \tag{8}
\end{equation*}
$$

$R_{\text {SET }}$ should be small enough to conserve power but large enough to limit maximum LED current. R3 should also be used in parallel with AD5228 to limit the LED current within an achievable range. A wider current adjustment range is possible by lowering the R2 to R1 ratio as well as changing R3 accordingly.

Figure 43. Adjustable Current Source for LEDs in Series

## AUTOMATIC LCD PANEL BACKLIGHT CONTROL

With the addition of a photocell sensor, an automatic brightness control can be achieved. As shown in Figure 44, the resistance of the photocell changes linearly but inversely with the light output. The brighter the light output, the lower the photocell resistance and vice versa. The AD5228 sets the voltage level that is gained up by U2 to drive N1 to a desirable brightness. With the photocell acting as the variable feedback resistor, the change in the light output changes the R2 resistance, therefore causing U 2 to drive N1 accordingly to regulate the output. This simple low cost implementation of an LED controller can compensate for the temperature and aging effects typically found in high power LEDs. Similarly, for power efficiency, a PWM signal can be applied at the gate of N2 to switch the LED on and off without noticeable effect.

Figure 44. Automatic LCD Panel Backlight Control

## AUDIO AMPLIFIER WITH VOLUME CONTROL

The AD5228 and SSM2211 can form a 1.5 W audio amplifier with volume control that has adequate power and quality for portable devices such as PDAs and cell phones. The SSM2211 can drive a single speaker differentially between Pins 5 and 8 without any output capacitor. The high-pass cutoff frequency is $\mathrm{f}_{\mathrm{H} 1}=1 /(2 \times \pi \times \mathrm{R} 1 \times \mathrm{C} 1)$. The SSM2211 can also drive two speakers as shown in Figure 45. However, the speakers must be configured in single-ended mode, and output coupling capacitors are needed to block the dc current. The output capacitor and the speaker load form an additional high-pass cutoff frequency as $\mathrm{f}_{\mathrm{H} 2}=1 /(2 \times \pi \times \mathrm{R} 5 \times \mathrm{C} 3)$. As a result, C 3 and C 4 must be large to make the frequency as low as $f_{H 1}$.

Figure 45. Audio Amplifier with Volume Control

## CONSTANT BIAS WITH SUPPLY TO RETAIN RESISTANCE SETTING

Users who consider EEMEM potentiometers but cannot justify the additional cost and programming for their designs can consider constantly biasing the AD5228 with the supply to retain the resistance setting as shown in Figure 46. The AD5228 is designed specifically with low power to allow power conservation even in battery-operated systems. As shown in Figure 47, a similar low power digital potentiometer is biased with a 3.4 V $450 \mathrm{~mA} /$ hour Li-Ion cell phone battery. The measurement shows that the device drains negligible power. Constantly biasing the potentiometer is a practical approach because most of the portable devices do not require detachable batteries for charging. Although the resistance setting of the AD5228 is lost when the battery needs to be replaced, this event occurs so infrequently that the inconvenience is minimal for most applications.

[^1]NOTES

## NOTES

[^0]:    ${ }^{1} R_{\text {wA }}$ increments if $R_{\text {wB }}$ decrements and vice versa.

[^1]:    ${ }^{1}$ The end-to-end resistance $R_{A B}$ is available in $10 \mathrm{k} \Omega, 50 \mathrm{k} \Omega$, and $100 \mathrm{k} \Omega$. The final three characters of the part number determine the nominal resistance value, for example, $10 \mathrm{k} \Omega=10$.
    ${ }^{2} Z=$ Pb-free part.
