### 11.3 Gbps, Active Back-Termination, Differential VCSEL Driver

## FEATURES

Up to 11.3 Gbps operation
$-40^{\circ} \mathrm{C}$ to $+100^{\circ} \mathrm{C}$ operation
Very low power: Isupply $=65 \mathrm{~mA}$
Typical 26 ps rise/fall times
Full back-termination of output transmission lines
Crosspoint adjust function
PECL-/CML-compatible data inputs
Bias current range: $\mathbf{2} \mathbf{~ m A}$ to $\mathbf{2 5} \mathbf{~ m A}$
Differential modulation current range: $\mathbf{2 . 2} \mathbf{~ m A}$ to $\mathbf{2 3} \mathbf{~ m A}$
Automatic laser shutdown (ALS)

### 3.3 V operation

Compact $3 \mathrm{~mm} \times 3 \mathrm{~mm}$ LFCSP
Voltage-input control for bias and modulation currents XFP-compliant bias current monitor

## APPLICATIONS

10 Gb Ethernet optical transceivers
10G-BASE-LRM optical transceivers
$8 \times$ and $10 \times$ Fibre Channel optical transceivers
XFP/X2/XENPAK/MSA 300 optical modules
SONET OC-192/SDH STM-64 optical transceivers

## GENERAL DESCRIPTION

The ADN2530 laser diode driver is designed for direct modulation of packaged VCSELs with a differential resistance ranging from $35 \Omega$ to $140 \Omega$. The active back-termination technique provides excellent matching with the output transmission lines while reducing the power dissipation in the output stage. The back-termination in the ADN2530 absorbs signal reflections from the TOSA end of the output transmission lines, enabling excellent optical eye quality to be achieved even when the TOSA end of the output transmission lines is significantly misterminated. The small package provides the optimum solution for compact modules where laser diodes are packaged in low pin count optical subassemblies.

The modulation and bias currents are programmable via the MSET and BSET control pins. By driving these pins with control voltages, the user has the flexibility to implement various average power and extinction ratio control schemes, including closed-loop control and look-up tables. The eye crosspoint in the output eye diagram is adjustable via the crosspoint adjust (CPA) control voltage input. The automatic laser shutdown (ALS) feature allows the user to turn on/off the bias and modulation currents by driving the ALS pin with the proper logic levels. The product is available in a space-saving $3 \mathrm{~mm} \times 3 \mathrm{~mm}$ LFCSP specified from $-40^{\circ} \mathrm{C}$ to $+100^{\circ} \mathrm{C}$.

## ABSOLUTE MAXIMUM RATINGS

Table 3.

| Parameter | Rating |
| :--- | :--- |
| Supply Voltage-VCC to GND | -0.3 V to +4.2 V |
| IMODP, IMODN to GND | $\mathrm{VCC}-1.5 \mathrm{~V}$ to +4.5 V |
| DATAP, DATAN to GND | $\mathrm{VCC}-1.8 \mathrm{~V}$ to $\mathrm{VCC}-0.4 \mathrm{~V}$ |
| All Other Pins | -0.3 V to $\mathrm{VCC}+0.3 \mathrm{~V}$ |
| Junction Temperature | $150^{\circ} \mathrm{C}$ |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Soldering Temperature <br> $\quad$ (Less than 10 sec) | $300^{\circ} \mathrm{C}$ |

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## ADN2530

## THEORY OF OPERATION

As shown in Figure 1, the ADN2530 consists of an input stage and two voltage-controlled current sources for bias and modulation. The bias current is available at the IBIAS pin. It is controlled by the voltage at the BSET pin and can be monitored at the IBMON pin. The differential modulation current is available at the IMODP and IMODN pins. It is controlled by the voltage at the MSET pin. The output stage implements the active back-termination circuitry for proper transmission line matching and power consumption reduction. The ADN2530 can drive a load with differential resistance ranging from $35 \Omega$ to $140 \Omega$. The excellent back-termination in the ADN2530 absorbs signal reflections from the TOSA end of the output transmission lines, enabling excellent optical eye quality to be achieved even when the TOSA end of the output transmission lines is significantly misterminated.

## INPUT STAGE

The input stage of the ADN2530 converts the data signal applied to the DATAP and DATAN pins to a level that ensures proper operation of the high speed switch. The equivalent circuit of the input stage is shown in Figure 22.

Figure 22. Equivalent Circuit of the Input Stage
The DATAP and DATAN pins are terminated internally with a $100 \Omega$ differential termination resistor. This minimizes signal reflections at the input that could otherwise lead to degradation in the output eye diagram. It is not recommended to drive the ADN2530 with single-ended data signal sources.

The ADN2530 input stage must be ac-coupled to the signal source to eliminate the need for matching between the commonmode voltages of the data signal source and the input stage of the driver (see Figure 23). The ac-coupling capacitors should have an impedance less than $50 \Omega$ over the required frequency range. Generally, this is achieved using 10 nF to 100 nF capacitors.

## BIAS CURRENT

The bias current is generated internally using a voltage-to-current converter consisting of an internal operational amplifier and a transistor, as shown in Figure 24.

Figure 24. Voltage-to-Current Converter Used to Generate IBIAS
The BSET to IBIAS voltage-to-current conversion factor is set at $20 \mathrm{~mA} / \mathrm{V}$ by the internal resistors, and the bias current is monitored at the IBMON pin using a current mirror with a gain equal to $1 / 20$. By connecting a $750 \Omega$ resistor between IBMON and GND, the bias current can be monitored as a voltage across the resistor. A low temperature coefficient precision resistor must be used for the IBMON resistor ( $\mathrm{R}_{\text {IBMON }}$ ). Any error in the value of $\mathrm{R}_{\text {IBmon }}$ due to tolerances or drift in its value over temperature contributes to the overall error budget for the IBIAS monitor voltage. If the IBMON voltage is being connected to an ADC for $\mathrm{A} / \mathrm{D}$ conversion, $\mathrm{R}_{\text {Iвмол }}$ should be placed close to the ADC to minimize errors due to voltage drops on the ground plane. See the Design Example section for example calculations of the accuracy of the IBIAS monitor as a percentage of the nominal IBIAS value.

The equivalent circuits of the BSET, IBIAS, and IBMON pins are shown in Figure 25 to Figure 27.

Figure 25. Equivalent Circuit of the BSET Pin

Figure 26. Equivalent Circuit of the IBIAS Pin

Figure 27. Equivalent Circuit of the IBMON Pin
The recommended configuration for BSET, IBIAS, and IBMON is shown in Figure 28.

Figure 28. Recommended Configuration for BSET, IBIAS, and IBMON Pins
The circuit used to drive the BSET voltage must be able to drive the $1 \mathrm{k} \Omega$ input resistance of the BSET pin. For proper operation of the bias current source, the voltage at the IBIAS pin must be between the compliance voltage specifications for this pin over supply, temperature, and bias current range (see Table 1). The maximum compliance voltage is specified for only two bias current levels ( 2 mA and 25 mA ), but it can be calculated for any bias current by

$$
V_{\text {COMPLIANCE }}(\mathrm{V})=V C C(\mathrm{~V})-0.75-22 \times \operatorname{IBIAS}(\mathrm{A})
$$

See the Headroom Calculations section for examples.
The function of Inductor $L$ is to isolate the capacitance of the IBIAS output from the high frequency signal path. For recommended components, see Table 6.

## AUTOMATIC LASER SHUTDOWN (ALS)

The ALS pin is a digital input that enables/disables both the bias and modulation currents, depending on the logic state applied, as shown in Table 5.

Table 5.

| ALS Logic State | IBIAS and IMOD |
| :--- | :--- |
| High | Disabled |
| Low | Enabled |
| Floating | Enabled |

The ALS pin is compatible with 3.3 V CMOS and TTL logic levels. Its equivalent circuit is shown in Figure 29.

Figure 29. Equivalent Circuit of the ALS Pin

## MODULATION CURRENT

The modulation current can be controlled by applying a dc voltage to the MSET pin. This voltage is converted into a dc current by using a voltage-to-current converter that uses an operational amplifier and a bipolar transistor, as shown in Figure 30.

Figure 30. Generation of Modulation Current on the ADN2530
This dc current is switched by the data signal applied to the input stage (DATAP and DATAN pins) and gained up by the output stage to generate the differential modulation current at the IMODP and IMODN pins. The output stage also generates the active back-termination, which provides proper transmission line termination. Active back-termination uses feedback around an active circuit to synthesize a broadband termination resistance.

## ADN2530

This provides excellent transmission line termination while dissipating less power than a traditional resistor passive backtermination. No portion of the modulation current flows in the active back-termination resistance. All of the preset modulation current IMOD, the range specified in Table 1, flows in the external load. The equivalent circuits for MSET, IMODP, and IMODN are shown in Figure 31 and Figure 32. The two $50 \Omega$ resistors in Figure 32 are not real resistors. They represent the active back-termination resistance.

Figure 31. Equivalent Circuit of the MSET Pin

Figure 32. Equivalent Circuit of the IMODP and IMODN Pins
The recommended configuration of the MSET, IMODP, and IMODN pins is shown in Figure 33. See Table 6 for recommended components. When the voltage on DATAP is greater than the voltage on DATAN, the modulation current flows into the IMODP pin and out of the IMODN pin, generating an optical Logic 1 level at the TOSA output when the TOSA is connected as shown in Figure 33.

Figure 33. Recommended Configuration for the MSET, IMODP, and IMODN Pins

The ratio between the voltage applied to the MSET pin and the differential modulation current available at the IMODP and IMODN pins is a function of the load resistance value, as shown in Figure 34.

Figure 34. MSET Voltage to Modulation Current Ratio vs. Differential Load Resistance

Using the resistance of the TOSA, the user can calculate the voltage range that should be applied to the MSET pin to generate the required modulation current range (see the example in the Applications Information section).

The circuit used to drive the MSET voltage must be able to drive the $1 \mathrm{k} \Omega$ resistance of the MSET pin. To be able to drive 23 mA modulation currents through the differential load, the output stage of the ADN2530 (IMODP and IMODN pins) must be ac-coupled to the load. The voltages at these pins have a dc component equal to VCC and an ac component with single-ended peak-to-peak amplitude of IMOD $\times 50 \Omega$. This is the case when the load impedance ( $\mathrm{R}_{\text {TosA }}$ ) is less than $100 \Omega$ differential because the transmission line characteristic impedance sets the peak-to-peak amplitude. For the case where $\mathrm{R}_{\text {TOSA }}$ is greater than $100 \Omega$, the single-ended, peak-to-peak amplitude is IMOD $\times \mathrm{R}_{\text {TOSA }} \div 2$. For proper operation of the output stage, the voltages at the IMODP and IMODN pins must be between the compliance voltage specifications for this pin over supply, temperature, and modulation current range, as shown in Figure 35. See the Headroom Calculations section for examples of headroom calculations.

Figure 35. Allowable Range for the Voltage at IMODP and IMODN

## LOAD MISTERMINATION

Due to its excellent S22 performance, the ADN2530 can drive differential loads that range from $35 \Omega$ to $140 \Omega$. In practice, many TOSAs have differential resistance not equal to $100 \Omega$. In this case, with $100 \Omega$ differential transmission lines connecting the ADN2530 to the load, the load end of the transmission lines are misterminated. This mistermination leads to signal reflections back to the driver. The excellent back-termination in the ADN2530 absorbs these reflections, preventing their reflection back to the load. This enables excellent optical eye quality to be achieved even when the load end of the transmission lines is significantly misterminated. The connection between the load and the ADN2530 must be made with $100 \Omega$ differential ( $50 \Omega$ single-ended) transmission lines so that the driver end of the transmission lines is properly terminated.

## CROSSPOINT ADJUST

The crossing level in the output electrical eye diagram can be adjusted between $35 \%$ and $65 \%$ using the crosspoint adjust (CPA) control input. This can be used to compensate for asymmetry in the VCSEL response and optimizes the optical eye mask margin. The CPA input is a voltage control input, and a plot of eye crosspoint vs. CPA control voltage is shown in Figure 15 and Figure 16 in the Typical Performance Characteristics section. The equivalent circuit for the CPA pin is shown in Figure 36. To disable the crosspoint adjust function and set the eye crossing to $50 \%$, the CPA pin should be tied to VCC.

Figure 36. Equivalent Circuit for CPA Pin

## POWER CONSUMPTION

The power dissipated by the ADN2530 is given by

$$
P=V C C \times\left(\frac{V_{M S E T}}{50}+I_{S U P P L Y}\right)+V_{I B I A S} \times(I B I A S \times 1.2)
$$

where:
$V C C$ is the power supply voltage.
IBIAS is the bias current generated by the ADN2530.
$V_{M S E T}$ is the voltage applied to the MSET pin.
$I_{\text {SUPPLY }}$ is the sum of the current that flows into the VCC, IMODP, and IMODN pins of the ADN2530 when IBIAS $=$ IMOD $=0$ expressed in amps (see Table 1).
$V_{I B I A S}$ is the average voltage on the IBIAS pin.
Considering VBSET/IBIAS $=50$ as the conversion factor from $\mathrm{V}_{\text {BSET }}$ to IBIAS, the dissipated power becomes

$$
P=V C C \times\left(\frac{V_{\text {MSET }}}{50}+I_{\text {SUPPLY }}\right)+V_{\text {IBIAS }} \times\left(\frac{V_{\text {BSET }}}{50} \times 1.2\right)
$$

To ensure long-term reliable operation, the junction temperature of the ADN2530 must not exceed $125^{\circ} \mathrm{C}$, as specified in Table 2. For improved heat dissipation, the module's case can be used as a heat sink, as shown in Figure 37.

Figure 37. Typical Optical Module Structure

## ADN2530

A compact optical module is a complex thermal environment, and calculations of device junction temperature using the package $\theta_{\text {IA }}$ (junction-to-ambient thermal resistance) do not yield accurate results. The following equation, derived from the model in Figure 38, can be used to estimate the IC junction temperature:

$$
T_{J}=\frac{P \times\left(\theta_{J-P A D} \times \theta_{J-T O P}\right)+T_{T O P} \times \theta_{J-P A D}+T_{P A D} \times \theta_{J-T O P}}{\theta_{J-P A D}+\theta_{J-T O P}}
$$

## where:

$T_{\text {TOP }}$ is the temperature at top of package in degrees Celsius.
$T_{\text {PAD }}$ is the temperature at package exposed paddle in degrees Celsius.
$T_{J}$ is the IC junction temperature in degrees Celsius.
$P$ is the ADN2530 power dissipation in watts.
$\theta_{J \text { JTOP }}$ is the thermal resistance from IC junction to package top.
$\theta_{I-\text { PAD }}$ is the thermal resistance from IC junction to package exposed pad.

$\mathrm{T}_{\text {TOP }}$ and $\mathrm{T}_{\text {PAD }}$ can be determined by measuring the temperature at points inside the module, as shown in Figure 37. The thermocouples should be positioned to obtain an accurate measurement of the package top and paddle temperatures. $\theta_{J-\text { TOP }}$ and $\theta_{J-\text { PAD }}$ are given in Table 2.

## APPLICATIONS INFORMATION

## TYPICAL APPLICATION CIRCUIT

Figure 39 shows the typical application circuit for the ADN2530. The dc voltages applied to the BSET and MSET pins control the bias and modulation currents. The bias current can be monitored as a voltage drop across the $750 \Omega$ resistor connected between the IBMON pin and GND. The dc voltage applied to the CPA pin controls the crosspoint in the output eye diagram. By tying the CPA pin to VCC, the CPA function is disabled. The ALS pin allows the user to turn on/off the bias and modulation currents depending on the logic level applied to the pin. The data signal source must be connected to the DATAP and DATAN pins of the ADN2530 using $50 \Omega$ transmission lines. The modulation current outputs, IMODP and IMODN, must be connected to the load (TOSA) using $100 \Omega$ differential ( $50 \Omega$ single-ended) transmission lines. Table 6 shows recommended components for the ac-coupling interface between the ADN2530 and TOSA. For additional application information and optical eye diagram performance data, see the application notes and reference design for the ADN2530 at www.analog.com.

Table 6.

| Component | Value | Description |
| :--- | :--- | :--- |
| R1, R2 | $110 \Omega$ | 0603 size resistor |
| R3, R4 | $300 \Omega$ | 0603 size resistor |

## LAYOUT GUIDELINES

Due to the high frequencies at which the ADN2530 operates, care should be taken when designing the PCB layout to obtain optimum performance. Controlled impedance transmission lines must be used for the high speed signal paths. The length of the transmission lines must be kept to a minimum to reduce losses and pattern-dependent jitter. The PCB layout must be symmetrical both on the DATAP and DATAN inputs and on the IMODP and IMODN outputs to ensure a balance between the differential signals. All VCC and GND pins must be connected to solid copper planes by using low inductance connections. When the connections are made through vias, multiple vias can be connected in parallel to reduce the parasitic inductance. Each GND pin must be locally decoupled to VCC with high quality capacitors, see Figure 39. If proper decoupling cannot be achieved using a single capacitor, the user can use multiple capacitors in parallel for each GND pin. A $20 \mu \mathrm{~F}$ tantalum capacitor must be used as the general decoupling capacitor for the entire module. For recommended PCB layouts, including those suitable for XFP modules, contact sales. For guidelines on the surface-mount assembly of the ADN2530, consult the Amkor Technology" "Application Notes for Surface Mount Assembly of Amkor's MicroLeadFrame (MLF*) Packages."

## ADN2530

## DESIGN EXAMPLE

This design example covers:

- Headroom calculations for IBIAS, IMODP, and IMODN pins.
- Calculation of the typical voltage required at the BSET and MSET pins to produce the desired bias and modulation currents.
- Calculations of the IBIAS monitor accuracy over the IBIAS current range.

This design example assumes that the impedance of the TOSA is $60 \Omega$, the forward voltage of the VCSEL at low current is $\mathrm{V}_{\mathrm{F}}=1.2 \mathrm{~V}$, IBIAS $=10 \mathrm{~mA}, \mathrm{IMOD}=10 \mathrm{~mA}$, and $\mathrm{VCC}=3.3 \mathrm{~V}$.

## Headroom Calculations

To ensure proper device operation, the voltages on the IBIAS, IMODP, and IMODN pins must meet the compliance voltage specifications in Table 1.

Considering the typical application circuit shown in Figure 39, the voltage at the IBIAS pin can be written as

$$
V_{I B I A S}=V C C-V_{F}-\left(I B I A S \times R_{T O S A}\right)-V_{L A}
$$

where:
$V C C$ is the supply voltage.
$V_{F}$ is the forward voltage across the laser at low current.
$R_{\text {TOSA }}$ is the resistance of the TOSA.
$V_{L A}$ is the dc voltage drop across L5, L6, L7, and L8.
For proper operation, the minimum voltage at the IBIAS pin should be greater than 0.55 V , as specified by the minimum IBIAS compliance specification in Table 1.

Assuming that the voltage drop across the $50 \Omega$ transmission lines is negligible and that $\mathrm{V}_{\mathrm{LA}}=0 \mathrm{~V}, \mathrm{~V}_{\mathrm{F}}=1.2 \mathrm{~V}$, and IBIAS $=10 \mathrm{~mA}$,

$$
\begin{aligned}
& V_{\text {IBIAS }}=3.3-1.2-(0.01 \times 60)=1.5 \mathrm{~V} \\
& V_{\text {IBIAS }}=1.5 \mathrm{~V}>0.55 \mathrm{~V} \text {, which satisfies the requirement }
\end{aligned}
$$

The maximum voltage at the IBIAS pin must be less than the maximum IBIAS compliance specification as described by

$$
V_{\text {COMPLIANCE_MAX }}=V C C-0.75-22 \times \text { IBIAS (A) }
$$

For this example,
$V_{\text {COMPLIANCE_MAX }}=V C C-0.75-22 \times 0.01=2.33 \mathrm{~V}$
$V_{\text {IBIAS }}=1.5 \mathrm{~V}<2.33 \mathrm{~V}$, which satisfies the requirement
To calculate the headroom at the modulation current pins (IMODP and IMODN), the voltage has a dc component equal to VCC due to the ac-coupled configuration and a swing equal to IMOD $\times 50 \Omega$, as $\mathrm{R}_{\text {TOSA }}<100 \Omega$. For proper operation of the ADN2530, the voltage at each modulation output pin should be within the normal operation region shown in Figure 35.

Assuming the dc voltage drop across L1, L2, L3, and L4 $=0 \mathrm{~V}$ and $\mathrm{IMOD}=10 \mathrm{~mA}$, the minimum voltage at the modulation output pins is equal to

$$
\begin{aligned}
& V C C-(I M O D \times 50) / 2=V C C-0.25 \\
& V C C-0.25>V C C-0.7 \mathrm{~V} \text {, which satisfies the requirement }
\end{aligned}
$$

The maximum voltage at the modulation output pins is equal to

$$
V C C+(I M O D \times 50) / 2=V C C+0.25
$$

$V C C+0.25<V C C+0.7 \mathrm{~V}$, which satisfies the requirement
Headroom calculations must be repeated for the minimum and maximum values of the required IBIAS and IMOD ranges to ensure proper device operation over all operating conditions.

## BSET and MSET Pin Voltage Calculation

To set the desired bias and modulation currents, the BSET and MSET pins of the ADN2530 must be driven with the appropriate dc voltage. The voltage range required at the BSET pin to generate the required IBIAS range can be calculated using the BSET voltage to IBIAS gain specified in Table 1. Assuming that IBIAS $=10 \mathrm{~mA}$ and the typical IBIAS/V $\mathrm{V}_{\text {BSET }}$ ratio of $20 \mathrm{~mA} / \mathrm{V}$, the BSET voltage is given by

$$
V_{B S E T}=\frac{\operatorname{IBIAS}(\mathrm{mA})}{20 \mathrm{~mA} / \mathrm{V}}=\frac{10}{20}=0.5 \mathrm{~V}
$$

The BSET voltage range can be calculated using the required IBIAS range and the minimum and maximum BSET voltage to IBIAS gain values specified in Table 1.

The voltage required at the MSET pin to produce the desired modulation current can be calculated using

$$
V_{M S E T}=\frac{I M O D}{K}
$$

where $K$ is the MSET voltage to $I M O D$ ratio.
The value of $K$ depends on the actual resistance of the TOSA and can be obtained from Figure 34. For a TOSA resistance of $60 \Omega$, the typical value of $\mathrm{K}=24 \mathrm{~mA} / \mathrm{V}$. Assuming that $\mathrm{IMOD}=$ 10 mA and using the preceding equation, the MSET voltage is given by

$$
V_{M S E T}=\frac{I M O D(\mathrm{~mA})}{24 \mathrm{~mA} / \mathrm{V}}=\frac{10}{24}=0.42 \mathrm{~V}
$$

The MSET voltage range can be calculated using the required IMOD range and the minimum and maximum K values. These can be obtained from the minimum and maximum curves in Figure 34.

## IBIAS Monitor Accuracy Calculations

Figure 40. Accuracy of IBIAS to IBMON Ratio
This example assumes that the nominal value of IBIAS is 8 mA and that the IBIAS range for all operating conditions is 4 mA to 14 mA . The accuracy of the IBIAS to IBMON ratio is given in the Table 1 and is plotted in Figure 40.

Referring to Figure 40, the IBMON output current accuracy is $\pm 4.3 \%$ for the minimum IBIAS of 4 mA and $\pm 3.0 \%$ for the maximum IBIAS value of 14 mA .

The accuracy of the IBMON output current as a percentage of the nominal IBIAS is given by

$$
I B M O N_{-} \text {Accuracy }_{\text {MIN }}=4 \mathrm{~mA} \frac{4.3}{100} \times \frac{100}{8 \mathrm{~mA}}= \pm 2.15 \%
$$

for the minimum IBIAS value, and by

$$
I B M O N_{-} \text {Accuracy }_{M A X}=14 \mathrm{~mA} \frac{3.0}{100} \times \frac{100}{8 \mathrm{~mA}}= \pm 5.25 \%
$$

for the maximum IBIAS value. This gives a worse-case accuracy for the IBMON output current of $\pm 5.25 \%$ of the nominal IBIAS value over all operating conditions. The IBMON output current accuracy numbers can be combined with the accuracy numbers for the $750 \Omega$ IBMON resistor ( $\mathrm{R}_{\text {IBMON }}$ ) and any other error sources to calculate an overall accuracy for the IBMON voltage.

## ADN2530

## OUTLINE DIMENSIONS

ORDERING GUIDE

| Model | Temperature Range | Package Description | Package Option | Branding |
| :--- | :--- | :--- | :--- | :--- |
| ADN2530YCPZ-WP $^{1}$ | $-40^{\circ} \mathrm{C}$ to $+100^{\circ} \mathrm{C}$ | 16 -Lead LFCSP_VQ, 50-Piece Waffle Pack | CP-16-3 | F08 |
| ADN2530YCPZ-R2 ${ }^{1}$ | $-40^{\circ} \mathrm{C}$ to $+100^{\circ} \mathrm{C}$ | 16-Lead LFCSP_VQ, 250-Piece Reel | CP-16-3 | F08 |
| ADN2530YCPZ-REEL7 ${ }^{1}$ | $-40^{\circ} \mathrm{C}$ to $+100^{\circ} \mathrm{C}$ | 16 -Lead LFCSP_VQ, 1500-Piece Reel | CP-16-3 | F08 |
