

FEATURES

- IQ Modulator with Integrated Fractional-N PLL**
- Output frequency range: 1200 MHz to 2400 MHz**
- Internal LO Frequency Range: 1550 MHz to 2150 MHz**
- Output P1dB: +14 dBm**
- Output IP3: +29 dBm**
- Noise Floor: -158 dBm/Hz**
- Baseband Modulation bandwidth: 500 MHz (3 dB)**
- SPI Serial Interface for PLL Programming**
- Power Supply: +5 V / 210 mA**
- 40 Pin 6mm X 6mm LFCSP**

GENERAL DESCRIPTION

The ADRF6702 TxMod is an IQ modulator with integrated PLL and VCO. The PLL/Synthesizer uses a Fractional-N PLL to generate a $2 \cdot F_{LO}$ input to the I-Q modulator. The PLL reference input is supported from 12MHz to 160MHz. The phase detector output controls a chargepump whose output is integrated in an off-chip loop-filter. The loop filter output is then applied to an integrated VCO. The VCO output at $2 \cdot F_{LO}$ is then applied to a quadrature divider as well as to a programmable divider. The programmable divider is controlled by a sigma-delta modulator (SDM). The I-Q modulator has analog I + Q inputs which can be at baseband or optionally at a complex IF up to 200 MHz

Part #	Internal LO Range	+/-3dB RF Out Balun Range	+/-1dB RF Out Balun Range
ADRF6701	750 MHz	400 MHz	550 MHz
	1160 MHz	1300 MHz	1000 MHz
ADRF6702	1550 MHz	1200 MHz	1550 MHz
	2150 MHz	2400 MHz	2200 MHz
ADRF6703	2100 MHz	1600 MHz	1900 MHz
	2600 MHz	2600 MHz	2400 MHz
ADRF6704	2500 MHz	2200MHz	2400 MHz
	2900 MHz	3000MHz	2800 MHz

The modulator mixes the I-Q inputs from the analog inputs with the quadrature LO from the quadrature divider. The differential output is converted to a single-ended output intended to drive a 50-Ohm load with good output return-loss characteristics.

The ADRF6702 TxMod is fabricated using an advanced silicon-germanium BiCMOS. It is available in a 40-lead, exposed-paddle, Pb-free, 6mm x 6mm LFCSP package. Performance is specified over a -40°C to $+85^{\circ}\text{C}$ temperature range.

ABSOLUTE MAXIMUM RATINGS

Table 4. Absolute Maximum Ratings

Parameter	Rating
Supply Voltage VCC, VCCbb, VCCrf	-0.5 to 6 V
Digital I/O CLK, DATA, LE	-0.3 to 3.3 V
IBBP, IBBN, QBBP, QBBN	TBD V
θ_{JA} (Exposed Paddle Soldered Down)	TBD °C/W
Maximum Junction Temperature	125°C
Operating Temperature Range	-40°C to +85°C
Storage Temperature Range	-65°C to +150°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTIONAL DESCRIPTIONS

	EP	Exposed Paddle: The exposed paddle should be soldered to a low impedance ground plane.																														

THEORY OF OPERATION

The ADRF6702 integrates a high performance IQ modulator with a state of the art fractional-N PLL. The PLL also integrates a low noise VCO. The programmable SPI port allows the user to control the fractional-N PLL functions and the modulator optimization functions as well as allowing for an externally applied LO or VCO.

The quadrature modulator core within the ADRF670X family is the next generation of industry leading family of modulators from Analog Devices. The baseband inputs are converted to currents and then mixed to RF using high-performance NPN transistors. The mixer output currents are transformed to a single-ended RF output using an integrated RF transformer balun. The high performance active mixer core, coupled with the low-loss RF transformer balun results in an exceptional OIP3 and OP1dB, with a very low output noise floor for excellent dynamic range. The use of a passive transformer balun rather than an active output stage leads to an improvement in OIP3 with no sacrifice in noise floor. Over the specified frequency range the four devices in the ADRF670X typically provide RF output P1dB of 15dBm, OIP3 of 30dBm, and RF output noise floor of -158dBm/Hz. Typical image rejection under these conditions is 40dB with no additional I and Q gain compensation.

The fractional divide function of the PLL allows the frequency multiplication value from REFIN to LO Out to be a fractional value rather than restricted to an integer as in traditional PLLs. In operation, this multiplication value is $INT + (FRAC/MOD)$ where INT is the integer value, FRAC is the fractional value and MOD is the modulus value, all programmable via the SPI port. In previous frac-N PLL designs, the fractional multiplication was achieved by periodically changing the fractional value in a deterministic way. The down side of this was often spurious components close to the fundamental signal. In the ADRF670x family, a sigma-delta modulator is used to distribute the fractional value randomly, thus significantly reducing the spurious content due to the fractional function.

BASIC CONNECTIONS FOR OPERATION

The device's seven power supply pins should be individually decoupled using 1000 pF and 0.1 μF capacitors located as close as possible to the device. In addition, internal decoupling nodes (labeled DECL) should be decoupled with the capacitor values shown.

The four IQ inputs should be driven with a bias level of 500 mV. A peak-to-peak differential swing on the I and Q inputs of 1 V (0.353 Vrms for a sinewave input) results in a single sideband output power of +4 dBm. The I and Q inputs are high impedance and should normally be terminated with resistors to provide an appropriate match to the baseband filter which immediately precedes the IQ modulator in the signal chain.

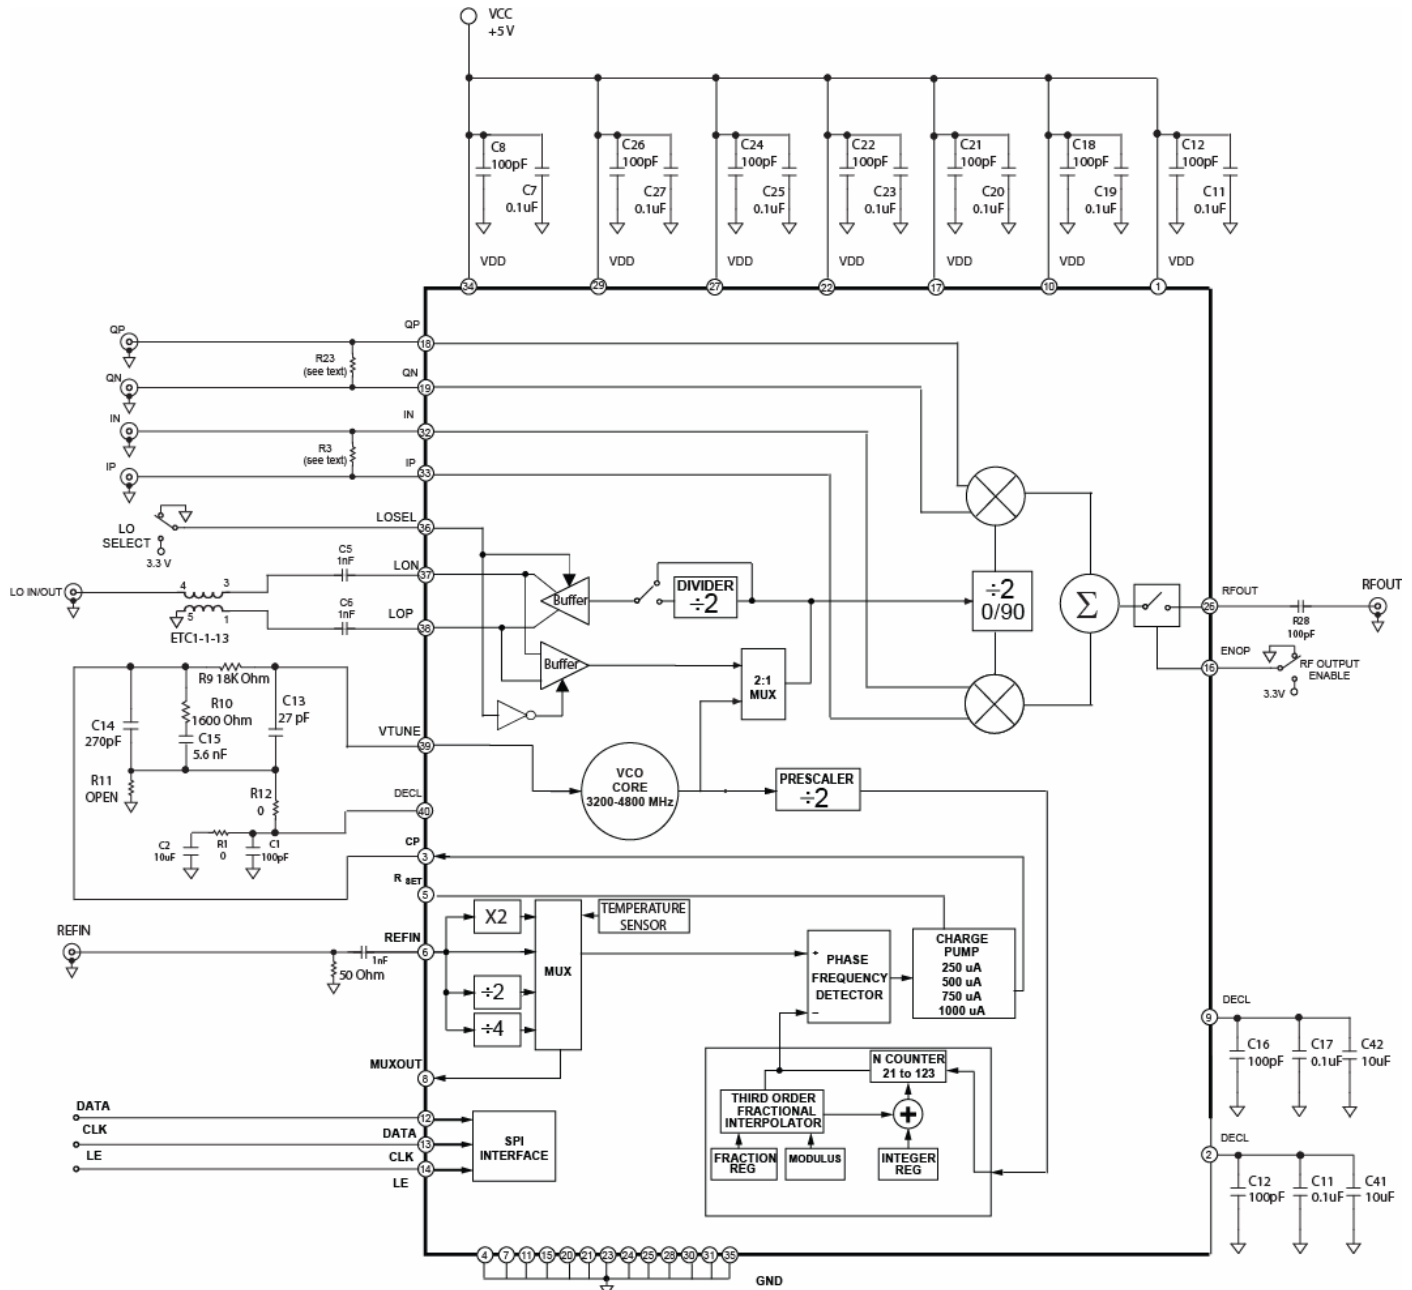

Figure 4. Basic Connections for Operation

DEVICE PROGRAMMING

Device programming is effected using a three pin SPI port. The description of timing requirements for the SPI port is given in Figure 2. There are eight programmable registers, each with 24 bits, controlling the operation of the device. The register functions can be broken down as follows;

Register 0 – Integer control for the PLL.

Register 1 – Modulus control for PLL.

Register 2 – Fractional control for PLL.

Register 3 – Sigma Delta Function

Register 4 – PLL Charge pump, PFD, reference path control

Register 5 – LO path and modulator control

Register 6 – VCO controls and VCO enable functions

Register 7 – Modulator bias enable, external VCO enable

Note - The PLL has internal calibration that must be run when the device is programmed with a given frequency. This calibration is automatically run whenever registers 0, 1, or 2 are programmed. Because the other registers affect PLL performance, the lower three registers should always be programmed last, preferably in the order 0, 1, 2.

Software is available on the Analog Devices website (www.analog.com) that allows easy programming from a PC running Windows XP™.

REGISTER 0 INTEGER DIVIDE CONTROL

With R0[2:0] set to 000, the on-chip integer divide control register is programmed as shown in figure 39.

INTEGER DIVIDE RATIO

The integer divide ratio is used to set the INT value in Equation 1. The INT, FRAC, and MOD values make it possible to generate output frequencies that are spaced by fractions of the PFD frequency. The VCO frequency (F_{VCO}) equation is:

$$F_{VCO} = 2 \times f_{PFD} \times (INT + (FRAC/MOD)) \quad (1)$$

Where:

F_{VCO} is the output frequency of the internal VCO.

INT is the preset integer divide ratio value (24 to 119 in fractional mode).

MOD is the preset fractional modulus (1 to 2047).

FRAC is the preset fractional divider ratio value (0 to MOD-1).

DIVIDE MODE

Divide mode determines whether fractional mode or integer mode is used. In integer mode, the RF VCO output frequency (F_{VCO}) is calculated using the following equation:

$$F_{VCO} = 2 \times f_{PFD} \times (INT) \quad (2)$$

where INT is the integer divide ratio value (21 to 123 in integer mode).

Figure 5. Integer Divide Control Register (R0)

Figure 6. Modulus Divide Control Register (R1)

REGISTER 1—MODULUS DIVIDE CONTROL

With R1[2:0] set to 001, the on-chip modulus divide control register is programmed as shown in figure 40.

The MOD value is the preset fractional modulus ranging from 1 to 2047.

Figure 8. Sigma Delta Modulator Dither Control Register (R3)

REGISTER 3—SIGMA DELTA MODULATOR DITHER CONTROL

With R3[2:0] set to 011, the on-chip sigma delta modulator dither control register is programmed as shown in figure 42.

The dither restart value can be programmed from 0 to 2¹⁷-1, though a value of 1 is typically recommended.

REGISTER 4—CHARGE PUMP, PFD AND REFERENCE PATH CONTROL

With R4[2:0] set to 100, the on-chip Charge Pump, PFD and Reference Path Control register is programmed as shown in figure 43.

The charge pump current is controlled by the base charge pump current ($I_{CP,BASE}$), and the value of the charge pump current multiplier ($I_{CP,MULT}$).

The base charge pump current can be set using an internal or external resistor (according to DB18 of Register 4). When using an external resistor, the value of $I_{CP,BASE}$ can be varied according to the following table.

$$R_{SET} [\Omega] = \left[\frac{217.4 \times I_{CP,BASE}}{250} \right] - 37.8$$

The actual charge pump current can be programmed to be a multiple (1, 2, 3, 4) of the charge pump base current. The multiplying value ($I_{CP,MULT}$) is equal to 1 plus the value of bits DB11 and DB10 in register 4.

The PFD phase offset multiplier ($\theta_{PFD,OFFS}$), which is set by bits DB16-DB12 of Register 4, will cause the PLL to lock with a nominally fixed phase offset between the PFD reference signal and the divided-down VCO signal. This phase offset is used to linearize the PFD-CP transfer function and can improve fractional spurs. The magnitude of the phase offset is determined by the following equation:

$$|\Delta\Phi| [\text{deg}] = 22.5 \frac{\theta_{PFD,OFFS}}{I_{CP,MULT}}$$

Finally, the phase offset can be either positive or negative depending on the value of DB17 in register 4.

The reference frequency applied to the PFD can be manipulated using the internal reference path source. The external reference frequency applied can be internally scaled in frequency by 2X, 1X, 0.5X, or 0.25X. This allows a broader range of reference frequency selections while keeping the reference frequency applied to the PFD within an acceptable range.

The ADRF6702 also provides a MUXOUT pin that can be programmed to output a selection of several internal signals. The default mode is to provide a lock-detect output to allow the user to verify when the PLL has locked to the target frequency. In addition, several other internal signals may be passed to the MUXOUT pin as described in figure 43.

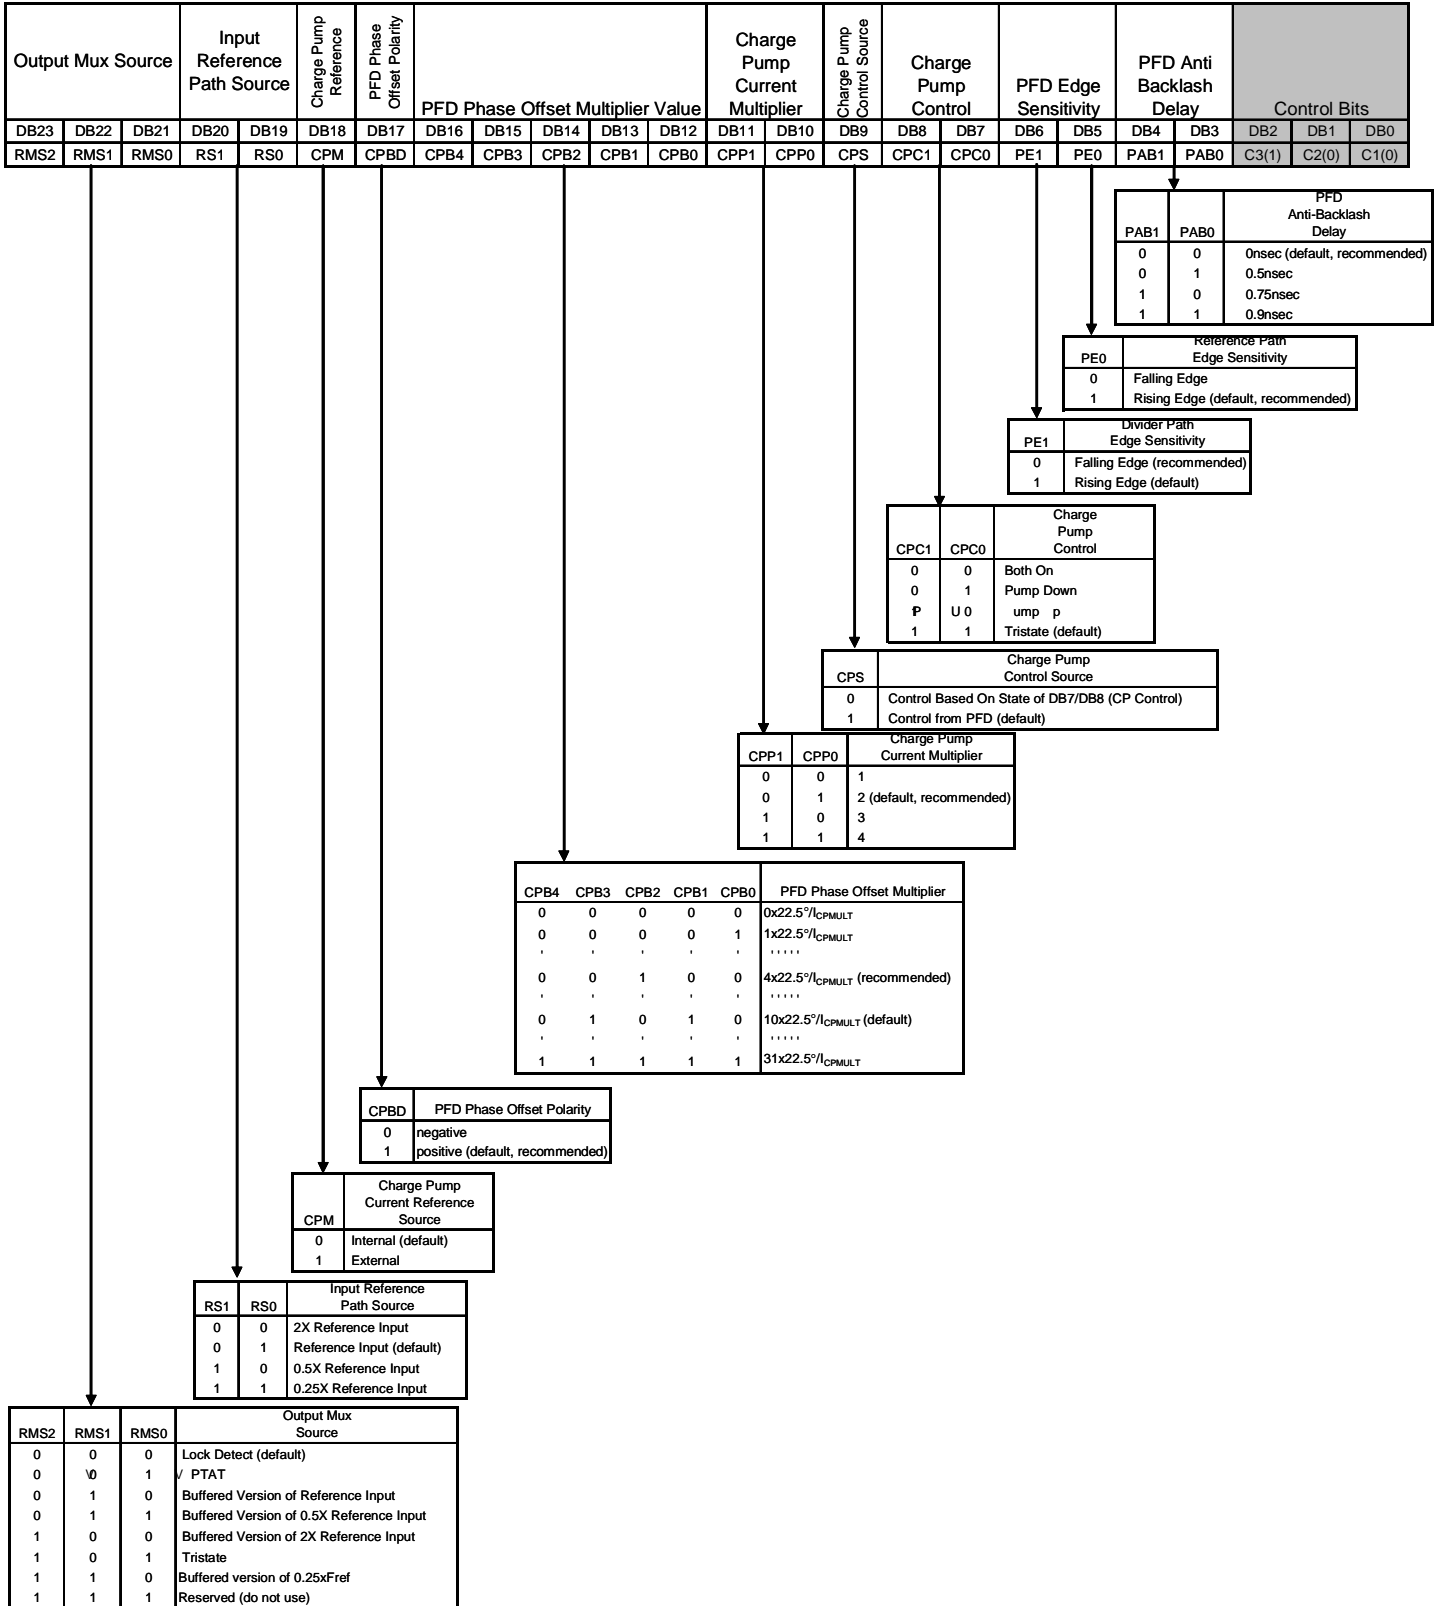

Figure 9. Charge Pump, PFD, and Reference Path Control Register (R4)

REGISTER 5 LO PATH AND MODULATOR CONTROL

The modulator output or the complete modulator can be disabled using the modulator bias enable and modulator output enable addresses of register 5.

The LO port (pins LOP and LON) can be used to apply an external 2X LO (i.e. bypass internal PLL) to the IQ Modulator. A differential LO drive of 0 dBm is recommended for best LO suppression at the RF output. When using an external frequency stable local oscillator signal to commutate the mixer core it is possible to shut down the PLL circuitry through the PLL enable address of register 5.

The LO port can also be used as an output where a 2X or 1X LO can be brought out and used to drive another mixer. The nominal output power provided at the LO port is +3 dBm.

The LO port's mode of operation is determined by the status of the LOSEL pin (3.3 V logic) along with the settings in a number of internal registers.

Table 6. LO Port Configuration

LON/LOP Function	LOSEL	R5:DB3 (LDRV)	R5:DB5 (LDIV)	R5:DB4(LXL)
Input (2XLO)	0	0	X	1
Output (1XLO)	X	1	0	X
Output (1XLO)	1	X	0	X
Output (2XLO)	X	1	1	X
Output (2XLO)	1	X	1	X

X = Don't Care

The device's internal VCO can also be bypassed. In this case, the charge pump output drives an external VCO through the loop filter. The loop is completed by routing the VCO in to the device through the LO Port.

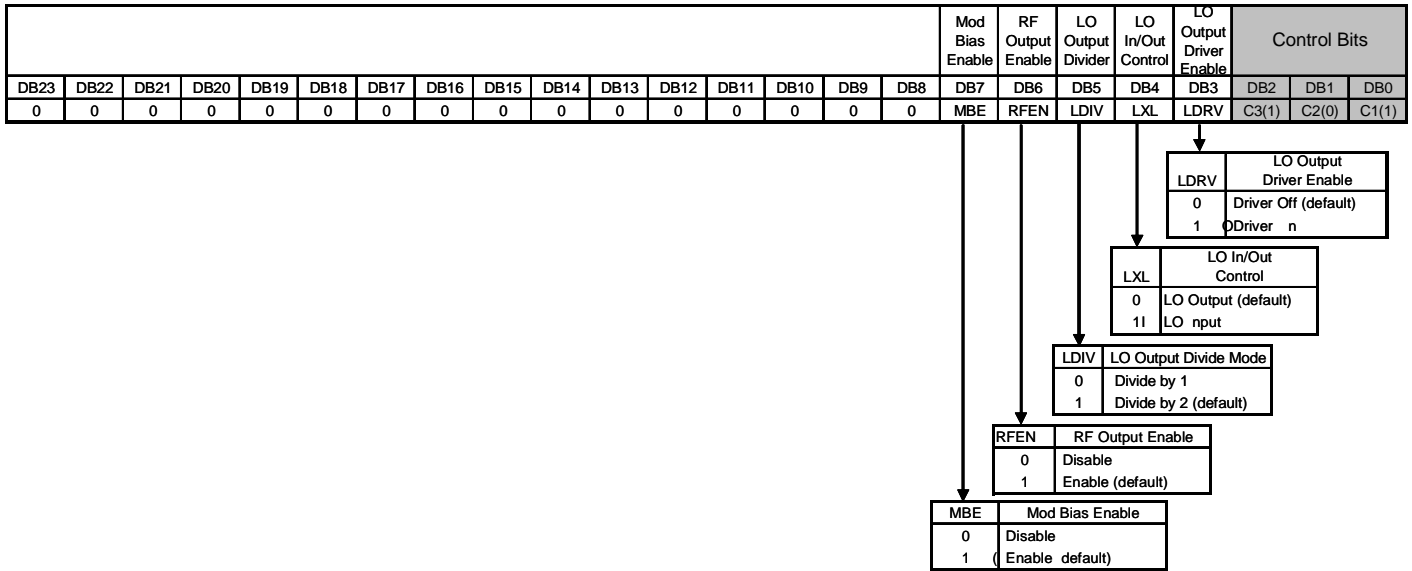

Figure 10. LO Path and Modulator Control (R5)

REGISTER 6 VCO CONTROL AND ENABLES

With R6[2:0] set to 110, the VCO Control and Enables register is programmed as shown in figure 16.

VCO band selection is normally selected based on BANDCAL calibration, though the user can directly select the VCO band using register 6. The VCO BS SRC determines whether the BANDCAL calibration will determine the optimum VCO tuning band, or if the external SPI interface will be used to select the VCO tuning band based on the value of the VCO Band Select.

The VCO amplitude can be controlled through register 6. The VCO amplitude setting can be controlled between 0 and 31 decimal, with a default value of 31.

The internal VCO can be disabled using register 6. The internal VCO LDO can be disabled if an external clean 2.5V supply is available to be applied to pins 9 and 16. Additionally the 3.3V on-board LDO can be disabled through register 6 and an external 3.3V supply can be applied to pin 2.

The internal charge pump can be disabled through register 6. Normally the charge pump will be enabled.

Figure 11. VCO Control and Enable(R6)

REGISTER 7 EXTERNAL VCO ENABLE

With R6[2:0] set to 111, the External VCO Control register is programmed as shown in figure 9.

The External VCO Enable bit allows the use of an external VCO in the PLL instead of the internal VCO. This can be advantageous in cases where the internal VCO is not capable of providing the desired frequency or where the internal VCO's

phase noise is higher than desired. By setting this bit (DB22) to 1, and setting Register 6, bits DB15-DB10 to 0, the internal VCO is disabled, and the output of an external VCO can be fed into the part differentially on pins 38,37 (LOP,LON). Since the loop filter is already external, the output of the loop filter simply needs to be connected to the external VCO's tuning voltage pin.
