

**KEY FEATURES**

- **SMPTE 292M and SMPTE 259M-C compliant descrambling and NRZI → NRZ decoding (with bypass)**
- **DVB-ASI sync word detection and 8b/10b decoding**
- **auto-configuration for HD-SDI, SD-SDI and DVB-ASI**
- **serial loop-through cable driver output selectable as reclocked or non-reclocked**
- **dual serial digital input buffers with 2 x 1 mux**
- **integrated serial digital signal termination**
- **integrated reclocker**
- **automatic or manual rate selection / indication (HD/SD)**
- **descrambler bypass option**
- **adjustable loop bandwidth**
- **user selectable additional processing features including:**
  - **CRC, TRS, ANC data checksum, line number and EDH CRC error detection and correction**
  - **programmable ANC data detection**
  - **illegal code re-mapping**
- **internal flywheel for noise immune H, V, F extraction**
- **FIFO load Pulse**
- **20-bit / 10-bit CMOS parallel output data bus**
- **148.5MHz / 74.25MHz / 27MHz / 13.5MHz parallel digital output**
- **automatic standards detection and indication**
- **1.8V core power supply and 3.3V charge pump power supply**
- **3.3V digital I/O supply**
- **JTAG test interface**
- **small footprint compatible with GS1561, GS1532, GS9060 and GS9062**

**APPLICATIONS**

- SMPTE 292M Serial Digital Interfaces
- SMPTE 259M-C Serial Digital Interfaces
- DVB-ASI Serial Digital Interfaces

**DESCRIPTION**

The GS1560A is a reclocking deserializer with a serial loop-through cable driver. When used in conjunction with the GS1524 Automatic Cable Equalizer and the GO1525 Voltage Controlled Oscillator, a receive solution can be realized for HD-SDI, SD-SDI and DVB-ASI applications.

In addition to reclocking and deserializing the input data stream, the GS1560A performs NRZI-to-NRZ decoding, descrambling as per SMPTE 292M/259M-C, and word alignment when operating in SMPTE mode. When operating in DVB-ASI mode, the device will word align the data to K28.5 sync characters and 8b/10b decode the received stream.

Two serial digital input buffers are provided with a 2x1 multiplexer to allow the device to select from one of two serial digital input signals.

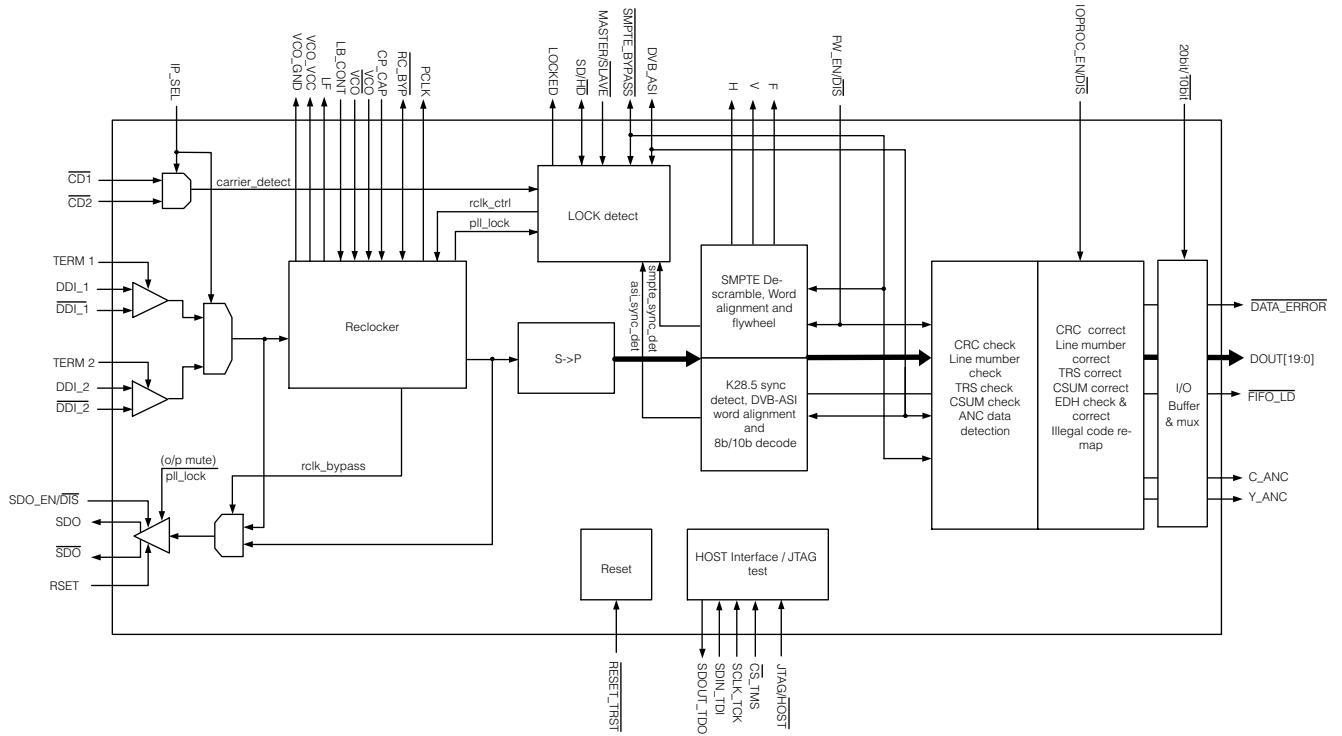

The integrated reclocker features a very wide Input Jitter Tolerance of  $\pm 0.3$  UI (total 0.6 UI), a rapid asynchronous lock time, and full compliance with DVB-ASI data streams.

A integrated cable driver is provided for serial input loop-through applications and can be selected to output either buffered or reclocked data. This cable driver also features an output mute on loss of signal, high impedance mode, adjustable signal swing, and automatic dual slew-rate selection depending on HD/SD operational requirements.

The GS1560A also includes a range of data processing functions such as error detection and correction, automatic standards detection, and EDH support. The device can also detect and extract SMPTE 325M payload identifier packets and independently identify the received video standard. This information is read from internal registers via the host interface port.

Line-based CRC errors, line number errors, TRS errors, EDH CRC errors and ancillary data checksum errors can all be detected. A single 'DATA\_ERROR' pin is provided which is a logical 'OR'ing of all detectable errors. Individual error status is stored in internal 'ERROR\_STATUS' registers.

Finally, the device can correct detected errors and insert new TRS ID words, line-based CRC words, ancillary data checksum words, EDH CRC words, and line numbers. Illegal code re-mapping is also available. All processing function may be individually enabled or disabled via host interface control.

GS1560A FUNCTIONAL BLOCK DIAGRAM

# 1. PIN OUT

## 1.1 PIN ASSIGNMENT

## 1.2 PIN DESCRIPTIONS

PIN NUMBER	NAME	TIMING	TYPE	DESCRIPTION
1	CP_VDD	-	Power	Power supply connection for the charge pump. Connect to +3.3V DC analog.
2	PDBUFF_GND	-	Power	Ground connection for the phase detector and serial digital input buffers. Connect to analog GND.
3	PD_VDD	-	Power	Power supply connection for the phase detector. Connect to +1.8V DC analog.
4	BUFF_VDD	-	Power	Power supply connection for the serial digital input buffers. Connect to +1.8V DC analog.
5	$\overline{CD1}$	Non Synchronous	Input	<p>STATUS SIGNAL INPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>Used to indicate the presence of a serial digital input signal. Normally generated by a Gennum automatic cable equalizer.</p> <p>When LOW, the serial digital input signal received at the DDI1 and <math>\overline{DDI1}</math> pins is considered valid.</p> <p>When HIGH, the associated serial digital input signal is considered to be invalid. In this case, the LOCKED signal is set LOW and all parallel outputs are muted.</p>
6,8	DDI1, $\overline{DDI1}$	Analog	Input	Differential input pair for serial digital input 1.
7	TERM1	Analog	Input	Termination for serial digital input 1. AC couple to PDBUFF_GND.
9	DVB_ASI	Non Synchronous	Input / Output	<p>CONTROL SIGNAL INPUT / STATUS SIGNAL OUTPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>This pin will be an input set by the application layer in slave mode, and will be an output set by the device in master mode.</p> <p>Master Mode (MASTER/<math>\overline{SLAVE}</math> = HIGH) The DVB_ASI signal will be HIGH only when the device has locked to a DVB-ASI compliant data stream. It will be LOW otherwise.</p> <p>Slave Mode (MASTER/<math>\overline{SLAVE}</math> = LOW) When set HIGH in conjunction with SD/<math>\overline{HD}</math> = HIGH and <math>\overline{SMPTE\_BYPASS}</math> = LOW, the device will be configured to operate in DVB-ASI mode.</p> <p>When set LOW, the device will not support the decoding or word alignment of received DVB-ASI data.</p>
10	IP_SEL	Non Synchronous	Input	<p>CONTROL SIGNAL INPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>Used to select DDI1 / <math>\overline{DDI1}</math> or DDI2 / <math>\overline{DDI2}</math> as the serial digital input signal, and <math>\overline{CD1}</math> or <math>\overline{CD2}</math> as the carrier detect input signal.</p> <p>When set HIGH, DDI1 / <math>\overline{DDI1}</math> is selected as the serial digital input and <math>\overline{CD1}</math> is selected as the carrier detect input signal.</p> <p>When set LOW, DDI2 / <math>\overline{DDI2}</math> serial digital input and <math>\overline{CD2}</math> carrier detect input signal is selected.</p>

## 1.2 PIN DESCRIPTIONS (CONTINUED)

PIN NUMBER	NAME	TIMING	TYPE	DESCRIPTION
11	SD/ $\overline{\text{HD}}$	Non Synchronous	Input / Output	<p>CONTROL SIGNAL INPUT / STATUS SIGNAL OUTPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>This pin will be an input set by the application layer in slave mode, and will be an output set by the device in master mode.</p> <p>Master Mode (MASTER/<math>\overline{\text{SLAVE}}</math> = HIGH) The SD/<math>\overline{\text{HD}}</math> signal will be LOW whenever the received serial digital signal is 1.485Gb/s or 1.485/1.001Gb/s.</p> <p>The SD/<math>\overline{\text{HD}}</math> signal will be HIGH whenever the received serial digital signal is 270Mb/s.</p> <p>Slave Mode (MASTER/<math>\overline{\text{SLAVE}}</math> = LOW) When set LOW, the device will be configured for the reception of 1.485Gb/s or 1.485/1.001Gb/s signals only and will not lock to any other serial digital signal.</p> <p>When set HIGH, the device will be configured for the reception of 270Mb/s signals only and will not lock to any other serial digital signal.</p>
12	20bit/ $\overline{10\text{bit}}$	Non Synchronous	Input	<p>CONTROL SIGNAL INPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>Used to select the output data bus width in SMPTE or Data-Through modes. This signal is ignored in DVB-ASI mode.</p> <p>When set HIGH, the parallel output will be 20-bit demultiplexed data.</p> <p>When set LOW, the parallel outputs will be 10-bit multiplexed data.</p>
13	IOPROC_EN/ $\overline{\text{DIS}}$	Non Synchronous	Input	<p>CONTROL SIGNAL INPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>Used to enable or disable I/O processing features.</p> <p>When set HIGH, the following I/O processing features of the device are enabled:</p> <ul style="list-style-type: none"> <li>• EDH CRC Error Correction (SD-only)</li> <li>• ANC Data Checksum Correction</li> <li>• Line-based CRC Error Correction (HD-only)</li> <li>• Line Number Error Correction (HD-only)</li> <li>• TRS Error Correction</li> <li>• Illegal Code Remapping</li> </ul> <p>To enable a subset of these features, keep IOPROC_EN/<math>\overline{\text{DIS}}</math> HIGH and disable the individual feature(s) in the IOPROC_DISABLE register accessible via the host interface.</p> <p>When set LOW, the I/O processing features of the device are disabled, regardless of whether the features are enabled in the IOPROC_DISABLE register.</p>

## 1.2 PIN DESCRIPTIONS (CONTINUED)

PIN NUMBER	NAME	TIMING	TYPE	DESCRIPTION
14	$\overline{CD2}$	Non Synchronous	Input	<p>STATUS SIGNAL INPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>Used to indicate the presence of a serial digital input signal. Normally generated by a Gennum automatic cable equalizer.</p> <p>When LOW, the serial digital input signal received at the DDI2 and <math>\overline{DDI2}</math> pins is considered valid.</p> <p>When HIGH, the associated serial digital input signal is considered to be invalid. In this case, the LOCKED signal is set LOW and all parallel outputs are muted.</p>
15,17	DDI_2, $\overline{DDI2}$	Analog	Input	Differential input pair for serial digital input 2.
16	TERM2	Analog	Input	Termination for serial digital input 2. AC couple to PDBUFF_GND.
18	$\overline{SMPTE\_BYPASS}$	Non Synchronous	Input / Output	<p>CONTROL SIGNAL INPUT / STATUS SIGNAL OUTPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>This pin will be an input set by the application layer in slave mode, and will be an output set by the device in master mode.</p> <p>Master Mode (MASTER/<math>\overline{SLAVE}</math> = HIGH) The <math>\overline{SMPTE\_BYPASS}</math> signal will be HIGH only when the device has locked to a SMPTE compliant data stream. It will be LOW otherwise.</p> <p>Slave Mode (MASTER/<math>\overline{SLAVE}</math> = LOW) When set HIGH in conjunction with DVB_ASI = LOW, the device will be configured to operate in SMPTE mode. All I/O processing features may be enabled in this mode.</p> <p>When set LOW, the device will not support the descrambling, decoding or word alignment of received SMPTE data. No I/O processing features will be available.</p>
19	RSET	Analog	Input	Used to set the serial digital loop-through output signal amplitude. Connect to CD_VDD through $281\Omega \pm 1\%$ for $800mV_{p-p}$ single-ended output swing.
20	CD_VDD	-	Power	Power supply connection for the serial digital cable driver. Connect to +1.8V DC analog.
21	SDO_EN/ $\overline{DIS}$	Non Synchronous	Input	<p>CONTROL SIGNAL INPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>Used to enable or disable the serial digital output loop-through stage.</p> <p>When set LOW, the serial digital output signals SDO and <math>\overline{SDO}</math> are disabled and become high impedance.</p> <p>When set HIGH, the serial digital output signals SDO and <math>\overline{SDO}</math> are enabled.</p>
22	CD_GND	-	Power	Ground connection for the serial digital cable driver. Connect to analog GND.

## 1.2 PIN DESCRIPTIONS (CONTINUED)

PIN NUMBER	NAME	TIMING	TYPE	DESCRIPTION
23, 24	SDO, $\overline{\text{SDO}}$	Analog	Output	Serial digital loop-through output signal operating at 1.485Gb/s, 1.485/1.001Gb/s, or 270Mb/s.  The slew rate of these outputs is automatically controlled to meet SMPTE 292M and 259M specifications according to the setting of the SD/ $\overline{\text{HD}}$ pin.
25	$\overline{\text{RESET\_TRST}}$	Non Synchronous	Input	CONTROL SIGNAL INPUT Signal levels are LVCMOS/LVTTL compatible.  Used to reset the internal operating conditions to default settings and to reset the JTAG test sequence.  Host Mode (JTAG/ $\overline{\text{HOST}}$ = LOW) When asserted LOW, all functional blocks will be set to default conditions and all input and output signals become high impedance, including the serial digital outputs SDO and $\overline{\text{SDO}}$ .  When set HIGH, normal operation of the device resumes 10usec after the LOW-to-HIGH transition of the $\overline{\text{RESET\_TRST}}$ signal.  JTAG Test Mode (JTAG/ $\overline{\text{HOST}}$ = HIGH) When asserted LOW, all functional blocks will be set to default and the JTAG test sequence will be held in reset.  When set HIGH, normal operation of the JTAG test sequence resumes.
26	JTAG/ $\overline{\text{HOST}}$	Non Synchronous	Input	CONTROL SIGNAL INPUT Signal levels are LVCMOS/LVTTL compatible.  Used to select JTAG Test Mode or Host Interface Mode.  When set HIGH, $\overline{\text{CS\_TMS}}$ , SDOUT_TDO, SDI_TDI and SCLK_TCK are configured for JTAG boundary scan testing.  When set LOW, $\overline{\text{CS\_TMS}}$ , SDOUT_TDO, SDI_TDI and SCLK_TCK are configured as GSPI pins for normal host interface operation.
27	$\overline{\text{CS\_TMS}}$	Synchronous with SCLK_TCK	Input	CONTROL SIGNAL INPUT Signal levels are LVCMOS/LVTTL compatible.  Chip Select / Test Mode Select  Host Mode (JTAG/ $\overline{\text{HOST}}$ = LOW) $\overline{\text{CS\_TMS}}$ operates as the host interface chip select, $\overline{\text{CS}}$ , and is active LOW.  JTAG Test Mode (JTAG/ $\overline{\text{HOST}}$ = HIGH) $\overline{\text{CS\_TMS}}$ operates as the JTAG test mode select, TMS, and is active HIGH.

## 1.2 PIN DESCRIPTIONS (CONTINUED)

PIN NUMBER	NAME	TIMING	TYPE	DESCRIPTION
28	SDOUT_TDO	Synchronous with SCLK_TCK	Output	<p>CONTROL SIGNAL OUTPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>Serial Data Output / Test Data Output</p> <p>Host Mode (JTAG/<math>\overline{\text{HOST}}</math> = LOW) SDOUT_TDO operates as the host interface serial output, SDOUT, used to read status and configuration information from the internal registers of the device.</p> <p>JTAG Test Mode (JTAG/<math>\overline{\text{HOST}}</math> = HIGH) SDOUT_TDO operates as the JTAG test data output, TDO.</p>
29	SDIN_TDI	Synchronous with SCLK_TCK	Input	<p>CONTROL SIGNAL INPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>Serial Data In / Test Data Input</p> <p>Host Mode (JTAG/<math>\overline{\text{HOST}}</math> = LOW) SDIN_TDI operates as the host interface serial input, SDIN, used to write address and configuration information to the internal registers of the device.</p> <p>JTAG Test Mode (JTAG/<math>\overline{\text{HOST}}</math> = HIGH) SDIN_TDI operates as the JTAG test data input, TDI.</p>
30	SCLK_TCK	Non Synchronous	Input	<p>CONTROL SIGNAL INPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>Serial Data Clock / Test Clock.</p> <p>Host Mode (JTAG/<math>\overline{\text{HOST}}</math> = LOW) SCLK_TCK operates as the host interface burst clock, SCLK. Command and data read/write words are clocked into the device synchronously with this clock.</p> <p>JTAG Test Mode (JTAG/<math>\overline{\text{HOST}}</math> = HIGH) SCLK_TCK operates as the JTAG test clock, TCK.</p>
31	$\overline{\text{DATA\_ERROR}}$	Synchronous with PCLK	Output	<p>STATUS SIGNAL OUTPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>The <math>\overline{\text{DATA\_ERROR}}</math> signal will be LOW when an error within the received data stream has been detected by the device. This pin is a logical 'OR'ing of all detectable errors listed in the internal ERROR_STATUS register.</p> <p>Once an error is detected, <math>\overline{\text{DATA\_ERROR}}</math> will remain LOW until the start of the next video frame / field, or until the ERROR_STATUS register is read via the host interface.</p> <p>The <math>\overline{\text{DATA\_ERROR}}</math> signal will be HIGH when the received data stream has been detected without error.</p> <p><b>NOTE:</b> It is possible to program which error conditions are monitored by the device by setting appropriate bits of the ERROR_MASK register HIGH. All error conditions are detected by default.</p>

## 1.2 PIN DESCRIPTIONS (CONTINUED)

PIN NUMBER	NAME	TIMING	TYPE	DESCRIPTION
32	$\overline{\text{FIFO\_LD}}$	Synchronous with PCLK	Output	<p>CONTROL SIGNAL OUTPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>Used as a control signal for external FIFO(s).</p> <p>Normally HIGH but will go LOW for one PCLK period at SAV.</p>
33, 68	CORE_GND	-	Power	Ground connection for the digital core logic. Connect to digital GND.
34	F	Synchronous with PCLK	Output	<p>STATUS SIGNAL OUTPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>Used to indicate the ODD / EVEN field of the video signal.</p> <p>The F signal will be HIGH for the entire period of field 2 as indicated by the F bit in the received TRS signals.</p> <p>The F signal will be LOW for all lines in field 1 and for all lines in progressive scan systems.</p>
35	V	Synchronous with PCLK	Output	<p>STATUS SIGNAL OUTPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>Used to indicate the portion of the video field / frame that is used for vertical blanking.</p> <p>The V signal will be HIGH for the entire vertical blanking period as indicated by the V bit in the received TRS signals.</p> <p>The V signal will be LOW for all lines outside of the vertical blanking interval.</p>
36	H	Synchronous with PCLK	Output	<p>STATUS SIGNAL OUTPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>Used to indicate the portion of the video line containing active video data. H signal timing is configurable via the H_CONFIG bit of the IOPROC_DISABLE register accessible via the host interface.</p> <p>Active Line Blanking (H_CONFIG = 0<sub>h</sub>) The H signal will be HIGH for the entire horizontal blanking period, including the EAV and SAV TRS words, and LOW otherwise. This is the default setting.</p> <p>TRS Based Blanking (H_CONFIG = 1<sub>h</sub>) The H signal will be HIGH for the entire horizontal blanking period as indicated by the H bit in the received TRS ID words, and LOW otherwise.</p>
37, 64	CORE_VDD	-	Power	Power supply connection for the digital core logic. Connect to +1.8V DC digital.

## 1.2 PIN DESCRIPTIONS (CONTINUED)

PIN NUMBER	NAME	TIMING	TYPE	DESCRIPTION	
38, 39, 42–48, 50	DOUT[0:9]	Synchronous with PCLK	Output	PARALLEL DATA BUS Signal levels are LVCMOS/LVTTL compatible.

**1.2 PIN DESCRIPTIONS (CONTINUED)**

PIN NUMBER	NAME	TIMING	TYPE	DESCRIPTION	
65	YANC	Synchronous with PCLK	Output	<p>STATUS SIGNAL OUTPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>Used to indicate the presence of ancillary data in the video stream.</p> <p>HD Mode (SD/<math>\overline{HD}</math> = LOW) The YANC signal will be HIGH when the device has detected VANC or HANC data in the luma video stream and LOW otherwise.</p> <p>SD Mode (SD/<math>\overline{HD}</math> = LOW) For 20-bit demultiplexed data (20bit/<math>\overline{10bit}</math> = HIGH), the YANC signal will be HIGH when VANC or HANC data is detected in the luma video stream and LOW otherwise. For 10-bit multiplexed data (20bit/<math>\overline{10bit}</math> = LOW), the YANC signal will be HIGH when VANC or HANC data is detected anywhere in the data stream and LOW otherwise.</p>	
66	CANC	Synchronous with PCLK	Output	<p>STATUS SIGNAL OUTPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>Used to indicate the presence of ancillary data in the video stream.</p> <p>HD Mode (SD/<math>\overline{HD}</math> = LOW) The CANC signal will be HIGH when the device has detected VANC or HANC data in the chroma video stream and LOW otherwise.</p> <p>SD Mode (SD/<math>\overline{HD}</math> = LOW) For 20-bit demultiplexed data (20bit/<math>\overline{10bit}</math> = HIGH), the CANC signal will be HIGH when VANC or HANC data is detected in the chroma video stream and LOW otherwise. For 10-bit multiplexed data (20bit/<math>\overline{10bit}</math> = LOW), the CANC signal will be HIGH when VANC or HANC data is detected anywhere in the data stream and LOW otherwise.</p>	
67	FW_EN/ $\overline{DIS}$	Non Synchronous	Input	<p>CONTROL SIGNAL INPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>Used to enable or disable the noise immune flywheel of the device.</p> <p>When set HIGH, the internal flywheel is enabled. This flywheel is used in the extraction and generation of TRS timing signals, in automatic video standards detection, and in manual switch line lock handling.</p> <p>When set LOW, the internal flywheel is disabled and TRS correction and insertion is unavailable.</p>	
69	PCLK	-	Output	PARALLEL DATA BUS CLOCK Signal levels are LVCMOS/LVTTL compatible.	
				HD 20-bit mode	PCLK = 74.25MHz or 74.25/1.001MHz
				HD 10-bit mode	PCLK = 148.5MHz or 148.5/1.001MHz
				SD 20-bit mode	PCLK = 13.5MHz
				SD 10-bit mode	PCLK = 27MHz

## 1.2 PIN DESCRIPTIONS (CONTINUED)

PIN NUMBER	NAME	TIMING	TYPE	DESCRIPTION
70	$\overline{RC\_BYP}$	Non Synchronous	Input /Output	<p>CONTROL SIGNAL INPUT / STATUS SIGNAL OUTPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>This pin will be an input set by the application layer in slave mode, and will be an output set by the device in master mode.</p> <p>Master Mode (MASTER/<math>\overline{SLAVE}</math> = HIGH) The <math>\overline{RC\_BYP}</math> signal will be HIGH only when the device has successfully locked to a SMPTE or DVB-ASI compliant input data stream. In this case, the serial digital loop-through output will be a reclocked version of the input.</p> <p>The <math>\overline{RC\_BYP}</math> signal will be LOW whenever the input does not conform to a SMPTE or DVB-ASI compliant data stream. In this case, the serial digital loop-through output will be a buffered version of the input.</p> <p>Slave Mode (MASTER/<math>\overline{SLAVE}</math> = LOW) When set HIGH, the serial digital output will be a reclocked version of the input signal regardless of whether the device is in SMPTE, DVB-ASI or Data-Through mode.</p> <p>When set LOW, the serial digital output will be a buffered version of the input signal in all modes.</p>
71	MASTER/ $\overline{SLAVE}$	Non Synchronous	Input	<p>CONTROL SIGNAL INPUT Signal levels are LVCMOS/LVTTL compatible.</p> <p>Used to determine the input / output selection for the DVB_ASI, SD/<math>\overline{HD}</math>, <math>\overline{RC\_BYP}</math> and <math>\overline{SMPTE\_BYPASS}</math> pins.</p> <p>When set HIGH, the GS1560A is set to operate in master mode where DVB_ASI, SD/<math>\overline{HD}</math>, <math>\overline{RC\_BYP}</math> and <math>\overline{SMPTE\_BYPASS}</math> become status signal output pins set by the device. In this mode, the GS1560A will automatically detect, relock, deserialize and process SD SMPTE, HD SMPTE, or DVB-ASI input data.</p> <p>When set LOW, the GS1560A is set to operate in slave mode where DVB_ASI, SD/<math>\overline{HD}</math>, <math>\overline{RC\_BYP}</math> and <math>\overline{SMPTE\_BYPASS}</math> become control signal input pins. In this mode, the application layer must set these external device pins for the correct reception of either SMPTE or DVB-ASI data. Slave mode also supports the reclocking and deserializing of data not conforming to SMPTE or DVB-ASI streams.</p>
72	LOCKED	Synchronous with PCLK	Output	<p>STATUS SIGNAL OUTPUT Signal levels are LVCMOS / LVTTL compatible.</p> <p>The LOCKED signal will be HIGH whenever the device has correctly received and locked to SMPTE compliant data in SMPTE mode or DVB-ASI compliant data in DVB-ASI mode, or when the reclocker has achieved lock in Data-Through mode. It will be LOW otherwise.</p>

## 1.2 PIN DESCRIPTIONS (CONTINUED)

PIN NUMBER	NAME	TIMING	TYPE	DESCRIPTION
73, 74	VCO, $\overline{VCO}$	Analog	Input	Differential inputs for the external VCO reference signal. For single ended devices such as the GO1525, $\overline{VCO}$ should be AC coupled to VCO_GND. VCO is nominally 1.485GHz.
75	VCO_GND	-	Power	Ground reference for the external voltage controlled oscillator. Connect to pins 2, 4, 6, and 8 of the GSO1525. Should be isolated from all other grounds.
76	VCO_VCC	-	Power	Power supply for the external voltage controlled oscillator. Connect to pin 5 of the GO1525. Should be isolated from all other power supplies.
77	LF	Analog	Output	Control voltage to external voltage controlled oscillator. Nominally +1.25V DC.
78	CP_CAP	Analog	Input	PLL lock time constant capacitor connection. Normally connected to VCO_GND through 2.2nF.
79	LB_CONT	Analog	Input	Control voltage to set the loop bandwidth of the integrated reclocker. Normally connected to VCO_VCC through 40k $\Omega$ .
80	CP_GND	-	Power	Ground connection for the charge pump. Connect to analog GND.

## 2. ELECTRICAL CHARACTERISTICS

### 2.1 ABSOLUTE MAXIMUM RATINGS

PARAMETER	VALUE/UNITS
Supply Voltage Core	-0.3V to +2.1V
Supply Voltage I/O	-0.3V to +4.6V
Input Voltage Range (any input)	-2.0V to + 5.25V
Ambient Operating Temperature	$-20^{\circ}\text{C} \leq T_A \leq 85^{\circ}\text{C}$
Storage Temperature	$-40^{\circ}\text{C} \leq T_{\text{STG}} \leq 125^{\circ}\text{C}$
Lead Temperature (soldering, 10 sec)	230°C

**NOTES:**

1. See reflow profile solder

Fig. 1 Reflow Solder Profile

## 2.2 DC ELECTRICAL CHARACTERISTICS

$T_A = 0^\circ\text{C}$  to  $70^\circ\text{C}$ , unless otherwise specified.

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS	TEST LEVEL	NOTES
System								
Operation Temperature Range	$T_A$		0	-	70	$^\circ\text{C}$	-	1
Function Temperature Range			-25	-	85	$^\circ\text{C}$	-	2
Digital Core Supply Voltage	CORE_VDD		1.65	1.8	1.95	V	1	1
Digital I/O Supply Voltage	IO_VDD		3.0	3.3	3.6	V		
Charge Pump Supply Voltage	CP_VDD		3.0	3.3	3.6	V

Output								
Output Common Mode Voltage	$V_{CMOUT}$	75 $\Omega$ load, RSET=281 $\Omega$ , SD and HD	0.8	1.0	1.2	V	1	-

### TEST LEVELS

1. Production test at room temperature and nominal supply voltage with guardbands for supply and temperature ranges.
2. Production test at room temperature and nominal supply voltage with guardbands for supply and temperature ranges using correlated test.
3. Production test at room temperature and nominal supply voltage.
4. QA sample test.
5. Calculated result based on Level 1, 2, or 3.
6. Not tested. Guaranteed by design simulations.
7. Not tested. Based on characterization of nominal parts.
8. Not tested. Based on existing design/characterization data of similar product.
9. Indirect test.

### NOTES

1. All DC and AC electrical parameters within specification.
2. Guaranteed functional.
3. MIL STD 883 ESD protection will be applied to all pins on the device.
4. Input common mode is set by internal biasing resistors.
5. Set by the value of the RSET resistor.

## 2.3 AC ELECTRICAL CHARACTERISTICS

$T_A = 0^\circ\text{C}$  to  $70^\circ\text{C}$ , unless otherwise shown

### 3. DETAILED DESCRIPTION

#### 3.1 FUNCTIONAL OVERVIEW

The GS1560A is a multi-rate reclocking deserializer with an integrated serial digital loop-through output. When used in conjunction with the multi-rate GS1524 Adaptive Cable Equalizer and the external GO1525 Voltage Controlled Oscillator, a receive solution for input data at 1.485Gb/s, 1.485/1.001Gb/s or 270Mb/s is realized.

The device has two basic modes of operation which determine precisely how SMPTE or DVB-ASI compliant input data streams are reclocked and processed.

In master mode, ( $\overline{\text{MASTER/SLAVE}} = \text{HIGH}$ ), the GS1560A will automatically detect, reclock, deserialize and process SD SMPTE 259M-C, HD SMPTE 292M, or DVB-ASI input data.

In slave mode, ( $\overline{\text{MASTER/SLAVE}} = \text{LOW}$ ), the application layer must set external device pins for the correct reception of either SMPTE or DVB-ASI data. Slave mode also supports the reclocking and deserializing of data not conforming to SMPTE or DVB-ASI streams.

The provided serial loop-through outputs may be selected as either buffered or reclocked versions of the input signal and feature a high impedance mode, output mute on loss of signal and adjustable signal swing.

In the digital signal processing core, several data processing functions are implemented including error detection and correction and automatic video standards detection. These features are all enabled by default, but may be individually disabled via internal registers accessible through the GSPI host interface.

Finally, the GS1560A contains a JTAG interface for boundary scan test implementations and an active power-on reset.

#### 3.2 SERIAL DIGITAL INPUT

The GS1560A contains two current mode differential serial digital input buffers, allowing the device to be connected to two SMPTE 259M-C or 292M compliant input signals.

Both input buffers have internal  $50\Omega$  termination resistors which are connected to ground via the TERM1 and TERM2 pins. The input common mode level is set by internal biasing resistors such that the serial digital input signals must be AC coupled into the device. Gennum recommends using a capacitor value of 4.7uF to accommodate pathological signals.

The input buffers use a separate power supply of +1.8V DC supplied via the BUFF\_VDD and PDBUFF\_GND pins.

##### 3.2.1 Input Signal Selection

A 2x1 input multiplexer is provided to allow the application layer to select between the two serial digital input streams

using a single external pin. When IP\_SEL is set HIGH, serial digital input 1 (DDI1 /  $\overline{\text{DDI1}}$ ) is selected as the input to the GS1560A's reclocker stage. When IP\_SEL is set LOW, serial digital input 2 (DDI2 /  $\overline{\text{DDI2}}$ ) is selected.

##### 3.2.2 Carrier Detect Input

For each of the differential inputs, an associated carrier detect input signal is included, ( $\overline{\text{CD1}}$  and  $\overline{\text{CD2}}$ ). These signals are generated by Gennum's family of automatic cable equalizers.

When LOW,  $\overline{\text{CDx}}$  indicates that a valid serial digital data stream is being delivered to the GS1560A by the equalizer. When HIGH, the serial digital input to the device should be considered invalid. If no equalizer precedes the device, the application layer should set  $\overline{\text{CD1}}$  and  $\overline{\text{CD2}}$  accordingly.

*NOTE: If the GS1524 Automatic Cable Equalizer is used, the  $\overline{\text{MUTE/CD}}$  output signal from that device must be translated to TTL levels before passing to the GS1560A  $\overline{\text{CDx}}$  inputs. See section 4.1 for a recommended transistor network that will set the correct voltage levels.*

A 2x1 input multiplexer is also provided for these signals. The internal carrier\_detect signal is determined by the setting of the IP\_SEL pin and is used by the lock detect block of the GS1560A to determine the lock status of the device, (see section 3.6.1).

##### 3.2.3 Single Input Configuration

If the application requires a single differential input, the second set of inputs may be left unconnected. For greater noise immunity, however, terminate the unused pair to +3.3V DC. Tie the associated carrier detect pin HIGH, and leave termination pin unconnected.

#### 3.3 SERIAL DIGITAL RECLOCKER

The output of the 2x1 serial digital input multiplexer passes to the GS1560A's internal reclocker stage. The function of this block is to lock to the input data stream, extract a clean clock, and retiming the serial digital data to remove high frequency jitter.

The reclocker was designed with a 'hexabang' phase and frequency detector. That is, the PFD used can identify six 'degrees' of phase / frequency misalignment between the input data stream and the clock signal provided by the VCO, and correspondingly signal the charge pump to produce six different control voltages. This results in fast and accurate locking of the PLL to the data stream.

In master mode, the operating center frequency of the reclocker is toggled between 270Mb/s and 1.485Gb/s by the lock detect block, (see section 3.6.1). In slave mode, however, the center frequency is determined entirely by the SD/ $\overline{\text{HD}}$  input control signal set by the application layer.

If lock is achieved, the reclocker provides an internal pll\_lock signal to the lock detect block of the device.

### 3.3.1 External VCO

The GS1560A requires the external GO1525 Voltage Controlled Oscillator as part of the reclocker's phase-locked loop. This external VCO implementation was chosen to ensure high quality reclocking.

Power for the external VCO is generated entirely by the GS1560A from an integrated voltage regulator. The internal regulator uses +3.3V DC supplied via the CP\_VDD / CP\_GND pins to provide +2.5V DC on the VCO\_VCC / VCO\_GND pins.

The control voltage to the VCO is output from the GS1560A on the LF pin and requires 4.7k $\Omega$  pull-up and pull-down resistors to ensure correct operation.

The GO1525 produces a 1.485GHz reference signal for the reclocker, input on the VCO pin of the GS1560A. Both LF and VCO signals should be referenced to the supplied VCO\_GND as shown in the recommended application circuit of section 4.1.

### 3.3.2 Loop Bandwidth

The loop bandwidth of the integrated reclocker is nominally 1.4MHz, but may be increased or decreased via the LB\_CONT pin. It is recommended that this pin be connected to VCO\_GND through 39.2k $\Omega$  to maximize the input jitter tolerance of the device.

## 3.4 SERIAL DIGITAL LOOP-THROUGH OUTPUT

The GS1560A contains an integrated current mode differential serial digital cable driver with automatic slew rate control. When enabled, this serial digital output provides an active loop-through of the input signal.

To enable the loop-through output, SDO\_EN/DIS must be set HIGH by the application layer. Setting the SDO\_EN/DIS signal LOW will cause the SDO and  $\overline{\text{SDO}}$  output pins to become high impedance, resulting in reduced device power consumption.

With suitable external return loss matching circuitry, the GS1560A's loop-through outputs will provide a minimum output return loss of -15dB at SD rates. Gennum recommends using the GS1528 SDI Dual Slew-Rate Cable Driver to meet output return loss specifications at HD rates.

The integrated cable driver uses a separate power supply of +1.8V DC supplied via the CD\_VDD and CD\_GND pins.

### 3.4.1 Output Swing

Nominally, the voltage swing of the serial digital loop-through output is 800mV<sub>p-p</sub> single-ended into a 75 $\Omega$  load. This is set externally by connecting the RSET pin to CD\_VDD through 281 $\Omega$ .

The loop-through output swing may be decreased by increasing the value of the RSET resistor. The relationship is approximated by the curve shown in Figure 7.

Alternatively, the serial digital output swing may be decreased by using a 50 $\Omega$  load in place of the nominal 75 $\Omega$ . In this case, the output swing is reduced by a factor of approximately two thirds.

Fig. 7 Serial Digital Loop-Through Output Swing

### 3.4.2 Reclocker Bypass Control

The serial digital loop-through output may be either a buffered version of the serial digital input signal, or a reclocked version of that signal.

When operating in slave mode, the application layer may choose the reclocked output by setting  $\overline{\text{RC\_BYP}}$  to logic HIGH. If  $\overline{\text{RC\_BYP}}$  is set LOW, the data stream will bypass the internal reclocker and the serial digital output will be a buffered version of the input.

When operating in master mode, the device will assert the  $\overline{\text{RC\_BYP}}$  pin HIGH only when it has successfully locked to a SMPTE or DVB-ASI input data stream, (see section 3.6.1). In this case, the serial digital loop-through output will be a reclocked version of the input.

### 3.4.3 Serial Digital Output Mute

The GS1560A will automatically mute the serial digital loop-through output in both master and slave modes when the internal carrier\_detect signal indicates an invalid serial input.

The loop-through output will also be muted in slave mode when SDO/ $\overline{\text{SDO}}$  is selected as reclocked, ( $\overline{\text{RC\_BYP}}$  = HIGH), but the lock detect block has failed to lock to the data stream, (LOCKED = LOW).

Table 1 summarizes the possible states of the serial digital loop-through output data stream.

Table 1: Serial Digital Loop-Through Output Status

SLAVE MODE			
SDO	$\overline{CD}$	LOCKED	$\overline{RC\_BYP}$ (INPUT)
RELOCKED	LOW	HIGH	HIGH
BUFFERED	LOW	X	LOW
MUTED	LOW	LOW	HIGH
MUTED	HIGH	LOW*	X
MASTER MODE			
SDO	$\overline{CD}$	LOCKED	$\overline{RC\_BYP}$ (OUTPUT)
RELOCKED	LOW	HIGH	HIGH
BUFFERED	LOW	LOW	LOW
MUTED	HIGH	LOW*	LOW

\*NOTE: LOCKED = HIGH if and only if  $\overline{CD}$  = LOW

### 3.5 SERIAL-TO-PARALLEL CONVERSION

The retimed data and phase-locked clock signals from the reclocker are fed to the serial-to-parallel converter. The function of this block is to extract 10-bit or 20-bit parallel data words from the reclocked serial data stream and present them to the SMPTE and DVB-ASI word alignment blocks simultaneously.

### 3.6 MODES OF OPERATION

The GS1560A has two basic modes of operation which determine how the lock detect block controls the integrated reclocker. Master mode is enabled when the application layer sets the MASTER/ $\overline{SLAVE}$  pin HIGH, and slave mode is enabled when MASTER/ $\overline{SLAVE}$  is set LOW.

#### 3.6.1 Lock Detect

The lock detect block controls the center frequency of the integrated reclocker to ensure lock to the received serial digital data stream is achieved, and indicates via the LOCKED output pin that the device has detected the appropriate sync words.

Lock detection is a continuous process, which begins at device power up or after a system reset, and continues until the device is powered down or held in reset.

The lock detection algorithm first determines if a valid serial digital input signal has been presented to the device by sampling the internal carrier\_detect signal. As described in section 3.2.2, this signal will be LOW when a good serial digital input signal has been detected.

If the carrier\_detect signal is HIGH, the serial data into the device is considered invalid, and the VCO frequency will be set to the center of the pull range. The LOCKED pin will be LOW and all outputs of the device except for the PCLK output will be muted. Instead, the PCLK output frequency will operate within +/-3% of the rates shown in Table 16 of section 3.11.5.

*NOTE: When the device is operating in DVB-ASI Slave mode only, the parallel outputs will not mute when the carrier\_detect signal is HIGH. The LOCKED signal will function normally.*

If a valid input signal has been detected, and the device is in master mode, the lock algorithm will enter a hunt phase where four attempts are made to detect the presence of either SMPTE TRS sync words or DVB-ASI sync words. At each attempt, the center frequency of the reclocker will be toggled between 270Mb/s and 1.485Gb/s.

Assuming that a valid SMPTE or DVB-ASI signal has been applied to the device, asynchronous lock times will be as listed in the AC Characteristics Table, (section 2.3).

In slave mode, the application layer fixes the center frequency of the reclocker such that the lock algorithm will attempt to lock within the single data rate determined by the setting of the SD/ $\overline{HD}$  pin. Asynchronous lock times are also listed in the AC Characteristics Table, (section 2.3).

*NOTE: The PCLK output will continue to operate during the lock detection process. The frequency may toggle between 148MHz and 27MHz when the 20bit/ $\overline{10bit}$  pin is set LOW, or between 74MHz and 13.5MHz when 20bit/ $\overline{10bit}$  is set HIGH.*

For SMPTE and DVB-ASI inputs, the lock detect block will only assert the LOCKED output signal HIGH if (1) the reclocker has locked to the input data stream as indicated by the internal pll\_lock signal, AND (2) TRS or DVB-ASI sync words have been correctly identified.

If after four attempts lock has not been achieved, the lock detection algorithm will enter into PLL lock mode. In this mode, the reclocker will attempt to lock to the input data stream without detecting SMPTE TRS or DVB-ASI sync words. This unassisted process can take up to 10ms to achieve lock.

When reclocker lock as indicated by the internal pll\_lock signal is achieved in this mode, one of the following will occur:

1. In slave mode, data will be passed directly to the parallel outputs without any further processing taking place and the LOCKED signal will be asserted HIGH if and only if the  $\overline{SMPTE\_BYPASS}$  and DVB-ASI input pins are set LOW; or
2. In master mode, the LOCKED signal will be asserted LOW, the parallel outputs will be latched to logic LOW, and the  $\overline{SMPTE\_BYPASS}$  and DVB-ASI output signals will also be set LOW.

### 3.6.2 Master Mode

Recall that the GS1560A is said to be in master mode when the MASTER/SLAVE input signal is set HIGH. In this case, the following four device pins become output status signals:

- $\overline{\text{SMPTE\_BYPASS}}$
- DVB\_ASI
- $\text{SD}/\overline{\text{HD}}$
- $\overline{\text{RC\_BYP}}$

The combined setting of these four pins will indicate whether the device has locked to valid SMPTE or DVB-ASI data at SD or HD rates. Table 2 shows the possible combinations.

### 3.6.3 Slave Mode

The GS1560A is said to be in slave mode when the MASTER/SLAVE input signal is set LOW. In this case, the four device pins listed in section 3.6.2 become input control signals.

It is required that the application layer set the first three inputs to reflect the appropriate input data format ( $\overline{\text{SMPTE\_BYPASS}}$ , DVB\_ASI, and  $\text{SD}/\overline{\text{HD}}$ ). If just one of these three is configured incorrectly, the device will not lock to the input data stream, and the DATA\_ERROR pin will be set LOW.

The fourth input signal,  $\overline{\text{RC\_BYP}}$ , allows the application layer to determine whether the serial digital loop-through output will be a reclocked or buffered version of the input, (see section 3.4.2). Table 3 shows the required settings for various input formats.

Table 2: Master Mode Output Status Signals

FORMAT	PIN SETTINGS			
	$\overline{\text{SMPTE\_BYPASS}}$	DVB_ASI	$\text{SD}/\overline{\text{HD}}$	$\overline{\text{RC\_BYP}}$
HD SMPTE	HIGH	LOW	LOW	HIGH
SD SMPTE	HIGH	LOW	HIGH	HIGH
DVB-ASI	LOW	HIGH	HIGH	HIGH
NOT SMPTE OR DVB-ASI*	LOW	LOW	HIGH OR LOW	LOW

\*NOTE: When the device locks to the data stream in PLL lock mode, the parallel outputs will be latched LOW, and the serial loop-through output will be a buffered version of the input.

Table 3: Slave Mode Input Control Signals

FORMAT	PIN SETTINGS		
	$\overline{\text{SMPTE\_BYPASS}}$	DVB_ASI	$\text{SD}/\overline{\text{HD}}$
HD SMPTE	HIGH	LOW	LOW
SD SMPTE	HIGH	LOW	HIGH
DVB-ASI	LOW	HIGH	HIGH
NOT SMPTE OR DVB-ASI*	LOW	LOW	HIGH OR LOW

\*NOTE: See section 3.9 for a complete description of Data-Through mode.

### 3.7 SMPTE FUNCTIONALITY

The GS1560A is said to be in SMPTE mode once the device has detected SMPTE TRS sync words and locked to the input data stream as described in section 3.6.1. The device will remain in SMPTE mode until such time that SMPTE TRS sync words fail to be detected.

The lock detect block may also drop out of SMPTE mode under the following conditions:

- $\overline{\text{RESET\_TRST}}$  is asserted LOW
- $\overline{\text{CDx}}$  is HIGH
- $\overline{\text{SMPTE\_BYPASS}}$  is asserted LOW in slave mode
- $\text{DVB\_ASI}$  is asserted HIGH in slave mode

TRS word detection is a continuous process and both 8-bit and 10-bit TRS words will be identified by the device in both SD and HD modes.

In master mode, the GS1560A sets the  $\overline{\text{SMPTE\_BYPASS}}$  pin HIGH and the  $\text{DVB\_ASI}$  pin LOW to indicate that it has locked to a SMPTE input data stream. When operating in slave mode, the application layer must assert the  $\text{DVB\_ASI}$  pin LOW and the  $\overline{\text{SMPTE\_BYPASS}}$  pin HIGH in order to enable SMPTE operation.

#### 3.7.1 SMPTE Descrambling and Word Alignment

After serial-to-parallel conversion, the internal 10-bit or 20-bit data bus is fed to the SMPTE descramble and word alignment block. The function of this block is to carry out NRZI-to-NRZ decoding, descrambling according to SMPTE 259M or 292M, and word alignment of the data to the TRS sync words.

Word alignment occurs when three consecutive valid TRS words (SAV and EAV inclusive) with the same bit alignment have been detected (1½ video lines).

In normal operation, re-synchronization of the word alignment process will only take place when two consecutive identical TRS word positions have been detected. When automatic or manual switch line lock handling is 'actioned', (see section 3.7.3), word alignment re-synchronization will occur on the next received TRS code word.

#### 3.7.2 Internal Flywheel

The GS1560A has an internal flywheel which is used in the generation of internal / external timing signals, in the detection and correction of certain error conditions and in automatic video standards detection. It is only operational in SMPTE mode.

The flywheel consists of a number of counters and comparators operating at video pixel and video line rates. These counters maintain information about the total line length, active line length, total number of lines per field /

frame, and total active lines per field / frame for the received video stream.

The flywheel 'learns' the video standard by timing the horizontal and vertical reference information contained in the TRS ID words of the received video stream. Full synchronization of the flywheel to the received video standard therefore requires one complete video frame.

Once synchronization has been achieved, the flywheel will continue to monitor the received TRS timing information to maintain synchronization.

The  $\text{FW\_EN}/\overline{\text{DIS}}$  input pin controls the synchronization mechanism of the flywheel. When this input signal is LOW, the flywheel will re-synchronize all pixel and line based counters on every received TRS ID word.

When  $\text{FW\_EN}/\overline{\text{DIS}}$  is held HIGH, re-synchronization of the pixel and line based counters will only take place when a consistent synchronization error has been detected. Two consecutive video lines with identical TRS timing different to the current flywheel timing must occur to initiate re-synchronization of the counters. This provides a measure of noise immunity to internal and external timing signal generation.

The flywheel will be disabled should the LOCKED signal or the  $\overline{\text{RESET\_TRST}}$  signal be LOW. A LOW to HIGH transition on either signal will cause the flywheel to re-acquire synchronization on the next received TRS word, regardless of the setting of the  $\text{FW\_EN}/\overline{\text{DIS}}$  pin.

#### 3.7.3 Switch Line Lock Handling

The principal of switch line lock handling is that the switching of synchronous video sources will only disturb the horizontal timing and alignment of the stream, whereas the vertical timing remains in synchronization.

To account for the horizontal disturbance caused by a synchronous switch, it is necessary to re-synchronize the flywheel immediately after the switch has taken place. Rapid re-synchronization of the GS1560A to the new video standard can be achieved by controlling the flywheel using the  $\text{FW\_EN}/\overline{\text{DIS}}$  pin.

At every PCLK cycle the device samples the  $\text{FW\_EN}/\overline{\text{DIS}}$  pin. When a logic LOW to HIGH transition at this pin is detected anywhere within the active line, the flywheel will re-synchronize immediately to the next TRS word. This is shown in Figures 7a,b.

To ensure switch line lock handling, the  $\text{FW\_EN}/\overline{\text{DIS}}$  signal should be LOW for a minimum of one PCLK cycle (maximum one video line) anywhere within the active portion of the line on which the switch has taken place.

Fig. 7a Switch Line Locking - Source 1 leading Source 2

Fig. 7b Switch Line Locking - Source 1 leading Source 2

The ability to manually re-synchronize the flywheel is also important when switching asynchronous sources or to implement other non-standardized video switching functions.

The GS1560A also implements automatic switch line lock handling. By utilizing the synchronous switch points defined by SMPTE RP168 for all major video standards with the automatic video standards detect function, the device automatically re-synchronizes the flywheel at the switch point.

This function will occur regardless of the setting of the FW\_EN/DIS pin.

The switch line is defined as follows:

- For 525 line interlaced systems: re-sync takes place at the end of lines 10 & 273.
- For 525 line progressive systems: re-sync takes place at the end of line 10.
- For 625 line interlaced systems: re-sync takes place at the end of lines 6 & 319.

- For 625 line progressive systems: re-sync takes place at the end of line 6.
- For 750 line progressive systems: re-sync takes place at the end of line 7.
- For 1125 line interlaced systems: re-sync takes place at the end of lines 7 & 568.
- For 1125 line progressive systems: re-sync takes place at the end of line 7.

A full list of all major video standards and switching lines is shown in Table 4.

*NOTE 1 : The flywheel timing will define the line count such that the line numbers shown in Table 4 may not correspond directly to the digital line counts.*

*NOTE 2: Unless indicated by SMPTE 352M payload identifier packets, the GS1560A will not distinguish between 50/60 frames PsF and 25/30 frames interlaced for the 1125 line video systems; 24 PsF will be identified.*

Table 4: Switch Line Position for Digital Systems

SYSTEM	VIDEO FORMAT	SAMPLING	SIGNAL STANDARD	PARALLEL INTERFACE	SERIAL INTERFACE	SWITCH LINE NO.

### 3.7.4 HVF Timing Signal Generation

The GS1560A extracts critical timing parameters from either the received TRS signals (FW\_EN/DIS = LOW), or from the internal flywheel-timing generator (FW\_EN/DIS = HIGH).

Horizontal blanking period (H), vertical blanking period (V), and even / odd field (F) timing are all extracted and presented to the application layer via the H:V:F status output pins.

The H signal timing is configurable via the H\_CONFIG bit of the internal IOPROC\_DISABLE register as either active line based blanking, or TRS based blanking, (see section 3.10.6).

Active line based blanking is enabled when the H\_CONFIG bit is set LOW. In this mode, the H output is HIGH for the entire horizontal blanking period, including the EAV and SAV TRS words. This is the default H timing used by the device.

When H\_CONFIG is set HIGH, TRS based blanking is enabled. In this case, the H output will be HIGH for the entire horizontal blanking period as indicated by the H bit in the received TRS ID words.

The timing of these signals is shown in Figures 8a,b below.

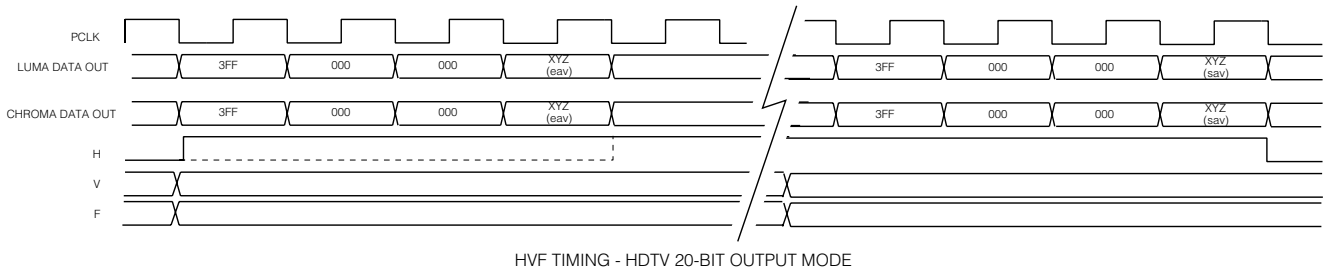

Fig. 8a HD H, V, F Timing

Fig. 8b SD H, V, F Timing

### 3.8 DVB-ASI FUNCTIONALITY

The GS1560A is said to be in DVB-ASI mode once the device has detected 32 consecutive DVB-ASI words without a single word or disparity error being generated. The device will remain in DVB-ASI mode until 32 consecutive DVB-ASI word or disparity errors are detected, or until SMPTE TRS ID words have been detected.

The lock detect block may also drop out of DVB-ASI mode under the following conditions:

- $\overline{\text{RESET\_TRST}}$  is asserted LOW
- $\overline{\text{CDx}}$  is HIGH
- $\overline{\text{SMPTE\_BYPASS}}$  is asserted HIGH in slave mode
- $\text{DVB\_ASI}$  is asserted LOW in slave mode

K28.5 sync patterns in the received DVB-ASI data stream will be detected by the device in either inverted or non-inverted form.

In master mode, the GS1560A sets the  $\overline{\text{SMPTE\_BYPASS}}$  pin LOW and the  $\text{DVB\_ASI}$  pin HIGH to indicate that it has locked to a DVB-ASI input data stream. When operating in slave mode, the application layer must set the  $\overline{\text{SD/HD}}$  pin HIGH, in addition to setting  $\overline{\text{SMPTE\_BYPASS}}$  LOW and  $\text{DVB\_ASI}$  HIGH, in order to enable DVB-ASI operation.

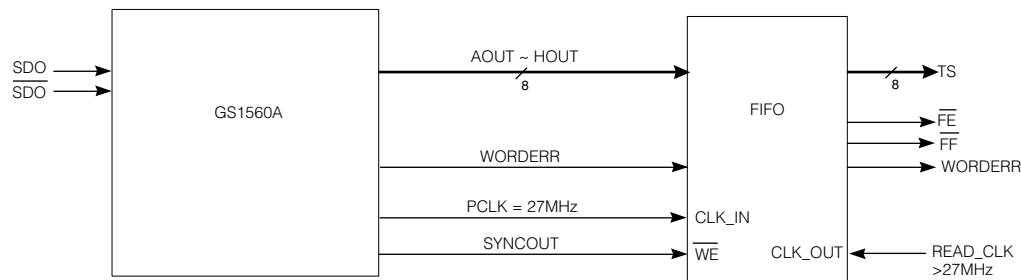

Fig. 9 DVB-ASI FIFO Implementation using the GS1560A

### 3.9 DATA THROUGH MODE

The GS1560A may be configured by the application layer to operate as a simple serial-to-parallel converter. In this mode, the device presents data to the output data bus without performing any decoding, descrambling or word-alignment.

Data through mode is enabled only when the  $\overline{\text{MASTER/SLAVE}}$ ,  $\overline{\text{SMPTE\_BYPASS}}$ , and  $\text{DVB\_ASI}$  input pins are set LOW. Under these conditions, the lock detection algorithm enters PLL lock mode, (see section 3.6.1), such that the device may relock data not conforming to SMPTE or DVB-ASI streams.

When operating in master mode, the GS1560A will set the  $\overline{\text{SMPTE\_BYPASS}}$  and  $\text{DVB\_ASI}$  signals to logic LOW if presented with a data stream without SMPTE TRS ID words or DVB-ASI sync words. The LOCKED and data bus outputs

#### 3.8.1 DVB-ASI 8b/10b Decoding and Word Alignment

After serial-to-parallel conversion, the internal 10-bit data bus is fed to the DVB-ASI 8b/10b decode and word alignment block. The function of this block is to word align the data to the K28.5 sync characters, and 8b/10b decode and bit-swap the data to achieve bit alignment with the data outputs.

The extracted 8-bit data will be presented to  $\text{DOUT}[17:10]$ , bypassing all internal SMPTE mode data processing.

#### 3.8.2 Status Signal Outputs

In DVB-ASI mode, the  $\text{DOUT19}$  and  $\text{DOUT18}$  pins will be configured as DVB-ASI status signals  $\text{SYNCOUT}$  and  $\text{WORDERR}$  respectively.

$\text{SYNCOUT}$  will be HIGH whenever a K28.5 sync character is present on the output. This output may be used to drive the write enable signal of an external FIFO, thus providing a means of removing the K28.5 sync characters from the data stream. Parallel DVB-ASI data may then be clocked out of the FIFO at some rate less than 27MHz. See Figure 9.

$\text{WORDERR}$  will be high whenever the device has detected a running disparity error or illegal code word.

will be forced LOW and the serial digital loop-through output will be a buffered version of the input.

### 3.10 ADDITIONAL PROCESSING FUNCTIONS

The GS1560A contains an additional data processing block which is available in SMPTE mode only, (see section 3.7).

#### 3.10.1 FIFO Load Pulse

To aid in the application-specific implementation of auto-phasing and line synchronization functions, the GS1560A will generate a FIFO load pulse to reset line-based FIFO storage.

The  $\overline{\text{FIFO\_LD}}$  output pin will normally be HIGH but will go LOW for one PCLK period, thereby generating a FIFO write reset signal.

The FIFO load pulse will be generated such that it is contimed to the SAV XYZ code word presented to the output data bus. This ensures that the next PCLK cycle will correspond to the first active sample of the video line.

Figures 10a,b show the timing relationship between the FIFO\_LD signal and the output video data.

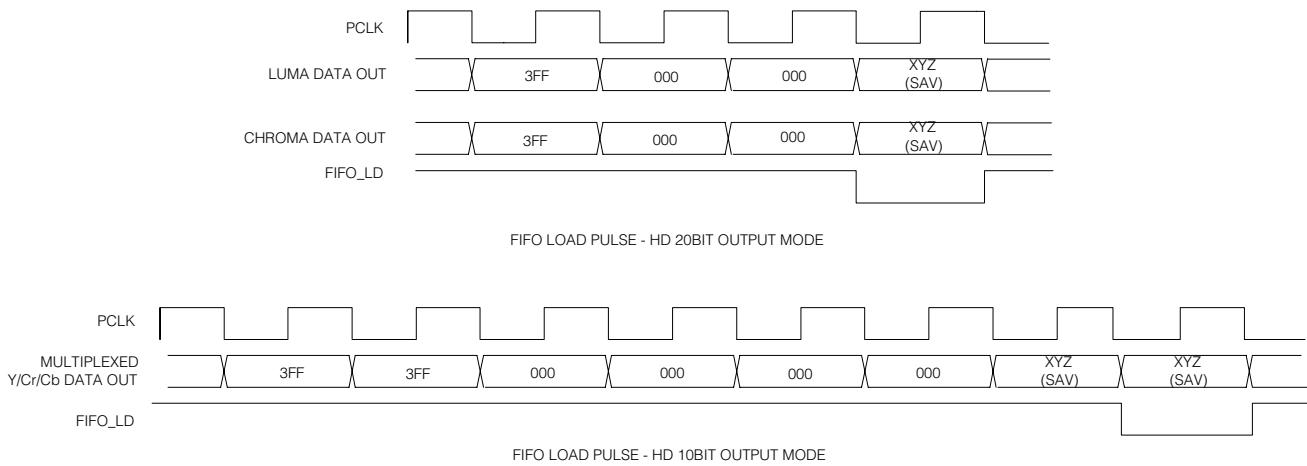

Fig. 10a HD FIFO\_LD Pulse Timing

Fig. 10b SD FIFO\_LD Pulse Timing

**3.10.2 Ancillary Data Detection and Indication**

The GS1560A will detect all types of ancillary data in either the vertical or horizontal blanking spaces and indicate via the status signal output pins YANC and CANC the position of ancillary data in the output data stream. These status signal outputs are synchronous with PCLK and can be used as clock enables to external logic, or as write enables to an external FIFO or other memory device.

When operating in HD mode, ( $SD/\overline{HD} = LOW$ ), the YANC signal will be HIGH whenever ancillary data is detected in the luma data stream, and the CANC signal will be HIGH whenever ancillary data is detected in the chroma data stream.

In SD mode, ( $SD/\overline{HD} = HIGH$ ), the YANC and CANC signal operation will depend on the output data format. For 20-bit demultiplexed data, (see section 3.11), the YANC and CANC signals will operate independently. However, for 10-bit multiplexed data, the YANC and CANC signals will both be HIGH whenever ancillary data is detected.

The signals will be HIGH from the start of the ancillary data preamble and will remain HIGH until after the ancillary data checksum.

The operation of the YANC and CANC signals is shown in Figures 11a,b.

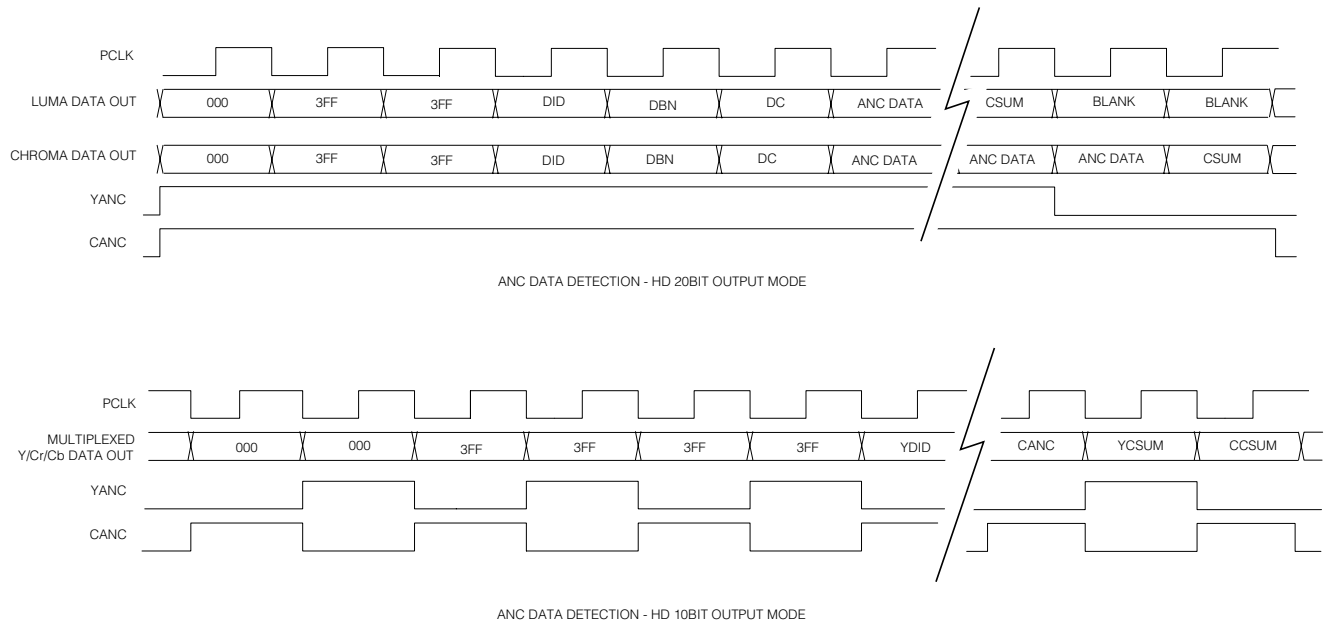

Fig. 11a HD YANC and CANC Output Signal Timing

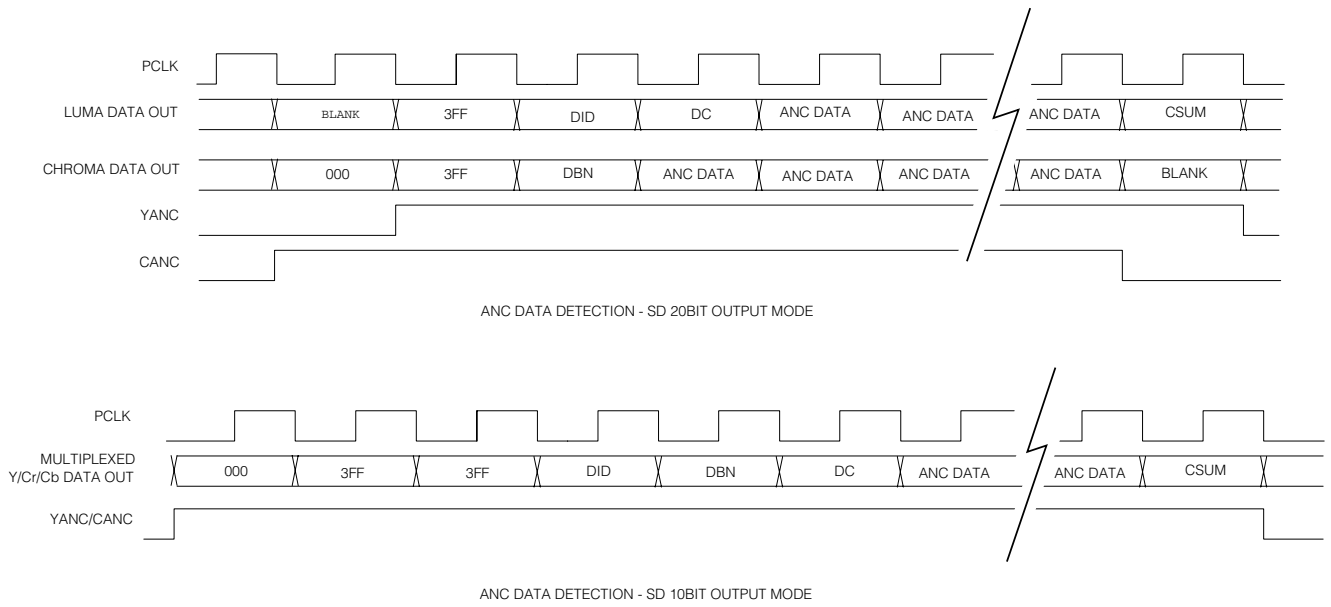

Fig. 11b SD YANC and CANC Output Signal Timing

### 3.10.2.1 Programmable Ancillary Data Detection

Although the GS1560A will detect all types of ancillary data by default, it also allows the host interface to specifically program up to five different ancillary data types for detection. This is accomplished via the ANC\_TYPE register (Table 5).

For each data type to be detected, the host interface must program the DID and/or SDID of the ancillary data type of interest. The GS1560A will compare the received DID and/or SDID with the programmed values and assert YANC and CANC only if an exact match is found.

If any DID or SDID value is set to zero in the ANC\_TYPE register, no comparison or match will be made for that value. For example, if the DID is programmed but the SDID

is set to zero, the device will detect all ancillary data types matching the DID value, regardless of the SDID.

In the case where all five DID and SDID values are set to zero, the GS1560A will detect all ancillary data types. This is the default setting after device reset or power-up.

Where one or more, but less than five, DID and/or SDID values have been programmed, then only those matching ancillary data types will be detected and indicated.

*NOTE 1: The GS1560A will always detect EDH ancillary data packets for EDH error detection purposes, regardless of which DID/SDID values have been programmed for ancillary data indication, (see section 3.10.5.2).*

*NOTE 2: See SMPTE 291M for a definition of ancillary data terms.*

Table 5: Host Interface Description for Programmable Ancillary Data Type Registers

REGISTER NAME	BIT	NAME	DESCRIPTION	R/W	DEFAULT
ANC_TYPE1 Address: 005h	15-8	ANC_TYPE1[15:8]	Used to program the DID for ancillary data detection at the YANC and CANC output	R/W	0
	7-0	ANC_TYPE1[7:0]	Used to program the SDID for ancillary data detection at the YANC and CANC output. Should be set to zero if no SDID is present in the ancillary data product to be detected.	R/W	0
ANC_TYPE2 Address: 006h	15-8	ANC_TYPE2[15:8]	Used to program the DID for ancillary data detection at the YANC and CANC output	R/W	0
	7-0	ANC_TYPE2[7:0]	Used to program the SDID for ancillary data detection at the YANC and CANC output. Should be set to zero if no SDID is present in the ancillary data product to be detected.	R/W	0
ANC_TYPE3 Address: 007h	15-8	ANC_TYPE3[15:8]	Used to program the DID for ancillary data detection at the YANC and CANC output	R/W	0
	7-0	ANC_TYPE3[7:0]	Used to program the SDID for ancillary data detection at the YANC and CANC output. Should be set to zero if no SDID is present in the ancillary data product to be detected.	R/W	0
ANC_TYPE4 Address: 008h	15-8	ANC_TYPE4[15:8]	Used to program the DID for ancillary data detection at the YANC and CANC output	R/W	0
	7-0	ANC_TYPE4[7:0]	Used to program the SDID for ancillary data detection at the YANC and CANC output. Should be set to zero if no SDID is present in the ancillary data product to be detected.	R/W	0
ANC_TYPE5 Address: 009h	15-8	ANC_TYPE5[15:8]	Used to program the DID for ancillary data detection at the YANC and CANC output	R/W	0
	7-0	ANC_TYPE5[7:0]	Used to program the SDID for ancillary data detection at the YANC and CANC output. Should be set to zero if no SDID is present in the ancillary data product to be detected.	R/W	0

### 3.10.3 SMPTE 352M Payload Identifier

The GS1560A can receive and detect the presence of the SMPTE 352M payload identifier ancillary data packet. This four word payload identifier packet may be used to indicate the transport mechanism, frame rate and line scanning / sampling structure.

Upon reception of this packet, the device will extract the four words describing the video format being transported and make this information available to the host interface via the four VIDEO\_FORMAT\_OUT registers (Table 6).

The VIDEO\_FORMAT\_OUT registers will only be updated if the received checksum is the same as the locally calculated checksum.

These registers will be cleared to zero, indicating an undefined format, if the device loses lock to the input data stream (LOCKED = LOW), or if the SMPTE\_BYPASS pin is asserted LOW. This is also the default setting after device reset or power-up.

The SMPTE 352M packet should be received once per field for interlaced systems and once per frame for progressive systems. If the packet is not received for two complete video frames, the VIDEO\_FORMAT\_OUT registers will be cleared to zero.

Table 6: Host Interface Description for SMPTE 352M Payload Identifier Registers

REGISTER NAME	BIT	NAME	DESCRIPTION	R/W	DEFAULT
VIDEO_FORMAT_OUT_B Address: 013h	15-8	SMPTE352M Byte 4	Data will be available in this register when Video Payload Identification Packets are detected in the data stream.	R	0
	7-0	SMPTE352M Byte 3	Data will be available in this register when Video Payload Identification Packets are detected in the data stream.	R	0
VIDEO_FORMAT_OUT_A Address: 012h	15-8	SMPTE352M Byte 2	Data will be available in this register when Video Payload Identification Packets are detected in the data stream.	R	0
	7-0	SMPTE352M Byte 1	Data will be available in this register when Video Payload Identification Packets are detected in the data stream.	R	0

### 3.10.4 Automatic Video Standard and Data Format Detection

The GS1560A can independently detect the input video standard and data format by using the timing parameters extracted from the received TRS ID words. This information is presented to the host interface via the VIDEO\_STANDARD register (Table 7).

Total samples per line, active samples per line, total lines per field/frame and active lines per field/frame are also calculated and presented to the host interface via the RASTER\_STRUCTURE registers (Table 8). These line and sample count registers are updated once per frame at the end of line 12. This is in addition to the information contained in the VIDEO\_STANDARD register.

After device reset or power up, the four RASTER\_STRUCTURE registers default to zero.

Table 7: Host Interface Description for Video Standard and Data Format Register

REGISTER NAME	BIT	NAME	DESCRIPTION	R/W	DEFAULT
VIDEO_STANDARD Address: 004h	15	Not Used			
	14-10	VD_STD[4:0]	Video Data Standard (see Table 12)	R	0
	9	INT_PROG	Interlace/Progressive: Set LOW if detected video standard is PROGRESSIVE and is set HIGH if it is INTERLACED.	R	0
	8	STD_LOCK	Standard Lock: Set HIGH when flywheel has achieved full synchronization.	R	0
	7-4	CDATA_FORMAT[3:0]	Chroma Data Format. Set HIGH in SD mode. Indicates chroma data format in HD mode (see Table 10).	R	F <sub>h</sub>
	3-0	YDATA_FORMAT[3:0]	Luma Data Format. Indicates Luma data format in HD mode and data format in SD mode (see Table 10).	R	F <sub>h</sub>

Table 8: Host Interface Description for Raster Structure Registers

REGISTER NAME	BIT	NAME	DESCRIPTION	R/W	DEFAULT
RASTER_STRUCTURE1 Address: 014h	15-12	Not Used			
	11-0	RASTER_STRUCTURE1[11:0]	Words Per Active Line.	R	0
RASTER_STRUCTURE2 Address: 015h	15-12	Not Used			
	11-0	RASTER_STRUCTURE2[11:0]	Words Per Total Line.	R	0
RASTER_STRUCTURE3 Address: 016h	15-11	Not Used

RASTER_STRUCTURE4 Address: 017h	15-11	Not Used			
	10-0	RASTER_STRUCTURE4[10:0]	Active Lines Per Field.	R	0

#### 3.10.4.1 Video Standard Indication

The video standard codes reported in the VD\_STD[4:0] bits of the VIDEO\_STANDARD register represent the SMPTE standards as shown in Table 9 below.

In addition to the 5-bit video standard code word, the VIDEO\_STANDARD register also contains two status bits. The STD\_LOCK bit will be set HIGH whenever the flywheel has achieved full synchronization. The INT\_PROG bit will be set HIGH if the detected video standard is progressive and LOW if the detected video standard is interlaced.

The VD\_STD[4:0], STD\_LOCK and INT\_PROG bits of the VIDEO\_STANDARD register will default to zero after device reset or power up. These bits will also default to zero if the device loses lock to the input data stream, (LOCKED = LOW), or if the SMPTE\_BYPASS pin is asserted LOW.

Table 9: Supported Video Standards

VD_STD[4:0]	SMPTE STANDARD	VIDEO FORMAT	LENGTH OF HANC	LENGTH OF ACTIVE VIDEO	TOTAL SAMPLES	SMPTE352M LINES
00h	296M (HD)	1280x720/60 (1:1)	358	1280	1650	13

### 3.10.4.2 Data Format Indication

The luma and chroma data format codes will be reported in the YDATA\_FORMAT[3:0] and CDATA\_FORMAT[3:0] bits of the VIDEO\_STANDARD register when the device is operating in HD mode, ( $\overline{SD/\overline{HD}} = \text{LOW}$ ).

In SD or DVB-ASI mode, the data format code will only appear in the YDATA\_FORMAT[3:0] bits. The CDATA\_FORMAT[3:0] bits will be set to 'F<sub>h</sub>'. These codes represent the data formats listed in Table 10.

The YDATA\_FORMAT[3:0] and CDATA\_FORMAT[3:0] bits of the VIDEO\_STANDARD register will default to 'F<sub>h</sub>' after device reset or power up. These bits will also default to 'F<sub>h</sub>' if the device loses lock to the input data stream, ( $\text{LOCKED} = \text{LOW}$ ), or if Data-Through mode is enabled, (see section 3.9).

Table 10: Data Format Codes

YDATA_FORMAT[3:0] OR CDATA_FORMAT[3:0]	DATA FORMAT	APPLICABLE STANDARDS
0h	SDTI DVCPRO - No ECC	SMPTE 321M
1h	SDTI DVCPRO - ECC	SMPTE 321M
2h	SDTI DVCAM	SMPTE 322M
3h	SDTI CP	SMPTE 326M
4h	Other SDTI fixed block size	-
5h	Other SDTI variable block size	-
6h	SDI	-
7h	DVB-ASI	-
8h	TDM data	SMPTE 346M
9h ~ Eh	Reserved	
Fh	Unknown data format	-

### 3.10.5 Error Detection and Indication

The GS1560A contains a number of error detection functions to enhance operation of the device when operating in SMPTE mode. These functions, (except lock error detection), will not be available in either DVB-ASI or Data-Through operating modes (see sections 3.8 and 3.9).

The device maintains an error status register at address 000<sub>h</sub> called ERROR\_STATUS (Table 11). Each type of error has a specific flag or bit in this register which is set HIGH whenever that error is detected.

The ERROR\_STATUS register will be cleared at the start of each video field or when read by the host interface, whichever condition occurs first. This means that the line-based error flags contained in this register are "sticky".

All bits of the ERROR\_STATUS register except the LOCK\_ERR bit will also be cleared if a change in the video standard is detected, or under the following conditions:

- $\overline{\text{RESET\_TRST}}$  is held LOW
- LOCKED is asserted LOW
- $\overline{\text{SMPTE\_BYPASS}}$  is asserted LOW in slave mode

In addition to the ERROR\_STATUS register, a register called ERROR\_MASK (Table 12) is included which allows the host interface to select the specific error conditions that will be detected. There is one bit in the ERROR\_MASK register for each type of error represented in the ERROR\_STATUS register.

The bits of the ERROR\_MASK register will default to '0' after device reset or power up, thus enabling all error types to be detected. The host interface may disable individual error detection by setting the corresponding bit HIGH in this register.

Error conditions are also indicated to the application layer via the status signal pin  $\overline{\text{DATA\_ERROR}}$ . This output pin is a logical 'OR'ing of each error status flag stored in the ERROR\_STATUS register.  $\overline{\text{DATA\_ERROR}}$  is normally HIGH, but will be set LOW by the device when an error condition that has not been masked is detected.

Table 11: Host Interface Description for Error Status Register

REGISTER NAME	BIT	NAME	DESCRIPTION	R/W	DEFAULT
ERROR_STATUS Address: 001h	15-11	Not Used			
	10	VD_STD_ERR	Video Standard Error Flag. Set HIGH when a mismatch between the received SMPTE352M packets and the calculated video standard occurs.	R	0
	9	FF_CRC_ERR	Full Field CRC Error Flag. Set HIGH in SD mode when a Full Field (FF) CRC mismatch has been detected in Field 1 or 2.	R	0
	8	AP_CRC_ERR	Active Picture CRC Error Flag. Set HIGH in SD mode when an Active Picture (AP) CRC mismatch has been detected in Field 1 or 2.	R	0
	7	LOCK_ERR	Lock Error Flag. Set HIGH whenever the LOCK pin is LOW (indicating the device not correctly locked).	R	0
	6	CCS_ERR	Chroma Checksum Error Flag. Set HIGH when ancillary data packet checksum error has been detected in the C channel.	R	0
	5	YCS_ERR	Luma Checksum Error Flag. Set HIGH when ancillary data packet checksum error has been detected in the Y channel.	R	0
	4	CCRC_ERR	Chroma CRC Error Flag. Set HIGH in HD mode when a mismatch occurs between the calculated and received CRC values in the C channel.	R	0
	3	YCRC_ERR	Luma CRC Error Flag. Set HIGH in HD mode when a mismatch occurs between the calculated and received CRC values in the Y channel.	R	0
	2	LNUM_ERR	Line Number Error Flag. Set HIGH in HD mode when a mismatch occurs between the calculated and received line numbers.	R	0
	1	SAV_ERR	Start of Active Video Error Flag. Set HIGH when TRS errors are detected in either 8-bit or 10-bit TRS words. In HD mode only Y channel TRS codes will be checked. FW_EN/DIS must be set HIGH.	R	0
	0	EAV_ERR	End of Active Video Error Flag. Set HIGH when TRS errors are detected in either 8-bit or 10-bit TRS words. In HD mode only Y channel TRS codes will be checked. FW_EN/DIS must be set HIGH.	R	0

Table 12: Host Interface Description for Error Mask Register

REGISTER NAME	BIT	NAME	DESCRIPTION	R/W	DEFAULT
ERROR_MASK Address: 026h	15-11	Not Used			
	10	VD_STD_ERR_MASK	Video Standard Error Flag Mask bit.	R/W	0
	9	FF_CRC_ERR_MASK	Full Field CRC Error Flag Mask bit.	R/W	0
	8	AP_CRC_ERR_MASK	Active Picture CRC Error Flag Mask bit.	R/W	0
	7	LOCK_ERR_MASK	Lock Error Flag Mask bit.	R/W	0
	6	CCS_ERR_MASK	Chroma Checksum Error Flag Mask bit.	R/W	0
	5	YCS_ERR_MASK	Luma Checksum Error Flag Mask bit.	R/W	0
	4	CCRC_ERR_MASK	Chroma CRC Error Flag Mask bit.	R/W	0
	3	YCRC_ERR_MASK	Luma CRC Error Flag Mask bit.	R/W	0
	2	LNUM_ERR_MASK	Line Number Error Flag Mask bit.	R/W	0
	1	SAV_ERR_MASK	Start of Active Video Error Flag Mask bit.	R/W	0
	0	EAV_ERR_MASK	End of Active Video Error Flag Mask bit.	R/W	0

#### 3.10.5.1 Video Standard Error Detection

If a mismatch between the received SMPTE 352M packets and the calculated video standard occurs, the GS1560A will indicate a video standard error by setting the VD\_STD\_ERR bit of the ERROR\_STATUS register HIGH.

#### 3.10.5.2 EDH CRC Error Detection

The GS1560A calculates Full Field (FF) and Active Picture (AP) CRC words according to SMPTE RP165 in support of Error Detection and Handling packets in SD signals.

These calculated CRC values are compared with the received CRC values. If a mismatch is detected, the error is flagged in the AP\_CRC\_ERR and/or FF\_CRC\_ERR bits of the ERROR\_STATUS register. These two flags are shared between fields 1 and 2.

The AP\_CRC\_ERR bit will be set HIGH when an active picture CRC mismatch has been detected in field 1 or 2. The FF\_CRC\_ERR bit will be set HIGH when a full field CRC mismatch has been detected in field 1 or 2.

EDH CRC errors will only be indicated when the device is operating in SD mode ( $SD/\overline{HD} = HIGH$ ), and when the device has correctly received EDH packets.

SMPTE RP165 specifies the calculation ranges and scope of EDH data for standard 525 and 625 component digital interfaces. The GS1560A will utilize these standard ranges by default.

If the received video format does not correspond to 525 or 625 digital component video standards as determined by the flywheel pixel and line counters, then one of two schemes for determining the EDH calculation ranges will be employed:

1. Ranges will be based on the line and pixel ranges programmed by the host interface; or
2. In the absence of user-programmed calculation ranges, ranges will be determined from the received TRS timing information.

The registers available to the host interface for programming EDH calculation ranges include active picture and full field line/pixel start and end positions for both fields. Table 13 shows the relevant registers, which default to '0' after device reset or power up.

If any or all of these register values are zero, then the EDH CRC calculation ranges will be determined from the flywheel generated H signal. The first active and full field pixel will always be the first pixel after the SAV TRS code word. The last active and full field pixel will always be the last pixel before the start of the EAV TRS code words.

Table 13: Host Interface Description for EDH Calculation Range Registers

REGISTER NAME	BIT	NAME	DESCRIPTION	R/W	DEFAULT
AP_LINE_START_F0 Address: 018h	15-10	Not Used			
	9-0	AP_LINE_START_F0[9:0]	Field 0 Active Picture start line data used to set EDH calculation range outside of SMPTE RP 165 values.	R/W	0
AP_LINE_END_F0 Address: 019h	15-10	Not Used			
	9-0	AP_LINE_END_F0[9:0]	Field 0 Active Picture end line data used to set EDH calculation range outside of SMPTE RP 165 values.	R/W	0
AP_LINE_START_F1 Address: 020h	15-10	Not Used			
	9-0	AP_LINE_START_F1[9:0]	Field 1 Active Picture end line data used to set EDH calculation range outside of SMPTE RP 165 values.	R/W	0
AP_LINE_END_F1 Address: 021h	15-10	Not Used			
	9-0	AP_LINE_END_F1[9:0]	Field 1 Active Picture end line data used to set EDH calculation range outside of SMPTE RP 165 values.	R/W	0
FF_LINE_START_F0 Address: 022h	15-10	Not Used			
	9-0	FF_LINE_START_F0[9:0]	Field 0 Full Field start line data used to set EDH calculation range outside of SMPTE RP 165 values.	R/W	0
FF_LINE_END_F0 Address: 023h	15-10	Not Used			
	9-0	FF_LINE_END_F0[9:0]	Field 0 Full Field start line data used to set EDH calculation range outside of SMPTE RP 165 values.	R/W	0
FF_LINE_START_F1 Address: 024h	15-10	Not Used			
	9-0	FF_LINE_START_F1[9:0]	Field 1 Full Field start line data used to set EDH calculation range outside of SMPTE RP 165 values.	R/W	0
FF_LINE_END_F1 Address: 025h	15-10	Not Used			
	9-0	FF_LINE_END_F1[9:0]	Field 1 Full Field end line data used to set EDH calculation range outside of SMPTE RP 165 values.	R/W	0

### 3.10.5.3 Lock Error Detection

The LOCKED pin of the GS1560A indicates the lock status of the reclocker and lock detect blocks of the device. Only when the LOCKED pin is asserted HIGH has the device correctly locked to the received data stream, (see section 3.6.1).

The GS1560A will also indicate lock error to the host interface when LOCKED = LOW by setting the LOCK\_ERR bit in the ERROR\_STATUS register HIGH.

### 3.10.5.4 Ancillary Data Checksum Error Detection

The GS1560A will calculate checksums for all received ancillary data and compare the calculated values to the received checksum words. If a mismatch is detected, the error is flagged in the CCS\_ERR and/or YCS\_ERR bits of the ERROR\_STATUS register.

When operating in HD mode, ( $\overline{SD/HD}$  = LOW), the device will make comparisons on both the Y and C channels separately. If an error condition in the Y channel is detected, the YCS\_ERR bit will be set HIGH. If an error condition in the C channel is detected, the CCS\_ERR bit will be set HIGH.

When operating in SD mode, ( $\overline{SD/HD}$  = HIGH), only the YCS\_ERR bit will be set HIGH when checksum errors are detected.

Although the GS1560A will calculate and compare checksum values for all ancillary data types by default, the host interface may program the device to check only certain types of ancillary data checksums.

This is accomplished via the ANC\_TYPE register as described in section 3.10.2.1.

### 3.10.5.5 Line Based CRC Error Detection

The GS1560A will calculate line based CRC words for HD video signals for both the Y and C data channels. These calculated CRC values are compared with the received CRC values and any mismatch is flagged in the YCRC\_ERR and/or CCRC\_ERR bits of the ERROR\_STATUS register.

Line based CRC error flags will only be generated when the device is operating in HD mode, ( $\overline{SD/HD}$  = LOW).

If a CRC error is detected in the Y channel, the YCRC\_ERR bit in the error status register will be set HIGH. If a CRC error is detected in the C channel, the CCRC\_ERR bit in the error status register is set HIGH. Y and C CRC errors will also be generated if CRC values are not received.

### 3.10.5.6 HD Line Number Error Detection

When operating in HD mode, the GS1560A will calculate line numbers based on the timing generated by the internal flywheel. These calculated line numbers are compared with the received line numbers for the Y channel data and any mismatch is flagged in the LNUM\_ERR bit of the ERROR\_STATUS.

Line number errors will also be generated if line number values are not received.

### 3.10.5.7 TRS Error Detection

TRS errors flags are generated by the GS1560A when:

1. The received TRS timing does not correspond to the internal flywheel timing; or
2. The received TRS hamming codes are incorrect.

Both 8-bit and 10-bit SAV and EAV TRS words are checked for timing and data integrity errors. These are flagged via the SAV\_ERR and/or EAV\_ERR bits of the ERROR\_STATUS register.

Timing-based TRS errors will only be generated if the FW\_EN/ $\overline{DIS}$  pin is set HIGH.

*NOTE: In HD mode, ( $\overline{SD/HD}$  = LOW), only the Y channel TRS codes will be checked for errors.*

### 3.10.6 Error Correction and Insertion

In addition to signal error detection and indication, the GS1560A may also correct certain types of errors by inserting corrected code words, checksums and CRC values into the data stream. These features are only available in SMPTE mode and IOPROC\_EN/ $\overline{DIS}$  must be set HIGH. Individual correction features may be enabled or disabled via the IOPROC\_DISABLE register (Table 14).

All of the IOPROC\_DISABLE register bits default to '0' after device reset or power up, enabling all of the processing features. To disable any individual error correction feature, the host interface must set the corresponding bit HIGH in the IOPROC\_DISABLE register.

Table 14: Host Interface Description for Internal Processing Disable Register

REGISTER NAME	BIT	BIT NAME	DESCRIPTION	R/W	DEFAULT	
IOPROC_DISABLE Address: 000h	15-9	Not Used				
	8	H_CONFIG	Horizontal sync timing output configuration. Set LOW for active line blanking timing. Set HIGH for H blanking based on the H bit setting of the TRS words. See Figure 8.		0	
	7	Not Used				
	6	Not Used				
	5	ILLEGAL_REMAP	Illegal Code re-mapping. Correction of illegal code words within the active picture. Set HIGH to disable. The IOPROC_EN/DIS pin must be set HIGH.	R/W	0	
	4	EDH_CRC_INS	Error Detection & Handling (EDH) Cyclical Redundancy Check (CRC) error correction insertion. In SD mode set HIGH to disable. The IOPROC_EN/DIS pin must be set HIGH.	R/W	0	
	3	ANC_CSUM_INS	Ancillary Data Check-sum insertion. Set HIGH to disable. The IOPROC_EN/DIS pin must be set HIGH.	R/W	0	
	2	CRC_INS	Y and C line based CRC insertion. In HD mode, inserts line based CRC words in both the Y and C channels. Set HIGH to disable. The IOPROC_EN/DIS pin must be set HIGH.	R/W	0	
	1	LNUM_INS	Y and C line number insertion. In HD mode set HIGH to disable. The IOPROC_EN/DIS pin must be set HIGH.	R/W	0	
	0	TRS_INS	Timing Reference Signal Insertion. Set HIGH to disable. The IOPROC_EN/DIS pin must be set HIGH.	R/W	0	

### 3.10.6.1 Illegal Code Remapping

If the ILLEGAL\_REMAP bit of the IOPROC\_DISABLE register is set LOW, the GS1560A will remap all codes within the active picture between the values of 3FCh and 3FFh to 3FBh. All codes within the active picture area between the values of 000h and 003h will be re-mapped to 004h.

In addition, 8-bit TRS and ancillary data preambles will be remapped to 10-bit values if this feature is enabled.

### 3.10.6.2 EDH CRC Error Correction

The GS1560A will generate and insert active picture and full field CRC words into the EDH data packets received by the device. This feature is only available in SD mode and is enabled by setting the EDH\_CRC\_INS bit of the IOPROC\_DISABLE register LOW.

EDH CRC calculation ranges are described in section 3.10.5.2.

*NOTE: Although the GS1560A will modify and insert EDH CRC words and EDH packet checksums, EDH error flags will not be updated by the device.*

### 3.10.6.3 Ancillary Data Checksum Error Correction

When ancillary data checksum error correction and insertion is enabled, the GS1560A will generate and insert ancillary data checksums for all ancillary data words by default. Where user specified ancillary data has been programmed into the device (see section 3.10.2.1), only the checksums for the programmed ancillary data types will be corrected.

This feature is enabled when the ANC\_CSUM\_INS bit of the IOPROC\_DISABLE register is set LOW.

### 3.10.6.4 Line Based CRC Correction

The GS1560A will generate and insert line based CRC words into both the Y and C channels of the data stream. This feature is only available in HD mode and is enabled by setting the CRC\_INS bit of the IOPROC\_DISABLE register LOW.

### 3.10.6.5 HD Line Number Error Correction

In HD mode, the GS1560A will calculate and insert line numbers into the Y and C channels of the output data stream.

Line number generation is in accordance with the relevant HD video standard as determined by the device, (see section 3.10.4).

This feature is enabled when  $\overline{SD/HD}$  = LOW, and the LNUM\_INS bit of the IOPROC\_DISABLE register is set LOW.

### 3.10.6.6 TRS Error Correction

When TRS error correction and insertion is enabled, the GS1560A will generate and insert 10-bit TRS code words as required.

TRS word generation will be performed in accordance with the timing parameters generated by the flywheel to provide an element of noise immunity. As a result, TRS correction

will only take place if the flywheel is enabled, ( $\overline{FW\_EN/DIS}$  = HIGH).

In addition, the TRS\_INS bit of the IOPROC\_DISABLE register must be set LOW.

### 3.10.7 EDH Flag Detection

As described in section 3.10.5.2, the GS1560A can detect EDH packets in the received data stream. The EDH flags for ancillary data, active picture and full field areas are extracted from the detected EDH packets and placed in the EDH\_FLAG register of the device (Table 15).

One set of flags is provided for both fields 1 and 2. Field 1 flag data will be overwritten by field 2 flag data.

*NOTE: The GS1560A will detect EDH flags, but will not update the flags if an EDH CRC error is detected. Gennum's GS1532 Multi-Rate Serializer allows the host to individually set EDH flags.*

Table 15: Host Interface Description for EDH Flag Register

REGISTER NAME	BIT	NAME	DESCRIPTION	R/W	DEFAULT
EDH_FLAG Address: 003h	15		Not Used		
	14	ANC-UES out	Ancillary Unknown Error Status Flag.	R	0
	13	ANC-IDA out	Ancillary Internal device error Detected Already Flag.	R	0
	12	ANC-IDH out	Ancillary Internal device error Detected Here Flag.	R	0
	11	ANC-EDA out	Ancillary Error Detected Already Flag.	R	0
	10	ANC-EDH out	Ancillary Error Detected Here Flag.	R	0
	9	FF-UES out	Full Field Unknown Error Status Flag.	R	0
	8	FF-IDA out	Full Field Internal device error Detected Already Flag.	R	0
	7	FF-IDH out	Full Field Internal device error Detected Here Flag.	R	0
	6	FF-EDA out	Full Field Error Detected Already Flag.	R	0
	5	FF-EDH out	Full Field Error Detected Here Flag.	R	0
	4	AP-UES out	Active Picture Unknown Error Status Flag.	R	0
	3	AP-IDA out	Active Picture Internal device error Detected Already Flag.	R	0
	2	AP-IDH out	Active Picture Internal device error Detected Here Flag.	R	0
	1	AP-EDA out	Active Picture Error Detected Already Flag.	R	0
0	AP-EDH out	Active Picture Error Detected Here Flag.	R	0	

### 3.11 PARALLEL DATA OUTPUTS

Data outputs leave the device on the rising edge of PCLK as shown in Figures 12a and 12b.

The data may be scrambled or unscrambled, framed or unframed, and may be presented in 10-bit or 20-bit format. The output data bus width is controlled independently from the internal data bus width by the 20bit/10bit input pin.

Likewise, the output data format is defined by the setting of the external SD/HD, SMPTE\_BYPASS and DVB-ASI pins. Recall that in slave mode, these pins are set by the application layer as inputs to the device. In master mode, however, the GS1560A sets these pins as output status signals.

#### 3.11.1 Parallel Data Bus Buffers

The parallel data outputs of the GS1560A are driven by high-impedance buffers which support both LVTTTL and LVCMOS levels. These buffers use a separate power supply of +3.3V DC supplied via the IO\_VDD and IO\_GND pins.

All output buffers, including the PCLK output, may be driven to a high-impedance state if the RESET\_TRST signal is asserted LOW, or if power on reset is active.

Note that the timing characteristics of the parallel data output buffers are optimized for 10-bit HD operation. As shown in figure 12a, the output data hold time for HD is 1.5ns.

Due to this optimization, however, the output data hold time for SD data is so small that the rising edge of the PCLK is nearly incident with the data transition. To improve output hold time at SD rates, the PCLK output is inverted in SD mode, (SD/HD = HIGH). This is shown in figure 12b.

Fig. 12a HD PCLK to Data Timing

Fig. 12b SD PCLK to Data Timing

#### 3.11.2 Parallel Output in SMPTE Mode

When the device is operating in SMPTE mode, (see section 3.7), both SD and HD data may be presented to the output bus in either multiplexed or demultiplexed form depending on the setting of the 20bit/10bit input pin.

In 20-bit mode, (20bit/10bit = HIGH), the output data will be word aligned, demultiplexed luma and chroma data. Luma words will always appear on DOUT[19:10] while chroma words will occupy DOUT[9:0].

In 10-bit mode, (20bit/10bit = LOW), the output data will be word aligned, multiplexed luma and chroma data. The data will be presented on DOUT[19:10], and the device will force DOUT[9:0] LOW.

#### 3.11.3 Parallel Output in DVB-ASI Mode

When operating in DVB-ASI mode, (see section 3.8), the GS1560A automatically configures the output port for 10-bit operation regardless of the setting of the 20bit/10bit pin.

The extracted 8-bit data words will be presented on DOUT[17:10] such that DOUT17 = HOUT is the most significant bit of the decoded transport stream data and DOUT10 = AOUT is the least significant bit.

In addition, DOUT19 and DOUT18 will be configured as the DVB-ASI status signals SYNCOUT and WORDERR respectively. See section 3.8.2 for a description of these DVB-ASI specific output signals.

DOUT[9:0] will be forced LOW when the GS1560A is operating in DVB-ASI mode.

#### 3.11.4 Parallel Output in Data-Through Mode

When operating in Data-Through mode, (see section 3.9), the GS1560A presents data to the output data bus without performing any decoding, descrambling or word-alignment.

As described in section 3.9, the data bus outputs will be forced to logic LOW if the device is set to operate in master mode but cannot identify SMPTE TRS ID or DVB-ASI sync words in the input data stream.

### 3.11.5 Parallel Output Clock (PCLK)

The frequency of the PCLK output signal of the GS1560A is determined by the output data format. Table 16 below lists the possible output signal formats and their corresponding

parallel clock rates. Note that DVB-ASI output will always be in 10-bit format, regardless of the setting of the 20bit/10bit pin.

TABLE 16: Parallel Data Output Format

OUTPUT DATA FORMAT	STATUS / CONTROL SIGNALS*				DOUT [19:10]	DOUT [9:0]	PCLK
	20bit/10bit	SD/HD	SMPTE_BYPASS	DVB_ASI			
SMPTE MODE							
20bit DEMULTIPLEXED SD	HIGH	HIGH	HIGH	LOW	LUMA	CHROMA	13.5MHz
10bit MULTIPLEXED SD	LOW	HIGH			LUMA / CHROMA	FORCED LOW	27MHz
20bit DEMULTIPLEXED HD	HIGH	LOW			LUMA	CHROMA	74.25 or 74.25/1.001MHz
10bit MULTIPLEXED HD	LOW	LOW			LUMA / CHROMA	FORCED LOW	148.5 or 148.5/1.001MHz
DVB-ASI MODE							
10bit DVB-ASI	HIGH	HIGH	LOW	HIGH	DVB-ASI DATA	FORCED LOW	27MHz
	LOW						
DATA-THROUGH MODE**							
20bit DEMULTIPLEXED SD	HIGH	HIGH	LOW	LOW	LUMA	CHROMA	13.5MHz
10bit MULTIPLEXED SD	LOW	HIGH			LUMA / CHROMA	FORCED LOW	27MHz
20bit DEMULTIPLEXED HD	HIGH	LOW			LUMA	CHROMA	74.25 or 74.25/1.001MHz
10bit MULTIPLEXED HD	LOW	LOW			LUMA / CHROMA	FORCED LOW	148.5 or 148.5/1.001MHz

\*NOTE1: Recall that SD/HD, SMPTE\_BYPASS, and DVB\_ASI are input control pins in slave mode to be set by the application layer, but are output status signals set by the device in master mode.

\*\*NOTE2: Data-Through mode is only available in slave mode (see section 3.9).

### 3.12 GSPI HOST INTERFACE

The GSPI, or Genum Serial Peripheral Interface, is a 4-wire interface provided to allow the host to enable additional features of the device and /or to provide additional status information through configuration registers in the GS1560A.

The GSPI comprises a serial data input signal SDIN, serial data output signal SDOUT, an active low chip select  $\overline{CS}$ , and a burst clock SCLK.

Because these pins are shared with the JTAG interface port, an additional control signal pin JTAG/HOST is provided. When JTAG/HOST is LOW, the GSPI interface is enabled.

When operating in GSPI mode, the SCLK, SDIN, and  $\overline{CS}$  signals are provided by the host interface. The SDOUT pin is a high-impedance output allowing multiple devices to be

connected in parallel and selected via the  $\overline{CS}$  input. The interface is illustrated in the Figure 13 below.

All read or write access to the GS1560A is initiated and terminated by the host processor. Each access always begins with a 16-bit command word on SDIN indicating the address of the register of interest. This is followed by a 16-bit data word on SDIN in write mode, or a 16-bit data word on SDOUT in read mode.

Fig. 13 Gennum Serial Peripheral Interface (GSPPI)

### 3.12.1 Command Word Description

The command word is transmitted MSB first and contains a read/write bit, nine reserved bits and a 6-bit register address.

Command words are clocked into the GS1560A on the rising edge of the serial clock SCLK. The appropriate chip

select,  $\overline{CS}$ , signal must be asserted low a minimum of 1.5ns ( $t_0$  in Figures 16 and 17) before the first clock edge to ensure proper operation.

Each command word must be followed by only one data word to ensure proper operation.

Fig. 14 Command Word

Fig. 15 Data Word

### 3.12.2 Data Read and Write Timing

Read and write mode timing for the GSPPI interface is shown in Figures 16 and 17 respectively. The maximum SCLK frequency allowed is 6.6MHz.

When writing to the registers via the GSPPI, the MSB of the data word may be presented to SDIN immediately following

the falling edge of the LSB of the command word. All SDIN data is sampled on the rising edge of SCLK.

When reading from the registers via the GSPPI, the MSB of the data word will be available on SDOOUT 12ns following the falling edge of the LSB of the command word, and thus may be read by the host on the very next rising edge of the clock. The remaining bits are clocked out by the GS1560A on the negative edges of SCLK.

Fig. 16 GSPPI Read Mode Timing

Fig. 17 GSPPI Write Mode Timing

**3.12.3 Configuration and Status Registers**

Table 17 summarizes the GS1560A's internal status and configuration registers.

All of these registers are available to the host via the GSPI and are all individually addressable.

Where status registers contain less than the full 16 bits of information however, two or more registers may be combined at a single logical address.

Table 17: GS1560A internal registers

ADDRESS	REGISTER NAME	SEE SECTION
000h	IOPROC_DISABLE	3.10.6
001h	ERROR_STATUS	3.10.5
003h	EDH_FLAG	3.10.7
004h	VIDEO_STANDARD	3.10.4
005h - 009h	ANC_TYPE	3.10.2.1
012h - 013h	VIDEO_FORMAT	3.10.3
014h - 017h	RASTER_STRUCTURE	3.10.4
018h - 025h	EDH_CALC_RANGES	3.10.5.2
026h	ERROR_MASK	3.10.5

**3.13 JTAG**

When the JTAG/ $\overline{\text{HOST}}$  input pin of the GS1560A is set HIGH, the host interface port will be configured for JTAG test operation. In this mode, pins 27 through 30 become TMS, TDO, TDI, and TCK. In addition, the  $\overline{\text{RESET\_TRST}}$  pin will operate as the test reset pin.

Boundary scan testing using the JTAG interface will be enabled in this mode.

There are two methods in which JTAG can be used on the GS1560A:

1. As a stand-alone JTAG interface to be used at in-circuit ATE (Automatic Test Equipment) during PCB assembly; or
2. Under control of the host for applications such as system power on self tests.

When the JTAG tests are applied by ATE, care must be taken to disable any other devices driving the digital I/O pins. If the tests are to be applied only at ATE, this can be accomplished with tri-state buffers used in conjunction with the JTAG/ $\overline{\text{HOST}}$  input signal. This is shown in Figur 18.

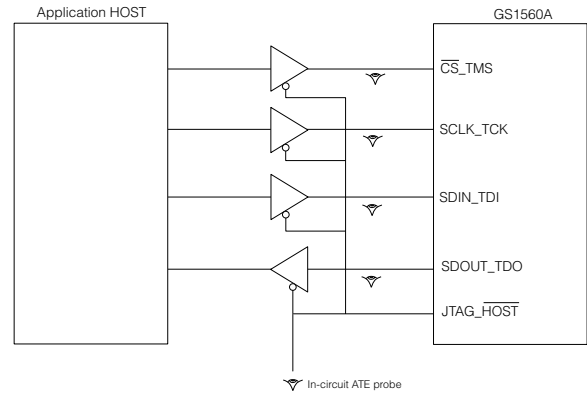

Fig. 18 In-Circuit JTAG

Alternatively, if the test capabilities are to be used in the system, the host may still control the JTAG/ $\overline{\text{HOST}}$  input signal, but some means for tri-stating the host must exist in order to use the interface at ATE. This is represented in Figure 19.

Fig. 19 System JTAG

Please contact your Gennum representative to obtain the BSDL model for the GS1560A.

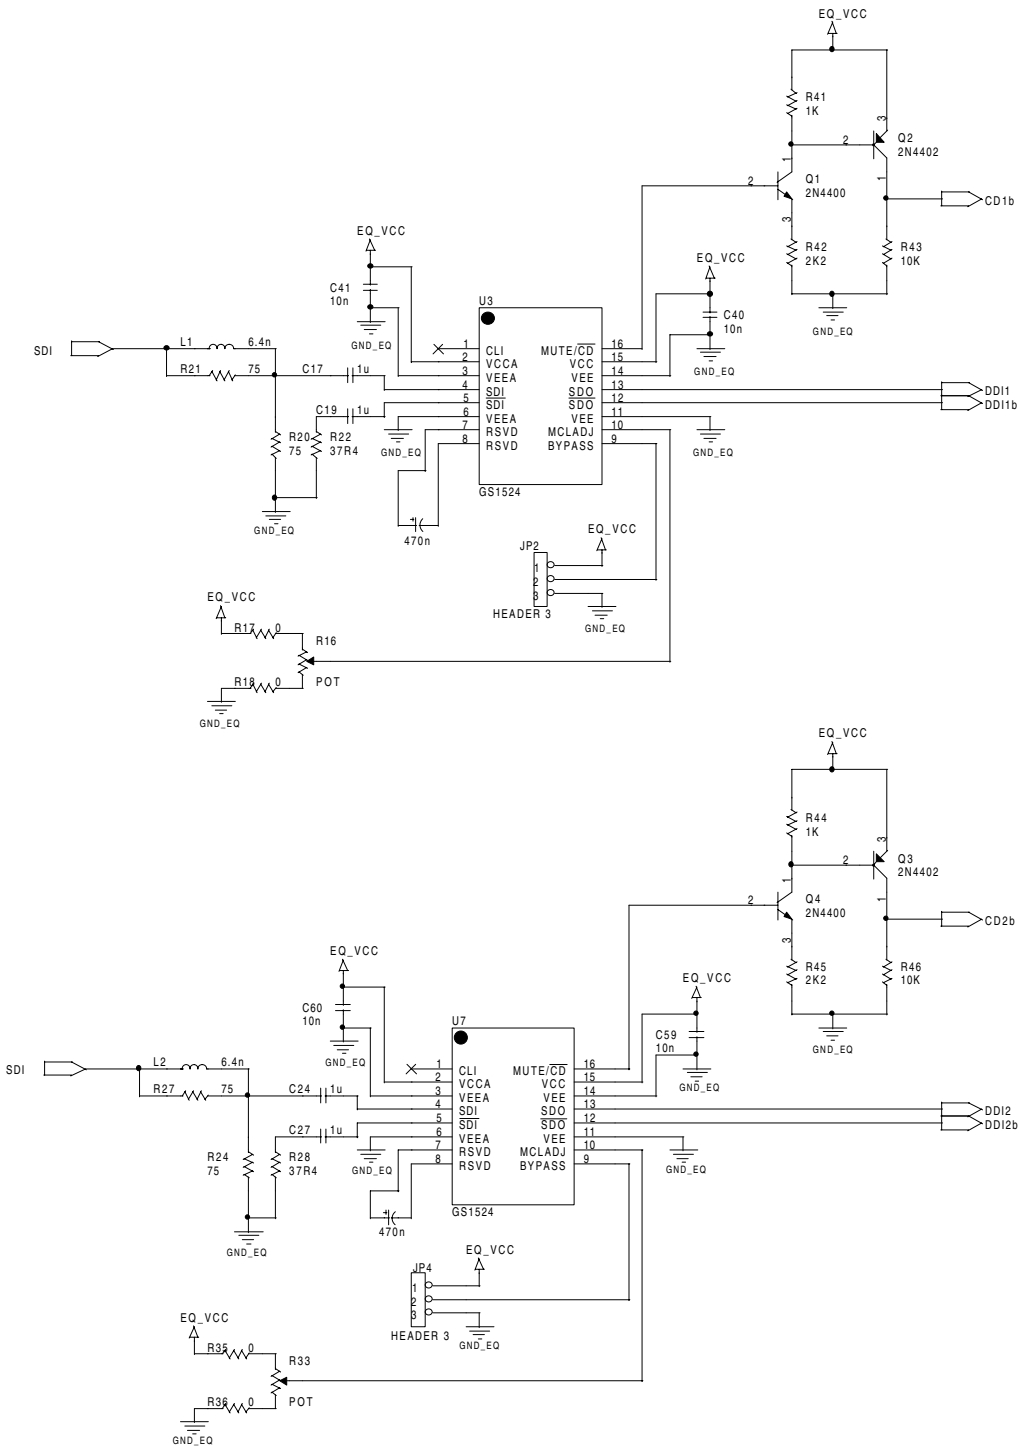

**3.14 DEVICE POWER UP**

Because the GS1560A is designed to operate in a multi-volt environment, any power up sequence is allowed. The charge pump, phase detector, core logic, serial digital input / output buffers and digital I/O buffers should all be powered up within 1ms of one another.

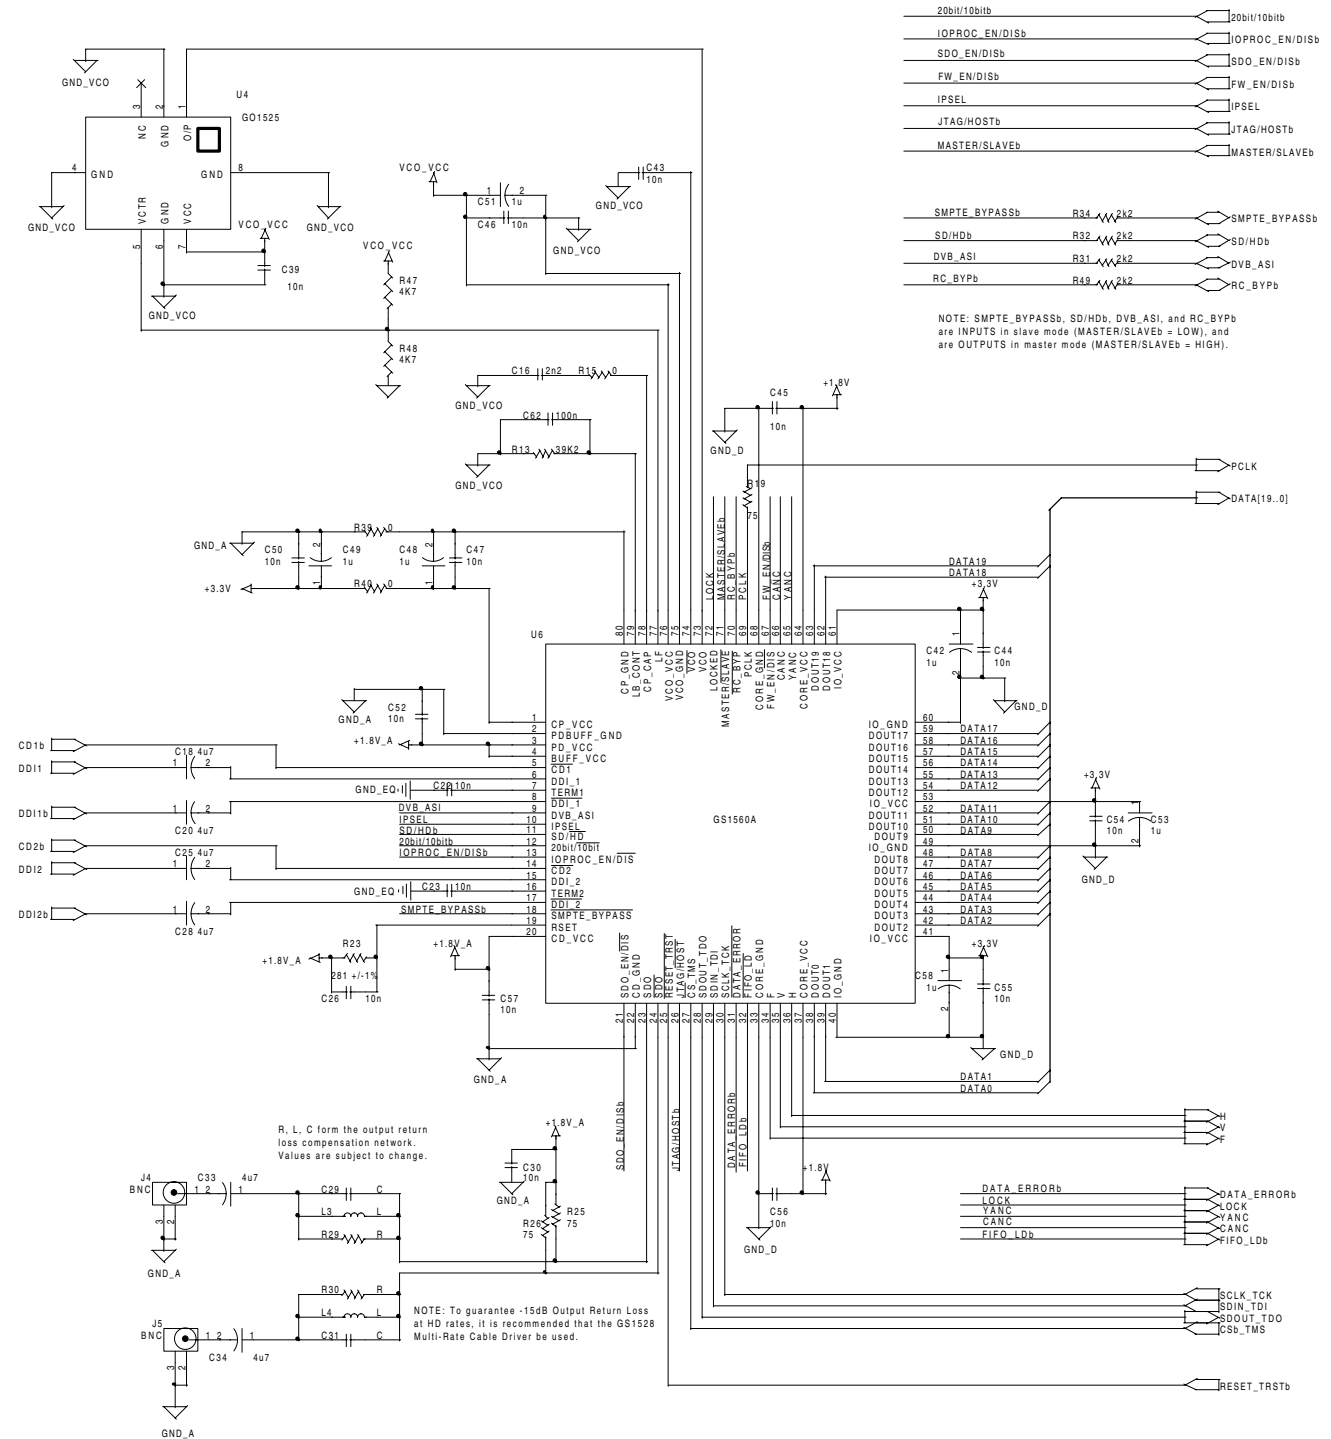

Device pins may also be driven prior to power up without causing damage.
