| $\mathrm{I}_{\mathrm{N}}$ | Stand By Current | $\mathrm{V}_{\mathrm{IN}}=40 \mathrm{~V}$ (Note 6) | 5 | 10 |  | 5 | 10 |  | mA |

Note 1: Unless otherwise stated, these specifications apply for $T_{A}=T_{J}=25^{\circ} \mathrm{C}$. Boldface numbers apply over the rated temperature range: LM 2524 D is $-40^{\circ}$ to $85^{\circ} \mathrm{C}$ and LM 3524 D is $0^{\circ} \mathrm{C}$ to $70^{\circ} \mathrm{C}$. $\mathrm{V}_{\mathrm{IN}}=20 \mathrm{~V}$ and f Osc $=20 \mathrm{kHz}$.
Note 2: For operation at elevated temperatures, devices in the $N$ package must be derated based on a thermal resistance of $86^{\circ} \mathrm{C} / \mathrm{W}$, junction to ambient. Devices in the M package must be derated at $125^{\circ} \mathrm{C} / \mathrm{W}$, junction to ambient.
Note 3: Tested limits are guaranteed and $100 \%$ tested in production.
Note 4: Design limits are guaranteed (but not $100 \%$ production tested) over the indicated temperature and supply voltage range. These limits are not used to calculate outgoing quality level.
Note 5: Absolute maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications do not apply when operating the device beyond its rated operating conditions.
Note 6: Pins 1, 4, 7, 8, 11, and 14 are grounded; Pin $2=2$ V. All other inputs and outputs open.
Note 7: The value of a $C_{t}$ capacitor can vary with frequency. Careful selection of this capacitor must be made for high frequency operation. Polystyrene was used in this test. NPO ceramic or polypropylene can also be used.
Note 8: OSC amplitude is measured open circuit. Available current is limited to 1 mA so care must be exercised to limit capacitive loading of fast pulses.

## Functional Description

## INTERNAL VOLTAGE REGULATOR

The LM3524D has an on-chip 5V, 50 mA , short circuit protected voltage regulator. This voltage regulator provides a supply for all internal circuitry of the device and can be used as an external reference.
For input voltages of less than 8 V the 5 V output should be shorted to pin $15, \mathrm{~V}_{\mathrm{IN}}$, which disables the 5 V regulator. With these pins shorted the input voltage must be limited to a maximum of 6 V . If input voltages of $6 \mathrm{~V}-8 \mathrm{~V}$ are to be used, a pre-regulator, as shown in Figure 1, must be added.

*Minimum $\mathrm{C}_{\mathrm{O}}$ of $10 \mu \mathrm{~F}$ required for stability.
FIGURE 1.

## OSCILLATOR

The LM3524D provides a stable on-board oscillator. Its frequency is set by an external resistor, $R_{T}$ and capacitor, $\mathrm{C}_{\mathrm{T}}$. A graph of $R_{T}, C_{T}$ vs oscillator frequency is shown is Figure 2. The oscillator's output provides the signals for triggering an internal flip-flop, which directs the PWM information to the outputs, and a blanking pulse to turn off both outputs during transitions to ensure that cross conduction does not occur. The width of the blanking pulse, or dead time, is controlled by the value of $C_{T}$, as shown in Figure 3. The recommended values of $R_{T}$ are $1.8 \mathrm{k} \Omega$ to $100 \mathrm{k} \Omega$, and for $\mathrm{C}_{\mathrm{T}}, 0.001 \mu \mathrm{~F}$ to $0.1 \mu \mathrm{~F}$.
If two or more LM3524D's must be synchronized together, the easiest method is to interconnect all pin 3 terminals, tie all pin 7's (together) to a single $\mathrm{C}_{\mathrm{T}}$, and leave all pin 6's open except one which is connected to a single $R_{T}$. This method works well unless the LM3524D's are more than 6" apart.
A second synchronization method is appropriate for any circuit layout. One LM3524D, designated as master, must have its $R_{T} C_{T}$ set for the correct period. The other slave LM3524D(s) should each have an $\mathrm{R}_{\mathrm{T}} \mathrm{C}_{\mathrm{T}}$ set for a $10 \%$ longer period. All pin 3's must then be interconnected to allow the master to properly reset the slave units.
The oscillator may be synchronized to an external clock source by setting the internal free-running oscillator frequency $10 \%$ slower than the external clock and driving pin 3 with a pulse train (approx. 3V) from the clock. Pulse width should be greater than 50 ns to insure full synchronization.

FIGURE 2.

FIGURE 3.

## ERROR AMPLIFIER

The error amplifier is a differential input, transconductance amplifier. Its gain, nominally 86 dB , is set by either feedback or output loading. This output loading can be done with either purely resistive or a combination of resistive and reactive components. A graph of the amplifier's gain vs output load resistance is shown in Figure 4.

FIGURE 4.
The output of the amplifier, or input to the pulse width modulator, can be overridden easily as its output impedance is very high ( $Z_{O} \cong 5 \mathrm{M} \Omega$ ). For this reason a DC voltage can be

## Functional Description <br> (Continued)

applied to pin 9 which will override the error amplifier and force a particular duty cycle to the outputs. An example of this could be a non-regulating motor speed control where a variable voltage was applied to pin 9 to control motor speed. A graph of the output duty cycle vs the voltage on pin 9 is shown in Figure 5.
The duty cycle is calculated as the percentage ratio of each output's ON-time to the oscillator period. Paralleling the outputs doubles the observed duty cycle.

FIGURE 5.
The amplifier's inputs have a common-mode input range of $1.5 \mathrm{~V}-5.5 \mathrm{~V}$. The on board regulator is useful for biasing the inputs to within this range.

## CURRENT LIMITING

The function of the current limit amplifier is to override the error amplifier's output and take control of the pulse width. The output duty cycle drops to about $25 \%$ when a current limit sense voltage of 200 mV is applied between the $+C_{L}$ and $-\mathrm{C}_{\mathrm{L}}$ sense terminals. Increasing the sense voltage approximately $5 \%$ results in a $0 \%$ output duty cycle. Care should be taken to ensure the -0.7 V to +1.0 V input common-mode range is not exceeded.
In most applications, the current limit sense voltage is produced by a current through a sense resistor. The accuracy of this measurement is limited by the accuracy of the sense resistor, and by a small offset current, typically $100 \mu \mathrm{~A}$, flowing from +CL to -CL.

## OUTPUT STAGES

The outputs of the LM3524D are NPN transistors, capable of a maximum current of 200 mA . These transistors are driven $180^{\circ}$ out of phase and have non-committed open collectors and emitters as shown in Figure 6.

FIGURE 11. Boosted Current Polarity Inverter

## BASIC SWITCHING REGULATOR THEORY AND APPLICATIONS

The basic circuit of a step-down switching regulator circuit is shown in Figure 12, along with a practical circuit design using the LM3524D in Figure 15.

FIGURE 12. Basic Step-Down Switching Regulator

The circuit works as follows: Q1 is used as a switch, which has ON and OFF times controlled by the pulse width modulator. When Q1 is ON, power is drawn from $\mathrm{V}_{\text {IN }}$ and supplied to the load through L1; $\mathrm{V}_{\mathrm{A}}$ is at approximately $\mathrm{V}_{\mathrm{IN}}$, D 1 is reverse biased, and $\mathrm{C}_{0}$ is charging. When Q1 turns OFF the inductor L1 will force $\mathrm{V}_{\mathrm{A}}$ negative to keep the current flowing in it, D1 will start conducting and the load current will flow through D 1 and L 1 . The voltage at $\mathrm{V}_{\mathrm{A}}$ is smoothed by the L1, $\mathrm{C}_{\mathrm{o}}$ filter giving a clean DC output. The current flowing through L 1 is equal to the nominal DC load current plus some $\Delta \mathrm{I}_{\mathrm{L}}$ which is due to the changing voltage across it. $A$ good rule of thumb is to set $\Delta I_{L P-P} \cong 40 \% \times I_{o}$.

## Typical Applications (Continued)

FIGURE 13. Relation of Switch Timing to Inductor Current in Step-Down Regulator

From the relation $\mathrm{V}_{\mathrm{L}}=\mathrm{L} \frac{\mathrm{d}_{\mathrm{i}}}{\mathrm{d}_{\mathrm{t}}}, \Delta \mathrm{I}_{\mathrm{L}} \cong \frac{\mathrm{V}_{\mathrm{L}} \mathrm{T}}{\mathrm{L} 1}$

$$
\Delta \mathrm{L}_{\mathrm{L}}+=\frac{\left(\mathrm{V}_{\mathrm{IN}}-\mathrm{V}_{0}\right) \mathrm{t}_{\mathrm{ON}}}{\mathrm{~L} 1} ; \Delta \mathrm{L}_{\mathrm{L}}^{-}=\frac{\mathrm{V}_{\mathrm{O}} \mathrm{t}_{\mathrm{OFF}}}{\mathrm{~L} 1}
$$

Neglecting $\mathrm{V}_{\mathrm{SAT}}, \mathrm{V}_{\mathrm{D}}$, and settling $\Delta \mathrm{I}_{\mathrm{L}}^{+}=\Delta \mathrm{I}_{\mathrm{L}}{ }^{-}$;

$$
\mathrm{v}_{\mathrm{O}} \cong \mathrm{~V}_{\mathrm{IN}}\left(\frac{\mathrm{t}_{\mathrm{ON}}}{\mathrm{t}_{\mathrm{OFF}}+\mathrm{t}_{\mathrm{ON}}}\right)=\mathrm{V}_{\mathrm{IN}}\left(\frac{\mathrm{t}_{\mathrm{ON}}}{\mathrm{~T}}\right) ;
$$

where T = Total Period
The above shows the relation between $\mathrm{V}_{\mathrm{IN}}, \mathrm{V}_{\mathrm{o}}$ and duty cycle.

$$
\mathrm{I}_{\mathrm{IN}(\mathrm{DC})}=\mathrm{I}_{\mathrm{OUT}(\mathrm{DC})}\left(\frac{t_{\mathrm{ON}}}{\mathrm{t}_{\mathrm{ON}}+\mathrm{t}_{\mathrm{OFF}}}\right)
$$

as Q1 only conducts during $t_{\mathrm{ON}}$.

$$
\begin{gathered}
P_{I N}=I_{I N(D C)} V_{I N}=\left(I_{O(D C)}\right)\left(\frac{t_{O N}}{t_{O N}+t_{O F F}}\right) V_{I N} \\
P_{O}=I_{O} V_{O}
\end{gathered}
$$

The efficiency, $\eta$, of the circuit is:

$$
\begin{aligned}
\eta \text { MAX } & =\frac{P_{0}}{P_{I N}}=\frac{I_{0} V_{0}}{I_{0} \frac{\left(t_{O N}\right)}{T} V_{I N}+\frac{\left(V_{S A T} t_{O N}+V_{D 1} t_{O F F}\right)}{T} I_{O}} \\
& =\frac{V_{0}}{V_{0}+1} \text { for } V_{S A T}=V_{D 1}=1 V .
\end{aligned}
$$

$\eta$ MAX will be further decreased due to switching losses in Q1. For this reason Q1 should be selected to have the maximum possible $f_{T}$, which implies very fast rise and fall times.

## CALCULATING INDUCTOR L1

$$
\begin{aligned}
t_{O N} \cong & \frac{\left(\Delta I_{\mathrm{L}}+\right) \times \mathrm{L} 1}{\left(\mathrm{~V}_{I N}-\mathrm{V}_{0}\right)}, \mathrm{t}_{\mathrm{OFF}}=\frac{\left(\Delta \mathrm{I}_{\mathrm{L}}^{-}\right) \times \mathrm{L} 1}{\mathrm{~V}_{\mathrm{O}}} \\
\mathrm{t}_{\mathrm{ON}}+\mathrm{t}_{\mathrm{OFF}}=\mathrm{T} & =\frac{\left(\Delta \mathrm{I}_{\mathrm{L}}+\right) \times \mathrm{L} 1}{\left(\mathrm{~V}_{I N}-\mathrm{V}_{\mathrm{Q}}\right)}+\frac{\left(\Delta \mathrm{I}_{\mathrm{L}}^{-}\right) \times \mathrm{L} 1}{\mathrm{~V}_{\mathrm{O}}} \\
& =\frac{0.4 \mathrm{I}_{\mathrm{L} 1}}{\left(\mathrm{~V}_{\mathrm{IN}}-\mathrm{V}_{\mathrm{O}}\right)}+\frac{0.41_{\mathrm{O}} \mathrm{~L} 1}{\mathrm{~V}_{\mathrm{O}}}
\end{aligned}
$$

$$
\mathrm{L} 1=\frac{2.5 \mathrm{~V}_{0}\left(\mathrm{~V}_{\mathrm{IN}}-\mathrm{V}_{0}\right)}{\mathrm{I}_{\mathrm{O}} \mathrm{~V}_{\mathrm{IN}} \mathrm{f}}
$$

where: L1 is in Henrys
f is switching frequency in Hz
Also, see LM1578 data sheet for graphical methods of inductor selection.

## CALCULATING OUTPUT FILTER CAPACITOR $\mathrm{C}_{\mathrm{o}}$ :

Figure 13 shows L1's current with respect to Q1's $t_{O N}$ and $t_{\text {OFF }}$ times ( $\mathrm{V}_{\mathrm{A}}$ is at the collector of Q1). This curent must flow to the load and $\mathrm{C}_{\mathrm{o}}$. $\mathrm{C}_{\mathrm{o}}$ 's current will then be the difference between $\mathrm{I}_{\mathrm{L}}$, and $\mathrm{I}_{\mathrm{o}}$.

$$
I_{o}=I_{L}-I_{o}
$$

From Figure 13 it can be seen that current will be flowing into $\mathrm{C}_{\mathrm{o}}$ for the second half of $\mathrm{t}_{\text {ON }}$ through the first half of $\mathrm{t}_{\text {OFF }}$, or a time, $\mathrm{t}_{\mathrm{ON}} / 2+\mathrm{t}_{\mathrm{OFF}} / 2$. The current flowing for this time is $\Delta \mathrm{I}_{\llcorner } / 4$. The resulting $\Delta \mathrm{V}_{\mathrm{c}}$ or $\Delta \mathrm{V}_{\mathrm{o}}$ is described by:

$$
\text { where: } C \text { is in farads, } T \text { is } \frac{1}{\text { switching frequency }}
$$

$$
\Delta V_{0} \text { is p-p output ripple }
$$

For best regulation, the inductor's current cannot be allowed to fall to zero. Some minimum load current $\mathrm{I}_{\mathrm{o}}$, and thus inductor current, is required as shown below:

$$
\mathrm{I}_{\mathrm{O}(\mathrm{MIN})}=\frac{\left(\mathrm{V}_{\mathrm{IN}}-\mathrm{V}_{0}\right) \mathrm{t}_{\mathrm{ON}}}{2 \mathrm{~L} 1}=\frac{\left(\mathrm{V}_{\mathrm{IN}}-\mathrm{V}_{0}\right) \mathrm{V}_{\mathrm{O}}}{2 \mathrm{fV}_{\mathrm{IN}} \mathrm{~L} 1}
$$

$$
\begin{aligned}
& \Delta \mathrm{V}_{\text {op-p }}=\frac{1}{\mathrm{C}} \times \frac{\Delta \mathrm{I}_{\mathrm{L}}}{4} \times\left(\frac{\mathrm{t}_{\mathrm{ON}}}{2}+\frac{\mathrm{t}_{\mathrm{OFF}}}{2}\right) \\
& =\frac{\Delta I_{\mathrm{L}}}{4 \mathrm{C}}\left(\frac{\mathrm{t}_{\mathrm{ON}}+\mathrm{t}_{\mathrm{OFF}}}{2}\right) \\
& \text { Since } \Delta L_{L}=\frac{V_{0}\left(T-t_{O N}\right)}{L 1} \text { and } t_{O N}=\frac{V_{0} T}{V_{I N}} \\
& \Delta V_{\text {op-p }}=\frac{V_{0}\left(T-\frac{V_{0} T}{V_{I N}}\right)}{4 C L 1}\left(\frac{T}{2}\right)=\frac{\left(V_{I N}-V_{0}\right) V_{0} T^{2}}{8 V_{I N} C_{0} L 1} \text { or } \\
& C_{o}=\frac{\left(V_{I N}-V_{0}\right) V_{0} T^{2}}{8 \Delta V_{0} V_{I N} L 1}
\end{aligned}
$$

Since $\Delta \mathrm{I}_{\mathrm{L}}{ }^{+}=\Delta \mathrm{I}_{\mathrm{L}}{ }^{-}=0.4 \mathrm{I}_{\mathrm{o}}$
Solving the above for L1

## Typical Applications (Continued)

FIGURE 14. Inductor Current Slope in Step-Down Regulator

A complete step-down switching regulator schematic, using the LM3524D, is illustrated in Figure 15. Transistors Q1 and Q2 have been added to boost the output to 1A. The 5V regulator of the LM3524D has been divided in half to bias the error amplifier's non-inverting input to within its common-mode
range. Since each output transistor is on for half the period, actually $45 \%$, they have been paralleled to allow longer possible duty cycle, up to $90 \%$. This makes a lower possible input voltage. The output voltage is set by:

$$
\mathrm{v}_{\mathrm{O}}=\mathrm{V}_{\mathrm{NI}}\left(1+\frac{\mathrm{R} 1}{\mathrm{R} 2}\right)
$$

where $\mathrm{V}_{\mathrm{NI}}$ is the voltage at the error amplifier's non-inverting input.
Resistor R3 sets the current limit to:

$$
\frac{200 \mathrm{mV}}{\mathrm{R} 3}=\frac{200 \mathrm{mV}}{0.15}=1.3 \mathrm{~A} .
$$

Figures 16, 17 and show a PC board layout and stuffing diagram for the 5V, 1A regulator of Figure 15. The regulator's performance is listed in Table 1.

FIGURE 15. 5V, 1 Amp Step-Down Switching Regulator

## Typical Applications (Continued)

## THE STEP-UP SWITCHING REGULATOR

Figure 18 shows the basic circuit for a step-up switching regulator. In this circuit Q1 is used as a switch to alternately apply $\mathrm{V}_{\mathrm{IN}_{N}}$ across inductor L1. During the time, $\mathrm{t}_{\mathrm{ON}}, \mathrm{Q} 1$ is ON and energy is drawn from $\mathrm{V}_{\mathrm{IN}}$ and stored in L1; D1 is reverse biased and $\mathrm{I}_{\mathrm{o}}$ is supplied from the charge stored in $\mathrm{C}_{\mathrm{o}}$. When Q1 opens, $t_{\text {OFF }}$, voltage V1 will rise positively to the point where D1 turns ON. The output current is now supplied through L1, D1 to the load and any charge lost from $\mathrm{C}_{0}$ during $\mathrm{t}_{\mathrm{ON}}$ is replenished. Here also, as in the step-down regulator, the current through L1 has a DC component plus some $\Delta I_{L} \cdot \Delta I_{L}$ is again selected to be approximately $40 \%$ of $I_{L}$. Figure 19 shows the inductor's current in relation to Q1's ON and OFF times

FIGURE 18. Basic Step-Up Switching Regulator

FIGURE 19. Relation of Switch Timing to Inductor Current in Step-Up Regulator

$$
\begin{aligned}
& \text { From } \Delta I_{\mathrm{L}}=\frac{\mathrm{V}_{\mathrm{L}} \mathrm{~T}}{\mathrm{~L}}, \Delta \mathrm{I}_{\mathrm{L}}+\cong \frac{\mathrm{V}_{\mathrm{IN}} \mathrm{t}_{\mathrm{ON}}}{\mathrm{L1}} \\
& \text { and } \Delta \mathrm{I}_{\mathrm{L}}^{-} \cong \frac{\left(\mathrm{V}_{0}-\mathrm{V}_{\mathrm{IN}}\right) \mathrm{t}_{\mathrm{OFF}}}{\mathrm{~L} 1}
\end{aligned}
$$

Since $\Delta \mathrm{I}_{\mathrm{L}}+=\Delta \mathrm{I}_{\mathrm{L}}, \mathrm{V}_{\text {IN }} \mathrm{t}_{\mathrm{ON}}=\mathrm{V}_{\mathrm{O}} \mathrm{t}_{\text {OFF }}-\mathrm{V}_{\text {IN }} \mathrm{t}_{\mathrm{OFF}}$, and neglecting $V_{\text {SAT }}$ and $V_{D 1}$

$$
v_{0} \cong v_{I N}\left(1+\frac{t_{\mathrm{ON}}}{t_{\mathrm{OFF}}}\right)
$$

The above equation shows the relationship between $\mathrm{V}_{\mathrm{IN}}, \mathrm{V}_{\mathrm{o}}$ and duty cycle.
In calculating input current $\mathrm{I}_{\left.\mathrm{IN}_{\mathrm{NCO}}\right)}$, which equals the inductor's DC current, assume first 100\% efficiency:

$$
\begin{gathered}
P_{\text {IN }}=I_{I N(D C)} V_{I N} \\
P_{\text {OUT }}=I_{\mathrm{O}} V_{\mathrm{O}}=I_{\mathrm{O}} V_{\mathrm{IN}}\left(1+\frac{t_{\mathrm{ON}}}{t_{\mathrm{OFF}}}\right)
\end{gathered}
$$

for $\eta=100 \%, P_{\text {OUT }}=P_{\text {IN }}$

$$
\begin{gathered}
\mathrm{I}_{0} \mathrm{~V}_{\mathrm{IN}}\left(1+\frac{t_{\mathrm{ON}}}{t_{\mathrm{OFF}}}\right)=\mathrm{I}_{\mathrm{IN}(\mathrm{DC})} \mathrm{V}_{\mathrm{IN}} \\
\mathrm{I}_{\mathrm{IN}(\mathrm{DC})}=\mathrm{I}_{\mathrm{O}}\left(1+\frac{t_{\mathrm{ON}}}{t_{\mathrm{OFF}}}\right)
\end{gathered}
$$

This equation shows that the input, or inductor, current is larger than the output current by the factor $\left(1+t_{\mathrm{ON}} / \mathrm{t}_{\mathrm{OFF}}\right)$. Since this factor is the same as the relation between $V_{o}$ and $\mathrm{V}_{\mathrm{IN}}, \mathrm{I}_{\mathrm{IN}(\mathrm{DC})}$ can also be expressed as:

$$
I_{\mathrm{IN}(\mathrm{DC})}=\mathrm{I}_{0}\left(\frac{\mathrm{~V}_{0}}{\mathrm{~V}_{\mathrm{IN}}}\right)
$$

So far it is assumed $\eta=100 \%$, where the actual efficiency or $\eta_{\text {MAX }}$ will be somewhat less due to the saturation voltage of Q1 and forward on voltage of D1. The internal power loss due to these voltages is the average $\mathrm{I}_{\mathrm{L}}$ current flowing, or $\mathrm{I}_{\mathbb{N}}$, through either $\mathrm{V}_{\mathrm{SAT}}$ or $\mathrm{V}_{\mathrm{D} 1}$. For $\mathrm{V}_{\mathrm{SAT}}=\mathrm{V}_{\mathrm{D} 1}=1 \mathrm{~V}$ this power loss becomes $\mathrm{I}_{\mathrm{IN}(\mathrm{DC})}(1 \mathrm{~V}) . \eta_{\text {MAX }}$ is then:

$$
\eta_{M A X}=\frac{P_{0}}{P_{I N}}=\frac{v_{0} I_{0}}{V_{0} I_{0}+I_{I N}(1 V)}=\frac{v_{0} I_{0}}{v_{0} I_{0}+I_{0}\left(1+\frac{t_{0 N}}{t_{0 F F}}\right)}
$$

$$
\text { From } \mathrm{V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{IN}}\left(1+\frac{\mathrm{t}_{\mathrm{ON}}}{\mathrm{t}_{\mathrm{OFF}}}\right)
$$

$$
\eta_{\max }=\frac{\mathrm{V}_{\mathrm{IN}}}{\mathrm{~V}_{\mathrm{IN}}+1}
$$

This equation assumes only DC losses, however $\eta_{\text {MAX }}$ is further decreased because of the switching time of Q1 and D1.

## Typical Applications (Continued)

In calculating the output capacitor $\mathrm{C}_{0}$ it can be seen that $\mathrm{C}_{\mathrm{o}}$ supplies $I_{0}$ during $t_{O N}$. The voltage change on $\mathrm{C}_{0}$ during this time will be some $\Delta \mathrm{V}_{\mathrm{c}}=\Delta \mathrm{V}_{\text {}}$ or the output ripple of the regulator. Calculation of $\mathrm{C}_{\mathrm{o}}$ is:

$$
\begin{aligned}
& \Delta V_{0}=\frac{I_{0} t_{O N}}{C_{0}} \text { or } C_{0}=\frac{I_{0} t_{O N}}{\Delta V_{0}} \\
& \text { From } \mathrm{V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{IN}}\left(\frac{\mathrm{~T}}{\mathrm{t}_{\mathrm{OFF}}}\right) ; \text { toFF }=\frac{\mathrm{V}_{\mathrm{IN}}}{\mathrm{~V}_{\mathrm{O}}} \mathrm{~T} \\
& \text { where } T=t_{\text {ON }}+t_{\text {OFF }}=\frac{1}{f} \\
& \mathrm{t}_{\mathrm{ON}}=\mathrm{T}-\frac{\mathrm{V}_{\mathrm{IN}}}{\mathrm{~V}_{\mathrm{O}}} \mathrm{~T}=\mathrm{T}\left(\frac{\mathrm{~V}_{\mathrm{O}}-\mathrm{V}_{\mathrm{IN}}}{\mathrm{~V}_{\mathrm{O}}}\right) \text { therefore: } \\
& C_{0}=\frac{I_{0} T\left(\frac{V_{0}-V_{I N}}{V_{0}}\right)}{\Delta V_{0}}=\frac{I_{0}\left(V_{0}-V_{I N}\right)}{f \Delta V_{0} V_{0}}
\end{aligned}
$$

where: $C_{o}$ is in farads, $f$ is the switching frequency,
$\Delta \mathrm{V}_{\mathrm{o}}$ is the p-p output ripple
Calculation of inductor L1 is as follows:

$$
\mathrm{L} 1=\frac{\mathrm{V}_{\mathrm{IN}^{t} \mathrm{ON}}}{\Delta \mathrm{I}_{\mathrm{L}}{ }^{+}} \text {, since during } \mathrm{t}_{\mathrm{ON}} \text {, }
$$

$\mathrm{V}_{\mathrm{IN}}$ is applied across L1

$$
\begin{gathered}
\Delta \mathrm{I}_{\mathrm{Lp}-\mathrm{p}}=0.4 \mathrm{I}_{\mathrm{L}}=0.41 \mathrm{I}_{\mathrm{IN}}=0.4 \mathrm{I}_{\mathrm{O}}\left(\frac{\mathrm{~V}_{\mathrm{O}}}{\mathrm{~V}_{\mathrm{IN}}}\right) \text {, therefore: } \\
\mathrm{L} 1=\frac{\mathrm{V}_{\mathrm{IN}^{\prime} \mathrm{ON}}}{0.4 \mathrm{I}_{\mathrm{O}}\left(\frac{\mathrm{~V}_{\mathrm{O}}}{\mathrm{~V}_{\mathrm{IN}}}\right)} \text { and since } \mathrm{t}_{\mathrm{ON}}=\frac{\mathrm{T}\left(\mathrm{~V}_{\mathrm{O}}-\mathrm{V}_{\mathrm{IN}}\right)}{\mathrm{V}_{\mathrm{O}}} \\
\mathrm{~L} 1=\frac{2.5 \mathrm{~V}_{\mathrm{IN}}{ }^{2}\left(\mathrm{~V}_{\mathrm{O}}-\mathrm{V}_{\mathrm{IN}}\right)}{\mathrm{fl}_{\mathrm{O}} \mathrm{~V}_{\mathrm{O}}^{2}}
\end{gathered}
$$

where: L 1 is in henrys, f is the switching frequency in Hz To apply the above theory, a complete step-up switching regulator is shown in Figure 20. Since $\mathrm{V}_{\text {IN }}$ is 5 V , $\mathrm{V}_{\text {REF }}$ is tied to $\mathrm{V}_{\mathbb{I N}}$. The input voltage is divided by 2 to bias the error amplifier's inverting input. The output voltage is:

$$
\mathrm{V}_{\mathrm{OUT}}=\left(1+\frac{\mathrm{R} 2}{\mathrm{R} 1}\right) \times \mathrm{V}_{\mathrm{INV}}=2.5 \times\left(1+\frac{\mathrm{R} 2}{\mathrm{R} 1}\right)
$$

The network D1, C1 forms a slow start circuit.
This holds the output of the error amplifier initially low thus reducing the duty-cycle to a minimum. Without the slow start circuit the inductor may saturate at turn-on because it has to supply high peak currents to charge the output capacitor from 0 V . It should also be noted that this circuit has no supply rejection. By adding a reference voltage at the non-inverting input to the error amplifier, see Figure 21, the input voltage variations are rejected.
The LM3524D can also be used in inductorless switching regulators. Figure 22 shows a polarity inverter which if connected to Figure 20 provides a -15 V unregulated output.
