## Chapter 5 Pin Descriptions

This section provides a detailed description of each signal. The signals are arranged in functional groups according to their associated interface.

The “n” symbol in the signal name indicates that the active, or asserted, state occurs when the signal is at a low voltage level. When “n” is not present before the signal name, the signal is asserted at the high voltage level.

The terms assertion and negation are used exclusively. This is done to avoid confusion when working with a mixture of “active low” and “active high” signals. The term assert, or assertion, indicates that a signal is active, independent of whether that level is represented by a high or low voltage. The term negate, or negation, indicates that a signal is inactive.

## Chapter 7 DC Parameters

### 7.1 Maximum Guaranteed Ratings

PARAMETER	SYMBOL	MIN	MAX	UNITS	COMMENTS
Storage Temperature	$T_A$	-55	150	°C	
Lead Temperature			325	°C	Soldering < 10 seconds
3.3V supply voltage	$V_{DD33}$ , $V_{DDA33}$	-0.5	4.0	V	
Voltage on USB+ and USB- pins		-0.5	$(3.3V \text{ supply voltage} + 2) \leq 6$	V	
Voltage on GPIO10		-0.5	$V_{DD33} + 0.3$	V	When internal power FET operation of this pin is enabled, this pin may be simultaneously shorted to ground or any voltage up to 3.63V indefinitely, without damage to the device as long as $V_{DD33}$ and $V_{DDA33}$ are less than 3.63V and $T_A$ is less than 70°C.
Voltage on any signal pin		-0.5	$V_{DD33} + 0.3$	V	
Voltage on XTAL1		-0.5	4.0	V	
Voltage on XTAL2		-0.5	$V_{DD18} + 0.3$	V	

**Note 7.1** Stresses above the specified parameters may cause permanent damage to the device. This is a stress rating only and functional operation of the device at any condition above those indicated in the operation sections of this specification is not implied.

**Note 7.2** When powering this device from laboratory or system power supplies, it is important that the Absolute Maximum Ratings not be exceeded or device failure can result. Some power supplies exhibit voltage spikes on their outputs when the AC power is switched on or off. In addition, voltage transients on the AC power line may appear on the DC output. When this possibility exists, it is suggested that a clamp circuit be used.

## 7.2 Recommended Operating Conditions

PARAMETER	SYMBOL	MIN	MAX	UNITS	COMMENTS
Operating Temperature	$T_A$	0	70	°C	
3.3V supply voltage	$V_{DD33}, V_{DDA33}$	3.0	3.6	V	(Note 7.3)
3.3V supply rise time	$t_{RT}$	0	400	$\mu$ s	
Voltage on USB+ and USB- pins		-0.3	5.5	V	If any 3.3V supply voltage drops below 3.0V, then the MAX becomes: $(3.3V \text{ supply voltage}) + 0.5 \leq 5.5$
Voltage on any signal pin		-0.3	$V_{DD33}$	V	
Voltage on XTAL1		-0.3	$V_{DDA33}$	V	
Voltage on XTAL2		-0.3	$V_{DD18}$	V	

**Note 7.3** A 3.3V regulator with an output tolerance of 1% must be used if the output of the internal power FET's must support a 5% tolerance.

**Note 7.9** The 3.3V supply should be at least at 75% of its operating condition before the 1.8V supply is allowed to ramp up.
