

OBDH Bus Terminal

The OBT ASIC will interface any user to the ESA On Board Data Handling bus. Developed under ESA Contract, it conforms to ESA OBDH, Digital Bus Interface and Internal User Bus Standards.

The OBT has 2 separate functions. The first is a 5 channel modem which, on the bus side, provides the digital waveforms necessary to operate the Litton Bus drivers, and receives the outputs of the Litton bus detectors. On the user side, it provides an input / output at Digital Bus Interface level. The second function, internally coupled to the first, provides a multiplexing / demultiplexing function of the DBI signals down to Internal User Bus levels and vectored 16 bit serial register read and write commands (see section 7.2 of ESA standard TTC-B-01). In effect, the second function of the OBT provides the core of an RTU.

The Interrogation and Response bus data streams of the two functions may be either coupled together (in RT mode) or isolated (in CT mode). The device may hence be used as a modem only, an RTU kernel only or as a combined modem and RTU kernel. In RT mode, the Interrogation bus data stream can be observed and the Response bus data from associated devices, such as an MA28138 Remote Bus Interface, can be combined with that from the RTU kernel before being used by the modem circuits to modulate the Response bus. Bi-directional access to the Block Transfer bus is provided in either mode.

When used to interface a central terminal to the OBDH bus, the OBT should be continuously clocked in order to output timing to all users on the I-bus as dummy interrogations from the CT. Commands and telemetry are normally sent on the I and BT busses whilst responses and telemetry normally return on the R and BT busses.

FEATURES

- Radiation Hard
- Low Power Consumption
- Single CMOS-SOS ASIC Implementation
- Latch-up Free
- High SEU Immunity
- Fully Compliant with ESA OBDH, IUB, DBI and RBI Specification
- Contains OBDH Bus Modem and RTU Kernel
- Supports Bi-directional Data Transfer on Response and Block Transfer Bus

Figure 1: Block Diagram

APPLICATION

Figure 2: Application

PAYLOAD INTERFACES

The OBT converts the OBDH bus to an Internal User Bus, and a Digital Bus Interface. The OBT can connect OBDH to existing ESA standard payload interfaces such as the MSS PIU (payload interface unit), ICU (intelligent control unit), SBC (single board MIL-STD-1750 computer) or FTC (fault tolerant computer).

The OBT and analogue components/transformers can be integrated in the PIU, ICU, SBC, etc.

FUNCTIONAL DESCRIPTION

In RT mode, power up resets the OBT and causes it to deselect both busses. Two watchdog counters monitor the Nominal I-bus and the Redundant I-bus. If either bus becomes active, that bus will be selected. If the selected bus stops, the OBT watchdog times out and resets both the OBT and the user. If both busses become active, the Nominal bus will be selected in preference to the Redundant one. A change in bus selection will always result in the OBT and the user being reset. Responses from the user are always returned on the selected bus. Setting 'SIMUL' high causes both BATs to drive both the Nominal and the Redundant busses irrespective of the current bus selection. The time-out period may be set to any desired number of bits by varying the 'LOSC' frequency. The OBT derives all timing from, and is synchronous with, the selected I-bus. The OBT demodulates the I-bus to the DBI and decodes commands to the IUB.

The CTpRTn mode pin causes the modem circuits and the RTU Kernel to be either cascade or isolated. If CTpRTn is low (RT mode), the RIRSYNC, CLK, DATA and VAL signals are routed to the RTU Kernel and the associated pins act as outputs; responses from the RTU Kernel are ORed with those from the external RRTDATA and RRTEN inputs and can be independently monitored on the DATARRT and ENRRT pins. In this mode any reset caused by the Clock Detector watchdogs is also combined with the power up reset input.

If CTpRTn is high (CT mode), the modem and RTU Kernel functions are isolated to permit the device to be used as either a modem within the CTU or an RTU Kernel interfacing to an external modem where the RIRSYNC, CLK, DATA and VAL pins act as inputs. The right-hand multiplexer bank is switched to the upper position so that the CT drives the OBDH via the CIT and CBT (if used) pins and receives responses/telemetry via the CRR and CBR (if used) pins. Note: in CT mode, BAT1 must be connected to the l-busses.

In RT mode, the CITSEL, MOD, CLK, SYNC and INV pins are disabled and the clocks are supplied by the I-bus BAR in response to the selected bus. In CT mode, the Clock Detector is functional and drives the TIMEOUTn pin but is unable to cause internal reset on time-out; in this mode the CT must supply all clocks and select the operational bus.

Functional Signal	CT Mode Source (CTpRTn = '1')	RT Mode Source (CTpRTn = '0')
BAT1, 2 modulation clock	CITMOD input pin	Recovered R2F
BAT1, 2 data clock	CITCLK input pin	Recovered RIRCLK
BAT1 data input	RRTDATA input pin	RRTDATA OR DATARRT (RTU Kernel)
BAT1 tx enable	'1'	RRTEN OR DATAEN (RTU Kernel)
BAT1 sync code tx enable	CITSYNC input pin	·0'
BAT1 bit invalidate tx enable	CITINV input Pin	·0'
BAT1, 2 bus selection	CITSEL and SIMUL input pins	Detected active bus and SIMUL input pin
BAT2 data input	RBTDATA input Pin	RBTDATA input pin
BAT2 tx enable	RBTEN input pin	RBTEN input pin
BAT1, 2, BAR1, 2, 3 reset	MRSTn input pin	TIMEOUTn AND MRSTn input pin
RIRSYNC, CLK, DATA, VAL pin direction	outputs	inputs
BAT/BAR and RTU Kernel coupling	separated	coupled

The changes depending upon selection of RT mode or CT mode with the CTpRTn pin are defined in the table below:

Figure 4: Architecture

Note: Switches in lower position - RT mode Switches in upper position - CT mode

MODEM Modulation Waveforms are compliant with ESA document THB/Apo/KZ/1386/av. Waveforms indicating the operation of BAT1, 2 and BAR1, 2, 3 in both the CT and RT modes are shown in Figures 5 to 8.

CLOCK DETECTOR OPERATION

The Clock Detector architecture is shown in Figure 9; a separate channel is essentially provided for each of the Nominal and Redundant Interrogation busses. Associated waveforms are shown in Figure 10.

Each channel contains an Edge Detector and a 5-bit Watchdog Counter which respond only to high-to-low transitions on their respective Interrogation bus DS1n inputs. A common Bus Usage Detection circuit is used to generate timeout pulses (used for internal and external reset) and bus selection signals from the results of the watchdogs.

The local oscillator input, LOSC, is divided and decoded to generate an active low reset and an active high sample clock. When applied to both input Edge Detectors, these signals permit input high-to-low transitions to be detected for one LOSC cycle in every two (between the reset \downarrow and sample clock \uparrow). Once such transitions have been detected by a sample clock, the associated watchdog counter is reset. The MSB of each watchdog counter is used as an indication of its bus's status - active or inactive. Should the watchdog counter overflow (i.e. its MSB be set to 1), the associated bus will be considered inactive.

The status of the Nominal and Redundant Interrogation busses is used to determine internal bus selection for the modulation of Response and Block Transfer data in the device's RT mode. If neither bus is considered active, the TIMEOUTn pin will be held low and RT mode reception of all 3 busses will be inhibited. If one bus is considered active, RT mode reception will occur on the same set of bus circuits (redundancy) as the active Interrogation bus. If both busses are considered active, RT mode reception from the Nominal set of bus circuits will be performed. RT mode transmission will always occur on the same set of bus circuits (redundancy) as selected for reception unless the SIMUL pin is held high, in which case transmission will occur simultaneously on both the Nominal and Redundant busses. Both watchdog counters are fully set at power up to mark both busses as inactive - in this way, a missing LOSC input will not cause inactive busses to be deemed active.

For a single detected input transition, 17.5 to 18.5 LOSC cycles will elapse before the relevant bus is considered inactive. If near-instantaneous Nominal-to-Redundant or Dual-to-Redundant bus handover occurs, the change-over will be delayed by 18 to 19 LOSC cycles, in order to preserve the priority of the Nominal bus. If near-instantaneous Redundant-to-Nominal or Redundant-to-Dual bus handover occurs, the change-over will occur after 1.5 to 2.5 LOSC cycles since the Nominal bus takes priority. In either of these cases, a 1 LOSC cycle TIMEOUTn pulse is always generated to ensure that internal reset occurs.

The frequency of the local oscillator may be varied to make the nominal time-out period of 17.5 LOSC cycles correspond to any desired number of (missing) bits on the Interrogation bus. Variation of the duty cycle does not vary the time-out period. After 16 LOSC cycles without detected input transitions, the associated watchdog times-out and is detected on the next LOSC \uparrow edge; the generation of a TIMEOUTn pulse and reset are then inevitable.

For proper Clock Detector operation, (at least) one high-tolow input transition must be detected within a period of 16 LOSC cycles of the last such detection, but transitions made during alternate LOSC cycles (the phase is difficult to predict) will not be detected. Local oscillator clock signals which are harmonically-related to the modulation clock by an integer ratio are thus a cause for concern, although this problem is perhaps only likely to occur in experimental set-ups.

Figure 10: MA28139 Clock Detector Operation

The requirement to respect set-up and hold times for the capture of the Edge Detector outputs by the LOSC high-to-low transition means that LOSC signals which are harmonically-related to the Litton modulation clock but whose phase can not be controlled can never be guaranteed to provide reliable operation.

For asynchronous local oscillator signals, there will be no concern if we are simply able to place two or more Litton DSn high-to-low edges into each LOSC cycle, so that:

 $\tau_{\text{MOD}} \leq \tau_{\text{LOSC}} \text{ - } t_{\text{SU}} \text{ - } t_{\text{HOLD}}$

and the time-out period of 16 τ_{LOSC} is hence approximately 8 bit periods or more.

However, suppose that the periods of the modulation clock and the local oscillator clock are such that the relationship between them is:

 $\tau_{MOD} = m \tau_{LOSC}$

where m is a positive integer.

In order to respect the setup and hold times, t_{SU} + t_{HOLD} respectively, between the DSn \downarrow , and LOSC \downarrow edges, it is necessary to avoid such harmonic relationships; it can be shown that around these spot frequencies it is necessary to ensure that either:

 $\label{eq:total_states} \begin{array}{l} w \ \tau_{MOD} \geq x \ \tau_{LOSC} + t_{SU} + t_{HOLD} \\ \text{or} \\ y \ \tau_{MOD} \leq z \ \tau_{LOSC} \text{-} t_{SU} \text{-} t_{HOLD} \end{array}$

where the integer constants w, x, y and z are given in the table below.

Since two modulation clock cycles occur per bit, the timeout period at these harmonics will then be:

16 $\tau_{LOSC} \approx$ 16 τ_{MOD} / m \approx 8 / m bit periods.

m	w	x	у	Z	Approx. time-out period (bit periods)
1	15	15	17	17	8
2	7	15	8	15	4
3	5	15	5	15	2.67
4	3	13	4	15	2
5	3	15	3	15	1.6
6	2	13	2	11	1.33
7	1	7	1	7	1.14
8	1	9	2	15	1
9	1	9	1	9	0.88
10	1	11	1	9	0.8
11	1	11	1	11	0.73
12	1	13	1	11	0 67
13	1	13	1	13	0.62
14	1	15	1	13	0.57
15	1	15	1	15	0.53

In summary, slow local oscillator clocks which cause relatively long timeout periods ≥ 8 bit periods are not considered a problem; very long time-outs can be reliably implemented. For shorter time-out periods, however, it is necessary to avoid harmonic relationships between the Litton modulation clock and the local oscillator. The simplest practical method for avoiding such relationships would be to arrange for the ratio

 $n = \tau_{MOD} / \tau_{LOSC}$

to have a half-integer value such that n = 0.5, 1.5, 2.5, ...using an independent crystal oscillator if necessary.

OBDH / IUB INTERFACE

The Central Terminal Unit controls timing, commands and telemetry to all subsystems on the OBDH bus. ESA TTC-B-01 specifies the OBDH to be 2 redundant sets (Nominal and Redundant) of 2 twisted pairs (Interrogation and Response bus) plus an optional redundant 3rd twisted pair (Block Transfer bus), Litton modulated (self clocking with parity on each bit), balanced transformer coupled for less than 1 error in 100 million bits on a 25 metre bus. The data rate is nominally 500K Bits/sec although the chip itself supports up to 5MBits/ sec. The OBT is transformer coupled with adjustable reference and threshold levels as shown below. Litton more positive than V_{th+} makes discriminator signal NIDS1n low. Litton more negative than V_{th-} makes NIDS2n low. OBT RR1n, RR2, RR3n, RR4 control 4 switches which drive the bus with bipolar Litton code when enabled. For clarity redundancy is not shown below:

TTC-B-01 also specifies the IUB. The OBT supplies specified clocks, memory load address for ML data (or channel address for mode command) and responds on the R bus with a 13 zeroes response as acknowledgement. If the command requires data aquisition, the OBT responds with a 13 or 21 bit response containing 8 or 16 bits (respectively) of user data, controlling external ADC as required.

Figure 11: OBDH to IUB interface

RTU KERNEL PROTOCOL VIOLATIONS

Some commands to the RTU Kernel cannot be completed within one Interrogation period (or "slot") because of the need to provide a slow external interface as defined in ESA standard TTC-B-01. These are commands for 16-bit Digital Serial Acquisition (S16) and 16-bit Memory Load (ML). In addition, it is also possible to inhibit On/Off commands by pin configuration.

Consequently:

- a Memory Load command cannot be followed by another Memory Load command in the next Interrogation; the second command of such a sequence will be ignored,
- a 16-bit Digital Serial Acquisition (S16) cannot be followed by another acquisition or command in the next Interrogation; the second command of such a sequence will be ignored,
- a Long On/Off command will be ignored if the On/Off command Inhibit input pin, OOINH, is high.

Note that in all MODE Dependent Command and Acquisition Interrogations, bits 23 to 30 of the Interrogation are output as an 8 bit channel address on CHADD(0:7). ESA standard TTC-B-01, p.110 specifies a 7 bit channel address in bits 27 to 29, leaving bit 30 as Reserved. For complete compliance with this standard, CHADD(7) should be disregarded and CHADD(0:6) only should be used.

The signals generated by the RTU Kernel during 8-bit Single-Ended and 8-bit Double-Ended Analog Data Acquisitions are intended for connection to an 8-bit serial ADC module. The outputs PC, ANCLK, SOC and SH are intended to provide ADC power control, conversion clock, start of conversion pulse and sample/hold control respectively.

RTU Kernel BroadCast Pulse and BCP Validity Waveforms are shown in Figure 12.

RTU Kernel Memory Load Command Waveforms are shown in Figure 13.

RTU Kernel MODE Dependent Command and Acquisition Waveforms are shown in Figures 14 - 17.

RTU KERNEL MODE DEFINITIONS

The mode field contained in bits 19 to 22 of the Interrogation is decoded during acquisition commands to drive one of the MOSC, MOLC, MOHL, MOBT, MODBL, MODS8, MODS16, MOANS or MOAND outputs. Mode decoding is an extension of that defined in ESA standard TTC-B-01 Table 7.1 and is shown in Table 1 below:

Mode Code				Associated	
Bit 19	Bit 20	Bit 21	Bit 22	Function	Output Pin
0	0	0	0	Unused	-
0	0	0	1	Short Switch Closure On/Off Command	MOSC
0	0	1	0	Long Switch Closure On/Off Command	MOLC
0	0	1	1	High Power Switch Closure On/Off Cmd	MOHL
0	1	0	0	Unused	-

Note 2: For any acquisition command to be decoded, the evaluated Memory Load Address must be zero. An evaluated Memory Load Address of non-zero does not imply data acquisition. Note 3: The Memory Load Address which is evaluated for decoding and addressing usage may vary from 3 to 5 bits. If (EXTMLA1 = 1) and (EXTMLA2 = 0), the Memory Load Address field is extended to 4 bits and bit 11 of the Interrogation will be treated as MLA(1). If (EXTMLA2 = 1), the Memory Load Address field is extended to 5 bits and bits 10 and 11of the Interrogation will be treated as MLA(0:1). Any Interrogation bits treated as Extended Memory Load Address bits will not be treated as Terminal Address bits; this facility is intended for 2x or 4x size expansion provided that up to 4 consecutive Terminal Addresses can be used. The Short-Command, Long-Command, High-Level Switch Closure and Block Transfer command responses are always 13-zeroes. Note 4:

Figure 17: Short-Command, Long-Command and High-Level Switch Closure and Block Transfer Command Waveforms

THE ESA ON-BOARD DATA HANDLING (OBDH) BUS

The dual redundant OBDH bus is connected to the OBT bus interface via an input descriminator and an output bridge driver circuit. These convert between the bipolar LITTON code and the standard CMOS inputs and outputs of the IC.

The OBDH bus is divided into three parts:

A. INTERROGATION BUS (I BUS)

This bus is used to transfer data from the CT to the RTs, as commands of 32 bit words, each bit being modulated according to the Litton scheme shown in Figure 18. Each Interrogation (or command) "slot" comprises 3 Sync bits, 3 or 4 BroadCast Pulses, 5 or 6 Terminal Address bits, 4 Destination Address bits, 16 Data bits and a Parity bit.

B. RESPONSE BUS (R BUS)

This bus is used to send data from the RTs to the CT, (can be used by RTs to receive data). Each response word comprises the 4 Destination Address bits sent in the corresponding Interrogation, either 8 or 16 Data bits from the user (8 bits unless a 16 bit acquisition was requested and 8 zeros if no response data is required) and a single Stop bit (used to ensure data is fully clocked through bus modems and 0 by convention).

C. BLOCK TRANSFER BUS (BT BUS)

Used to transfer blocks of data between the CT and RTs, in either direction, as a contiguous block or stream of data bits.

FASTER OBDH/DBI COMPATIBLE NETWORKS

With analog components the OBT can interface any equipment to the specified ESA OBDH bus at the nominal data rate of 0.5 Mbps. Contract 5352 proved that analog components limit OBDH data rate to 2 Mbps maximum. But OBTs work to over 5 Mbps (10MHz with 2 clocks/bit Litton coded). OBTs may be directly networked via digital bus drivers/receivers, (eliminating analog components) using Litton coded 4 wire (R2/DS1 and R4/DS2) busses (see OBDH application note 1). MSS made a 3 metre optical OBDH network for the Pegasus ion source.

DBIs may be directly connected but will not be Litton coded with Parity on every bit, or exhibit modulation and demodulation delays.

Figure 18: Litton Coded Data

CONNECTIONS TO THE OBDH I, R AND BT BUSSES (SUGGESTED SCHEMES ONLY) TRANSMITTER

Storage Temperature	-65	+150	°C

DC CHARACTERISTICS AND RATINGS

Note: Stresses above those listed may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these conditions, or at any other condition above those indicated in the operations section of this specification, is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Symbol	Parameter	Conditions	Min.	Тур.	Max.	Units

I _{DD1}	Static Power supply Current	$V_{DD} = 5.5V$	-	0.02	8	mΑ
I _{DD2}	Dynamic Power supply Current	$f = 1MHz, V_{DD} = 5.5V$	-	6	20	mA

Table 2: Absolute Maximum Ratings

Notes: 1. $V_{DD} = 5V \pm 10\%$ over full temperature range.

2. Total dose radiation not exceeding 10^5 Rads(Si).

3. Mil-Std-883, method 5005, subgroups 1, 2, 3.

4. All outputs are suitable for TTL/CMOS drive.

5. Electro-Static Discharge protection is provided for all pins.

6. Internal pull-up or pull-down resistors should not be relied upon for proper operation and/or termination of input levels under all operating conditions without prior consultation with GPS.

7. Input and output leakage measurements are guaranteed but not tested at -55°C.

T35a	ANSIN to RIRCLK ↑ hold	RTU mode	30	-	ns
T36	NIDS1n, NIDS2n, RIDS1n, RIDS2n \downarrow to DATARRT, ENRRT	RTU mode	-	75	ns

Note 1: RTU mode timing parameters not explicitly stated will be lower than the sum of the appropriate parameters for the RTU Kernel, BAR1 and BAT2. Parameters T34 and T36 above may be used to estimate the difference in timing between CTU mode (i.e. where the RTU Kernel, BAR1 and BAT2 are not coupled together) and RTU mode usage

(i.e. where those components are coupled together).

Note 2: Configuration pins such as TA(0:5), EXTFMT, EXTMLA1 and EXTMLA2 and MRSTn are not considered here because they do not need to be dynamically changed.

Note 3: $V_{DD} = 5V \pm 10\%$ over full temperature range. $V_{OH} = V_{OL} = V_{DD}/2$, $V_{IL} = V_{SS}$, $V_{IH} = V_{DD}$, $C_L = 50 pF$.

Note 4: Total dose radiation not exceeding 10⁵ Rads (Si).

Note 5: Tables 4, 5, 6 & 7 contain Mil-Std-883, method 5005, subgroups 9, 10, 11.

Table 7: RTU Kernel Characterisation

44	TAV	I (PULL-DOWN)	Terminal available (take low to disable responses from RTU kernal)

OBT POWER SUPPLY DISTRIBUTION PINS

No.	Name	Туре	Description
55, 113	V _{DD}	P	Positive supply nominally +5 volts. Connect both pins.
14, 47, 80	V _{SS}	P	Power and signal ground. Connect all pins.

Notes: 1. CSCHMITT means CMOS Schmitt-trigger inputs. 2. Internal pull-up or pull-down resistors should not be relied upon for proper operation and/or termination of input levels under all operating conditions without prior consultation with GPS.

Figure 22: Package Dimensions

RADIATION TOLERANCE

Total Dose Radiation Testing

For product procured to guaranteed total dose radiation levels, each wafer lot will be approved when all sample devices from each lot pass the total dose radiation test.

The sample devices will be subjected to the total dose radiation level (Cobalt-60 Source), defined by the ordering code, and must continue to meet the electrical parameters specified in the data sheet. Electrical tests, pre and post irradiation, will be read and recorded.

GEC Plessey Semiconductors can provide radiation testing compliant with Mil-Std-883 test method 1019 Ionizing Radiation (total dose).

Total Dose (Function to specification)*	1x10 ⁵ Rad(Si)
Transient Upset (Stored data loss)	5x10 ¹⁰ Rad(Si)/sec
Transient Upset (Survivability)	>1x10 ¹² Rad(Si)/sec
Neutron Hardness (Function to specification)	>1x10 ¹⁵ n/cm ²
Single Event Upset**	<1x10 ⁻¹⁰ Errors/bit day
Latch Up	Not possible

* Other total dose radiation levels available on request

** Worst case galactic cosmic ray upset - interplanetary/high altitude orbit

POWER ASSEMBLY CAPABILITY

The Power Assembly group was set up to provide a support service for those customers requiring more than the basic semiconductor, and has developed a flexible range of heatsink and clamping systems in line with advances in device voltages and current capability of our semiconductors.

We offer an extensive range of air and liquid cooled assemblies covering the full range of circuit designs in general use today. The Assembly group offers high quality engineering support dedicated to designing new units to satisfy the growing needs of our customers.

Using the latest CAD methods our team of design and applications engineers aim to provide the Power Assembly Complete Solution (PACs).

HEATSINKS

The Power Assembly group has its own proprietary range of extruded aluminium heatsinks which have been designed to optimise the performance of Dynex semiconductors. Data with respect to air natural, forced air and liquid cooling (with flow rates) is available on request.

For further information on device clamps, heatsinks and assemblies, please contact your nearest sales representative or Customer Services.

HEADQUARTERS OPERATIONS **DYNEX SEMICONDUCTOR LTD** Doddington Road, Lincoln. Lincolnshire. LN6 3LF. United Kingdom. Tel: +44-(0)1522-500500 Fax: +44-(0)1522-500550 http://www.dynexsemi.com

e-mail: power_solutions@dynexsemi.com

CUSTOMER SERVICE Tel: +44 (0)1522 502753 / 502901. Fax: +44 (0)1522 500020

Datasheet Annotations:

Dynex Semiconductor annotate datasheets in the top right hard corner of the front page, to indicate product status. The annotations are as follows:-

Target Information: This is the most tentative form of information and represents a very preliminary specification. No actual design work on the product has been started.

Preliminary Information: The product is in design and development. The datasheet represents the product as it is understood but details may change.

Advance Information: The product design is complete and final characterisation for volume production is well in hand.

UNITED KINGDOM

No Annotation: The product parameters are fixed and the product is available to datasheet specification.

This publication is issued to provide information only which (unless agreed by the Company in writing) may not be used, applied or reproduced for any purpose nor form part of any order or contract nor to be regarded as a representation relating to the products or services concerned. No warranty or guarantee express or implied is made regarding the capability, performance or suitability of any product or service. The Company reserves the right to alter without prior ordice the specification, design or price of any product or service. Information concerning possible methods of use is provided as a utilability of any equipment using such information and to ensure that such methods of uses is provided as a utilability of any equipment using such information and to ensure that any publication or data used is up to date and has not been superseded. These products are not suitable for use in any medical products whose failure to perform may result in significant injury or death to the user. All products are sold and services provided subject to the Company's conditions of sale, which are available on request.

All brand names and product names used in this publication are trademarks, registered trademarks or trade names of their respective owners.
