## 12-Bit High Speed Low Power Sampling ANALOG-TO-DIGITAL CONVERTER

### FEATURES

- 500kHz THROUGHPUT RATE
- 2.5V INTERNAL REFERENCE
- LOW POWER: 11mW
- SINGLE SUPPLY +5V OPERATION
- DIFFERENTIAL INPUT
- SERIAL INTERFACE
- GUARANTEED NO MISSING CODES
- MINI-DIP-8 AND MSOP-8
- 0V TO  $V_{REF}$  INPUT RANGE

### APPLICATIONS

- BATTERY OPERATED SYSTEMS
- DIGITAL SIGNAL PROCESSING
- HIGH SPEED DATA ACQUISITION
- WIRELESS COMMUNICATION SYSTEMS

### DESCRIPTION

The ADS7834 is a 12-bit sampling analog-to-digital converter (A/D) complete with sample/hold, internal 2.5V reference, and synchronous serial interface. Typical power dissipation is 11mW at a 500kHz throughput rate. The device can be placed into a power-down mode which reduces dissipation to just 2.5mW. The input range is zero to the reference voltage, and the internal reference can be overdriven by an external voltage.

Low power, small size, and high-speed make the ADS7834 ideal for battery operated systems such as wireless communication devices, portable multi-channel data loggers, and spectrum analyzers. The serial interface also provides low-cost isolation for remote data acquisition. The ADS7834 is available in a plastic mini-DIP-8 or an MSOP-8 package and is guaranteed over the  $-40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$  temperature range.

## ABSOLUTE MAXIMUM RATINGS<sup>(1)</sup>

+V <sub>CC</sub> to GND .....	-0.3V to 6V
Analog Inputs to GND .....	-0.3V to (V <sub>CC</sub> + 0.3V)
Digital Inputs to GND .....	-0.3V to (V <sub>CC</sub> + 0.3V)
Power Dissipation .....	325mW
Maximum Junction Temperature .....	+150°C
Operating Temperature Range .....	-40°C to +85°C
Storage Temperature Range .....	-65°C to +150°C
Lead Temperature (soldering, 10s) .....	+300°C

NOTE: (1) Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. Exposure to absolute maximum conditions for extended periods may affect device reliability.

## ELECTROSTATIC DISCHARGE SENSITIVITY

Electrostatic discharge can cause damage ranging from performance degradation to complete device failure. Burr-Brown Corporation recommends that all integrated circuits be handled and stored using appropriate ESD protection methods.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet published specifications.

## PIN CONFIGURATION

## PIN ASSIGNMENTS

PIN	NAME	DESCRIPTION
1	V <sub>REF</sub>	Reference Output. Decouple to ground with a 0.1μF ceramic capacitor and a 2.2μF tantalum capacitor.
2	+IN	Non-Inverting Input.
3	-IN	Inverting Input. Connect to ground or to remote ground sense point.
4	GND	Ground.
5	CONV	Convert Input. Controls the sample/hold mode, start of conversion, start of serial data transfer, type of serial transfer, and power down mode. See the Digital Interface section for more information.
6	DATA	Serial Data Output. The 12-bit conversion result is serially transmitted most significant bit first with each bit valid on the rising edge of CLK. By properly controlling the CONV input, it is possible to have the data transmitted least significant bit first. See the Digital Interface section for more information.
7	CLK	Clock Input. Synchronizes the serial data transfer and determines conversion speed.
8	+V <sub>CC</sub>	Power Supply. Decouple to ground with a 0.1μF ceramic capacitor and a 10μF tantalum capacitor.

# THEORY OF OPERATION

The ADS7834 is a high speed successive approximation register (SAR) analog-to-digital converter (A/D) with an internal 2.5V bandgap reference. The architecture is based on capacitive redistribution which inherently includes a sample/hold function. The converter is fabricated on a 0.6μ CMOS process. See Figure 1 for the basic operating circuit for the ADS7834.

The ADS7834 requires an external clock to run the conversion process. This clock can vary between 200kHz (12.5kHz throughput) and 8MHz (500kHz throughput). The duty cycle of the clock is unimportant as long as the minimum HIGH and LOW times are at least 50ns and the clock period is at least 125ns. The minimum clock frequency is set by the leakage on the capacitors internal to the ADS7834.

The analog input is provided to two input pins: +IN and -IN. When a conversion is initiated, the differential input on these pins is sampled on the internal capacitor array. While a conversion is in progress, both inputs are disconnected from any internal function.

The range of the analog input is set by the voltage on the V<sub>REF</sub> pin. With the internal 2.5V reference, the input range is 0V to 2.5V. An external reference voltage can be placed on V<sub>REF</sub>, overdriving the internal voltage. The range for the external voltage is 2.0V to 2.55V, giving an input voltage range of 2.0V to 2.55V.

The digital result of the conversion is provided in a serial manner, synchronous to the CLK input. The result is provided most significant bit first and represents the result of the conversion currently in progress—there is no pipeline delay. By properly controlling the CONV and CLK inputs, it is possible to obtain the digital result least significant bit first.

## ANALOG INPUT

The +IN and -IN input pins allow for a differential input signal to be captured on the internal hold capacitor when the converter enters the hold mode. The voltage range on the -IN input is limited to -0.2V to 0.2V. Because of this, the differential input can be used to reject only small signals that

are common to both inputs. Thus, the -IN input is best used to sense a remote ground point near the source of the +IN signal. If the source driving the +IN signal is nearby, the -IN should be connected directly to ground.

The input current into the analog input depends on input voltage and sample rate. Essentially, the current into the device must charge the internal hold capacitor (typically 20pF) during the sample period. After this capacitance has been fully charged, there is no further input current. The source of the analog input voltage must be able to charge the input capacitance to a 12-bit settling level within the sample period—which can be as little as 350ns in some operating modes. While the converter is in the hold mode or after the sampling capacitor has been fully charged, the input impedance of the analog input is greater than 1GΩ.

Care must be taken regarding the input voltage on the +IN and -IN pins. To maintain the linearity of the converter, the +IN input should remain within the range of GND - 200mV to V<sub>REF</sub> + 200mV. The -IN input should not drop below GND - 200mV or exceed GND + 200mV. Outside of these ranges, the converter's linearity may not meet specifications.

## REFERENCE

The reference voltage on the V<sub>REF</sub> pin directly sets the full-scale range of the analog input. The ADS7834 can operate with a reference in the range of 2.0V to 2.55V, for a full-scale range of 2.0V to 2.55V.

The voltage at the V<sub>REF</sub> pin is internally buffered and this buffer drives the capacitor DAC portion of the converter. This is important because the buffer greatly reduces the dynamic load placed on the reference source. However, the voltage at V<sub>REF</sub> will still contain some noise and glitches from the SAR conversion process. These can be reduced by carefully bypassing the V<sub>REF</sub> pin to ground as outlined in the sections that follow.

## INTERNAL REFERENCE

The ADS7834 contains an on-board 2.5V reference, resulting in a 0V to 2.5V input range on the analog input. The specification table gives the various specifications for the

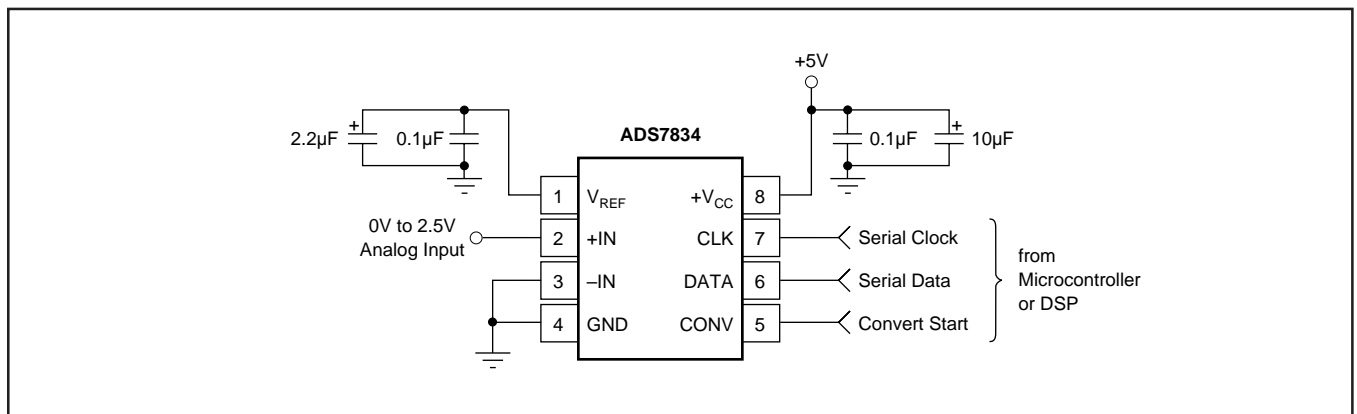

FIGURE 1. Basic Operation of the ADS7834.

internal reference. This reference can be used to supply a small amount of source current to an external load, but the load should be static. Due to the internal 10kΩ resistor, a dynamic load will cause variations in the reference voltage, and will dramatically affect the conversion result. Note that even a static load will reduce the internal reference voltage seen at the buffer input. The amount of reduction depends on the load and the actual value of the internal “10kΩ” resistor. The value of this resistor can vary by ±30%.

The  $V_{REF}$  pin should be bypassed with a 0.1μF capacitor placed as close as possible to the ADS7834 package. In addition, a 2.2 μF tantalum capacitor should be used in parallel with the ceramic capacitor. Placement of this capacitor, while not critical to performance, should be placed as close to the package as possible.

## EXTERNAL REFERENCE

The internal reference is connected to the  $V_{REF}$  pin and to the internal buffer via a 10kΩ series resistor. Thus, the reference voltage can easily be overdriven by an external reference voltage. The voltage range for the external voltage is 2.0V to 2.55V, corresponding to an analog input range of 2.0V to 2.55V.

While the external reference will not source significant current into the  $V_{REF}$  pin, it does have to drive the series 10kΩ resistor that is terminated into the 2.5V internal reference (the exact value of the resistor will vary up to ±30% from part to part). In addition, the  $V_{REF}$  pin should still be bypassed to ground with at least a 0.1 μF ceramic capacitor (placed as close to the ADS7834 as possible). The reference will have to be stable with this capacitive load. Depending on the particular reference and A/D conversion speed, additional bypass capacitance may be required, such as the 2.2μF tantalum capacitor shown in Figure 1.

Reasons for choosing an external reference over the internal reference vary, but there are two main reasons. One is to achieve a given input range. For example, a 2.048V reference provides for a 0V to 2.048V input range—or 500nV per LSB. The other is to provide greater stability over temperature. (The internal reference is typically 20ppm/°C which translates into a full-scale drift of roughly 1 output code for every 12°C. This does not take into account other sources of full-scale drift). If greater stability over temperature is needed, then an external reference with lower temperature drift will be required.

## DIGITAL INTERFACE

Figure 2 shows the serial data timing and Figure 3 shows the basic conversion timing for the ADS7834. The specific timing numbers are listed in Table I. There are several important items in Figure 3 which give the converter additional capabilities over typical 8-pin converters. First, the transition from sample mode to hold mode is synchronous to the falling edge of CONV and is not dependent on CLK. Second, the CLK input is not required to be continuous during the sample mode. After the conversion is complete, the CLK may be kept LOW or HIGH.

FIGURE 2. Serial Data and Clock Timing.

SYMBOL	DESCRIPTION	MIN	TYP	MAX	UNITS
$t_{ACQ}$	Acquisition Time	350			ns
$t_{CONV}$	Conversion Time	1.625			μs
$t_{CKP}$	Clock Period	125		5000	ns
$t_{CKL}$	Clock LOW	50			ns
$t_{CKH}$	Clock HIGH	50			ns
$t_{CKDH}$	Clock Falling to Current Data Bit No Longer Valid	5	15		ns
$t_{CKDS}$	Clock Falling to Next Data Valid		30	50	ns
$t_{CVL}$	CONV LOW	40			ns
$t_{CVH}$	CONV HIGH	40			ns
$t_{CKCH}$	CONV Hold after Clock Falls <sup>(1)</sup>	10			ns
$t_{CKCS}$	CONV Setup to Clock Falling <sup>(1)</sup>	10			ns
$t_{CKDE}$	Clock Falling to DATA Enabled		20	50	ns
$t_{CKDD}$	Clock Falling to DATA High Impedance		70	100	ns
$t_{CKSP}$	Clock Falling to Sample Mode		5		ns
$t_{CKPD}$	Clock Falling to Power-Down Mode		50		ns
$t_{CVHD}$	CONV Falling to Hold Mode (Aperture Delay)		5		ns
$t_{CVSP}$	CONV Rising to Sample Mode		5		ns
$t_{CVPU}$	CONV Rising to Full Power-up		50		ns
$t_{CVDD}$	CONV Changing State to DATA High Impedance		70	100	ns
$t_{CVPD}$	CONV Changing State to Power-Down Mode		50		ns
$t_{DRP}$	CONV Falling to Start of CLK (for hold droop < 0.1 LSB)			5	μs

Note: (1) This timing is not required under some situations. See text for more information.

TABLE I. Timing Specifications ( $T_A = -40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$ ,  $C_{LOAD} = 30\text{pF}$ ).

The asynchronous nature of CONV to CLK raises some interesting possibilities, but also some design considerations. Figure 3 shows that CONV has timing restraints in relation to CLK ( $t_{CKCH}$  and  $t_{CKCS}$ ). However, if these times are violated (which could happen if CONV is completely asynchronous to CLK), the converter will perform a conversion correctly, but the exact timing of the conversion is indeterminate. Since the setup and hold time between CONV and CLK has been violated in this example, the start of conversion could vary by one clock cycle. (Note that the start of conversion can be detected by using a pull-up resistor on DATA. When DATA drops out of high-impedance and goes LOW, the conversion has started and that clock cycle is the first of the conversion.)

In addition if CONV is completely asynchronous to CLK and CLK is continuous, then there is the possibility that CLK will transition just prior to CONV going LOW. If this

occurs faster than the 10ns indicated by  $t_{CKCH}$ , then there is a chance that some digital feedthrough may be coupled onto the hold capacitor. This could cause a small offset error for that particular conversion.

Thus, there are two basic ways to operate the ADS7834. CONV can be synchronous to CLK and CLK can be continuous. This would be the typical situation when interfacing the converter to a digital signal processor. The second method involves having CONV asynchronous to CLK and gating the operation of CLK (a non-continuous clock). This method would be more typical of an SPI-like interface on a microcontroller. This method would also allow CONV to be generated by a trigger circuit and to initiate (after some delay) the start of CLK. These two methods are covered under DSP Interfacing and SPI Interfacing.

### POWER-DOWN TIMING

The conversion timing shown in Figure 3 does not result in the ADS7834 going into the power-down mode. If the conversion rate of the device is high (approaching 500kHz), then there is very little power that can be saved by using the power-down mode. However, since the power-down mode incurs no conversion penalty (the very first conversion is valid), at lower sample rates, significant power can be saved by allowing the device to go into power-down mode between conversions.

Figure 4 shows the typical method for placing the A/D into the power-down mode. If CONV is kept LOW during the conversion and is LOW at the start of the 13 clock cycle, then the device enters the power-down mode. It remains in this mode until the rising edge of CONV. Note that CONV must be HIGH for at least  $t_{ACQ}$  in order to sample the signal properly as well as to power-up the internal nodes.

There are two different methods for clocking the ADS7834. The first involves scaling the CLK input in relation to the conversion rate. For example, an 8MHz input clock and the timing shown in Figure 3 results in a 500kHz conversion rate. Likewise, a 1.6MHz clock would result in a 100kHz conversion rate. The second method involves keeping the clock input as close to the maximum clock rate as possible and starting conversions as needed. This timing is similar to that shown in Figure 4. As an example, a 50kHz conversion rate would require 160 clock periods per conversion instead of the 16 clock periods used at 500kHz.

The main distinction between the two is the amount of time that the ADS7834 remains in power-down. In the first mode, the converter only remains in power-down for a small number of clock periods (depending on how many clock periods there are per each conversion). As the conversion rate scales, the converter always spends the same percentage of time in power-down. Since less power is drawn by the digital logic, there is a small decrease in power consumption, but it is very slight. This effect can be seen in the typical performance curve "Supply Current vs Sample Rate."

FIGURE 3. Basic Conversion Timing.

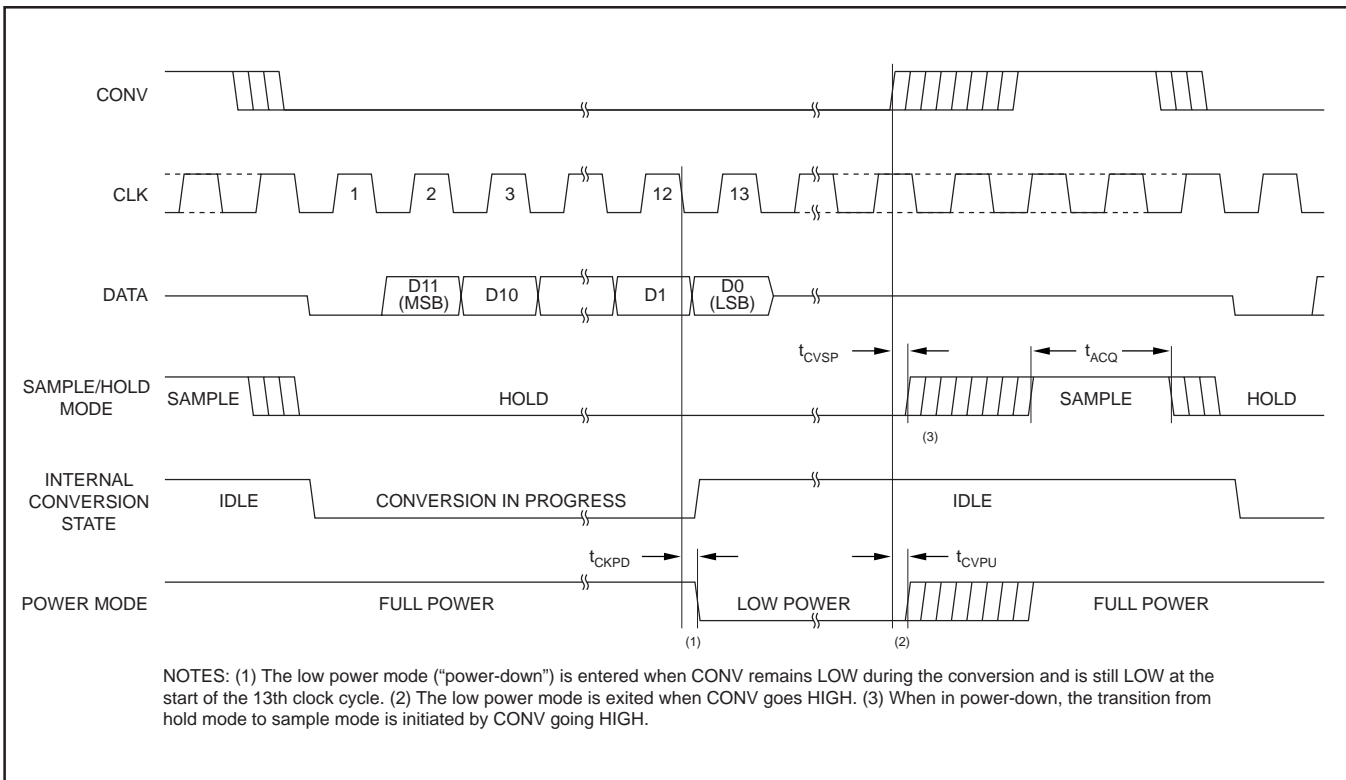

FIGURE 4. Power-down Timing.

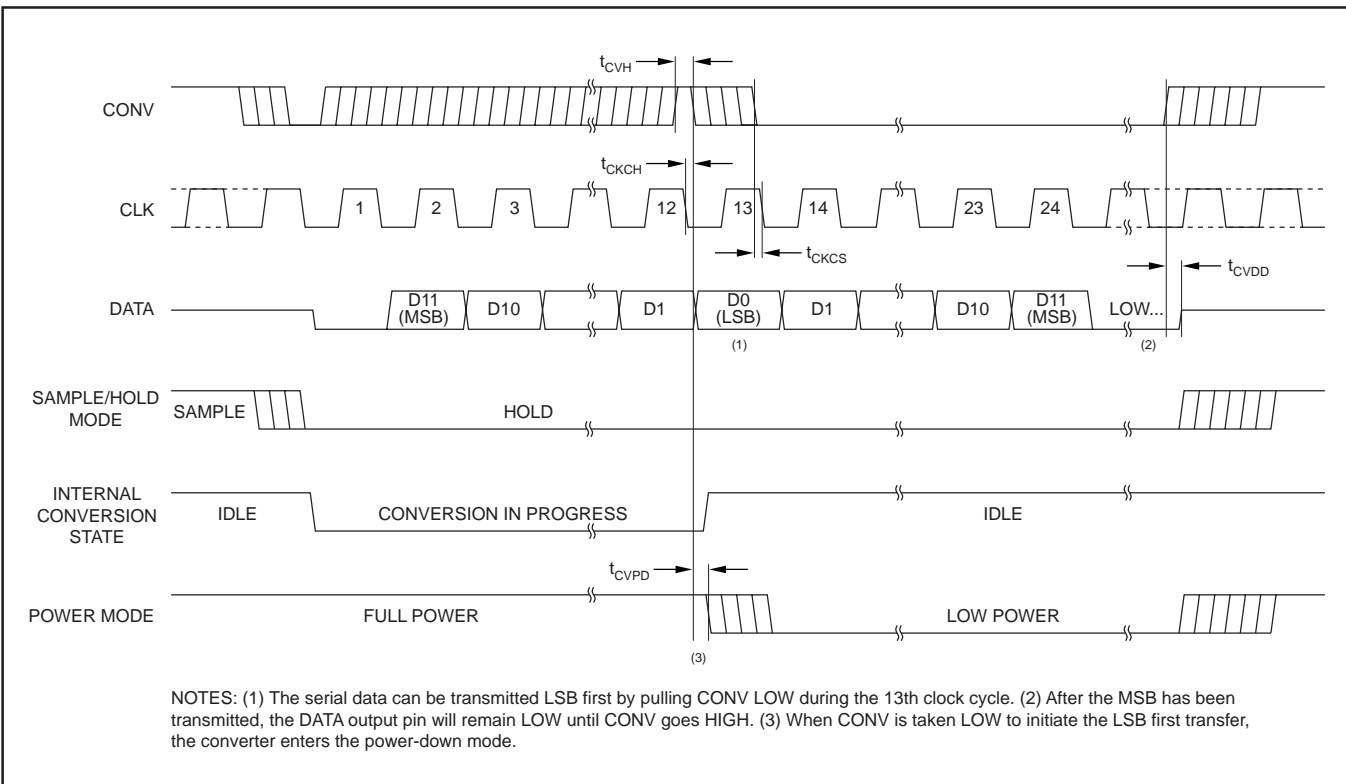

FIGURE 5. Serial Data "LSB-First" Timing.

In contrast, the second method (clocking at a fixed rate) means that each conversion takes X clock cycles. As the time between conversions get longer, the converter remains in power-down an increasing percentage of time. This re-

duces total power consumption by a considerable amount. For example, a 50kHz conversion rate results in roughly 1/10 of the power (minus the reference) that is used at a 500kHz conversion rate.

Table II offers a look at the two different modes of operation and the difference in power consumption.

$f_{\text{SAMPLE}}$	POWER WITH CLK = 16 • $f_{\text{SAMPLE}}$	POWER WITH CLK = 8MHz
500kHz	11mW	11mW
250kHz	10mW	7mW
100kHz	9mW	4mW

TABLE II. Power Consumption versus CLK Input.

### LSB FIRST DATA TIMING

Figure 5 shows a method to transmit the digital result in a least-significant bit (LSB) format. This mode is entered when CONV is pulled HIGH during the conversion (before the end of the 12th clock) and then pulled LOW during the 13th clock (when D0, the LSB, is being transmitted). The next 11 clocks then repeat the serial data, but in an LSB first format. The converter enters the power-down mode during the 13th clock and resumes normal operation when CONV goes HIGH.

### SHORT-CYCLE TIMING

The conversion currently in progress can be “short-cycled” with the technique shown in Figure 6. This term means that

the conversion will terminate immediately, before all 12 bits have been decided. This can be a very useful feature when a resolution of 12 bits is not needed. An example would be when the converter is being used to monitor an input voltage until some condition is met. At that time, the full resolution of the converter would then be used. Short-cycling the conversion can result in a faster conversion rate or lower power dissipation.

There are several very important items shown in Figure 6. The conversion currently in progress is terminated when CONV is taken HIGH during the conversion and then taken LOW prior to  $t_{\text{CKCH}}$  before the start of the 13th clock cycle. Note that if CONV goes LOW during the 13th clock cycle, then the LSB-first mode will be entered (Figure 5). Also, when CONV goes LOW, the DATA output immediately transitions to high impedance. If the output bit that is present during that clock period is needed, CONV must not go LOW until the bit has been properly latched into the receiving logic.

### DATA FORMAT

The ADS7834 output data is in straight binary format as shown in Figure 7. This figure shows the ideal output code for the given input voltage and does not include the effects of offset, gain, or noise.

FIGURE 6. Short-cycle Timing.

FIGURE 7. Ideal Input Voltages and Output Codes.

### DSP INTERFACING

Figure 8 shows a timing diagram that might be used with a typical digital signal processor such as a TI DSP. For the buffered serial port (BSP) on the TMS320C54X family, CONV would be tied to BFSX, CLK would be tied to BCLKX, and DATA would be tied to BDR.

### SPI/QSPI INTERFACING

Figure 9 shows the timing diagram for a typical serial peripheral interface (SPI) or queued serial peripheral interface (QSPI). Such interfaces are found on a number of

microcontrollers from various manufacturers. CONV would be tied to a general purpose I/O pin (SPI) or to a PCX pin (QSPI), CLK would be tied to the serial clock, and DATA would be tied to the serial input data pin such as MISO (master in slave out).

Note the time  $t_{DRP}$  shown in Figure 9. This represents the maximum amount of time between CONV going LOW and the start of the conversion clock. Since CONV going LOW places the sample and hold in the hold mode and because the hold capacitor loses charge over time, there is a requirement that time  $t_{DRP}$  be met as well as the maximum clock period ( $t_{CKP}$ ).

## LAYOUT

For optimum performance, care should be taken with the physical layout of the ADS7834 circuitry. This is particularly true if the CLK input is approaching the maximum input rate.

The basic SAR architecture is sensitive to glitches or sudden changes on the power supply, reference, ground connections, and digital inputs that occur just prior to latching the output of the analog comparator. Thus, during any single conversion for an n-bit SAR converter, there are n “windows” in which large external transient voltages can easily affect the conversion result. Such glitches might originate from switching power supplies, nearby digital logic, and high power devices. The degree of error in the digital output depends on the reference voltage, layout, and the exact timing of the external event. The error can change if the external event changes in time with respect to the CLK input.

With this in mind, power to the ADS7834 should be clean and well bypassed. A 0.1 $\mu$ F ceramic bypass capacitor should be placed as close to the device as possible. In addition, a 1 $\mu$ F to 10 $\mu$ F capacitor is recommended. If needed, an even larger capacitor and a 5 $\Omega$  or 10 $\Omega$  series resistor may be used to lowpass filter a noisy supply.

The ADS7834 draws very little current from an external reference on average as the reference voltage is internally buffered. However, glitches from the conversion process appear at the  $V_{REF}$  input and the reference source must be able to handle this. Whether the reference is internal or external, the  $V_{REF}$  pin should be bypassed with a 0.1 $\mu$ F

capacitor. An additional larger capacitor may also be used, if desired. If the reference voltage is external and originates from an op-amp, make sure that it can drive the bypass capacitor or capacitors without oscillation.

The GND pin should be connected to a clean ground point. In many cases, this will be the “analog” ground. Avoid connections which are too near the grounding point of a microcontroller or digital signal processor. If needed, run a ground trace directly from the converter to the power supply entry point. The ideal layout will include an analog ground plane dedicated to the converter and associated analog circuitry.
