PMC-Sierra, Inc. expressly disclaims all representations and warranties of any kind regarding the contents or use of the information, including, but not limited to, express and implied warranties of accuracy, completeness, merchantability, fitness for a particular use, or non-infringement.

In no event will PMC-Sierra, Inc. be liable for any direct, indirect, special, incidental or consequential damages, including, but not limited to, lost profits, lost business or lost data resulting from any use of or reliance upon the information, whether or not PMC-Sierra, Inc. has been advised of the possibility of such damage.

### Trademarks

PMC-Sierra, FREEDM 32A1024L, Any-PHY, SPECTRA-622, and TEMUX-84 are trademarks of PMC-Sierra, Inc. Other product and company names mentioned herein may be the trademarks of their respective owners.

### Patents

#### Granted

The technology discussed in this document is protected by one or more of the following patent grants:

U.S. Patent Nos. 5,640,398, 6,188,699, 6,333,935 and 6,584,521

Can. Patent Nos. 2,161,921, 2,224,392 and 2,234,493

Other relevant patent grants may also exist.

## Revision History

Issue No.	Issue Date	Details of Change
2	October 2003	Released version. Addresses various documentation issues, including those discussed in issue 2 of the device prototype errata. Change bars reflect differences between issue 1 and issue 2 of the data sheet.
1	July 2003	First Issue

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 0:02:17 PM

# 1 Definitions

The following table defines terms and abbreviations used in this document.

**Table 1 Definitions**

Term	Definition
ADDR	The Address Field in a PPP header
Any-PHY	Saturn Interface Specification and Interoperability Framework for Packet and Cell transfers between Physical layer and Link Layer devices
APPI	Any-PHY Packet Interface
B	The Begin bit of a fragment
BECN	Backward Explicit Congestion Notification
C/R	Command/Response bit in the Q.922 Header
CI	Connection Identifier
CRC	Cyclic Redundancy Check
CRC-CCITT	Cyclic Redundancy Check as specified by the CCITT
CNTL	Control field in a PPP header
COS	Class of Service
Datagram	A fragment, packet or frame
DE	Discard Eligibility
DLL	Digital Delay Lock Loop
DSLAM	Digital Subscriber Line Access Multiplexer
E	The End bit of a fragment
EC	Error Code
ECC	Error Correcting Code
Egress	Traffic flow from the switch to the line is defined as Egress traffic – equivalent to transmit
EOP	End of Packet
FECN	Forward Explicit Congestion Notification
FIFO	First In First Out
FCS	Frame Check Sequence
FR	Frame Relay
Fragment	A sub-unit of a packet or frame
Frame	A Frame Relay unit of transfer
FUNI	Frame Relay User to Network Interface
HDLC	High level Data Link Control
Ingress	Traffic flow from the line side to switch is defined as Ingress traffic – equivalent to receive
IETF	Internet Engineering Task Force
MIB	Management Information Database
ML	Multi-link
ML-FR	Multi-link Frame Relay
ML-PPP	Multi-link PPP

Term	Definition
MTU	Maximum Transmission Unit
MRU	Maximum Receive Unit
NNI	Network-to-Network Interface
Packet	An IP data unit
PID	Protocol ID field in a PPP header
PPP	Point to Point Protocol
Q.922	ISDN Data Link Layer Specification for Frame Mode Bearer Services
RFC	Request For Comments
SBI	Scalable Bandwidth Interface
SBI336	A Scalable Bandwidth Interface operating at 77.76 MHz capable of supporting 336 T1 links
SDRAM	Synchronous Dynamic Random Access Memory
SN	Sequence Number
SPE	Synchronous Payload Envelope
SSRAM	Synchronous Static Random Access Memory
TM	Traffic Management
UNI	User-to-Network Interface
ZBT	Zero Bus Turnaround

Downloaded [controlled] by he hai of neiep on Friday, 29 August 2018 05:02:17 PM

## 2 Features

The PM7312 FREEDM 32A1024L is a Frame Engine and Data Link Manager with these features:

- Single-chip multi-channel HDLC controller with either a 52 MHz 16 bit Any-PHY Level 2 or a 104 MHz 8 bit Any-PHY Level 3 packet interface for transfer of packet, frame data using an external controller.
- Supports line rate throughput for 32 T1s or E1s. (40 byte packets encapsulated in PPP over HDLC (50 byte transfers (RFC 1661) or 55 byte transfers (RFC 1990))).
- Provides simultaneous support of PPP, Frame Relay, multi-link-PPP and multi-link-Frame Relay protocols. Alternative protocols supported via HDLC termination and full packet store of the data within the HDLC structure.
- Supports 2 levels of priority queuing in the egress direction. When the device is configured to fragment low priority traffic, high priority traffic, if present, will be inserted in between low priority fragments on a link.

### 2.1 Interfaces

- A 52MHz, 16-bit Any-PHY Level 2 or 104MHz, 8-bit Any-PHY Level 3 packet interface for system side connection.
  - The interface is capable of supporting full datagram transfer on a per Any-PHY channel basis or
  - Fragmented packets or frames on a per Any-PHY channel basis.
- A single 19.44 MHz SBI or 77.76 MHz SBI336 bus supporting up to 32 links.
- A 100 MHz, 48-bit SDRAM interface for ingress and egress per packet/fragment storage.
- A 100 MHz, 32-bit SDRAM interface for ingress re-sequencing data structures.
- A 100 MHz, 36-bit SSRAM interface for Ingress/Egress Context storage.
- The device provides the standard 5 signal P1149.1 JTAG test port for boundary scan.
- A 32-bit microprocessor interface for configuration and status monitoring.

### 2.2 Channelization / HDLC Features

- Support for up to 1024 HDLC channels in both the ingress and egress direction, with individual HDLC channel speeds ranging from 56Kbps to 2 Mbps.
- The 1024 HDLC channels can be assigned to a mixture of physical links via the SBI interface. The SBI transports the equivalent of 3 STS-1 synchronous payload envelopes (SPE). Each STS-1 SPE can be individually configured to carry 28 T1/J1s or 21 E1s. The FREEDM 32A1024 can flexibly carry up to 32 T1s or E1s on these SPEs.
- In a channelized application, the number of time-slots assigned to an HDLC channel is programmable from 1 to 24 (for T1/J1) and from 1 to 31 (for E1).
- For each channel, the HDLC receiver supports programmable flag sequence detection, bit stuffing and frame check sequence validation. The receiver supports the validation of both CRC-CCITT and CRC-32 frame check sequences.

- For each HDLC channel, the receiver checks for packet abort sequences, octet alignment, and for minimum and maximum packet length.
- For each HDLC channel, time-slots are selectable to be in 56 Kbps format or 64 Kbps clear channel format.
- For each HDLC channel, the HDLC transmitter supports programmable flag sequence generation, bit stuffing and frame check sequence generation. The transmitter supports the generation of both CRC-CCITT and CRC-32 frame check sequences. The transmitter also aborts packets under the direction of the external TM engine or automatically when the channel underflows.
- Support for 2 levels of transmit priority per HDLC channel. (Only single link channels support this feature, not multi-link bundles.) High and low priority packets are queued separately. High priority traffic, when present, is always transmitted before low priority traffic. When low priority traffic is fragmented, high priority traffic is inserted in between low priority fragments.

## 2.3 PPP Features

- Link Control Protocol packet identification. Packets are identified by the PID as control protocols and will be forwarded to the Any-PHY interface.
- Capable of supporting line rate transfers of packet sizes from 40 to 9.6K bytes.
- Support for PPP header compression as per RFC 1661 on sequenced links. On receive, compressed headers are detected and processed appropriately as they arrive on an HDLC channel. Compressed PPP headers are passed to the system side via the Any-PHY interface. On transmit, compressed headers are accepted from the system side device via the Any-PHY interface. On sequenced links, all required processing is provided to correctly insert the compressed PPP headers into the 1024 HDLC channels. On non-sequenced links, header compression is only supported through the use of transparent mode.
- RFC-1990 Multi-link PPP bundles:
  - Capable of supporting fragment sizes from 6 to 9.6K bytes with the restriction that the maximum number of fragments per packet is 81.
  - Support for 3 egress fragmentation sizes (128, 256, and 512 bytes) configurable per connection. Optionally, full packet transfers are supported on a per connection basis. The FREEDM 32A1024L supports header compression but does not perform it.
  - Either 12 bit or 24 bit sequence number, with short and long fragment header formats, is supported.
  - Supports 16 bundles in ingress direction. These bundles are composed of independent HDLC channels.
  - Supports 16 bundles in egress direction. These bundles are composed of independent HDLC channels.
  - Support for fragmentation on a single HDLC channel.
  - Support for 16 COS levels in accordance with RFC 2686.
  - Support for up to 100ms of intra bundle skew in the receive direction when supporting the minimum fragment size. Capable of supporting larger skews (<400ms) with larger fragment sizes. The intra-bundle skew is limited by 12 bit sequence number capabilities.
  - Up to 12 member links per bundle.

- Each member link is required to operate at the same speed. Either T1/J1 or E1 rates.

## 2.4 Frame Relay Features

- Link layer address lookup can be performed based on HDLC or Any-PHY channel and DLCI for HDLC channels supporting Frame Relay protocols.
- Capable of supporting line rate transfers of frame sizes from 40 to 9.6K bytes.
- FRF.16 Multi-link FR bundles and FRF.12 UNI, NNI or End-to-End fragmentation:
  - Capable of supporting fragment sizes from 4 to 9.6K bytes with the restriction that the maximum number of fragments per packet is 81.
  - 10-bit DLCI format supported for channels operating in Frame Relay mode. Alternative DLCI formats supported when the lookup is based on HDLC channel only.
  - The lookup algorithm can support a maximum of 16K connection identifiers (CIs) amongst all channels in use.
  - FRF.16 Control Frames (Link Integrity Protocol) are identified and forwarded to the Any-PHY interface
  - Support for 3 egress fragmentation sizes (128, 256, and 512 bytes) configurable per connection. Optionally, full packet transfers are supported on a per connection basis.
  - 12 bit sequence numbers supported.
  - Support for fragmentation on a single HDLC channel. (Note – End-to-End fragmentation is only supported on single HDLC channels, not multilink bundles.)
  - 16 bundles in ingress direction. These bundles are composed of independent HDLC channels.
  - 16 bundles in egress direction. These bundles are composed of independent HDLC channels.
  - Support for up to 100ms intra-bundle skew within the limits of 12-bit sequence number capabilities when supporting the minimum fragment size. Capable of supporting larger skews (<400ms) with larger fragment sizes.
  - Up to 12 member links per bundle.
    - Each member link operates at the same speed either T1/J1 or E1.
    - FECN, BECN, and DE ingress processing as per FRF.12. The C/R value passed out in frame out mode is the value received on the Begin fragment.

## 2.5 Statistics

- FREEDM 32A1024L maintains the following counters on a per-HDLC channel basis:
  - CRC Errors observed by the HDLC framer.
  - HDLC framing aborts.
  - Non-Octet aligned frames.
  - HDLC MRU exceeded.
  - Bytes and datagrams received.
  - Bytes and datagrams transmitted.
- Additionally, the FREEDM 32A1024L provides the following counters per Ingress CI:

- Number of Lost Sequence Number events.
- Number of Unexpected Sequence Number events.
- Number of Frame Relay datagrams received with DE bit set.
- Additionally, the FREEDM 32A1024L provides the following global error counters:
  - Number of bytes discarded due to transmit overflows, receive overflows in the presence of link failures, and line rate arrivals of small (< 40 byte) packets.
  - Number of Lost fragment events
  - FIFO overflows and underruns.
  - Additional error states are also tracked.
- Additionally, FREEDM 32A1024L supports the MFR MIB by detecting and informing the host of unexpected sequence numbers and time outs.

## 2.6 Fault Isolation Features

- Two levels of loop-back are provided:
  - SBI tributary loopback
  - System side loop-back per HDLC channel.

## 2.7 Technologies

- 520 pin (1.27 mil pitch) thermally enhanced ball grid array (TEBGA) package.
- 331 signal pins, 3.3V I/O.
- Low power 0.18 $\mu$ m CMOS technology using 1.8V core power.

### 3 Applications

- IETF PPP interfaces for routers.
- Frame Relay interfaces for ATM or Frame Relay switches and multiplexers.
- FUNI or Frame Relay service inter-working interfaces for ATM switches and multiplexers.
- Internet/Intranet access equipment.
- Multi-service DSLAM equipment.

## 6 Block Diagram

Figure 2 Block Diagram of FREEDM 32A1024L

## 7 Description

The FREEDM 32A1024L device is a monolithic integrated circuit supporting highly channelized termination of HDLC-framed Point to Point Protocol (PPP) and Frame Relay, including multi-link variants.

On the Line side, the FREEDM 32A1024L device supports an SBI interface supporting up to 1024 HDLC channels. On the system side, the FREEDM 32A1024L provides a Level 2 and Level 3 APPI presenting a channelized interface capable of supporting full frame/packet transfers as well as fragment data transfers. Rate adaptation between the line and system side interfaces is provided by external buffers.

The FREEDM 32A1024L terminates up to 1024 HDLC channels of HDLC framed PPP or Frame Relay with speeds ranging from 56 Kbps to 2 Mbps in the ingress direction. HDLC channels may contain a mix of protocols and speeds up to an aggregate of 2 Mbps. FREEDM 32A1024L provides HDLC header removal, CRC checking and stripping. Data path termination including frame/packet re-assembly and multi-link termination is provided in hardware.

In the egress direction, the FREEDM 32A1024L receives packets from the external controller. The FREEDM 32A1024L provides support for ML-FR and ML-PPP protocols by fragmenting transmitted packets, appending the appropriate sequence number and assigning the fragment to an HDLC channel within the multi-link bundle. FREEDM 32A1024L is also capable of supporting full packet transfer on up to 1024 HDLC channels that are not configured to support multi-link. The HDLC processor within FREEDM 32A1024L encapsulates the data with HDLC flags, CRC bytes and performs the appropriate bit stuffing.

The FREEDM 32A1024L supports two levels of priority for egress traffic on HDLC channels that are not configured as part of a multi-link bundle. The priority of each packet received from the external controller is indicated by an additional address bit in the Any-PHY in-band address header word. Packets received with different priorities on a given channel are stored in separate queues for transmission. If the FREEDM 32A1024L is configured to fragment low-priority packets, any high priority data received following a low priority packet will be transmitted at the first available opportunity, and will be interleaved between fragments of the low priority packet if possible.

## 8 Pin Diagram

The FREEDM 32A1024L is manufactured in a 520-pin (1.27 mil pitch) thermally enhanced ball grid array package. (Bottom View)

## 9 Pin Description

Table 2 SBI Interface Signals (30 Pins)

Pin Name	Type	Pin No.	Function
REFCLK	Input	P30	<p>The SBI reference clock signal (REFCLK) provides reference timing for the SBI ADD and DROP buses.</p> <p>REFCLK is nominally a 50% duty cycle clock of frequency 19.44 MHz <math>\pm</math>50ppm for SBI bus operation or 77.76 MHz <math>\pm</math>20ppm for SBI336 bus operation</p>
DC1FP	Input	P31	<p>The C1 octet frame pulse signal (DC1FP) for the drop bus provides frame synchronization for devices connected via an SBI interface. DC1FP must be asserted for 1 REFCLK cycle every 500 <math>\mu</math>s or multiples thereof (i.e. every 38880 x n REFCLK cycles, where n is a positive integer). All devices interconnected via the SBI drop interface must be synchronized to a DC1FP signal from a single source.</p> <p>DC1FP is sampled on the rising edge of REFCLK.</p> <p>Note – If the SBI bus is being operated in synchronous mode, DC1FP must be asserted for 1 REFCLK cycle every 6 ms or multiples thereof.</p>
AC1FP	Input	K30	<p>The C1 octet frame pulse signal (AC1FP) for the add bus provides frame synchronization for devices connected via an SBI interface. AC1FP must be asserted for 1 REFCLK cycle every 500 <math>\mu</math>s or multiples thereof (i.e. every 38880 n REFCLK cycles, where n is a positive integer). All devices interconnected via the add SBI interface must be synchronized to an AC1FP signal from a single source.</p> <p>AC1FP is sampled on the rising edge of REFCLK.</p> <p>Note – If the SBI bus is being operated in synchronous mode, AC1FP must be asserted for 1 REFCLK cycle every 6 ms or multiples thereof.</p>
C1FPOUT	Output	K31	<p>The C1 octet frame pulse output signal (C1FPOUT) may be used to provide frame synchronization for devices interconnected via an SBI interface. C1FPOUT is asserted for 1 REFCLK cycle every 500 <math>\mu</math>s (i.e. every 38880 REFCLK cycles).</p> <p>C1FPOUT is updated on the rising edge of REFCLK.</p> <p>Note – The C1FPOUT pulse is not suitable for use in systems in which the SBI bus is operated in synchronous mode.</p>
DDATA[0] DDATA[1] DDATA[2] DDATA[3] DDATA[4] DDATA[5] DDATA[6] DDATA[7]	Input	R27 R28 R29 R30 R31 U31 U30 U27	<p>The SBI DROP bus data signals (DDATA[7:0]) contain the time division multiplexed receive data from the up to 32 independently timed links. Data from each link is transported as a tributary within the SBI TDM bus structure. Multiple PHY devices can drive the SBI DROP bus at uniquely assigned tributary column positions.</p> <p>DDATA[7:0] are sampled on the rising edge of REFCLK.</p>

Pin Name	Type	Pin No.	Function
DDP	Input	V31	<p>The SBI DROP bus parity signal (DDP) carries the even or odd parity for the DROP bus signals. The parity calculation encompasses the DDATA[7:0], DPL and DV5 signals.</p> <p>Multiple PHY devices can drive DDP at uniquely assigned tributary column positions. This parity signal is intended to detect accidental PHY source clashes in the column assignment.</p> <p>DDP is sampled on the rising edge of REFCLK.</p>
DPL	Input	V30	<p>The SBI DROP bus payload signal (DPL) indicates valid data within the SBI TDM bus structure. This signal is asserted during all octets making up a tributary. This signal may be asserted during the V3 octet within a tributary to accommodate negative timing adjustments between the tributary rate and the fixed TDM bus structure. This signal may be de-asserted during the octet following the V3 octet within a tributary to accommodate positive timing adjustments between the tributary rate and the fixed TDM bus structure.</p> <p>Multiple PHY devices can drive DPL at uniquely assigned tributary column positions.</p> <p>DPL is sampled on the rising edge of REFCLK.</p>
DV5	Input	V29	<p>The SBI DROP bus payload indicator signal (DV5) locates the position of the floating payloads for each tributary within the SBI TDM bus structure. Timing differences between the port timing and the TDM bus timing are indicated by adjustments of this payload indicator relative to the fixed TDM bus structure.</p> <p>Multiple PHY devices can drive DV5 at uniquely assigned tributary column positions. All movements indicated by this signal must be accompanied by appropriate adjustments in the DPL signal.</p> <p>DV5 is sampled on the rising edge of REFCLK.</p>
ADATA[0] ADATA[1] ADATA[2] ADATA[3] ADATA[4] ADATA[5] ADATA[6] ADATA[7]	Tristate Output	L28 L29 L30 M27 M28 M29 M30 M31	<p>The SBI ADD bus data signals (ADATA[7:0]) contain the time division multiplexed transmit data from the up to 32 independently timed links. Data from each link is transported as a tributary within the SBI TDM bus structure. Multiple link layer devices can drive the SBI ADD bus at uniquely assigned tributary column positions. When the FREEDM 32A1024L is not outputting data on a particular tributary column the ADATA[7:0] are driven or tri-stated based on the DEFAULT_DRV register value.</p> <p>ADATA[7:0] are updated on the rising edge of REFCLK.</p>
ADP	Tristate Output	N27	<p>The SBI ADD bus parity signal (ADP) carries the even or odd parity for the ADD bus signals. The parity calculation encompasses the ADATA[7:0], APL and AV5 signals.</p> <p>Multiple link layer devices can drive this signal at uniquely assigned tributary column positions. When the FREEDM 32A1024L is not outputting data on a particular tributary column, ADP is driven or tri-stated based on the DEFAULT_DRV register value. This parity signal is intended to detect accidental link layer source clashes in the column assignment.</p> <p>ADP is updated on the rising edge of REFCLK.</p>
APL	Tristate Output	N28	<p>The SBI ADD bus payload signal (APL) indicates valid data within the SBI TDM bus structure. This signal is asserted during all octets making up a tributary. This signal may be asserted during the V3 octet within a tributary to accommodate negative timing adjustments between the tributary rate and the fixed TDM bus structure. This signal may be de-asserted during the octet following the V3 octet within a tributary to accommodate positive timing</p>

Pin Name	Type	Pin No.	Function
			<p>adjustments between the tributary rate and the fixed TDM bus structure.</p> <p>Multiple link layer devices can drive this signal at uniquely assigned tributary column positions. When the FREEDM 32A1024L is not outputting data on a particular tributary column, APL is driven or tristated based on the DEFAULT_DRV register value.</p> <p>APL is updated on the rising edge of REFCLK.</p>
AV5	Tristate output	N30	<p>The SBI ADD bus payload indicator signal (AV5) locates the position of the floating payloads for each tributary within the SBI TDM bus structure. Timing differences between the port timing and the TDM bus timing are indicated by adjustments of this payload indicator relative to the fixed TDM bus structure.</p> <p>Multiple link layer devices can drive this signal at uniquely assigned tributary column positions. When the FREEDM 32A1024L is not outputting data on a particular tributary column, AV5 is driven or tristated based on the DEFAULT_DRV register value.</p> <p>AV5 is updated on the rising edge of REFCLK.</p>
ADETECT[0] ADETECT[1]	Input	P28 P29	<p>The SBI ADD bus conflict detection signals (ADETECT[1:0]) may be connected to the AACTIVE outputs of other link layer devices sharing the SBI ADD bus. FREEDM 32A1024L will tristate the SBI ADD bus signals ADATA[7:0], ADP, APL and AV5 if either of ADETECT[1] and ADETECT[0] is asserted.</p> <p>ADETECT[1:0] are asynchronous inputs.</p>
AJUST_REQ	Input	N31	<p>The SBI ADD bus justification request signal (AJUST_REQ) is used to speed up or slow down the output data rate of the FREEDM 32A1024L.</p> <p>Negative timing adjustments are requested by asserting AJUST_REQ during the V3 octet of the drop bus depending on the tributary type. In response to this the FREEDM 32A1024L will send an extra byte in the V3 octet of the next frame on the add bus along with a valid APL indicating a negative justification.</p> <p>Positive timing adjustments are requested by asserting AJUST_REQ during the octet following the V3 octet of the drop bus, depending on the tributary type. FREEDM 32A1024L will respond to this by not sending an octet during the octet following the V3 octet of the next frame on the add bus and de-asserting APL to indicate a positive justification.</p> <p>AJUST_REQ is sampled on the rising edge of REFCLK.</p>
AACTIVE	Output	P27	<p>The SBI ADD bus active indicator signal (AACTIVE) is asserted whenever FREEDM 32A1024L is driving the SBI ADD bus signals, ADATA[7:0], ADP, APL and AV5.</p> <p>All other Link Layer devices driving the SBI ADD bus should monitor this signal (to detect multiple sources accidentally driving the bus) and should cease driving the bus whenever a conflict is detected.</p> <p>AACTIVE is updated on the rising edge of REFCLK.</p>

**Table 3 Any-PHY Packet Interface Signals (71 Pins)**

**Note:** Any-PHY Level is s/w programmable.

Pin Name	Type	Pin No.	Function
TXCLK	Input	Y3	The transmit clock signal (TXCLK) provides timing for the transmit

Pin Name	Type	Pin No.	Function
			<p>Any-PHY packet interface.</p> <p><b>Any-PHY Level 2 Mode:</b> TXCLK is a nominally 50% duty cycle, 25 to 52 MHz clock.</p> <p><b>Any-PHY Level 3 Mode:</b> TXCLK is a nominally 50% duty cycle, 50 to 104 MHz clock.</p>
TXADDR[0] TXADDR[1] TXADDR[2] TXADDR[3] TXADDR[4] TXADDR[5] TXADDR[6] TXADDR[7] TXADDR[8] TXADDR[9] TXADDR[10] TXADDR[11] TXADDR[12] TXADDR[13] TXADDR[14] TXADDR[15]	Input	V5 V4 V3 V2 V1 U5 U4 U3 U2 U1 R1 R2 R5 P1 P2 P3	<p>The transmit address signals (TXADDR[15:0]) provide a channel address for polling a transmit Any-PHY channel FIFO. The FREEDM 32A1024L compares the TXADDR[15:0] to the base and range registers to determine if the Any-PHY channel being polled resides within the FREEDM 32A1024L. An Any-PHY channel with an address that is greater than or equal to the base register and less than or equal to the maximum address as defined by the range plus channel base address resides within the FREEDM 32A1024L.</p> <p>The TXADDR[15:0] signals are sampled on the rising edge of TXCLK.</p>
TPA_LO TPA_HI	Tristate Output	P4 R3	<p>The transmit packet available (TPA_xx) signals reflect the status of a poll of a transmit Any-PHY channel FIFO pair. TPA_LO returns the polled results for the low priority FIFO queue for Any-PHY channel address 'n' provided on TXADDR[15:0] and TPA_HI returns the results for the high priority queue. TPA_xx are coded as follows:</p> <p>TPA_xx = "1" =&gt; FIFO has space available.            TPA_xx = "0" =&gt; FIFO is full</p> <p>The thresholds, which determine whether or not a FIFO has space, are individually programmable for each channel and priority.</p> <p>It is the responsibility of the external controller to prevent Any-PHY channel underflow or overflow conditions by adequately polling each channel before data transfer.</p> <p>TPA_xx are updated on the rising edge of TXCLK. TPA_xx are tristate during reset.</p> <p><b>Any-PHY Level 2 Mode:</b></p> <p>TPA_xx are tristate when an Any-PHY channel address other than Any-PHY channels residing in the FREEDM is provided on TXADDR[15:0]. An Any-PHY channel with an address that is less than the channel base address register or outside the range address register within the FREEDM 32A1024L is identified as an Any-PHY channel that does not reside within the FREEDM 32A1024L.</p> <p>TPA_xx are tristate when an unprovisioned channel is polled.</p> <p>It is recommended that TPA_xx be connected externally to a weak pull-down, e.g. 470Ω.</p> <p><b>Any-PHY Level 3 Mode:</b></p> <p>TPA_xx return the value "0" when an Any-PHY channel address other than Any-PHY channels residing in the FREEDM is provided on TXADDR[15:0]. The TPA poll response is invalid if it corresponds to a TXADDR poll coincident with the start of a segment transfer (i.e. on the cycle in which TSX is driven high).</p>

Pin Name	Type	Pin No.	Function
			TPA_xx are 0 when an unprovisioned channel is polled.
TXDATA[0] TXDATA[1] TXDATA[2] TXDATA[3] TXDATA[4] TXDATA[5] TXDATA[6] TXDATA[7] TXDATA[8] TXDATA[9] TXDATA[10] TXDATA[11] TXDATA[12] TXDATA[13] TXDATA[14] TXDATA[15]	Input	P5 N1 N2 N3 N5 M1 M2 M3 M4 M5 L2 L3 L4 K1 K2 K3	<p><b>Any-PHY Level 2 Mode</b></p> <p>The transmit data signals (TXDATA[15:0]) contain the transmit Any-PHY packet interface (APPI) data provided by the external controller. Data must be presented in big endian order, i.e. the byte in TXDATA[15:8] is transmitted by the FREEDM 32A1024L before the byte in TXDATA[7:0].</p> <p>The first word of each data transfer contains an address to identify the device and Any-PHY channel associated with the data being transferred. This prepended address must be qualified with the TSX signal. The FREEDM 32A1024L compares the first two bytes to the base and range registers to determine if the Any-PHY channel resides within the FREEDM 32A1024L. The FREEDM 32A1024L will not respond to Any-PHY channel addresses outside the high and low address registers stored in the TAPI-12 base and range address registers.</p> <p>Bit 10 of the prepended address indicates the priority level of the data. Bit 10 = 0 indicates low priority and Bit 10 = 1 indicates high priority.</p> <p>The second and any subsequent words of each data transfer contain packet data.</p> <p>The TXDATA[15:0] signals are sampled on the rising edge of TXCLK.</p> <p><b>Any-PHY Level 3 Mode:</b></p> <p>The transmit data signals (TXDATA[7:0]) contain the transmit Any-PHY packet interface (APPI) data provided by the external controller.</p> <p>The first two bytes of each data transfer contains an address to identify the device and Any-PHY channel associated with the data being transferred. The first byte of this prepended address must be qualified with the TSX signal. The FREEDM 32A1024L compares the first two bytes to the TAPI-12 base and range registers to determine if the Any-PHY channel resides within the FREEDM 32A1024L. The FREEDM 32A1024L will not respond to Any-PHY channel addresses outside the base and range registers.</p> <p>Bit 10 of the prepended address (bit 2 of the first byte of the transfer) indicates the priority level of the data. Bit 10 = 0 indicates low priority and Bit 10 = 1 indicates high priority.</p> <p>The third and any subsequent bytes of each data transfer contain packet data.</p> <p>The TXDATA[7:0] signals are sampled on the rising edge of TXCLK.</p> <p>TXDATA[15:8] are not used by FREEDM 32A1024L when operating in Any-PHY Level 3 mode and should be tied low.</p>
TXPRTY	Input	K4	<p><b>Any-PHY Level 2 Mode:</b></p> <p>The transmit parity signal (TXPRTY) reflects the odd parity calculated over the TXDATA[15:0] signals (regardless of TMOD state). TXPRTY is only valid when TXDATA[15:0] are valid.</p> <p><b>Any-PHY Level 3 Mode:</b></p> <p>The transmit parity signal (TXPRTY) reflects the odd parity calculated over the TXDATA[7:0] signals. TXPRTY is only valid when TXDATA[7:0] are valid.</p> <p>Regardless of mode of operation TXPRTY is sampled on the rising</p>

Pin Name	Type	Pin No.	Function
			edge of TXCLK.
TRDY	Tristate Output	J1	<p>The transmit ready signal (TRDY) indicates the ability of the transmit Any-PHY packet interface (APPI) to accept data. When TRDY is set low, the transmit APPI is unable to accept further data. When TRDY is set high, data provided on the transmit APPI will be accepted by the FREEDM 32A1024L device</p> <p>If TRDY is driven low, the external controller must hold the data on TXDATA until TRDY is driven high. TRDY may be driven low for 0 or more TXCLK cycles before it is driven high. TRDY is considered valid from two cycles after the start of transfer until the cycle in which it is asserted high (it can only backpressure once at the start of transfer).</p> <p>A new transfer cannot be initiated earlier than one clock after TRDY is sampled high.</p> <p>TRDY is tristate during reset.</p> <p>TRDY is updated on the rising edge of TXCLK.</p> <p><b>Any-PHY Level 2 Mode</b></p> <p>TRDY is valid one TXCLK cycle after TSX is sampled high. TRDY is asserted by the FREEDM 32A1024L device, which was selected by the in-band Any-PHY channel address on TXDATA[15:0].</p> <p>TRDY will only be driven high for one clock cycle, it is always driven tristate one TXCLK cycle after it is driven high.</p> <p>It is recommended that TRDY be connected externally to a weak pull-up, e.g. 10 kΩ.</p> <p><b>Any-PHY Level 3 Mode</b></p> <p>TRDY is valid one TXCLK cycle after TSX is sampled high and remains valid up to and including the cycle in which it is driven high.</p>
TSX	Input	K5	<p>The transmit start of transfer signal (TSX) denotes the start of data transfer on the transmit APPI.</p> <p>The TSX signal is sampled on the rising edge of TXCLK.</p> <p><b>Any-PHY Level 2 Mode</b></p> <p>When the TSX signal is sampled high, the sampled word on the TXDATA[15:0] signals contain the Any-PHY channel address and priority associated with the data to follow. When the TSX signal is sampled low, the sampled word on the TXDATA[15:0] signals does not contain the Any-PHY channel address/priority.</p> <p><b>Any-PHY Level 3 Mode:</b></p> <p>When the TSX signal is sampled high, the sampled byte on the TXDATA[7:0] signals contain the most significant byte of the Any-PHY channel address and priority associated with the data to follow. When the TSX signal is sampled low, the sampled word on the TXDATA[7:0] signals does not contain the first byte of the Any-PHY channel address/priority.</p>
TEOP	Input	J2	<p>The transmit end of packet signal (TEOP) denotes the end of a packet. TEOP is only valid during data transfer.</p> <p>TEOP is sampled on the rising edge of TXCLK.</p> <p><b>Any-PHY Level 2 Mode</b></p> <p>When TEOP is sampled high, the data on TXDATA[15:0] is the last word of a packet. When TEOP is sampled low, the data on TXDATA[15:0] is not the last word of a packet (fragment).</p>

Pin Name	Type	Pin No.	Function
			<p><b>Any-PHY Level 3 Mode:</b></p> <p>When TEOP is sampled high, the data on TXDATA[7:0] is the last byte of a packet (fragment). When TEOP is sampled low, the data on TXDATA[7:0] is not the last byte of a packet (fragment).</p>
TMOD	Input	J3	<p><b>Any-PHY Level 2 Mode</b></p> <p>The transmit word modulo signal (TMOD) indicates the size of the current word on TXDATA[15:0]. TMOD is only valid when TEOP is sampled high. When TMOD is sampled high and TEOP is sampled high, only the TXDATA[15:8] signals contain valid data and the TXDATA[7:0] signals are invalid. When TMOD is sampled low and TEOP is sampled high, the complete word on TXDATA[15:0] contains valid data. TMOD must be set low when TEOP is set low. TMOD is sampled on the rising edge of TXCLK.</p> <p><b>Any-PHY Level 3 Mode:</b></p> <p>TMOD is not used. The last valid byte of data on TXDATA[7:0] is sampled when TEOP is sampled high.</p>
TERR	Input	J4	<p>The transmit error signal (TERR) indicates that the current packet is erred and should be aborted. TERR is only valid when TEOP is sampled high. When TERR is sampled high and TEOP is sampled high, the current packet is erred and the FREEDM 32A1024L will respond accordingly. When TERR is sampled low and TEOP is sampled high, the current packet is not erred. TERR must be set low when TEOP is set low.</p> <p>TERR is sampled on the rising edge of TXCLK.</p>
RXCLK	Input	AE5	<p>The receive clock signal (RXCLK) provides timing for the receive Any-PHY packet interface (APPI).</p> <p><b>Any-PHY Level 2 Mode</b></p> <p>RXCLK is a nominally 50% duty cycle, 25 to 52 MHz clock.</p> <p><b>Any-PHY Level 3 Mode:</b></p> <p>RXCLK is a nominally 50% duty cycle, 50 to 104 MHz clock.</p>
RXADDR[0] RXADDR[1] RXADDR[2] RXADDR[3]	Input	AF2 AE4 AE3 AE2	<p><b>Any-PHY Level 2 Mode:</b></p> <p>The receive address signals (RXADDR[3:0]) serve two functions – device polling and device selection. When polling, the RXADDR[3:0] signals provide an address for polling a FREEDM 32A1024L device for receive data available in any one of its 1024 Any-PHY channels. Polling results are returned on the RPA tristate output. During selection, the address on the RXADDR[3:0] signals is qualified with the RENB signal to select a FREEDM 32A1024L device enabling it to output data on the receive APPI. Note that up to fifteen FREEDM 32A1024L devices may share a single external controller (one address is reserved as a null address). The Rx APPI of each FREEDM 32A1024L device is identified by the device base address in the RAPI-12 Base Address register.</p> <p>The RXADDR[3:0] signals are sampled on the rising edge of RXCLK.</p> <p><b>Any-PHY Level 3 Mode:</b></p> <p>RXADDR is not used as the interface is point-to-point.</p>
RPA	Tristate Output	AE1	<p>The receive packet/fragment available signal (RPA) reflects the status of a poll on the receive APPI of a FREEDM 32A1024L device.</p> <p>RPA is tristate during reset and when a device address other than the FREEDM 32A1024L's device base address is provided on</p>

Pin Name	Type	Pin No.	Function
			<p>RXADDR[3:0].</p> <p>An FREEDM 32A1024L device must not be selected for receive data transfer unless it has been polled and responded that it has data ready to transfer.</p> <p>When the RXADDR[3:0] inputs match the device base address in the RAPI-12 Base Address register, that FREEDM 32A1024L device drives RPA one RXCLK cycle after sampling RXADDR[3:0]. RPA is updated on the rising edge of RXCLK.</p> <p><b>Any-PHY Level 2 Packet Mode:</b></p> <p>When RPA is set high, the polled FREEDM 32A1024L still has sufficient data to undertake another Any-PHY transfer. When RPA is set low, the polled FREEDM 32A1024L device does not have data ready to transfer.</p> <p><b>Any-PHY Level 3 Mode:</b></p> <p>RPA is not used and is tri-stated.</p>
RENB	Input	AD4	<p>The receive enable signal (RENB) is used to throttle the FREEDM 32A1024L.</p> <p>RENB is sampled on the rising edge of RXCLK.</p> <p>To commence data transfer, RENB must be sampled low.</p> <p><b>Any-PHY Level 2 Mode:</b></p> <p>The receive enable signal (RENB) qualifies the RXADDR[3:0] signals for selection of a FREEDM 32A1024L device. When RENB is sampled high and then low in consecutive RXCLK cycles, the address on RXADDR[3:0] during the cycle when RENB is sampled high selects a FREEDM 32A1024L device enabling it to output data on the receive APPI. The Rx APPI of each FREEDM 32A1024L device is identified by the device base address in the RAPI-12 Base Address register.</p> <p>RENB may also be used to throttle the FREEDM 32A1024L during data transfer on the Rx APPI. When the FREEDM 32A1024L samples RENB high during data transfer, the FREEDM 32A1024L will pause the data transfer and tri-state the receive APPI outputs (except RPA) until RENB is returned low. Since the Any-PHY bus specification does not support deselecting during data transfers, the address on the RXADDR[3:0] inputs during the cycle before RENB is returned low must either re-select the same FREEDM 32A1024L device or be a null address.</p> <p>The polling function of the RXADDR[3:0] and RPA signals operates regardless of the state of RENB.</p> <p>It is the responsibility of the external controller to prevent overflow by providing each FREEDM 32A1024L device on an Any-PHY point to multi-point bus sufficient bandwidth through selection.</p> <p><b>Any-PHY Level 3 Mode:</b></p> <p>RENB is used to throttle the FREEDM 32A1024L during data transfer on Rx APPI. When the FREEDM 32A1024L samples RENB high during data transfer, the FREEDM 32A1024L will pause the data transfer until RENB is returned low.</p>

Pin Name	Type	Pin No.	Function																								
RXDATA[0] RXDATA[1] RXDATA[2] RXDATA[3] RXDATA[4] RXDATA[5] RXDATA[6] RXDATA[7] RXDATA[8] RXDATA[9] RXDATA[10] RXDATA[11] RXDATA[12] RXDATA[13] RXDATA[14] RXDATA[15]	Tristate Output	AD3 AD2 AC5 AD1 AC4 AC2 AB5 AC1 AB4 AB3 AB2 AB1 AA4 AA3 AA2 Y5	<p><b>Any-PHY Level 2 Mode</b></p> <p>The receive data signals (RXDATA[15:0]) contain the receive Any-PHY packet interface (APPI) data output by the FREEDM 32A1024L when selected. Data is presented in big endian format; i.e. the byte in RXDATA[15:8] was received by the FREEDM 32A1024L before the byte in RXDATA[7:0].</p> <p>The first word of each data transfer (when RSX is high) contains an address to identify the device and Any-PHY channel associated with the data being transferred. The second and any subsequent words of each data transfer contain valid data. The FREEDM 32A1024L may be programmed to overwrite RXDATA[7:0] of the final word of each packet transfer (REOP is high) with the status of packet reception when that packet is erred (RERR is high). This status information is encoded as follows:</p> <table border="0"> <tr> <td><u>RXDATA[7:0]</u></td> <td><u>Error</u></td> </tr> <tr> <td>01H</td> <td>Channel FIFO Overrun</td> </tr> <tr> <td>02H</td> <td>Packet Length violation</td> </tr> <tr> <td>04H</td> <td>FCS Error</td> </tr> <tr> <td>08H</td> <td>Non-Octet Aligned</td> </tr> <tr> <td>10H</td> <td>HDLC Packet Abort</td> </tr> <tr> <td>81H</td> <td>Unexpected Presence of SN</td> </tr> <tr> <td>82H</td> <td>Unsupported Header Format</td> </tr> <tr> <td>84H</td> <td>Lost Datagram</td> </tr> <tr> <td>88H</td> <td>Unexpected SN</td> </tr> <tr> <td>90H</td> <td>Excessive Number of Fragments</td> </tr> <tr> <td>A0H</td> <td>Seq. DQM	Output	AC3	Drives DQMH and DQML inputs of all SDRAMs. During the SDRAM initialization sequence this signal is set "high". Otherwise it is "low" at all times as the DRAM Controllers do not utilize the "masking" functionality of the memories. DQM is updated on the rising edge of SYSCLK.

**Table 5 Context Memory Synchronous SSRAM Interface (57 Signals)**

Pin Name	Type	Pin No.	Function
CCDAT[0] CCDAT[1] CCDAT[2] CCDAT[3] CCDAT[4] CCDAT[5] CCDAT[6] CCDAT[7] CCDAT[8] CCDAT[9] CCDAT[10] CCDAT[11] CCDAT[12] CCDAT[13] CCDAT[14] CCDAT[15] CCDAT[16] CCDAT[17] CCDAT[18] CCDAT[19] CCDAT[20] CCDAT[21] CCDAT[22] CCDAT[23] CCDAT[24] CCDAT[25] CCDAT[26] CCDAT[27] CCDAT[28] CCDAT[29] CCDAT[30] CCDAT[31] CCDAT[32] CCDAT[33] CCDAT[34] CCDAT[35]	I/O	A20 B20 C20 D20 E20 B21 C21 D21 A22 B22 C22 D22 A23 E22 B23 C23 D23 A24 E23 D24 A25 E24 C25 D25 B26 E25 C26 A27 D26 B27 E26 C27 B28 D27 E28 D30	Context Memory SSRAM Data. The bi-directional SSRAM data bus pins interface directly with the synchronous SSRAM data ports.  The FREEDM 32A1024L presents valid data on the CCDAT[35:0] pins upon the rising edge of SYSCLK during write cycles. CCDAT [35:0] is tristated on the rising edge of SYSCLK for read cycles.  CCDAT [35:0] is sampled/updated/tristated on the rising edge of SYSCLK.
CCADD[0] CCADD[1] CCADD[2] CCADD[3] CCADD[4] CCADD[5] CCADD[6] CCADD[7] CCADD[8] CCADD[9] CCADD[10] CCADD[11] CCADD[12] CCADD[13] CCADD[14] CCADD[15] CCADD[16] CCADD[17]	Output	J31 K27 J28 H31 J27 H30 H29 H28 G31 G30 G29 G28 F30 G27 F29 E31 F28 E30	Context Memory SSRAM Address. The SSRAM address outputs identify the SSRAM locations accessed.  CCADD[17:0] is updated on the rising edge of SYSCLK.
CCWEB	Output	F27	Context Memory SSRAM Write Bar. CCWEB determines the cycle type when CCSELB is asserted low. When CCWEB is asserted high, the cycle type is a read. When CCWEB is asserted low, the

Pin Name	Type	Pin No.	Function
			cycle type is a write. CCWEB is updated on the rising edge of SYSCLK.
CCSELB	Output	E29	Context Memory SSRAM Chip Enable Bar. CCSELB initiates an access. When CCSELB is asserted low, the external SSRAM samples the address and CCWEB asserted by the FREEDM 32A1024L. CCSELB is updated on the rising edge of SYSCLK.
CCBSELB	Output	K29	SSRAM Bank Select This active low output is provided to enable glueless connection to 4 banks of Standard/ZBT SSRAM: CCBSELB is the inverse of CCADD[16]. CCBSELB and CCADD[16:17] are used to select 4 banks when 64x36 devices are used.

**Table 6 Chunk Buffer SDRAM Interface (67 Signals)**

Pin Name	Type	Pin No.	Function
CBCSB	Output	AF5	Chunk Buffer SDRAM Chip Select Bar. CBCSB, CBRASB, CBCASB, and CBWEB define the command being sent to the SDRAM. CBCSB is updated on the rising edge of SYSCLK.
CBRASB	Output	AG2	Chunk Buffer SDRAM Row Address Strobe Bar. CBCSB, CBRASB, CBCASB, and CBWEB define the command being sent to the SDRAM. CBRASB is updated on the rising edge of SYSCLK.
CBCASB	Output	AF4	Chunk Buffer SDRAM Column Address Strobe Bar. CBCSB, CBRASB, CBCASB, and CBWEB define the command being sent to the SDRAM. CBCASB is updated on the rising edge of SYSCLK.
CBWEB	Output	AG3	Chunk Buffer SDRAM Write Enable Bar. CBCSB, CBRASB, CBCASB, and CBWEB define the command being sent to the SDRAM. CBWEB is updated on the rising edge of SYSCLK.
CBADD[0] CBADD[1] CBADD[2] CBADD[3] CBADD[4] CBADD[5] CBADD[6] CBADD[7] CBADD[8] CBADD[9] CBADD[10] CBADD[11] CBADD[12]	Output	AH7 AK6 AG7 AJ6 AL5 AH6 AK5 AG6 AJ5 AK4 AH5 AG4 AH2	Chunk Buffer SDRAM Address. The Chunk Buffer SDRAM address outputs identify the row address (CBADD[12:0]) and column address (CBADD[8:0]) for the locations accessed. CBADD[12:0] is updated on the rising edge of SYSCLK.
CBBS[0] CBBS[1]	Output	AG1 AF3	Chunk Buffer SDRAM Bank Select. The bank select signal determines which bank of a dual/quad bank Chunk Buffer SDRAM chip is active. CBBS[1:0] is generated along with the row address when CBRASB is asserted low. CBBS[1:0] is updated on the rising edge of SYSCLK.

**Table 7 Microprocessor Interface Signals (44)**

Pin Name	Type	Pin No.	Function
BCLK	Input	G5	Bus Clock. This clock is the bus clock for the microprocessor interface. BCLK must cycle at 33-66 MHz instantaneous rate.

Pin Name	Type	Pin No.	Function
AD[0] AD[1] AD[2] AD[3] AD[4] AD[5] AD[6] AD[7] AD[8] AD[9] AD[10] AD[11] AD[12] AD[13] AD[14] AD[15] AD[16] AD[17] AD[18] AD[19] AD[20] AD[21] AD[22] AD[23] AD[24] AD[25] AD[26] AD[27] AD[28] AD[29] AD[30] AD[31]	I/O	F3 E1 F4 E2 F5 E3 D2 E4 D5 B4 C5 E6 B5 D6 A5 C6 E7 B6 D7 C7 B7 A7 D8 C8 B8 E9 A8 D9 E10 A9 D10 C10	Multiplexed Address Data Bus. The multiplexed address data bi-directional bus AD[31:0] is used to connect the FREEDM 32A1024L to the microprocessor.  During the address phase when ADSB = 0, AD[1:0] are ignored as all transfers are 32 bits wide.  AD[31:0] is sampled/updated/tristated on the rising edge of BCLK.
ADSB	Input	B10	Address Status. This signal is active-low and indicates a long-word address is present on the address/data bus AD[31:2].  ADSB is sampled on the rising edge of BCLK.
CSB	Input	A10	Active Low Chip Select. The chip select (CSB) signal is low during the address cycle (as defined by ADSB) FREEDM 32A1024L register accesses.  CSB is sampled on the rising edge of BCLK.
WR	Input	D11	Write/Read. The write/read (WR) signal is evaluated when the ADSB and CSB are sampled active by FREEDM 32A1024L. The BUSPOL input pin controls the polarity of this input.  WR is sampled on the rising edge of BCLK.
BURSTB	Input	C11	Burst Bar. This signal is evaluated when the ADSB and CSB are sample active by FREEDM 32A1024L. When low, this signal indicates that the current access is a burst access (and the BLAST input can be used to detect the end of the transaction).  BURSTB is sampled on the rising edge of BCLK.
BLAST	Input	B11	Burst Last. This signal indicates the last data access of the transfer. When the BURSTB input is low, the BLAST input is driven active during the last transfer of a transaction (even if the transaction is one word in length). When the BURSTB input is high, the BLAST input is ignored by FREEDM 32A1024L. The BUSPOL input pin controls the polarity of this input.  BLAST is sampled on the rising edge of BCLK.

Pin Name	Type	Pin No.	Function
READYB	Tri-state Output	E12	Ready Bar. This active low signal indicates that data on the AD[31:0] bus has been accepted (for writes), or data on the AD[31:0] is valid (for reads). This signal may be used by FREEDM 32A1024L to delay a data transaction. This output is tristated one clock cycle after an FREEDM 32A1024L access, allowing multiple slave devices to be tied together in the system. This output should be pulled up externally. READYB is updated on the rising edge of BCLK.
BTERMB	Tri-state Output	D12	Burst Terminate Bar. This signal is asserted low by FREEDM 32A1024L when a data transfer has reached the address boundary of a burstable range. The maximum burst range supported is 4. Attempts to extend the burst transfer after this signal is asserted will be ignored. This output is tristated one clock cycle after an FREEDM 32A1024L access, allowing multiple slave devices to be tied together in the system. This output should be pulled up externally. BTERMB is updated on the rising edge of BCLK.
WRDONEB	Output	C12	Write Done Bar. This signal is asserted low by FREEDM 32A1024L when the most recent write access to internal registers is complete. This signal may be used by external circuitry to delay the issuance of a write operation address cycle until FREEDM 32A1024L can accept write data. This signal is only needed in systems where the READYB output cannot be used to delay a write data transaction (due to microprocessor restrictions). WRDONEB is updated on the rising edge of BCLK.
INTHIB	OD	B12	Active Low Open-Drain High Priority Interrupt. This signal goes low when a FREEDM 32A1024L high priority interrupt source is active and that source is unmasked. The FREEDM 32A1024L may be enabled to report many alarms or events via interrupts. INTHIB becomes high impedance when the interrupt is acknowledged via an appropriate register access. INTHIB is an asynchronous signal.
INTLOB	OD	A12	Active Low Open-Drain Low Priority Interrupt. This signal goes low when a FREEDM 32A1024L low priority interrupt source is active and that source is unmasked. The FREEDM 32A1024L may be enabled to report many alarms or events via interrupts. INTLOB becomes high impedance when the interrupt is acknowledged via an appropriate register access. INTLOB is an asynchronous signal.
BUSPOL	Input	E13	Bus Control Polarity. This signal indicates the polarity of the WR and BLAST inputs to FREEDM 32A1024L. When high, the BLAST pin is active high (high indicates the last word of the burst) and the WR pin is active low (low indicates write). When low, the BLAST pin is active low (low indicates the last word of the burst) and the WR pin is active high (high indicates write). BUSPOL is sampled on the rising edge of BCLK.

**Table 8 Miscellaneous Interface Signals (10 Pins)**

Pin Name	Type	Pin No.	Function
SYSCLK	Input	H1	The system clock (SYSCLK) provides timing for the core logic. SYSCLK is nominally a 50% duty cycle clock of frequency 100 MHz ±50ppm.

Pin Name	Type	Pin No.	Function
RSTB	Input	H3	The active low reset signal (RSTB) signal provides an asynchronous FREEDM 32A1024L reset. RSTB is an asynchronous input. When RSTB is set low, all FREEDM 32A1024L registers are forced to their default states. This signal must be held low for a minimum of 320ns. In addition, all SBI, APPI and $\mu$ P interface output pins are forced tristate and will remain tristated until RSTB is set high. RSTB must be asserted until the SDRAMs are out of reset.
PMCTEST	Input	H4	The PMC production test enable signal (PMCTEST) places the FREEDM 32A1024L in scan mode. PMCTEST must be tied low for normal operation (and during BIST).
DLLTEST	Input	H2	The DLL test enable signal (DLLTEST) places the DLL in scan mode. DLLTEST must be tied low for normal operation (and during BIST).
SCAN_EN	Input	D13	The PMC Production SCAN_EN signal is used during scan mode. It must be tied low for normal operation.
TCK	Input	G3	The test clock signal (TCK) provides timing for test operations that can be carried out using the IEEE P1149.1 test access port. TMS and TDI are sampled on the rising edge of TCK. TDO is updated on the falling edge of TCK.
TMS	Input	G4	The test mode select signal (TMS) controls the test operations that can be carried out using the IEEE P1149.1 test access port. TMS is sampled on the rising edge of TCK. TMS has an integral pull up resistor.
TDI	Input	H5	The test data input signal (TDI) carries test data into the FREEDM 32A1024L via the IEEE P1149.1 test access port. TDI is sampled on the rising edge of TCK. TDI has an integral pull up resistor.
TDO	Tristate Output	G1	The test data output signal (TDO) carries test data out of the FREEDM 32A1024L via the IEEE P1149.1 test access port. TDO is updated on the falling edge of TCK. TDO is a tristate output, which is inactive except when scanning of data is in progress.
TRSTB	Input	F2	The active low test reset signal (TRSTB) provides an asynchronous FREEDM 32A1024L test access port reset via the IEEE P1149.1 test access port. TRSTB is an asynchronous input with an integral pull up resistor. Note that when TRSTB is not being used, it must be connected to the RSTB input.

**Notes on Pin Description:**

1. All FREEDM 32A1024L inputs and bi-directionals present minimum capacitive loading.
2. All FREEDM 32A1024L outputs can be tristated under control of the IEEE P1149.1 test access port, even those that do not tristate under normal operation. All outputs and bi-directionals are 3.3 V tolerant when tristated.
3. Inputs TMS, TDI and TRSTB have internal pull-up resistors.
4. Power to the VDD3V3 pins should be applied *before* power to the VDD1V8 pins is applied. Similarly, power to the VDD1V8 pins should be removed *before* power to the VDD3V3 pins is removed.

## 10 Functional Description

### 10.1 Interfaces

#### 10.1.1 Scaleable Bandwidth Interconnect (SBI) Interface

The Scaleable Bandwidth Interconnect is a synchronous, time-division multiplexed bus designed to transfer, in a pin-efficient manner, data belonging to a number of independently timed links of varying bandwidth. The SBI interface supported in FREEDM 32A1024L is a parallel 8 bit wide 19.44 MHz or 77.76 MHz bus.

Timing is communicated across the Scaleable Bandwidth Interconnect by floating data structures. Payload indicator signals in the SBI control the position of the floating data structure and therefore the timing. When sources are running faster than the SBI the floating payload structure is advanced by an octet by passing an extra octet in the V3 octet locations. When the source is slower than the SBI the floating payload is retarded by leaving the octet after the V3 octet unused. Both these rate adjustments are indicated by the SBI control signals.

The SBI multiplexing structure is modeled on the SONET/SDH standards. The SONET/SDH virtual tributary structure is used to carry T1/J1 and E1 links.

An SBI interface consists of a DROP BUS and an ADD BUS. On the DROP BUS all timing is sourced from the PHY and is passed onto the FREEDM 32A1024L by the arrival rate of data over the SBI. On the ADD BUS either the PHY or the FREEDM 32A1024L can control timing. When the FREEDM 32A1024L is the timing master, the PHY device determines its transmit timing information from the arrival rate of data across the SBI. When the PHY device is the timing master, it signals the FREEDM 32A1024L to speed up or slow down with justification request signals. The PHY timing master indicates a speedup request to the Link Layer by asserting the justification request signal high during the V3 octet of the DROP bus. When this is detected by the FREEDM 32A1024L it will advance the channel by inserting data in the next V3 octet as described above. The PHY timing master indicates a slowdown request to the FREEDM 32A1024L by asserting the justification request signal high during the octet after the V3 octet of the DROP bus. The FREEDM 32A1024L responds by leaving the octet following the next V3 octet unused. Both advance and retard rate adjustments take place in the frame or multi-frame following the justification request.

The SBI structure uses a locked SONET/SDH structure fixing the position of the TUG-3/TU-3 relative to the STS-12/STM-4 transport frame. The SBI is also of fixed frequency and alignment as determined by the reference clock (REFCLK) and frame indicator signal (AC1FP or DC1FP). Adjusting the location of the T1/J1/E1 channels using floating tributaries as determined by the V5 indicator and payload signals (DV5, AV5, DPL and APL) compensates frequency deviations.

The multiplexed links are separated into three Synchronous Payload Envelopes. Each envelope may be configured independently to carry up to 28 T1/J1s or 21 E1s.

#### 10.1.2 Any-PHY Interface

The Any-PHY Interface is an asynchronous interface that supports the transfer of data to and from the Any-PHY channels within the FREEDM 32A1024L. Two variants of the Any-PHY interface are supported in FREEDM 32A1024L: a parallel 52 MHz 16 bit wide bus (Any-PHY Level 2), and a parallel 8 bit wide 104 MHz bus (Any-PHY Level-3).

Datagrams are transferred across the interface as a series of continuous segments. A segment (see Figure 4 to Figure 13 for examples) consists of an address/priority prepend and a fixed size of data (except at the end of packet, when the segment may be shorter). The prepend indicates the Any-PHY channel associated with the segment. Three segment sizes are possible (64,128,and 256 bytes.) The address prepend is not included in this segment size. A transfer will be terminated early if the end of packet occurs before the end of a segment. The minimum packet/frame size supported is 2 bytes.

In the egress path, only complete packets can be transferred over the Any-PHY Interface while in the ingress path, either complete packets or FRF.12 and RFC 1990 fragments may be transferred. Begin (B) and End (E) bits are used to identify the starting fragment of a packet (B=1) and the last fragment of a packet (E=1). When a complete packet is transferred across the interface both bits (B and E) are set to 1.

### Transmit Any-PHY Considerations

In the transmit (egress) direction, Bit 10 of the prepend indicates whether the data is high or low priority. For single (i.e. non-multi-link) links, the Any-PHY channel is mapped to an HDLC channel via entries in the TFRAG Any-PHY Channel RAM. For multi-link bundles, the Any-PHY channel is mapped to a multi-link bundle via entries in the TFRAG Any-PHY Channel RAM. Only one level of data priority is supported for multi-link bundles and the priority bit in the prepend of multi-link data segments must be set to 0.

Provided that FIFO space is available (TPA\_HI and/or TPA\_LO return 1 in response to a channel poll), the FREEDM 32A1024L expects an entire packet/fragment to be transferred. It is not permitted to interleave the segments of packets destined for different channels, nor to interleave segments of high-priority and low-priority packets belonging to the same channel.

The address prepend identifies the Any-PHY channel and priority associated with the segment. In the transmit direction, the FREEDM 32A1024L uses the address prepend to index Any-PHY channel records that indicate the configuration of the Any-PHY channel and priority. A connection identifier is used to index connection context records that dictate how FREEDM 32A1024L should process the datagram. The connection record contains various connection information including an indication of whether the connection is to be fragmented. A connection identifier must be present on all PPP and FR datagrams.

It should be noted that the PID values (PID(H) and PID(L)) referenced in the following diagrams refers to the multi-link PID = 0x003D if the connection is sequenced or the PID of the actual datagram if the connection is non-sequenced. In the case of a sequenced connection, the first Payload data will then be the actual PID of the datagram.

For uncompressed PPP packets, the FREEDM 32A1024L will accept any value of address and control fields (so as not to prohibit future changes of these values).

### Any-PHY Segment Formats

The Address/Priority Prepend bytes in Figure 4 to Figure 13 refer only to the Egress path. In the Ingress path the bytes are simply an Address Prepend.

**Any-PHY Level 2 Mode** – Figure 4 to Figure 11 illustrate the transfer requirements for the various transfer types using this mode.

## 10.2 Memory Port

### 10.2.1 Writing

Write operations to external memory can be performed in up to 4-long word bursts to the memory port. The procedure is as follows:

1. The microprocessor polls the MPBusy bit of the Memory Port Control register (or monitors the MPISTATI interrupt) to verify that the previous write is complete. Alternatively, this step may be skipped if the system application allows FREEDM 32A1024L to withhold the READYB for write accesses. In this case, FREEDM 32A1024L will delay write operations to the write burst registers and overflow register until the previous write command is complete.
2. The microprocessor writes up to 4 long words of data into the write burst register array and the overflow register (for 48-bit accesses).
3. The microprocessor writes a command to the memory burst control register. The command indicates the aperture, the quad-long word address in memory, the type of write (masked or unmasked), and the 4 long word enables. MPBusy will be set until the write is complete.
4. FREEDM 32A1024L arbitrates for the appropriate memory, performs the write to memory, and clears the MPBusy bit in the control register.

### 10.2.2 Reading

Reads from external memory can be performed in 4-long word bursts from the memory port. The procedure is as follows:

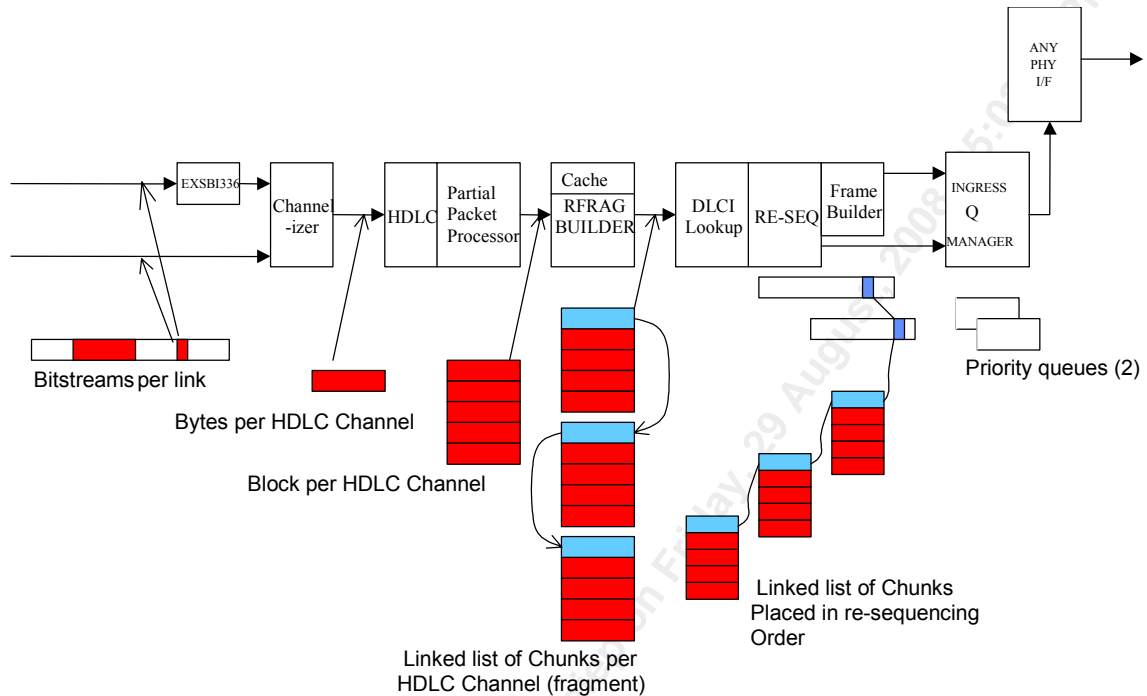

1. The microprocessor issues a read command to the Memory Port Control register. The command indicates aperture, the quad-long word address in memory, and 4 long word enables. The MPBusy bit will be set by the FREEDM 32A1024L.
2. FREEDM 32A1024L arbitrates for the appropriate memory, performs the read from memory and loads the read burst registers with the results, and clears the MPBusy bit in the control register.
3. The microprocessor polls the MPBusy bit of the Memory Port Control register status (or monitors the MPISTATI interrupt) to verify that the read is complete. Alternatively, this step may be skipped if the system application can tolerate long response times for read accesses. In this case, FREEDM 32A1024L will delay read operations from the read burst registers and overflow register until the read command is complete.
4. The microprocessor reads up to 4 long words of data from the read burst register array and the overflow register (for 48-bit accesses).

## 10.3 Packet Walkthrough

### 10.3.1 Ingress Path

Figure 14 shows the elements and data transformations that occur as data traverses the FREEDM 32A1024L from the SBI to the Any-PHY interface.

**Figure 14 Ingress Data Flow**

Data arriving via the SBI interface is extracted from the SBI format and associated with an HDLC channel. Each link is independent and has its own associated clock. For each link, a serial to parallel conversion forms the data bytes. The data bytes are multiplexed, in byte serial format, for delivery to the HDLC/Partial Packet Processor block.

The HDLC engine receives the incoming byte stream and examines the byte stream to delineate the opening and closing of the HDLC packet. Bit de-stuffing is performed, FCS checking and minimum/maximum packet size checking is performed. The HDLC engine is capable of simultaneously processing 1024 independent HDLC channels. The resulting HDLC data and status information is passed to the Partial Packet Processor to be stored in the appropriate HDLC channel FIFO buffer.

The Partial Packet Processor controls a 64 Kbyte partial packet RAM. Data is written into the RAM at a location that is associated with the HDLC channel. As more data arrives for a given HDLC channel, it is stored with the previous bytes of data for a given HDLC channel forming a chunk of data. Packets are not intermingled within chunks. Completed chunks are passed to the fragment builder.

Fragments are defined as per FRF.12 and RFC 1990. The chunk is stored in external SDRAM in a data structure that is indexed on a per datagram basis. The fragment builder can simultaneously reconstruct 1024 datagrams (one per HDLC channel).

Completed datagrams are forwarded to the lookup and re-sequencing stage. This stage performs a header lookup that is used to determine the connection identifier. A connection record associated with the CI contains a number of state variables used in the re-sequencing operation and to guide the remaining ingress operations for the datagram. Re-sequencing is required when ML-FR or ML-PPP is active on a given set of HDLC channels. Given the variable length of data transfers and

skew between the physical links in the multi-link bundle, re-sequencing is essential to enabling multi-link protocols. Both 12 and 24 bit sequence numbers are supported for PPP while the 12 bit FRF.12 format is supported for FR.

The incoming sequence number is compared with the expected sequence number. If the two are equal, the datagram does not need to be re-sequenced and is logically passed to the ingress queue or the packet/frame builder depending on the style of data transfer (packet or fragment) requested for the Any-PHY channel.

If the sequence numbers do not align, a re-sequencing operation is triggered and the datagram is logically placed in the re-sequencing buffers. The datagram is removed from the re-sequencing buffers when the re-sequencing operation has correctly re-sequenced the datagrams. These datagrams are passed to the frame builder or the ingress queue manager depending on the mode of transfer. In addition to re-sequencing, a loss detection algorithm detects lost datagrams.

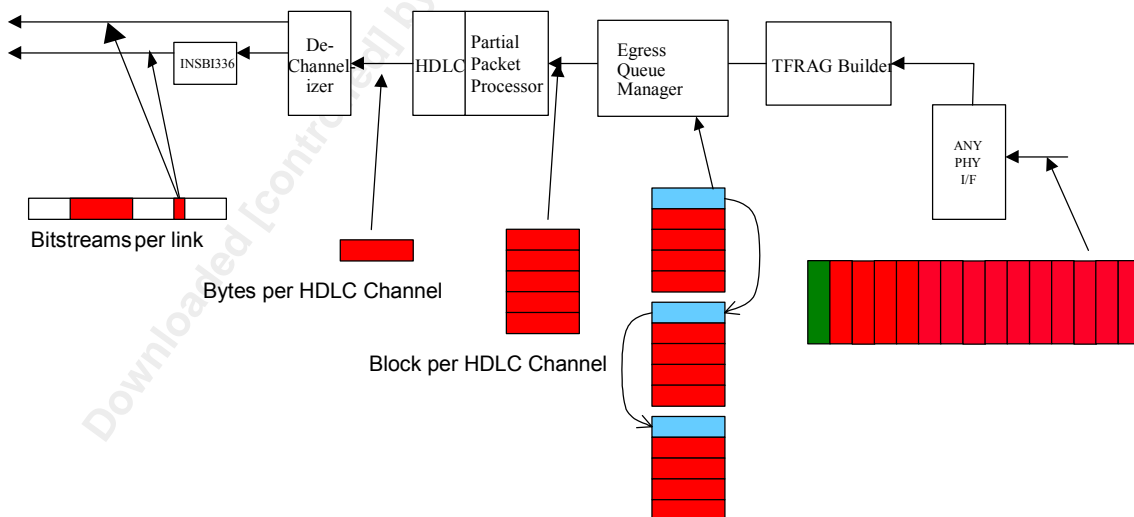

When the Any-PHY transfer is frame/packet based, the frame builder constructs complete frames or packets from the datagrams that have been constructed by the fragmentation builder. These complete frames/packets are transferred to the ingress queue manager.

The ingress queue manager retrieves the frame/packet from the external chunk buffer memory and transfers it to the upstream system device via the Any-PHY interface.

### 10.3.2 Egress Path

Figure 15 shows the elements and data transformations that occur as data traverses the FREEDM 32A1024L from the Any-PHY to the SBI interface.

**Figure 15 Egress Data Flow**

Full packets must be transferred from the upstream device to the FREEDM 32A1024L via the Any-PHY interface. When supporting a multi-link bundle, the Any-PHY channel is mapped to multiple HDLC channels. The transmit fragmentor will fragment packets/frames and distribute the fragments across all the HDLC channels in the multi-link bundle applying the appropriate sequence number to each of the fragments. The fragmentation size is programmable on a per connection basis. The

fragmentation size is referenced to the number of bytes transferred on the link and includes the multi-link header.

On an HDLC channel and priority basis the datagrams are decomposed into chunks and are stored in an external SDRAM memory. A chunk is defined as a fixed length unit of data (32 bytes) plus a 4 byte header, or a partially completed unit of data. A chunk will only consist of data from one packet/frame.

The Egress Queue Manager maintains a separate linked list of chunks for each HDLC channel and priority level. Single link HDLC channels have two priority levels whereas HDLC channels, which are part of multi-link bundles, have only one priority level.

The chunk transmitter controls a 64 Kbyte partial packet RAM. A data chunk is transferred from external memory into the partial packet RAM in a burst. Data is read from the RAM a byte at a time and delivered to the HDLC engine. The chunk transmitter can support 1024 simultaneous byte transfer sessions (one per HDLC channel). As chunks are depleted, the chunk transmitter requests the next chunk for the associated HDLC channel from the egress queue manager. The egress queue manager will read a chunk from the appropriate link list, giving preference to high priority data over low priority data.

The HDLC engine receives the incoming byte stream and encapsulates the data stream with a HDLC header, bit stuffing and a FCS trailer. The HDLC engine is capable of simultaneously processing 1024 independent HDLC channels. The resulting HDLC data and status is passed to the de-channelizer to be transferred onto the links.

Data arriving at the SBI interface is inserted into the SBI format at the correct tributary and timeslot associated with a HDLC channel.

## 10.4 Loop Back

### 10.4.1 SBI Line Loop Back

When enabled, the data on tributary #n output by the EXSBI block is looped back to the tributary #n in the INSBI block. (Note: The FREEDM must be the master of the tributary to enable SBI line loop back.)

When loop back is disabled, transmit data for tributary #n is provided by the TCAS-12 block (i.e. processed normally).

### 10.4.2 System Side Loop Back

The loop back controller block in the RCAS-12 TSB implements the channel based diagnostic loop back function. Every valid data byte belonging to a channel with diagnostic loop back enabled from the Transmit HDLC Processor / Partial Packet Buffer block (THDL-12) is written into a 1024 word FIFO in the RCAS-12 block. The loop back controller monitors for an idle time-slot or a time-slot carrying a channel with diagnostic loop back enabled. If either condition holds, the current data byte is replaced by data retrieved from the loop back data FIFO.

## 10.5 Initialization Process

Configuration of a channel/CI cannot be changed while data is flowing on that channel/CI.

### 10.5.1 CB and RS Memory FPP Initialization

1. After a hardware or software reset is issued, the chip goes into an initialization sequence. The RST\_DONEI bit in the F32 Master High Priority Interrupt Status register will indicate when this sequence is complete. At this stage, all the registers and memories internal to the chip and the external SRAM can be accessed.
2. Wait for SDRAM\_INIT to be cleared in XX\_DRAMC Status and Control Registers (PROV\_MODE will also be set at this point).
3. Test memories if desired by s/w.
4. FPP FIFO Initialization
  - Option 1 (s/w init)
    - Write ECC\_OFF bit as desired
    - Write to the memory setting up the FPP FIFO as described in the XX\_DRAMC memory map descriptions
    - Write FUNC\_MODE=1 and PROV\_MODE=0 in the XX\_DRAMC Status and Control Registers
  - Option 2 (h/w init)
    - Write ECC\_OFF bit to 1
    - Write FPP\_INIT bit =1 and PROV\_MODE=0 in the XX\_DRAMC Status and Control Registers
    - Wait for FUNC\_MODE to be set indicating completion (PROV\_MODE will also be cleared)
5. Initialization Complete

### 10.5.2 Connection Initialization for Sequenced Links

6. When adding a connection to a multi-link bundle (including first connection setup), the FREEDM 32A1024L takes the first sequence number it receives to start re-sequencing. Due to differential delay between links, if this isn't the fastest link, this might not be the start of packet. All subsequent fragments with lower sequence numbers will not be included in the re-sequencing and will be sent out the Any-PHY tagged as unexpected sequence number. The number of packets tagged as USN will depend on packet size and egress scheduling algorithm. Once the first re-sequenced packet is complete (if in packet out mode), this packet will be sent out missing the first few fragments but will not be tagged as erred. This may happen with every new connection.

## 10.6 Any-PHY Tear Down Procedure

Before tearing down an Any-PHY channel, all CI's associated with that Any-PHY channel must be torn down according to the procedure described in section 10.7. In addition, the data must be drained for the channel. This is done by:

1. Unprovision RCAS channel

2. Disable EXSBI channel
3. Reduce LOST timer for all constituent CIs to 10ms (this is not required, just suggested in case holes remain)
4. Wait for AP\_NCHNKS (in RFRAG Memory Map) to go to zero.

## 10.7 CI Tear Down Procedure

A CI tear-down procedure must be followed when decommissioning an active CI to avoid loss of resources shared among all active CIs. Since the decommissioned CI continues to hold up to one LSB record, the algorithm that assigns active CI's from the pool of inactive CI's should recycle previously used CI's before assigning a previously unused CI. This will result in the best use of shared resources.

The tear-down procedure is comprised of the following seven steps:

1. Remove the CI from the CI Lookup table to ensure no additional datagrams are received for the CI undergoing decommissioning
2. Read the Resequencing Active (RESEQ\_ACT) bit and the FIFO Active (FIFO\_ACT) bit in the connection context memory for the CI. If both bits are inactive skip the next two steps
3. If resequencing is flagged as active set the Lost Timeout Period (LOST\_CNT) register to "0001" in the connection context memory for the CI
4. Periodically read the RESEQ\_ACT and FIFO\_ACT bits until both are inactive
5. Read the MSB record associated with the CI and extract the valid LSB record pointer, if applicable. To identify a valid LSB record pointer within the MSB record structure all 128 locations of the MSB record must be read and examined. Bit 15, the 16th bit, of each 32-bit data word returned indicates whether the lower 15-bits identify a valid LSB record pointer (LSB\_POINTER). This pointer is used to determine what LSB status locations to clear for the CI being decommissioned. An MSB record is extracted from the external resequencing SDRAM memory by reading 128 consecutive locations beginning at the address as determined by the following equation: MSB Record begin address = 800,000H + CI\_number x 80H.
6. If applicable, clear the LSB status for the active LSB record. Each 32-bit location within the LSB record status field contains status for 16 datagrams. Therefore to clear the status for the entire 128-location LSB record, 8 LSB status locations must be cleared to zero. The 8 consecutive locations requiring clearing begin at the address determined by the following equation: LSB status begin address = 400,000H + LSB\_POINTER x 8H.
7. Clear connection context memory for the CI. At this point tear-down is completed

## 10.8 Restrictions on Any-PHY to CI Mapping

For proper operation:

1. No CI may be shared across multiple Any-PHY channels.

2. A non-sequenced CI value may be shared among various DLCI's within a single HDLC channel.
3. In multilink applications, the sequenced CI value corresponding to a particular DLCI\COS value must be shared across all HDLC channels of the bundle. However, except in the case of the default CI, the sequenced CI value must NOT be shared across different DLCI\COS values.
4. HDLC channels of a ML bundle must map to the same Any-PHY channel.

## 10.9 Block Descriptions

### 10.9.1 Extract Scaleable Bandwidth Interconnect (EXSBI)

The SBI Extract block receives data from the SBI DROP BUS and converts it to an internal parallel bus format. The SBI Extract block may be configured to enable or disable reception of individual tributaries within the SBI DROP bus. Individual tributaries may also be configured to operate in framed or unframed mode. Tributaries may be configured to support channelized T1/J1/E1 traffic or unframed traffic at T1/J1 or E1 rates.

### 10.9.2 Receive Channel Assignor (RCAS-12)

The Receive Channel Assignor block (RCAS-12) processes up to 32 links. When receiving data from the SBI blocks, links may be configured to support channelized T1/J1/E1 traffic or unframed traffic at T1/J1 or E1 rates.

The data bytes are multiplexed, in byte serial format together with data from EXSBI, for delivery to the Receive HDLC Processor / Partial Packet Buffer block (RHDL-12) at SYSCLK rate. In the event when multiple streams have accumulated a byte of data, multiplexing is performed on a fixed priority basis with link #0 having the highest priority and link #332 the lowest.

The 32 RCAS links can be mapped to any of the 84 SPE and tributary numbers on the SBI DROP BUS as shown in the following table.

**Table 10 SBI SPE/Tributary to RCAS Link Mapping**

SPE No.	SBI Trib. No.	RCAS Link No.	SPE No.	SBI Trib. No.	RCAS Link No.	SPE No.	SBI Trib. No.	RCAS Link No.
1	1	0	2	1	4	3	1	8
1	2	12	2	2	16	3	2	20
1	3	24	2	3	28	3	3	32
●								●
●								●
●								●
1	28	324	2	28	328	3	28	332

Links containing a T1/J1 or an E1 stream may be channelized. Data at each time-slot may be independently assigned to a different HDLC channel. The RCAS-12 performs a table lookup to

associate the link and time-slot identity with an HDLC channel. The position of T1/J1 and E1 framing bits/bytes is identified by frame pulse signals generated by the EXSBI. The RCAS-12 performs a table lookup using only the link number to determine the associated HDLC channel, as time-slots are non-existent in unchannelized links. Links may additionally be configured to operate in an unframed “clear channel” mode, in which all bit positions, including those normally reserved for framing information, are assumed to be carrying HDLC data. Links so configured operate as unchannelized regardless of link rate and the RCAS-12 performs a table lookup using only the link number to determine the associated HDLC channel.

All timeslots in a link must be provisioned to a valid channel number before the link is enabled. For unused timeslots, a valid unused channel number must be set but the PROV bit is not set. All unused timeslots in the device can be mapped to the same unused channel number. When unprovisioning a channel, the INVERT bit in register 0x208 must be cleared (if set), The PROV bit is then set to 0 but the channel number must be written back into the channel number field. This will flush out any data on this channel still present in the chip. This sequence must occur before the link is disabled.

The loop back controller block implements the channel based diagnostic loop back function. Every valid data byte belonging to a channel with diagnostic loop back enabled from the Transmit HDLC Processor / Partial Packet Buffer block (THDL-12) is written into a 1024 word FIFO. The loop back controller monitors for an idle time-slot or a time-slot carrying a channel with diagnostic loop back enabled. If either condition holds, the current data byte is replaced by data retrieved from the loop back data FIFO.

### 10.9.3 Receive HDLC Protocol Engine (RHDL-12)

The HDLC engine receives the incoming byte stream and examines the stream to determine the opening and closing of the HDLC packet. Bit de-stuffing, FCS checking and minimum/maximum packet size checking is performed. The HDLC engine is capable of simultaneously processing 1024 independent HDLC channels. The resulting HDLC data and status information is passed to the Partial Packet Processor to be stored in the appropriate HDLC channel FIFO buffer.

Figure 16 shows a diagram of the synchronous HDLC protocol supported by the FREEDM 32A1024L device. The incoming stream is examined for flag bytes (0111110 bit pattern) that delineate the opening and closing of the HDLC packet. The packet is bit de-stuffed which discards a “0” bit which directly follows five contiguous “1” bits. The resulting HDLC packet size must be a multiple of an octet (8 bits) and within the expected minimum and maximum packet length limits. The minimum packet length is that of a packet containing two information bytes (address and control) and FCS bytes. For packets with CRC-CCITT as FCS, the minimum packet length is four bytes while those with CRC-32 as FCS; the minimum length is six bytes. An HDLC packet is aborted when seven contiguous “1” bits (with no inserted “0” bits) are received. At least one flag byte must exist between HDLC packets for delineation. Contiguous flag bytes, or all ones bytes between packets are used as an “inter-frame time fill”. Adjacent flag bytes may share zeros.

**Figure 16 HDLC Frame**

The CRC algorithm for the frame checking sequence (FCS) field is either a CRC-CCITT or CRC-32 function. Figure 17 shows a CRC encoder block diagram using the generating polynomial  $g(X) = 1 + g_1X + g_2X^2 + \dots + g_{n-1}X^{n-1} + X^n$ . The CRC-CCITT FCS is two bytes in size and has a generating polynomial  $g(X) = 1 + X^5 + X^{12} + X^{16}$ . The CRC-32 FCS is four bytes in size and has a generating polynomial  $g(X) = 1 + X + X^2 + X^4 + X^5 + X^7 + X^8 + X^{10} + X^{11} + X^{12} + X^{16} + X^{22} + X^{23} + X^{26} + X^{32}$ . The first FCS bit received is the residue of the highest term.

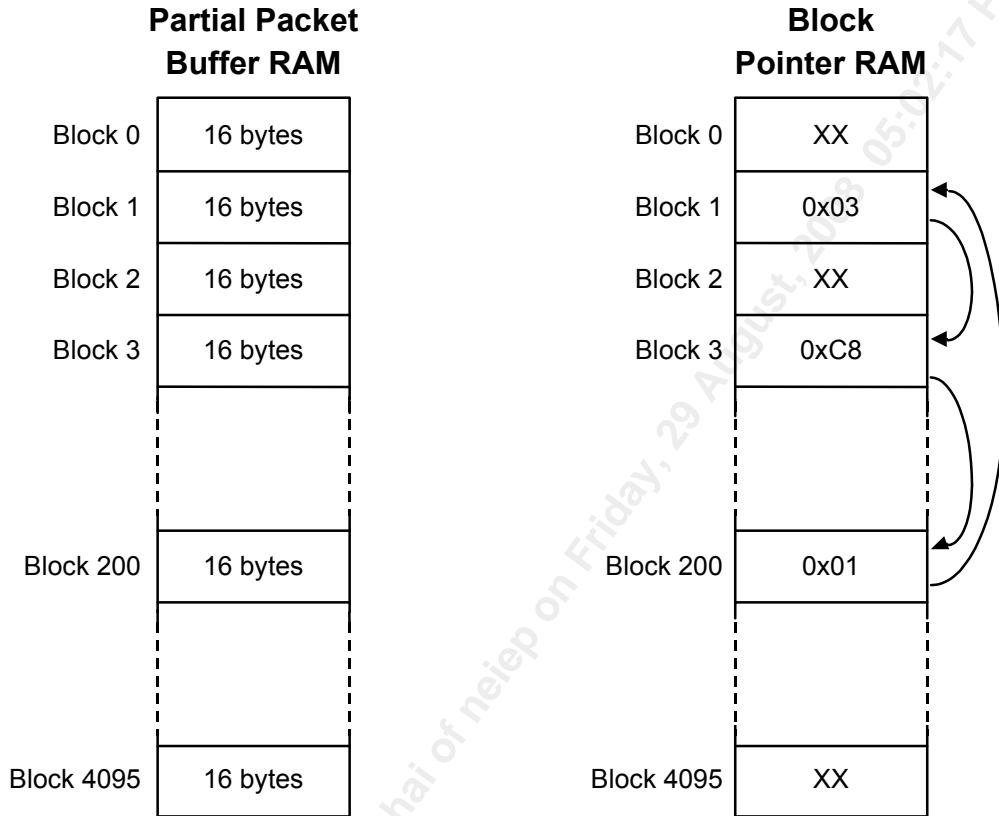

**Figure 17 CRC Generator**

**Partial Packet Buffer Processor**

The partial packet buffer processor controls the 64 Kbyte partial packet RAM, which is divided into 4K 16 byte blocks. A block pointer RAM is used to chain the partial packet blocks into circular HDLC channel FIFO buffers. Thus, non-contiguous sections of the RAM can be allocated in the partial packet buffer RAM to create an HDLC channel FIFO. System software is responsible for the assignment of blocks to individual HDLC channel FIFOs. Figure 18 shows an example of three blocks (blocks 1, 3, and 200) linked together to form a 48 byte HDLC channel FIFO.

**Figure 18 Partial Packet Buffer Structure**

The partial packet buffer processor is divided into three sections: writer, reader and roamer. The writer is a time-sliced state machine that writes the HDLC data and status information from the HDLC processor into a channel FIFO in the packet buffer RAM. The reader transfers HDLC channel FIFO data from the packet buffer RAM to the downstream fragment builder block (RFRAG). The roamer is a time-sliced state machine that tracks HDLC channel FIFO buffer depths and signals the reader to service a particular HDLC channel. If a buffer over-run occurs, the writer ends the current packet from the HDLC processor in the HDLC channel FIFO with an overrun flag and ignores the rest of the packet.

The FIFO algorithm of the partial packet buffer processor is based on a programmable per-HDLC channel transfer size. Instead of tracking the number of full blocks in an HDLC channel FIFO, the processor tracks the number of transactions. Whenever the partial packet writer fills a transfer-sized number of blocks or writes an end-of-packet flag to the HDLC channel FIFO, a transaction is created. Whenever the partial packet reader transmits a transfer-size number of blocks or an end-of-packet flag to the RFRAG block, a transaction is deleted. Thus, small packets less than the transfer size will be naturally transferred to the RFRAG block without having to precisely track the number of full blocks in the HDLC channel FIFO.

The partial packet roamer performs the transaction accounting for all HDLC channel FIFOs. The roamer increments the transaction count when the writer signals a new transaction and sets a per-HDLC channel flag to indicate a non-zero transaction count. The roamer searches the flags in a round-robin fashion to decide for which HDLC channel FIFO to request transfer by the RFRAG block. The roamer informs the partial packet reader of the HDLC channel to process. The reader

transfers the data to the RFRAG until the HDLC channel transfer size is reached or an end of packet is detected. The reader then informs the roamer that a transaction is consumed. The roamer updates its transaction count and clears the non-zero transaction count flag if required. The roamer then services the next HDLC channel with its transaction flag set high.

The writer and reader determine empty and full FIFO conditions using flags. Each block in the partial packet buffer has an associated flag. The writer sets the flag after the block is written and the reader clears the flag after the block is read. The flags are initialized (cleared) when the block pointers are written using indirect block writes. The writer declares an HDLC channel FIFO overrun whenever the writer tries to store data to a block with a set flag. In order to support optional removal of the FCS from the packet data, the writer does not declare a block as filled (set the block flag nor increment the transaction count) until the first double word of the next block in the HDLC channel FIFO is filled. If the end of a packet resides in the first double word, the writer declares both blocks as full at the same time. When the reader finishes processing a transaction, it examines the first double word of the next block for the end-of-packet flag. If the first double word of the next block contains only FCS bytes, the reader would, optionally, process next transaction (end-of-packet) and consume the block, as it contains information not transferred to the RFRAG block.

#### 10.9.4 Receive Fragment Builder (RFRAG)

The receive fragment builder re-constructs datagrams from the incoming data stream, moves data chunks from the partial packet processor into external memory, and manages the assignment of free external memory addresses to data chunks. The receive fragment builder also discards datagrams under the following conditions:

- Small datagrams (shorter than a user-programmable length) are discarded when an excessive number of datagrams are waiting to be processed by the re-sequencer.
- All datagrams received on a particular channel are discarded when the associated an Any-PHY channel's chunk storage allocation has been exceeded.

The external chunk buffer memory is partitioned into data units called chunks. A chunk is a block (36 bytes) of contiguous memory used to store parts of the data frames. Associated with each chunk is an address that is used to index the chunk. The addresses are stored in the external memory in a free list FIFO. The Free list FIFO contains addresses of all the chunks that are available for the storage of data. A chunk of data is unavailable when the data stored within the chunk is part of a datagram that is being actively processed by the FREEDM 32A1024L. Chunks become available when the FREEDM 32A1024L completes the processing of the data in the chunk (i.e. the datagram is transferred across the Any-PHY interface to the rest of the system).

Data received from the partial packet RAM is encapsulated (Figure 19). The encapsulation contains the next address pointer, Last and Full flags, Error codes and an error correction code that covers the encapsulation header. The next address pointer is used to create a linked list of chunks that comprise a datagram (Figure 21). The address indicates where the next chunk of the datagram is located in the external memory. This effectively links the chunks of a datagram in external memory. The last flag is used to tag the last chunk of a datagram. The full flag indicates if the chunk contains 32 bytes of data. If the data chunk of a datagram is partially filled, the full flag is false and the number of valid bytes in the chunk is inserted in byte 0. The error codes are used to capture HDLC or RFRAG processing errors that have occurred. The error codes are provided to

the system via the Any-PHY interface enabling the system to observe the behavior of the HDLC channels.

The Partial packet RAM also passes the associated HDLC channel ID, End of datagram indication, and error flags (Bad FCS, Abort, etc.). The HDLC channel ID is used to index a data record that provides the next chunk pointer. This data record is also used to store frame relay header bits (Sequence number, DLCI, BE, FE, DE, B, E, C) or PPP header bits (Address, Control, PID, COS, and Sequence number, B, E), and the address of the first chunk in the datagram. These header fields are passed to the frame builder after the last chunk in a given datagram is stored. Header bits are extracted from the first data chunk of a datagram. Corrupted datagrams are tagged and the starting address is passed forward to the re-sequencer.

The RFRAG can be configured to accept compressed PPP headers. The RFRAG will correctly interpret the compressed header, and extract the information required for downstream processing from the packet.

The encapsulated data chunk, and an address pointer are passed to the DRAMC controller for storage in external SDRAM. The address pointer is contained in the HDLC channel record and points to the memory location that is placed in the next address pointer field of the previous data chunk for a given datagram. The initial chunk of a datagram is stored at an address location, (starting address of the datagram).

Datagrams may also be discarded before they are stored in the external SDRAM. When there are too many datagrams waiting to be processed by the re-sequencer, any datagram smaller than either a default 40-byte limit, or a programmable 0 to 56-byte threshold, will be discarded, except if it is tagged as the last fragment of a multi-fragment frame/packet. Furthermore, each Any-PHY channel has a limit in the maximum number of chunks that it can have stored in the external SDRAM at any time. If this limit is exceeded, all datagrams for this Any-PHY channel will be discarded until the number of chunks stored in the external SDRAM is reduced below the limit.

The free list FIFO is stored in external memory. To reduce the accesses to external memory, an address cache is used to hold addresses that can be used for next pointer values. When a chunk is encapsulated, the HDLC channel record will fetch, from the local cache, an address that can serve as the next address for the following data chunk in the datagram. As chunks are retrieved from the external memory for the address is returned to the cache. When the cache needs to be replenished, a request is made to the DRAMC. A set of new addresses is provided from external memory. The external read request is triggered off of a threshold. When the internal Cache crosses the threshold, it requests a read from external memory.

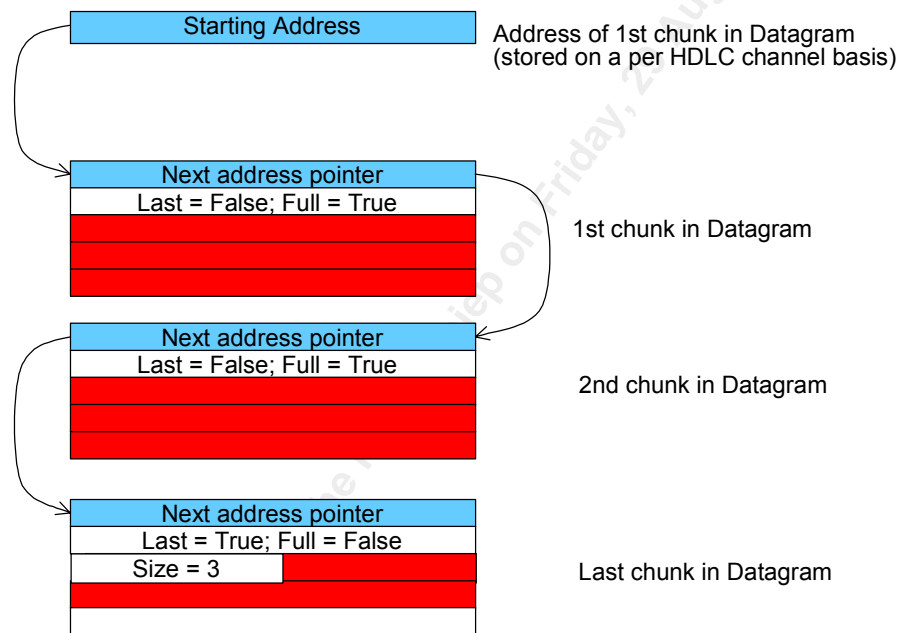

**Figure 19 Encapsulated Chunk Structures (Full = True)**

### 10.9.5 Frame Builder (FRMBLD)

Re-assembling frames/packets from fragments requires several steps: 1) the specific session has to be identified, 2) individual fragments must be re-sequenced, and 3) packets must be re-constructed from the re-sequenced fragments.

#### Connection Identification

The header of the datagram is used to index internal record structures needed to support re-sequencing, and ingress queuing.

A lookup is used for HDLC channels supporting the Frame Relay protocol. The objective is to reduce the HDLC channel (10 bits) and the Q.922 header (10 bit DLCI) to a 14-bit CI. The HDLC channel number is concatenated with two bits indicating if the datagram is sequenced, non-sequenced, corrupt, or control. This value is then concatenated with the DLCI(0-1023) for sequenced and non sequenced datagrams to produce an index into the SSRAM memory. Contained at the memory location is the 14 bit CI.

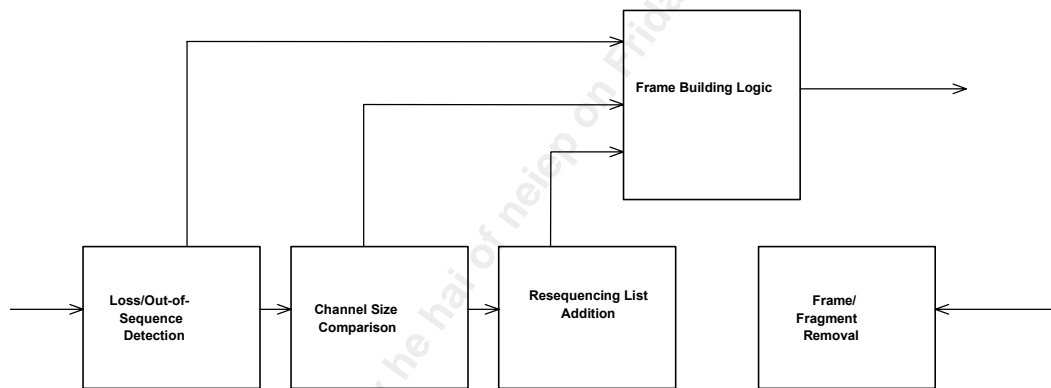

For PPP header identification, the HDLC channel number is concatenated with two bits indicating if the datagram is sequenced, non-sequenced, corrupt, or control. This value is then concatenated with the COS (0-15) for sequenced, and 0 for non sequenced datagrams to produce an index into the SSRAM memory. Contained at the memory location is the 14 bit CI.

Unique CI's must be used for each HDLC channel.

### Re-Sequencing Builder

The Re-Sequencing blocks provide the logic and data structures necessary to support the re-ordering of ingress datagrams. This includes the detection of lost or out of bound datagrams, the placement of sequences numbers in the correct order, the construction of frames/packets out of fragments, and the transfer of resequenced/reassembled frames/packets to the ingress queue manager.

**Figure 22 Elements in the Re-sequencing Block**

### Loss Detection/Out of Bounds Checking

The loss detection block is based on the use of timers. Timers associated with each resequencing session would be used to detect the lost datagram and advance the resequencing engine. Each multi-link re-sequencing session has an associated timer. When the multi-link session transitions from in sequence to out of sequence, a timer is started. This timer is cleared when the session returns to being in sequence. All timers are periodically polled to detect sessions that have been out of sequence for an extended period of time.

### Size Comparison/Timers

The chunk buffer and re-sequencing structures are shared resources. To ensure that a multi-link bundle or HDLC channel does not consume more than an allocated amount of resources the number of bytes in the bundle or channel is compared against a threshold (allocated bytes). If the threshold is exceeded, the datagram is discarded. The primary reasons for exceeding the threshold are loss of a link within a multi-link bundle or a number of ML-FR DLCIs losing datagrams. The first situation would cause the re-sequencing engine to stall on the first lost datagram. Incoming fragments from other links would then build up and create a backlog of datagrams.

### Re-sequencing List Addition

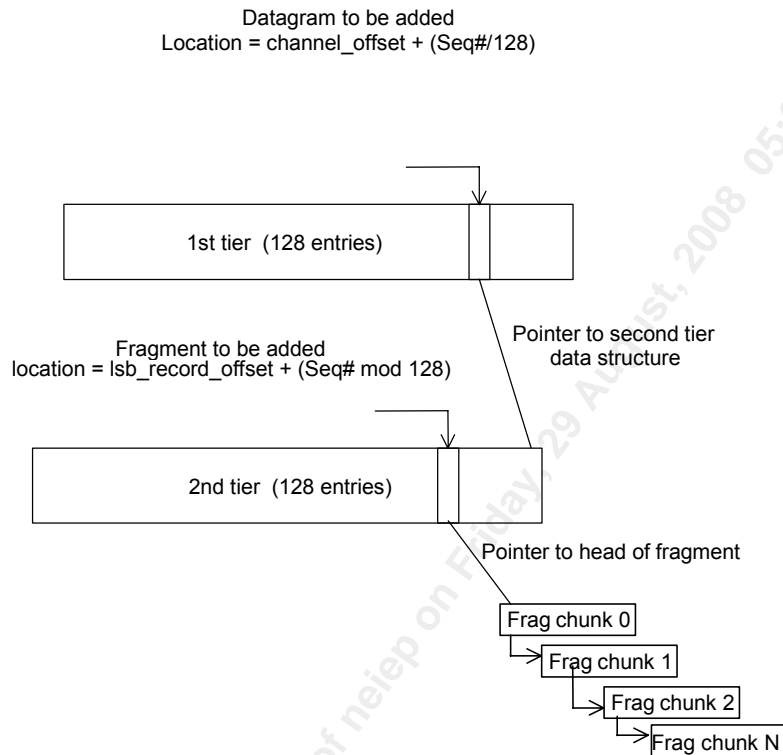

Datagrams that have not been discarded are entered in the re-sequencing list. The resequencing algorithm in FREEDM 32A1024L supports the worst case number of packets on a multi-link bundle of T1/E1s that have experienced an intra skew delay of 100ms. To support that a subset of the 24-bit sequence number space is supported. Fourteen of the 24 bits are used for re-sequencing. All 12 bits are used when supporting 12 bit sequence numbers. On initialization, the Head Sequence number is set to the sequence number of the first fragment received. Subsequent sequence numbers are declared as USN if they are within a small range prior to the Head Sequence number. Arriving datagrams are placed in the sliding window with an offset determined by distance (difference) between the sequence number at the head of the window and the current sequence number.

**Figure 23 14-bit Sliding Window Used for Re-sequencing**

The sliding window (Figure 23) is realized as a two tiered data structure (Figure 24). This is done to reduce the memory required to support 16K simultaneous multi-link sessions. The initial tier is present for all multi-link sessions. Secondary tiers are added and removed when needed. The number of second tiers is limited. Enough are provided to support the simultaneous resequencing on all multi-link sessions.

**Figure 24 Elements in the Re-sequencing Block**

The incoming sequence number is compared with the expected sequence number (head + 1). If the two are equal, the datagram is in sequence. The end of packet marker is examined to determine if a complete frame/packet is available for transfer. This is signaled to the frame builder block. A session that was previously out-of-sequence may have a backlog of frames/packets ready for transfer once the in-sequence frame/packet is received. This is signaled to the frame assembly block.

If the sequence numbers do not align, and the multi-link session was previously in sequence, a re-sequencing operation is triggered and the datagram is logically placed in the re-sequencing buffers.

The datagram is removed from the re-sequencing buffers when the re-sequencing operation has correctly re-sequenced the datagrams. These datagrams are passed to the frame builder of the ingress queue manager depending on the mode of transfer.

Frames/packets without sequence numbers use the same data structures to queue frames. However the re-sequencing and frame detection logic is not required. FRF12 fragmentation (single link sequencing for QOS reasons) and the potential equivalent for PPP are supported via the structures in place.

In order to preserve integrity of the data structures in the event of a soft error the addresses are protected by ECC capable of detecting 2 and correcting 1 error.

## Frame Building

Frame or packet transfers across the Any-PHY interface require all the fragments of a frame/packet to be present and in sequence before the transfer can occur. The frame building block monitors incoming datagrams, and determines when a complete frame/packet has been received and is ready for transfer. Examining status fields associated with datagrams that are entered in the 14 bit-sliding window provides the necessary information. Multi-link sessions that are in-sequence require the end-of-packet marker of incoming packets to be examined. When the frame builder detects the end of packet marker, the CI is sent to the ingress queue manager. This signals that a frame/packet is ready for transfer.

Out-of-sequence multi-link sessions require the frame builder to rapidly parse the fragment entries in the data structure once the multi-link session returns to in-sequence state. This is required as there may be a large number of fragments that are available for transmission once the session becomes in-sequence (i.e. the outstanding fragment arrives and completes the sequence). To support this, the frame builder maintains a block of status structures. Each block contains 128 status entries. This enables the frame builder to review a large number of fragments once the session is in sequence. If one or more complete frames are identified, the frame builder provides the associated connection identifier to the ingress queue and the number of frames available.

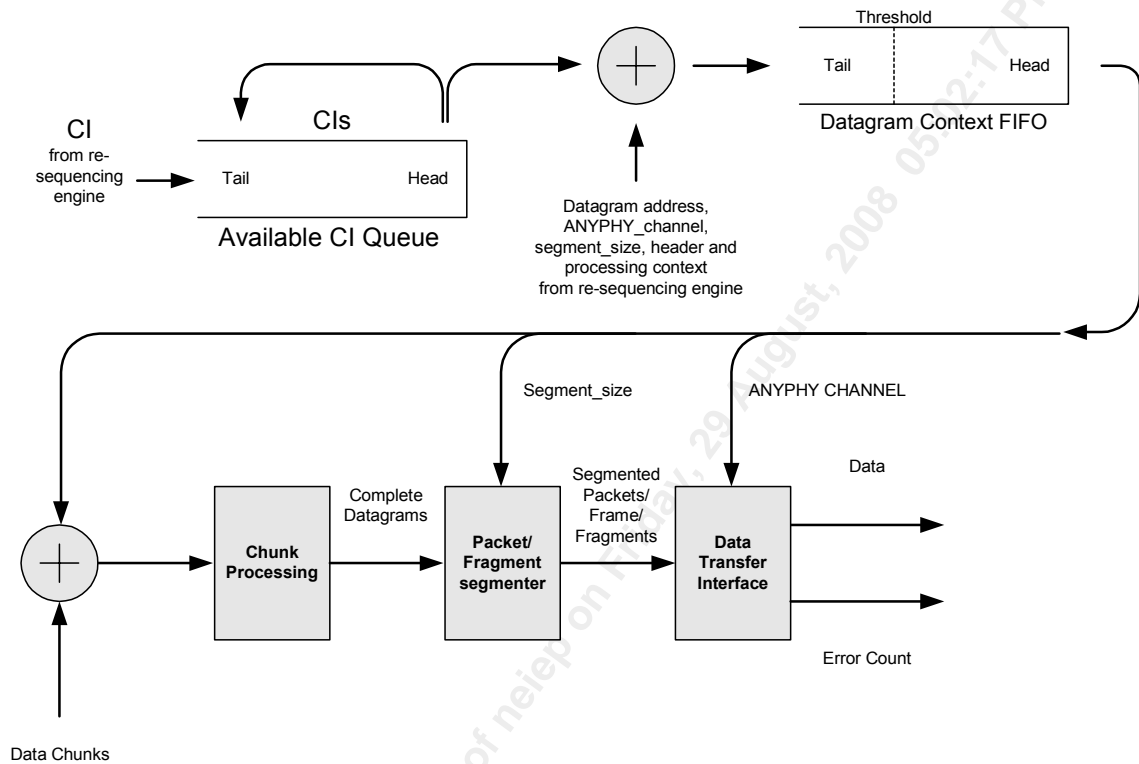

## Frame/Fragment Removal

The connection identifier selected by the ingress queue manager is used to extract the datagram at the head of the connection queue. If this is the last entry in a secondary tier, the re-sequencing data structure is returned to the free list of data structures. When the data is extracted, the corresponding status bits (EOP, Active, BECN, FECN, DE) are cleared. The address field is cleared and a Null pointer is placed in the location.

### 10.9.6 Ingress Queue Manager (IQM-12)

The ingress queue manager is in charge of transferring data from the external chunk buffer memory to the Any-PHY interface logic. An overview of the ingress queue manager is presented in Figure 25

**Figure 25 - Ingress Queue Manager**

When a datagram (either a packet, fragment or complete frame depending on configuration) is formed, the re-sequencing block forwards a CI (connection identifier), to the ingress queue manager which is enqueued to the Available CI Queue. This queue de-couples the re-sequencing engine from the data retrieval and transfer process. When space is available in the Datagram Context FIFO, the CI tag at the head of the queue is extracted and passed to the re-sequencing engine, where it is used to extract the datagram context. If the CI has more datagrams to send, it is placed at the end of the queue.

Each CI request sent to the re-sequencing engine is answered with the pointers and associated context for the actual datagram ready to be transferred for the CI. While the Any-PHY interface logic is able to accept data and datagram context is available, requests for data are made to the external chunk buffer. As the data is received, complete packets/frames/fragments are constructed and are then segmented.

### 10.9.7 Receive Any-PHY Interface (RAPI-12)

The RAPI-12 contains a FIFO block for latency control as well as to segregate the APPI timing domain from the SYSCLK timing domain. The RAPI-12 contains the necessary logic to manage and respond to device polling from an upper layer device. The RAPI-12 also provides the upper layer device with status information on a per packet basis.

The RAPI-12 supports Any-PHY Level-2, and Any-PHY Level-3 modes of operation. When operating at 104 MHz the lower 8 bits of the data are active.

### FIFO Storage and Control

The FIFO block temporarily stores Any-PHY channel data during transfer across the Rx APPI. A separate storage element samples the 16-bit address prepend to associate the data in that FIFO with a specific Any-PHY channel. This Any-PHY channel ID is prepended in-band as the first word of every burst data transfer across the Rx APPI. In Any-PHY Level-3 mode, the address prepend is appended on the first two bytes of the packet.

The writer controller provides a means for writing data into the FIFO. The reader controller provides a means of reading data out of the FIFO onto the Rx APPI. When selected to do so the reader controller will read the data out of the FIFO. To prevent from overloading the Rx APPI with several small bursts of data, the RAPI-12 automatically deselects after every burst transfer. This provides time for the upper layer device to detect an end of packet indication and possibly reselect a different FREEDM 32A1024L device without having to store the extra word or two that may have been output onto the Rx APPI during the time it took for deselection.

The RAPI-12 provides packet status information on the Rx APPI at the end of every packet transfer. The RAPI-12 asserts RERR at the end of packet reception (REOP high) to indicate that the packet is in error. The RAPI-12 may optionally be programmed to overwrite RXDATA[7:0] of the final word of each packet transfer (REOP is high) with the status of packet reception when that packet is erred (RERR is high). Overwriting of status information is enabled by setting the STATEN bit in the RAPI-12 control register.

### Polling Control and Management

The RAPI-12 only responds to Any-PHY channel polls that match the device base address bits programmed in the RAPI-12 Base Address register. A positive poll response indicates that the FIFO is ready to be selected to transfer this data across the Rx APPI.

## 10.9.8 Transmit Any-PHY Interface (TAPI-12)

The Transmit Any-PHY Interface (TAPI-12) provides a low latency path for transferring data from the Transmit Any-PHY Packet Interface (Tx APPI) to the TFRAG engine or the EQM. The TAPI-12 contains a FIFO block for latency control as well as to segregate the APPI timing domain from the SYSCLK timing domain. The TAPI-12 contains the necessary logic to manage and respond to Any-PHY channel polling from an upper layer device.

The TAPI-12 supports ANY-PHY Level-2, and ANY-PHY Level-3 modes of operation. When operating at 104 MHz the lower 8 bits of the data are active.

### FIFO Storage and Control

The FIFO block temporarily stores Any-PHY channel data during transfer across the Tx APPI. TAPI-12 burst data transfers are transaction based on the writer side of the FIFO.

The first word of each burst transfer contains the address/priority prepend field. A separate storage element samples the address prepend to associate the data with a specific Any-PHY channel. The address prepend is compared to the base and range registers. The address prepend must correspond to an Any-PHY channel that is supported by the FREEDM 32A1024L for the TAPI-12 to respond to the data transaction on the Tx APPI.

The writer controller provides a means for writing data from the Tx APPI into the FIFO. The whisper controller provides the Any-PHY channel address of the data being written into the FIFO. As soon as the first word of data has been written into the FIFO, the whisper controller provides the Any-PHY channel information for that data to the downstream block. The whisper controller will wait for acknowledgement and the reader controller is then requested to read the data from the FIFO. Once the reader controller has commenced the data transfer, the whisper controller will provide the Any-PHY channel information for next data transfer received, if any.

The reader controller provides a means of reading data out of the FIFO. When the writer controller indicates that data has been written into the FIFO, the reader controller is permitted to read that data. The reader controller will then wait for a request for data from the downstream block. Because the reader controller reads data out of the FIFO in the order in which they were filled, the TFRAG block will request data for Any-PHY channels in the order in which they were whispered.

### **Polling Control and Management**

The TAPI-12 only responds to poll addresses that are identified by the base and range address registers in the TAPI-12 Control registers. The TAPI-12 maintains a mirror image of the status of each channel FIFO in the EQM-12. The EQM-12 continuously reports the status of the 2048 FIFOs (1024 channels x 2 priority levels) to the TAPI-12 and the TAPI-12 updates the mirror image accordingly.

### **10.9.9 Transmit Fragmentor (TFRAG)**

Datagrams are transferred from the upstream device to the FREEDM 32A1024L via the Any-PHY interface. The transmit fragmentor fragments (if required) the packet, encapsulates the fragments with a sequence number (in multi-link or fragmentation situations), assigns the datagram to an HDLC channel and segments the datagram into chunks for storage in the external SDRAM.

When supporting a multi-link bundle, the address prepend and the connection identifier that is provided on the Any-PHY interface are used to index the appropriate sequence number and an index to the HDLC channels associated with the multi-link bundle. The sequence number and additional header bits (B, E, and COS) are appended to arriving datagrams. The datagram is assigned to an HDLC channel in the multi-link bundle. HDLC channel assignment is based on the current occupancy of the HDLC channels in a multi-link bundle. The datagram is assigned to the HDLC channel with the lowest number of bytes in the channel queue.

Compressed PPP headers are detected by the TFRAG. The TFRAG is capable of appending sequence numbers onto multi-link packets with compressed headers.

On a per HDLC channel and per priority basis these datagrams are segmented into chunks and are stored in an external SDRAM memory. A HDLC chunk will only consist of data from one packet/frame. Segmented data is encapsulated (Figure 26) to form a 36 byte storage element. The encapsulation contains the next address pointer, the size and a local integrity check that covers the address field. The next address pointer is used to create a linked list of chunks that comprise a datagram.

The address indicates where the next chunk of the datagram is located in the external memory. This effectively links the chunks of a datagram in external memory. In the last data chunk, the next address is used to link to the start of the next datagram. The size field is used to indicate how many of the data bytes are actually valid, as the last chunk may not be completely full. The abort is used

to trigger an HDLC abort. If an unexpected TSX error occurs during an Any-PHY transfer or if the upstream device asserts the TERR signal, the abort is set.

The encapsulated data chunk, and an address pointer are passed to the DRAMC controller for storage in external SDRAM. The address pointer is contained in the HDLC channel record and points to the memory location that is placed in the next address pointer field of the previous data chunk for a given datagram. The initial chunk of a datagram is stored at an address location, (starting address of the datagram).

An address cache is used to hold addresses that can be used for next pointer values. When a chunk is encapsulated, the HDLC channel record will fetch, from the local cache, another address that can serve as the next address for the following data chunk in the datagram. The cache needs to be replenished; this is achieved by requesting, from the DRAMC, a set of new addresses after a threshold in the Cache has been crossed.

In order to preserve the address pointers in the presence of soft errors an ECC code is used to detect 2 errors and correct 1 error.

### Egress Queue Manager (EQM-12)

Managing the Any-PHY channel status, pushing the status to the TAPI-12, accepting transfer requests from the partial packet processor and arbitrating between the requests are the key tasks of the egress queue manager. Segmented datagrams are placed into external memory by the TFRAG block. The number of data bytes in the chunk is added to the Any-PHY channel size counter. The size is compared against a threshold. An Any-PHY channel size that exceeds the threshold will cause the EQM-12 to push a status message to the TAPI-12 indicating the Any-PHY channel is full and will not be accepting any more frames. The EQM-12 maintains the status of all 1024 Any-PHY channels including the 42 multi-link bundles and the 1024 HDLC channels. (For non-multi-link channels, two status bits are maintained, for the high priority queue and low priority queue respectively.)

The partial packet processor requests chunks, as memory becomes available. The egress queue manager determines the address of the chunk to be transferred to the partial packet processor. The EQM-12 updates the HDLC and Any-PHY channel context status and pushes the status of the Any-PHY channel to the TAPI-12. Any-PHY channel status is determined by comparing the size of the Any-PHY channel to the Any-PHY channel threshold. The two level feedback mechanism is used to avoid starvation of the HDLC channels. The thresholds are programmable and support a number of different bandwidths (DS0, nxDS0, T1, E1, nxT1, nxE1) and ensure that starvation is avoided.

### 10.9.10CB\_DRAMC

The CB\_DRAMC controls access to/from the Chunk Buffer SDRAM interface present on FREEDM 32A1024L. The external SDRAMs provide buffer storage for chunks and addresses pointing to the chunks. The CB\_DRAMC block supports a 48 bit wide SDRAM interface operating at 100 MHz. Refresh, bank switching, providing precharge and bus management are functions that reside in the CB\_DRAMC. Figure 29 shows the configuration for the external SDRAMs that comprise the Chunk Buffer.

### 10.9.11 RS\_DRAMC

The RS\_DRAMC controls access to/from the Re-sequencing SDRAM interface present on FREEDM 32A1024L. The external SDRAMs provide CI lookup information as well as pointers used in the resequencing operation. The RS\_DRAMC block supports a 32 bit wide SDRAM interface operating at 100 MHz. Refresh, bank switching, providing precharge and bus management are functions that reside in the RS\_DRAMC. Figure 30 shows the configuration for the external SDRAMs that comprise the Re-Sequencing buffer.

**Figure 29 DRAM Configuration for the Chunk Buffer Interface**

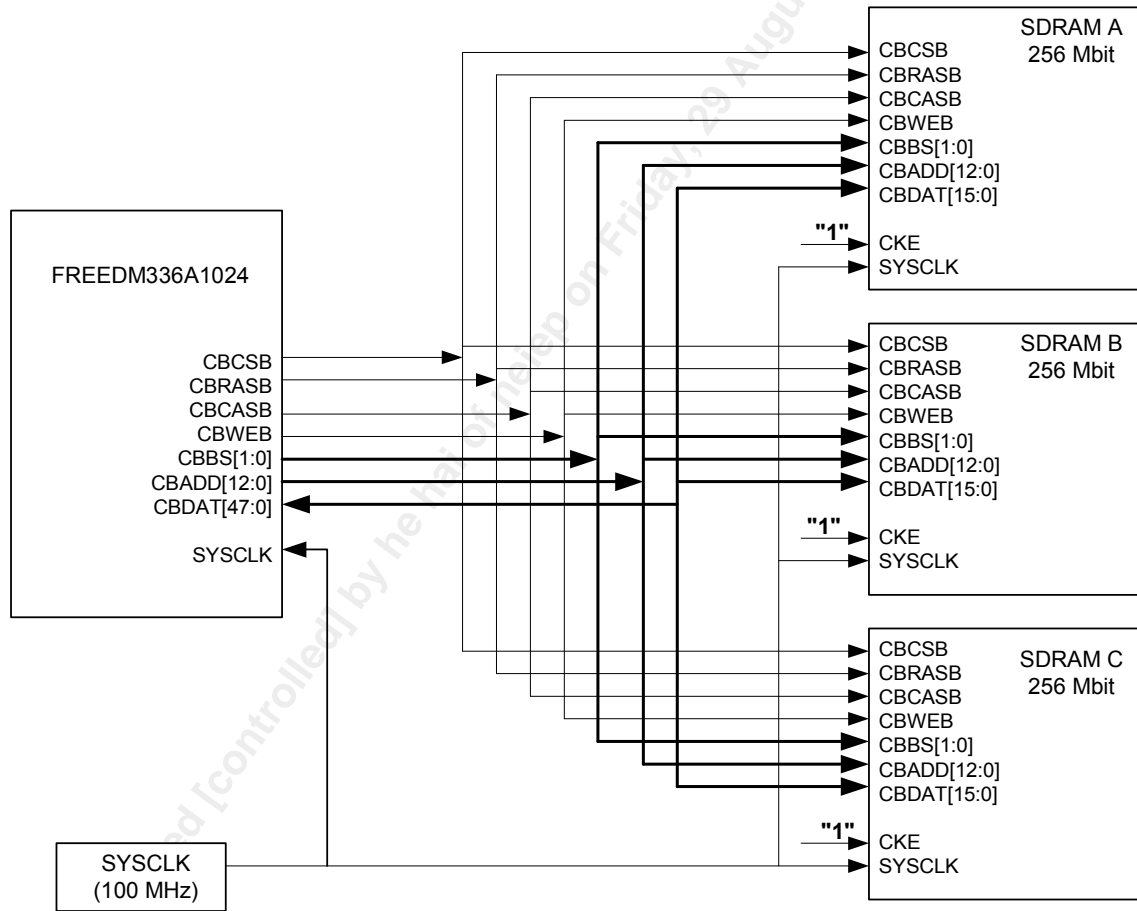

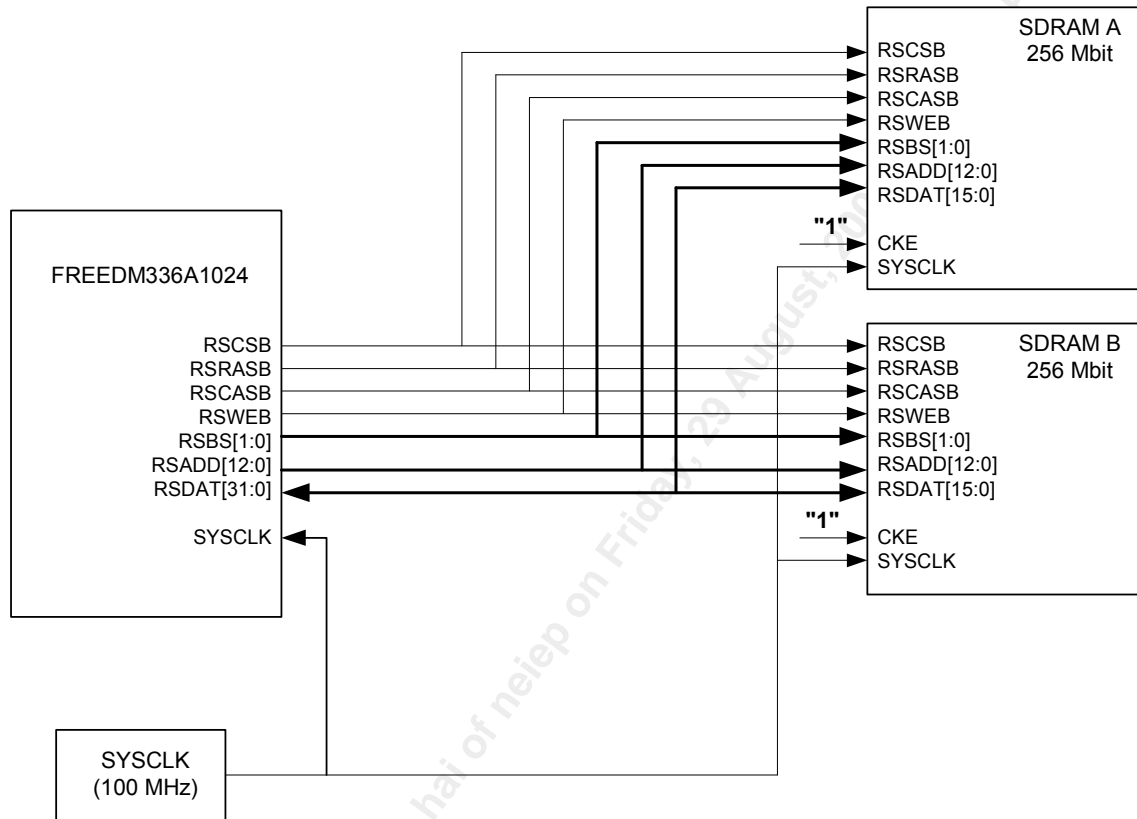

Figure 30 DRAM Configuration for the Re-Sequencing Memory Interface

### 10.9.12 SRAMC

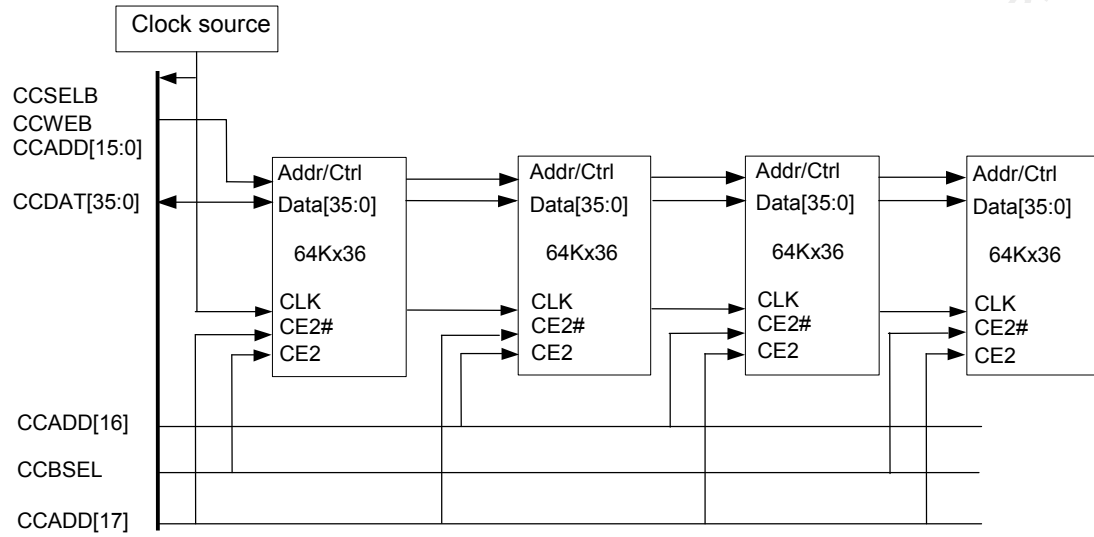

The external context memory holds data that needs to be accessed by a number of internal blocks. The role of the SRAMC block is to arbitrate these accesses. The Connection context memory supports the frame building block, TFRAG, and IQM-12.

The SRAMC supports glueless access to 1, 2 or 4 banks of Pipelined ZBT-compatible<sup>1</sup> or Standard SRAM. When FREEDM 32A1024L is configured to interface to Standard or ZBT-compatible SSRAM, CCBSSELB is the inverse of CCADD[16]. CCBSSELB and CCADD[16:17] are used to select 4 banks when 64Kx36 devices are used (see Figure 31). It should be noted that maximum performance is achieved with ZBT SSRAMs. Standard SSRAMs will degrade chip performance by approximately 20%.

<sup>1</sup> The ZBT-compatible SRAM family includes:

- ZBT, short for Zero Bus Turnaround, manufactured by IDT, Micron and Motorola,
- NoBL, short for No Bus Latency, manufactured by Cypress, and
- Nt, short for No turnaround, manufactured by Samsung

Figure 31 4-Bank Configuration for 8 MB of ZBT or Standard SSRAM

**Figure 32 2-Bank Configuration for Eight Mbit/s of ZBT-Compatible or Standard SSRAM**

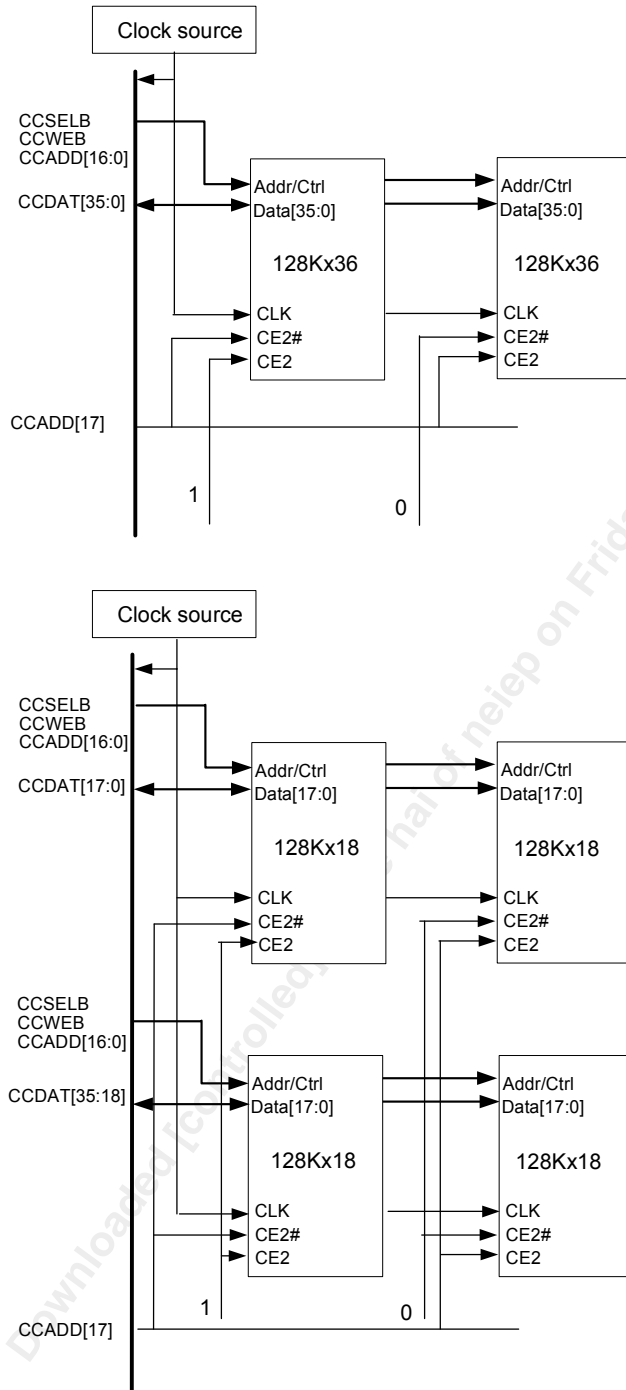

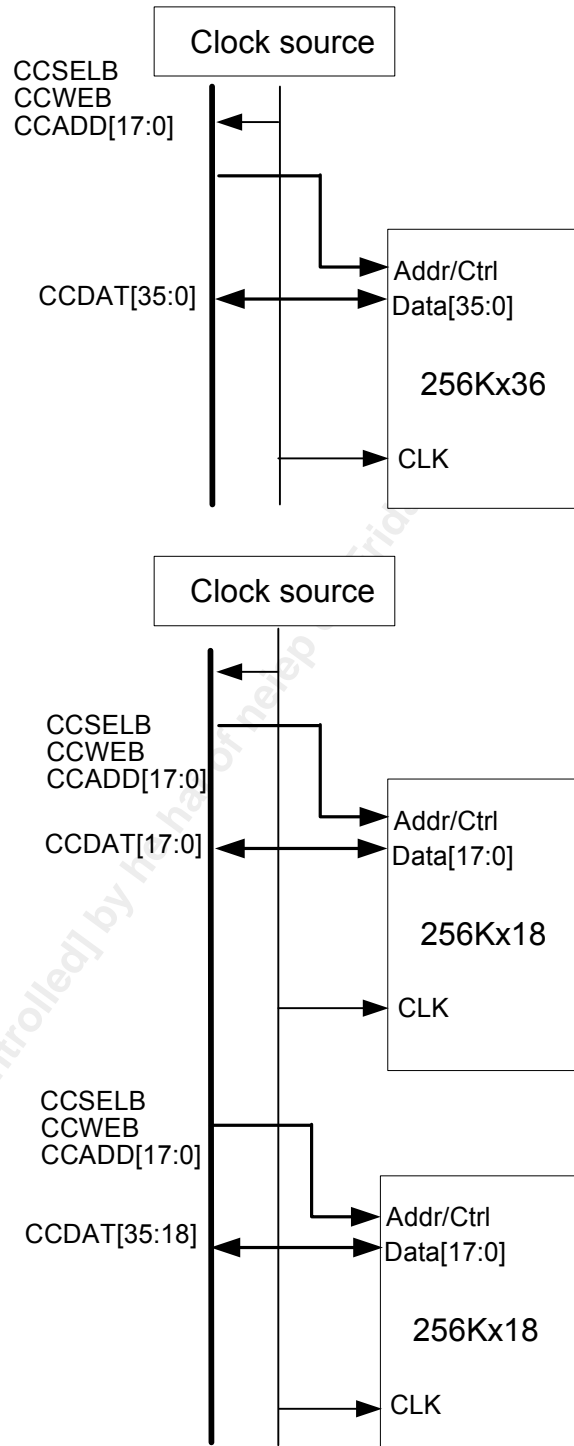

Figure 33 1-Bank Configuration for Eight Mbit/s of ZBT or Standard SSRAM

### 10.9.13 Transmit HDLC Processor (THDL-12)

The HDLC processor is a time-slice state machine that can process up to 1024 independent HDLC channels. The state vector and provisioning information for each HDLC channel is stored in a

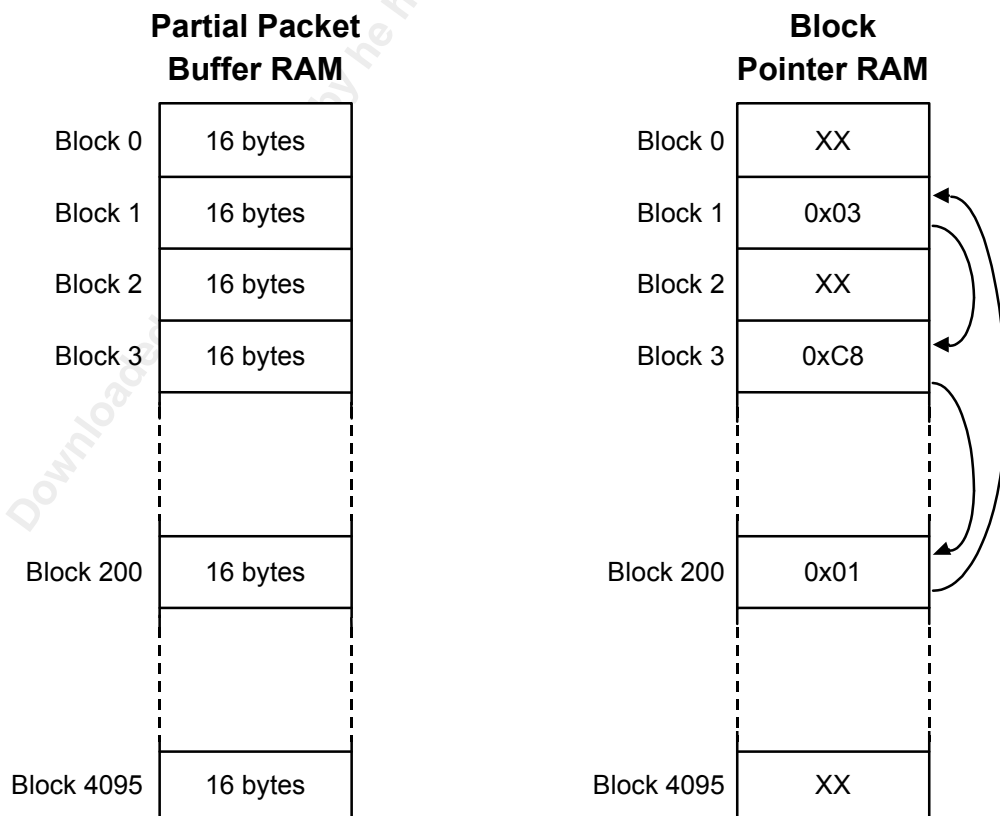

RAM. Whenever the TCAS-12 requests data, the appropriate state vector is read from the RAM, processed and finally written back to the RAM. The HDLC state-machine can be configured to perform flag insertion, bit stuffing and CRC generation. The HDLC processor requests data from the partial packet processor whenever a request for HDLC channel data arrives. However, the HDLC processor does not start transmitting a packet until the entire packet is stored in the HDLC channel FIFO or until the FIFO free space is less than the software programmable limit. If an HDLC channel FIFO under-runs, the HDLC processor aborts the packet, and generates an interrupt.

The configuration of the HDLC processor is accessed using indirect channel read and write operations. When an indirect operation is performed, the information is accessed from RAM during a null clock cycle inserted by the TCAS-12 block. Writing new provisioning data to an HDLC channel resets the channel's entire state vector.

### Transmit Partial Packet Buffer Processor

The partial packet buffer processor controls the 64 Kbyte partial packet RAM, which is divided into 16 byte blocks. A block pointer RAM is used to chain the partial packet blocks into circular HDLC channel FIFO buffers. Thus, non-contiguous sections of RAM can be allocated in the partial packet buffer RAM to create an HDLC channel FIFO. Figure 34 shows an example of three blocks (blocks 1, 3, and 200) linked together to form a 48 byte HDLC channel FIFO. The three pointer values would be written sequentially using indirect block write accesses. When an HDLC channel is provisioned within this FIFO, the state machine can be initialized to point to any one of the three blocks.

**Figure 34 Partial Packet Buffer Structure**

The partial packet buffer processor is divided into three sections: reader, writer and roamer. The roamer is a time-sliced state machine that tracks each HDLC channel's FIFO buffer free space and signals the writer to service a particular channel. The writer requests data from the EQM-12 block and transfers packet data from the EQM-12 to the associated HDLC channel FIFO. The reader is a time-sliced state machine that transfers the HDLC information from an HDLC channel FIFO to the HDLC processor in response to a request from the HDLC processor. If a buffer under-run occurs for an HDLC channel, the reader informs the HDLC processor and purges the rest of the packet. If a buffer overflow occurs for an HDLC channel (this can only happen if EQM-12 disregards the requests), the THDL-12 overwrites the FIFO contents resulting in data corruption on that particular HDLC channel. When an underflow or an overflow occurs, an interrupt is generated and the cause of the interrupt may be read via the interrupt status register using the microprocessor interface.

The writer and reader determine empty and full FIFO conditions using flags. Each block in the partial packet buffer has an associated flag. The writer sets the flag after the block is written and the reader clears the flag after the block is read. The flags are initialized (cleared) when the block pointers are written using indirect block writes. The reader declares an HDLC channel FIFO under-run whenever it tries to read data from a block without a set flag.

The FIFO algorithm of the partial packet buffer processor is based on per-HDLC channel software programmable transfer size and free space trigger level. Instead of tracking the number of full blocks in an HDLC channel FIFO, the processor tracks the number of empty blocks, called free space, as well as the number of end of packets stored in the FIFO. Recording the number of empty blocks instead of the number of full blocks reduces the amount of information the roamer must store in its state RAM.

The partial packet roamer records the FIFO free space and end-of-packet count for all HDLC channel FIFOs. When the reader signals that a block has been read, the roamer increments the FIFO free space and sets a per-HDLC channel request flag if the free space is greater than the hungry or starving threshold. The roamer pushes this status information to the EQM to indicate that it can accept at least one transfer of data. The roamer also decrements the end-of-packet count when the reader signals that it has passed an end of a packet to the HDLC processor. The roamer listens to control information from the EQM-12 to decide which HDLC channel FIFO requests data from the EQM block. The roamer informs the partial packet writer of the HDLC channel FIFO to process and the FIFO free space. The writer sends a request for data to the EQM-12 block, writes the response data to the HDLC channel FIFO, and sets the block full flags. The writer reports back to the roamer the number of blocks and end-of-packets transferred. The maximum amount of data transferred during one request is set by XFER.

The roamer round-robins between all HDLC channels FIFOs and pushes the status to the EQM-12 block. The status consists of two pieces of information: (1) is there space in the HDLC channel FIFO for at least 32 bytes of data, and (2) is this channel FIFO at risk of underflowing.

The configuration of the HDLC processor is accessed using indirect channel read and write operations as well as indirect block read and write operations. When an indirect operation is performed, the information is accessed from RAM during a null clock cycle identified by the TCAS-12 block. Writing new provisioning data to an HDLC channel resets the entire state vector.

#### **10.9.14 Transmit Channel Assignor (TCAS-12)**

The Transmit Channel Assignor block (TCAS-12) processes up to 1024 HDLC channels. Data for all HDLC channels is sourced from a single byte-serial stream from the Transmit HDLC Controller

/ Partial Packet Buffer block (THDL-12). The TCAS-12 demultiplexes the data and assigns each byte to any one of 32 links. When sending data to the SBI block, each link may be configured to support channelized T1/J1/E1 traffic or unframed traffic at T1/J1 or E1 rates.

The 32 TCAS links can be mapped to any of the 84 SPE and tributary numbers on the SBI ADD BUS as shown in the following table.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:02:17 PM

**Table 11 SBI-SPE Tributary to TCAS Link Mapping**

SPE No.	SBI Trib. No.	TCAS Link No.	SPE No.	SBI Trib. No.	TCAS Link No.	SPE No.	SBI Trib. No.	TCAS Link No.
1	1	0	2	1	4	3	1	8
1	2	12	2	2	16	3	2	20
1	3	24	2	3	28	3	3	32
●								●
●								●
●								●
1	28	324	2	28	328	3	28	332

Links containing a T1/J1 or an E1 stream may be channelized. Data at each time-slot can be independently assigned to be sourced from a different HDLC channel. The position of T1/J1 and E1 framing bits/bytes is identified by frame pulse. With knowledge of the transmit link and time-slot identity, the TCAS-12 performs a table look-up to identify the HDLC channel from which a data byte is to be sourced.

Links may additionally be configured to operate in an unframed “clear channel” mode, in which case the FREEDM 32A1024L will output HDLC data in all bit positions, including those normally reserved for framing information. Links so configured operate as unchannelized regardless of link rate and the TCAS-12 performs a table lookup using only the link number to determine the associated HDLC channel.

### 10.9.15 SBI Inserter

The SBI transmit circuitry processes data for the three Synchronous Payload Envelopes (SPEs) conveyed on the SBI ADD BUS. It receives data bytes from the transmit channel assignor and inserts it into the SBI ADD BUS. The SBI Insert block may be configured to enable or disable transmission of individual tributaries on to the SBI ADD bus. Individual tributaries may also be configured to operate in framed or unframed mode.

### 10.9.16 Performance Monitor

The Performance Monitor block (PM) contains the HDLC channel counters plus a series of error registers. The HDLC channel counters include:

- Bytes received per HDLC channel
- Bytes transmitted per HDLC channel
- Total datagrams received
- Total datagrams transmitted
- Bytes discarded from excess small datagrams
- Bytes discarded of Chunk Buffer allocation exceeded events

In addition a number of error conditions are tracked on a per HDLC channel basis:

- Erred HDLC Frames
- Tx HDLC framing aborts
- Rx HDLC framing aborts
- Small Datagrams discarded events
- Chunk Buffer allocation exceeded events

Additionally, the PM-12 block contains global error counters track performance of various aspects of the FREEDM 32A1024L. These include:

- Number of lost fragment events.
- Partial Packet overruns
- Partial Packet underruns
- Number of tiny Packets (min HDLC length)
- Number of excessive fragments per packet/frame events
- Number of unexpected sequence number events
- Number of bytes received with non-octet aligned errors
- Number of bytes received with MRU exceeded
- Number of bytes received with abort errors
- Number of bytes received with FCS errors
- Number of bytes received with partial packet overrun
- Number of bytes received with unexpected sequence number
- Number of bytes received with unsupported header format

#### 10.9.17 Digital Delay Lock Loop (DDLL)

The DLL is used to minimize output delay on all external RAMs. The DLL measures the phase difference between the external clock and a reference clock and generates an internal clock, which reduces the phase difference between the external clock and the reference clock to zero.

#### 10.9.18 JTAG Test Access Port

The JTAG Test Access Port block provides JTAG support for boundary scan. The standard JTAG EXTEST, SAMPLE, BYPASS, IDCODE and STCTEST instructions are supported. The FREEDM 32A1024L identification code is 073100CD hexadecimal.

#### 10.9.19 Microprocessor Interface

The FREEDM 32A1024L supports microprocessor access to an internal register space for configuring and monitoring the device. All registers are on 32 bit boundaries. Address Bit 12 on all registers must be set to 0. The registers are described in Table 12.

**Table 12 Normal Mode Microprocessor Accessible Registers Memory Map**

Address	Register

## 11 Normal Mode Register Description

Normal mode registers are used to configure and monitor the operation of the FREEDM 32A1024L.

### Notes on Normal Mode Register Bits:

1. Writing values into unused register bits has no effect. However, to ensure software compatibility with future, feature-enhanced versions of the product, unused register bits must be written with logic zero. Reading back unused bits can produce either a logic one or a logic zero; hence, unused register bits should be masked off by software when read.
2. Except where noted, all configuration bits that can be written into can also be read back. This allows the processor controlling the FREEDM 32A1024L to determine the programming state of the block.
3. Writeable normal mode register bits are cleared to logic zero upon reset unless otherwise noted.
4. Writing into read-only normal mode register bit locations does not affect FREEDM 32A1024L operation unless otherwise noted.
5. Certain register bits are reserved. These bits are associated with megacell functions that are unused in this application. To ensure that the FREEDM 32A1024L operates as intended, reserved register bits must only be written with their default values or defined setup values. Similarly, writing to reserved registers should be avoided.
6. The term “high” may be used to describe logic 1 and “low” may be used to describe logic 0.

### 11.1 Microprocessor Accessible Registers

For each register description below, the hexadecimal register number indicates the address in the FREEDM 32A1024L when accesses are made using the external microprocessor.

**Note:** These 32-bit registers are not byte addressable. Writing to any one of these registers modifies all bits in the register.

**Register 0x000: Master Reset and Control**

Bit	Type	Function	Default
Bit 31 To Bit 15		Unused	X
Bit 14	R/W	RESET	0
Bit 13	R/W	SRAMM1	0
Bit 12	R/W	SRAMM0	0
Bit 11	R	DTYPE[3]	0
Bit 10	R	DTYPE[2]	0
Bit 9	R	DTYPE[1]	0
Bit 8	R	DTYPE[0]	0
Bit 7	R	ID[7]	0
Bit 6	R	ID[6]	0
Bit 5	R	ID[5]	0
Bit 4	R	ID[4]	0
Bit 3	R	ID[3]	0
Bit 2	R	ID[2]	0
Bit 1	R	ID[1]	0
Bit 0	R	ID[0]	0

This register provides software reset capability, device ID information and SRAM configuration setup.

**RESET**

The RESET bit allows the FREEDM 32A1024L to be reset under software control. If the RESET bit is a logic one, the entire FREEDM 32A1024L, except the microprocessor interface, is held in reset. All registers are reset to their default values and some memories are set to their default values (for specific memory operation refer to memory descriptions). This bit is not self-clearing. Therefore, a logic zero must be written to bring the FREEDM 32A1024L out of reset. Holding the FREEDM 32A1024L in a reset state places it into a low power, stand-by mode. A hardware reset clears the RESET bit, thus negating the software reset.

**Note:** Unlike the hardware reset input (RSTB), RESET does not force the FREEDM 32A1024L's microprocessor interface pins tristate. RESET causes all registers to be set to their default values and forces the APPI outputs tristate.

SRAMM[1:0]

The SRAM Mode bits describe the choice of SSRAM used for the Connection Context (CC) external memory.

**Table 13 Memory mode Configuration**

SRAMM[1:0]	Configuration
00	Standard SRAM
01	Reserved
10	ZBT-like SRAM
11	Reserved

DTYPE[3:0]

The Device Type bits (DTYPE[3:0]) allow software to identify the device as the FREEDM 32A1024L member of the FREEDM family of products.

ID[7:0]

The Device ID bits (ID[7:0]) allow software to identify the version level of the FREEDM 32A1024L.

Downloaded [controlled] by he hai of neta on Friday, 29 August, 2008 05:02:17 AM

**Register 0x004: FREEDM 32A1024L Master High Priority Interrupt Enable**

Bit	Type	Function	Default
Bit 31 To Bit 22		Unused	X
Bit 21	R/W	CBLTEXE	0
Bit 20	R/W	SBIC1FPSE	0
Bit 19	R/W	SDGMDE	0
Bit 18	R/W	CBAEXE	0
Bit 17	R/W	Reserved	0
Bit 16	R/W	Reserved	0
Bit 15	R/W	UNSUPHE	0
Bit 14	R/W	BADSIZEE	0
Bit13	R/W	RSFPPEE	0
Bit 12	R/W	EFPPEE	0
Bit 11	R/W	IFPPEE	0
Bit 10	R/W	DLLE	0
Bit 9	R/W	SBIPARI	0
Bit 8	R/W	TXCHQOVRE	0
Bit 7	R/W	CFOVRE	0
Bit 6	R/W	TPRTYE	0
Bit 5	R/W	TFOVRE	0
Bit 4	R/W	TFUDRE	0
Bit 3	R/W	SRAMPE	0
Bit 2	R/W	UECCRSE	0
Bit 1	R/W	UECCBE	0
Bit 0	R/W	RFOVRE	0

This register provides interrupt enables for various events detected or initiated by the FREEDM 32A1024L. Each interrupt enable bit corresponds to the equivalent bit in the Master High Priority Interrupt Status register. All interrupt enable bits are active high. When high, interrupts are enabled. When low, interrupts are masked. While interrupts are masked the status bit in the status register may still be polled to detect the error event. Enabled High priority interrupts cause the INTHIB interrupt pin to be asserted.

Reserved

The Reserved bits must be set to 0 for correct operation of the FREEDM 32A1024L device.

**Register 0x008: Master High Priority Interrupt Status**

Bit	Type	Function	Default
Bit 31 To Bit 22		Unused	X
Bit 21	R/W	CBLTEXI	0
Bit 20	R/W	SBIC1FPSI	X
Bit 19	R/W	SDGMDI	0
Bit 18	R/W	CBAEXI	0
Bit 17	R/W	Reserved	X
Bit 16	R/W	RST_DONEI	0
Bit 15	R/W	UNSUPHFI	0
Bit 14	R/W	BADSIZEI	0
Bit 13	R/W	RSFPPEI	0
Bit 12	R/W	EFPPEI	0
Bit 11	R/W	IFPPEI	0
Bit 10	R/W	DLLI	0
Bit 9	R/W	SBIPARI	0
Bit 8	R/W	TXCHQOVRI	0
Bit 7	R/W	CFOVRI	0
Bit 6	R/W	TPRTYI	0
Bit 5	R/W	TFOVRI	0
Bit 4	R/W	TFUDRI	0
Bit 3	R/W	SRAMPI	0
Bit 2	R/W	UECCRSI	0
Bit 1	R/W	UECCBBI	0
Bit 0	R/W	RFOVRI	0

This register reports the high priority interrupt status for various events detected or initiated by the FREEDM 32A1024L. Reading this register acknowledges and clears the interrupts. The register is also writeable to allow s/w testing of interrupt generation and service routines.

**RFOVRI**

The receive Partial Packet FIFO overrun error interrupt status bit reports receive Partial Packet FIFO overrun error interrupts to the microprocessor. RFOVRI is set high on attempts to write data into the logical FIFO of a channel when it is already full. RFOVRI remains valid when interrupts are disabled and may be polled to detect receive FIFO overrun events.

## UECCBBI

The Uncorrected ECC Error detected on Chunk Buffer Memory interrupt status bit reports such an event to the microprocessor. UECCBBI is set high when an ECC Error that could not be corrected is detected during a memory access to the Chunk Buffer Memory. When set, the CB\_DRAMC\_UNCOECCE Register will hold the last DRAM address that was being accessed when an ECC Error occurred. UECCBBI and CB\_DRAMC\_UNCOECCE remain valid when interrupts are disabled and may be polled to detect error events.

## UECCRSI

The Uncorrected ECC Error detected on Re-sequencing Memory interrupt status bit reports such an event to the microprocessor. UECCRSI is set high when an ECC Error that could not be corrected is detected during a memory access to the Re-sequencing Memory. When set, the RS\_DRAMC\_UNCOECCE Register will hold the last DRAM address that was being accessed when an ECC Error occurred. UECCRSI and RS\_DRAMC\_UNCOECCE remain valid when interrupts are disabled and may be polled to detect error events.

## SRAMPI

SRAM Parity Error interrupt status bit reports parity error interrupts to the microprocessor. SRAMPI is set high whenever a parity error is detected on accesses to external SRAM. When set, the SRAM Parity Error Address (SPERRADD) Register will hold the last SRAM address that was being accessed when a parity error occurred. SRAMPI and SPERRADD remain valid when interrupts are disabled and may be polled to detect error events.

## TFUDRI

The transmit Partial Packet FIFO underflow error interrupt status bit reports transmit Partial Packet FIFO underflow error interrupts to the microprocessor. TFUDRI is set high upon attempts to read data from the logical FIFO when it is already empty. TFUDRI remains valid when interrupts are disabled and may be polled to detect transmit FIFO underflow events.

## TFOVRI

The transmit Partial Packet FIFO overflow error interrupt status bit reports transmit Partial Packet FIFO overflow error interrupts to the microprocessor. TFOVRI is set high upon attempts to write data to the logical FIFO when it is already full. TFOVRI remains valid when interrupts are disabled and may be polled to detect transmit FIFO overflow events.

## TPRTYI

The transmit parity error interrupt status bit reports the detection of a parity error on the transmit APPI. TPRTYI is set high upon detection of a parity error. TPRTYI remains valid when interrupts are disabled and may be polled to detect parity errors.

## CFOVRI

The Circular FIFO Overflow interrupt status bit reports TAPI Circular FIFO overflow error interrupts to the microprocessor. CFOVRI is set high upon attempts to write to the circular FIFO when it is already full. CFOVRI remains valid when interrupts are disabled and may be polled to detect Circular FIFO Overflow events. (NOTE – Circular FIFO overflows will not occur if the TRDY is observed or specified minimum spacing between small packets is adhered.)

## TXCHQOVRI

The Transmit Channel Queue Overflow interrupt status bit reports EQM-12 Channel Queue overflow error interrupts to the microprocessor. TXCHQOVRI is set high upon attempts to write to the Queue when it is already full. TXCHQOVRI remains valid when interrupts are disabled and may be polled to detect Queue Overflow events. (NOTE – Queue overflows will not occur if Channel availability polling is observed and adhered.)

## SBIPAR

The SBI Parity interrupt status bit (SBIPARI) reports a parity on the SBI bus. SBIPARI remains valid when interrupts are disabled and may be polled to detect SBI Parity error conditions.

## DLLI

The delay line error event interrupt status bit (DLLI) indicates the DLL ERROR register bit has gone high. When the DLL ERROR register changes from a logic zero to a logic one, the DLLI register bit is set to logic one. DLLI remains valid when interrupts are disabled and may be polled to detect DLL error events.

## IFPPEI

The Ingress FPP Empty interrupt status bit (IFPPEI) indicates that the Ingress FPP FIFO is empty. IFPPEI is set high upon detection of such this condition. IFPPEI remains valid when interrupts are disabled and may be polled.

## EFPPEI

The Egress FPP Empty interrupt status bit (EFPPEI) indicates that the Egress FPP FIFO is empty. EFPPEI is set high upon detection of such a condition. EFPPEI remains valid when interrupts are disabled and may be polled.

## RSFPPEI

The Re-sequencing FPP Empty interrupt status bit (RSFPPEI) indicates that the Re-sequencing Memories FPP FIFO is empty. RSFPPEI is set high upon detection of such a condition. RSFPPEI remains valid when interrupts are disabled and may be polled.

**BADSIZEI**

The Bad Size interrupt status bit (BADSIZEI) indicates that the RAPI-12 block received a segment of incorrect size. If such an interrupt occurs, the Any-PHY specification will be violated. BADSIZEI remains valid when interrupts are disabled and may be polled. Under normal operation, this interrupt will never occur. Assertion of this interrupt should trigger a chip reset.

**UNSUPHFI**

The IQM-12 interrupt status bit reports a datagram with an unsupported header format was detected. (In particular, Frame Relay datagrams carrying a 16, 17, or 23 bit DLCI, or PPP datagrams with PID(H) odd and/or PID(L) even). UNSUPHFI remains valid when interrupts are disabled and may be polled.

**RST\_DONEI**

The RST\_DONEI status bit reports the ending of the hardware reset or software reset operation, it indicates that all of the flip-flops and internal RAMs have been initialized. The RST\_DONEI cannot be enabled but can be polled to indicate reset completion.

**Reserved**

The reserved bit can be set to any value.

**CBAEXI**

The Chunk Buffer Allocation Exceeded Interrupt status bit reports chunk buffer allocation exceeded events. CBAEXI remains valid when interrupts are disabled and may be polled.

**SDGMDI**

The Small Datagram discard Interrupt status bit reports small datagram discard events due to insufficient bandwidth to sustain the number of small datagrams (less than 40 bytes) received. SDGMDI remains valid when interrupts are disabled and may be polled.

**SBIC1FPSI**

The SBIC1FPS Interrupt status bit reports C1FP realignment events on the SBI bus. SBIC1FPSI remains valid when interrupts are disabled and may be polled.

## CBLTEXI

The Chunk Buffer Lower Threshold Exceeded Interrupt status bit reports chunk buffer lower threshold exceeded events. When set, the Chunk Buffer Lower Threshold Exceeded Channel Register (CBLTEXCH) holds the Any-PHY channel number of the last channel to exceed its chunk buffer lower threshold. CBLTEXI remains valid when interrupts are disabled and may be polled.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:11:11 PM

**Register 0x00C: Master Clock / Frame Pulse Activity Monitor**

Bit	Type	Function	Default
Bit 31 to Bit 6		Unused	X
Bit 5	R	TXCLKA	X
Bit 4	R	RXCLKA	X
Bit 3	R	DC1FPA	X
Bit 2	R	AC1FPA	X
Bit 1	R	REFCLKA	X
Bit 0	R	SYSCCLKA	X

This register provides activity monitoring on the FREEDM 32A1024L SBI frame pulse inputs. When a monitored input makes a transition, the corresponding register bit is set high. The bit will remain high until this register is read, at which point, all the bits in this register are cleared. The corresponding register bit reading low indicates a lack of transitions. This register should be read periodically to detect stuck at conditions.

**SYSCCLKA**

The system clock active bit (SYSCCLKA) monitors for low to high transitions on the SYSCCLK input. SYSCCLKA is set high on a rising edge of SYSCCLK, and is set low when this register is read.

**REFCLKA**

The SBI reference clock active bit (REFCLKA) monitors for low to high transitions on the REFCLK input. REFCLKA is set high on a rising edge of REFCLK, and is set low when this register is read.

**AC1FPA**

The SBI Add Bus frame pulse active bit (AC1FPA) monitors for low to high transitions on the AC1FP input. AC1FPA is set high on a rising edge of AC1FP, and is set low when this register is read.

**DC1FPA**

The SBI Drop Bus frame pulse active bit (DC1FPA) monitors for low to high transitions on the DC1FP input. DC1FPA is set high on a rising edge of DC1FP, and is set low when this register is read.

**RXCLKA**

The Any-PHY receive clock active bit (RXCLKA) monitors for low to high transitions on the RXCLK input. RXCLKA is set high on a rising edge of RXCLK, and is set low when this register is read.

## TXCLKA

The Any-PHY transmit clock active bit (TXCLKA) monitors for low to high transitions on the TXCLK input. TXCLKA is set high on a rising edge of TXCLK, and is set low when this register is read.

**Register 0x018: Master Low Priority Interrupt Enable**

Bit	Type	Function	Default
Bit 31 To Bit 14		Unused	X
Bit 13	R/W	Reserved	0
Bit 12	R/W	UPSNEE	0
Bit 11	R/W	AUTODRE	0
Bit 10	R/W	UNTSXE	0
Bit 9	R/W	TUNPVE	0
Bit 8	R/W	CECCRSE	0
Bit 7	R/W	CECCCBE	0
Bit 6	R/W	RPFEE	0
Bit 5	R/W	RABRTE	0
Bit 4	R/W	RFCSEE	0
Bit 3	R/W	MPISTATE	0
Bit 2	R/W	ENFEE	0
Bit 1	R/W	USNEE	0
Bit 0	R/W	LSNEE	0

This register provides low priority interrupt enables for various events detected or initiated by the FREEDM 32A1024L. Each low priority interrupt enable bit corresponds to the equivalent bit in the Master Low Priority Interrupt Status register. All interrupt enable bits are active high. When high, interrupts are enabled. When low, interrupts are masked. While interrupts are masked the status bit in the status register may still be polled to detect the error event. Enabled low priority interrupts cause the INTLOB interrupt pin to be asserted.

**Register 0x01C: Master Low Priority Interrupt Status**

Bit	Type	Function	Default
Bit 31 To Bit 12		Unused	X
Bit 13	R/W	Reserved	0
Bit 12	R/W	UPSNEI	0
Bit 11	R/W	AUTODRI	0
Bit 10	R/W	UNTSXI	0
Bit 9	R/W	TUNPVI	0
Bit 8	R/W	CECCRSI	0
Bit 7	R/W	CECCCB1	0
Bit 6	R/W	RPFEI	0
Bit 5	R/W	RABRTI	0
Bit 4	R/W	RFCSEI	0
Bit 3	R/W	MPISTATI	0
Bit 2	R/W	ENFEI	0
Bit 1	R/W	USNEI	0
Bit 0	R/W	LSNEI	0

This register reports the interrupt status for various events detected or initiated by the FREEDM 32A1024L. Reading these registers acknowledges and clears the interrupts. The register is also writeable to allow s/w testing of interrupt generation and service routines.

**LSNEI**

The Lost Sequence Number Event interrupt status bit indicates a datagram has been declared lost or has been discarded because its Any-PHY channel's storage allocation (AP\_ALLOC\_THR or LT\_LEVEL) has been exceeded, yet did not trigger an unexpected sequence number event. A datagram is declared lost after the timeout period specified by LOST\_CNT in the Connection Context Memory has expired. When set, the Lost SN CI Register (LSNCI) holds the CI number of the last connection to detect a lost SN event. LSNEI and LSNCI remain valid when interrupts are disabled and may be polled to detect lost SN events.

**USNEI**

The Unexpected Sequence number interrupt status bit reports unexpected SN conditions to the microprocessor. USNEI is set high when an unexpected SN is detected. When set, the Unexpected SN CI Register (USNCI) holds the CI number of the last connection to detect an unexpected SN. USNEI and USNCI remain valid when interrupts are disabled and may be polled to detect unexpected SN events.

## ENFEI

The number of Fragments per packet greater than Maximum allowed interrupt status bit reports when a packet with 82 or more fragments has been detected. ENFEI is active high. When set, the Excessive Number of Fragments CI Register (ENFCI) holds the CI number that caused the interrupt. ENFEI and ENFCI remain valid when interrupts are disabled and may be polled. This interrupt is only generated when output format is frame/packet (not in fragment out mode).

## MPISTATI

When asserted, the Memory Port Idle Status bit indicates to the microprocessor that the memory port has completed its last command. This signal is the inverse of MPBusy found in the Memory Port Control Register. MPISTATI remains valid when interrupts are disabled and may be polled to indicate idle status.

## RFCSEI

The receive frame check sequence error interrupt status bit reports receive FCS error interrupts to the microprocessor. RFCSEI is set high when a mismatch between the received FCS code and the computed CRC residue is detected. RFCSEI remains valid when interrupts are disabled and may be polled to detect receive FCS error events. Erred datagrams will be redirected during CI lookup and can be programmed to a separate CI. In addition, the RERR bit on the Rx Any-PHY interface will be set.

## RABRTI

The receive abort interrupt status bit reports receive HDLC abort interrupts to the microprocessor. RABRTI is set high upon receipt of an abort code (at least 7 contiguous 1's). RABRTI remains valid when interrupts are disabled and may be polled to detect receive abort events.

## RPFEI

The receive packet format error interrupt status bit reports receive packet format error interrupts to the microprocessor. RPFEI is set high upon receipt of a packet that is longer than the maximum programmed length, of a packet that is shorter than 32 bits (CRC-CCITT) or 48 bits (CRC-32), or of a packet that is not octet aligned. RPFEI remains valid when interrupts are disabled and may be polled to detect receive packet format error events.

## CECCCB

The Corrected ECC Error on Chunk Buffer Memory interrupt status bit reports such an event to the microprocessor. CECCCB is set high when an ECC Error that was corrected is detected during a memory access to the Chunk Buffer Memory. When set, the CB\_DRAMC\_COECCE Register will hold the DRAM address that was being accessed when the ECC Error occurred. CECCCB and CB\_DRAMC\_COECCE remain valid when interrupts are disabled and may be polled to detect error events.

## CECCRSI

The Corrected ECC Error on Re-sequencing Memory interrupt status bit reports such an event to the microprocessor. CECCRSI is set high when an ECC Error that was corrected is detected during a memory access to the Re-sequencing Memory. When set, the RS\_DRAMC\_COECCE Register will hold the DRAM address that was being accessed when the ECC Error occurred. CECCRSI and RS\_DRAMC\_COECCE remain valid when interrupts are disabled and may be polled to detect error events.

## TUNPVI

The transmit unprovisioned error interrupt status bit reports an attempted data transmission to an unprovisioned Any-PHY channel. TUNPVI is set high upon attempts to transfer data over the Any-PHY interface to an unprovisioned Any-PHY channel. TUNPVI remains valid when interrupts are disabled and may be polled to detect an attempt to write data to an unprovisioned channel.

## UNTSXI

The Unexpected TSX interrupt status bit reports observation of invalid arrival of TSX to the microprocessor. UNTSXI is set high when such an event is reported. UNTSXI remains valid when interrupts are disabled and may be polled.

## AUTODRI

The Auto Do Not Resequence interrupt status bit reports occurrences of a DO\_NOT\_RESEQ bit in the connection context memory being set automatically as a result of an unacceptably high number of LOST events being detected on a CI. AUTODRI is set high when such an event is reported. When set, the Auto Do Not Re-Sequence CI Register (AUTODRICI) holds the CI number of the last connection to experience an auto do not re-sequence event. AUTODRI remains valid when interrupts are disabled and may be polled.

## UPSNEI

The Unexpected Presence of Sequence Number Event interrupt status bit reports unexpected presence of SN events to the microprocessor. UPSNEI is set high when a sequenced datagram is received on an Any-PHY channel whose AP\_CIOUT configuration bit is set to 0. UPSNEI remains valid when interrupts are disabled and may be polled.

## Reserved

The Reserved bit must be 0 for correct operation of the FREEDM 32A1024L device.

**Register 0x020: Miscellaneous Control**

Bit	Type	Function	Default
Bit 31 To Bit 2		Unused	X
Bit 1	R/W	CI_LOOKUP_CHAN	0
Bit 0	R/W	CC_CNT_INTVL	0

This register contains miscellaneous control bits.

**CC\_CNT\_INTVL**

The Connection Context Count Interval bit is used to initiate counting intervals for the LSNE\_CNT, USNE\_CNT and DE\_CNT counters in the Connection Context SRAM. A new counting interval is initiated every time this bit is toggled.

**CI\_LOOKUP\_CHAN**

The Any-PHY-based CI lookup bit controls the manner in which CI lookup operations in the Re-sequence Structures (RS) memory is performed for sequenced and transparent datagrams. When set to 1, the datagram's Any-PHY channel number is used as bits [21:12] of the lookup key. When set to 0, the datagram's HDLC channel number is used as bits [21:12] of the lookup key. See Table 36 for more details.

Downloaded [controlled] by he hai of [redacted] on Friday, 2 August, 2008 05:02:17 PM

**Register 0x048: SBI DROP BUS Master Configuration**

Bit	Type	Function	Default
Bit 31 To Bit 2		Unused	X
Bit 1 To Bit 0	R/W	Reserved	0

This register contains reserved bits.

Reserved

The Reserved bits must be set to 0 for correct operation of the FREEDM 32A1024L device.

Downloaded [controlled] by he hai of nelep on Friday, 23 August, 2008 05:02:17 PM

**Register 0x04C: SBI ADD BUS Master Configuration**

Bit	Type	Function	Default
Bit 31 To Bit 4		Unused	X
Bit 3	R/W	DEFAULT_DRV	0
Bit 2	R/W	SBI_MODE	0
Bit 1	R/W	Reserved	0
Bit 0	R/W	CLK_MSTR	0

This register configures the operation of the SBI ADD BUS.

**CLK\_MSTR**

The CLK\_MSTR bit is used to specify whether the Insert block functions as a clock master or a clock slave. When this bit is a '1' the Insert block is a clock master. When set high, this bit overrides the individual tributary settings for clock master. The default state of this bit is clock slave.

**Reserved**

The reserved bit must be set to 0 for correct operation of the FREEDM 32A1024L device.

**SBI\_MODE:**

The SBI\_MODE bit selects SBI versus SBI336 mode of operation. When set high, 19.44MHz (SBI bus) is selected. The default state of this bit is 77MHz (SBI336) mode of operation.

**DEFAULT\_DRV**

The Default Bus Driver selector bit (DEFAULT\_DRV) enables the FREEDM 32A1024L to drive the SBI ADD BUS when no other device is doing so. When set to 1, the INSBI will drive the bus whenever the ADETECT[1:0] inputs are both 0. When set to 0, the INSBI will only drive the bus when it has data to send (and when ADETECT[1:0] are both 0). It is recommended that one device connected to an SBI Bus be nominated as a default driver and configured to drive the bus when no other device is doing so.

**Register 0x068: DLL Configuration**

Bit	Type	Function	Default
Bit 31 To Bit 6		Unused	X
Bit 5	R/W	Reserved	0
Bit 4	R/W	Reserved	0
Bit 3		Unused	X
Bit 2	R/W	ERRORE	X
Bit 1	R/W	VERN_EN	0
Bit 0	R/W	LOCK	0

The DLL Configuration Register controls the basic operation of the DLL.

**LOCK**

The LOCK register is used to force the DLL to ignore phase offsets indicated by the phase detector after phase lock has been achieved. When LOCK is set to logic zero, the DLL will track phase offsets measured by the phase detector between the DLLSYSCLK and the DLLREFCLK inputs. When LOCK is set to logic one, the DLL will not change the tap after the phase detector indicates a zero phase offset between the DLLSYSCLK and the DLLREFCLK inputs for the first time.

**VERN\_EN**

The vernier enable register (VERN\_EN) forces the DLL to ignore the phase detector and use the tap number specified by the VERNIER[7:0] register bits. When VERN\_EN is set to logic zero, the DLL operates normally adjusting the phase offset based on the phase detector. When VERN\_EN is set to logic one, the delay line uses the tap specified by the VERNIER[7:0] register bits.

**ERRORE**

The ERROR interrupt enable (ERRORE) bit enables the error indication interrupt. When ERRORE is set high, an interrupt is generated upon assertion event of the ERR output and ERROR register. When ERRORE is set low, changes in the ERROR and ERR status do not generate an interrupt.

**Reserved**

The reserved bits must be set low for correct operation of the FREEDM 32A1024L device.

**Register 0x06C: DLL Vernier Control**

Bit	Type	Function	Default
Bit 31 To Bit 8		Unused	X
Bit 7	R/W	VERNIER[7]	0
Bit 6	R/W	VERNIER[6]	0
Bit 5	R/W	VERNIER[5]	0
Bit 4	R/W	VERNIER[4]	0
Bit 3	R/W	VERNIER[3]	0
Bit 2	R/W	VERNIER[2]	0
Bit 1	R/W	VERNIER[1]	0
Bit 0	R/W	VERNIER[0]	0

The Vernier Control Register provides the delay line tap control when using the vernier option.

**VERNIER[7:0]**

The vernier tap register bits (VERNIER[7:0]) specifies the phase delay through the DLL when using the vernier feature. When VERN\_EN is set high, the VERNIER[7:0] registers specify the delay tap used. When VERN\_EN is set low, the VERNIER[7:0] register is ignored.

A VERNIER[7:0] value of all zeros specifies the delay tap with the minimum delay through the delay line. A VERNIER[7:0] value of 255 specifies the delay tap with the maximum delay through the delay line.

**Register 0x070: DLL Delay Tap Status**

Bit	Type	Function	Default
Bit 31 To Bit 8		Unused	X
Bit 7	R/W	TAP[7]	X
Bit 6	R/W	TAP[6]	X
Bit 5	R/W	TAP[5]	X
Bit 4	R/W	TAP[4]	X
Bit 3	R/W	TAP[3]	X
Bit 2	R/W	TAP[2]	X
Bit 1	R/W	TAP[1]	X
Bit 0	R/W	TAP[0]	X

The DLL Delay Tap Status Register indicates the delay tap used by the DLL to generate the outgoing clock.

Writing to this register performs a software reset of the DLL. A software reset requires a maximum of 24\*256 DLLSYSCLK cycles for the DLL to regain lock. During this time the DLLDCLKO phase is adjusting from its current position to delay tap 0 and back to a lock position.

**TAP[7:0]**

The tap status register bits (TAP[7:0]) specifies the delay line tap the DLL is using to generate the outgoing clock DLLDCLKO.

When TAP[7:0] is logic zero, the DLL is using the delay line tap with minimum phase delay. When TAP[7:0] is equal to 255, the DLL is using the delay line tap with maximum phase delay. TAP[7:0] is invalid when vernier enable VERN\_EN is set to one.

**Register 0x074: DLL Control Status**

Bit	Type	Function	Default
Bit 31 To Bit 8		Unused	X
Bit 7	R	DLLSYSCLKI	X
Bit 6	R	DLLREFCLKI	X
Bit 5	R	ERRORI	X
Bit 4	R	CHANGEI	X
Bit 3		Unused	X
Bit 2	R	ERROR	X
Bit 1	R	CHANGE	X
Bit 0	R	RUN	X

The DLL Control Status Register provides information of the DLL operation.

**RUN**

The DLL lock status register bit (RUN) indicates the DLL found a delay line tap in which the phase difference between the rising edge of DLLREFCLK and the rising edge of SYSCLK is zero. After system reset, RUN is logic zero until the phase detector indicates an initial lock condition. When the phase detector indicates lock, RUN is set to logic 1.

The RUN register bit is cleared only by a hardware or a software reset. RUN is forced high when the VERN\_EN register is set high.

**CHANGE**

The delay line tap change register bit (CHANGE) indicates the DLL has moved to a new delay line tap. CHANGE is set high for eight DLLSYSCLK cycles when the DLL moves to a new delay line tap.

**ERROR**

The delay line error register bit (ERROR) indicates the DLL has run out of dynamic range. When the DLL attempts to move beyond the end of the delay line, ERROR is set high. When ERROR is high, the DLL cannot generate a DLLDCLKO phase, which causes the rising edge of DLLREFCLK to be aligned to the rising edge of DLLSYSCLK. ERROR is set low, when the DLL captures lock again.

ERROR is forced low when the VERN\_EN register is set high.

**CHANGEI**

The delay line tap change event register bit (CHANGEI) indicates the CHANGE register bit has changed value. When the CHANGE register changes from a logic zero to a logic one, the CHANGEI register bit is set to logic one.

## ERRORI

The delay line error event register bit (ERRORI) indicates the ERROR register bit has gone high. When the ERROR register changes from a logic zero to a logic one, the ERRORI register bit is set to logic one. If the ERRERE interrupt enable is high, the DLLI bit in the Master High Priority Interrupt Status Register is also asserted when ERRORI asserts.

## DLLREFCLKI

The reference clock event register bit DLLREFCLKI provides a method to monitor activity on the reference clock to the DLL. This reference clock is the feedback path from the far end of the clock tree to which the system clock is synchronized. When the DLLREFCLK primary input changes from a logic zero to a logic one, the DLLREFCLKI register bit is set to logic one.

## DLLSYSCLKI

The system clock event register bit DLLSYSCLKI provides a method to monitor activity on the system clock (SYSCLK). When the SYSCLK primary input changes from a logic zero to a logic one, the DLLSYSCLKI register bit is set to logic one. The DLLSYSCLKI register bit is cleared immediately after it is read, thus acknowledging the event has been recorded.

**Register 0x100: RCAS Indirect Context RAM Link Select**

Bit	Type	Function	Default
Bit 31 To Bit 12		Unused	X
Bit 11	R	BUSY	0
Bit 10	R/W	RWB	0
Bit 9	R/W	Reserved	0
Bit 8	R/W	Reserved	0
Bit 7	R/W	SBI	0
Bit 6	R/W	SPE[1]	0
Bit 5	R/W	SPE[0]	0
Bit 4	R/W	TRIB[4]	0
Bit 3	R/W	TRIB[3]	0
Bit 2	R/W	TRIB[2]	0
Bit 1	R/W	TRIB[1]	0
Bit 0	R/W	TRIB[0]	0

This register provides the link number used to access the RCAS context RAM. Writing to this register triggers an indirect register access.

Reserved:

The reserved bits must be set low for correct operation of the FREEDM 32A1024L device.

TRIB[4:0], SPE[1:0] and SBI

The TRIB[4:0], SPE[1:0] and SBI fields are used to fully specify to which SBI tributary the RCAS context RAM write or read operation will apply.

TRIB[4:0] specifies the SBI tributary number within the SBI SPE as specified by the SPE[1:0] and SBI fields. Legal values for TRIB[4:0] are b'00001' through b'11100'. Legal values for SPE[1:0] are b'01' through b'11'. SBI must be written to a logic one in the FREEDM 32A1024L device.

RWB

The indirect access control bit (RWB) selects between a configure (write) or interrogate (read) access to the RCAS context RAM. Writing a logic zero to RWB triggers an indirect write operation. Data to be written is taken from the LEN and SBI\_MODE[2:0] bits of the RCAS Indirect context RAM Data register. Writing a logic one to RWB triggers an indirect read operation. The data read can be found in the LEN and SBI\_MODE[2:0] bits of the RCAS Indirect context RAM Data register.

**BUSY**

The indirect access status bit (BUSY) reports the progress of an indirect access. BUSY is set high when this register is written, to trigger an indirect access, and will stay high until the access is complete. At which point, BUSY will be set low. This register should be polled to determine when data from an indirect read operation is available in the Indirect Data register or to determine when a new indirect write operation may commence.

Downloaded [controlled] by he hai of nelep on Friday, 29 August, 2008 05:11:11 PM

**Register 0x104: RCAS Indirect Context RAM Data**

Bit	Type	Function	Default
Bit 31 To Bit 4		Unused	X
Bit 3	R/W	SBI_MODE[2]	0
Bit 2	R/W	SBI_MODE[1]	0
Bit 1	R/W	SBI_MODE[0]	0
Bit 0	R/W	Reserved	0

This register provides the link enable bit and the frame mode or data type associated to this particular link in the RCAS context RAM.

**SBI\_MODE[2:0]**

The SBI Frame Mode bits (SBI\_MODE [2:0]), define the type of data for a specific link to be configured according to the following table.

**Table 14 SBI Mode**

SBI_MODE [2:0]	Configuration
000	Unused
001	28 Unframed T1/J1 links
010	21 Unframed E1 links
011	Unused
100	Unused
101	28 Framed Channelized T1/J1 links
110	21 Framed Channelized E1 links
111	Unused

**Register 0x108: RCAS Indirect Channel Provision RAM Link Select**

Bit	Type	Function	Default
Bit 15 To Bit 13		Unused	X
Bit 12	R/W	SBI_MODE[2]	0
Bit 11	R/W	SBI_MODE[1]	0
Bit 10	R/W	SBI_MODE[0]	0
Bit 9	R/W	Reserved	0
Bit 8	R/W	Reserved	0
Bit 7	R/W	SBI	0
Bit 6	R/W	SPE[1]	0
Bit 5	R/W	SPE[0]	0
Bit 4	R/W	TRIB[4]	0
Bit 3	R/W	TRIB[3]	0
Bit 2	R/W	TRIB[2]	0
Bit 1	R/W	TRIB[1]	0
Bit 0	R/W	TRIB[0]	0

This register provides the link number used to access the RCAS channel provision RAM.

Reserved:

The reserved bits must be set low for correct operation of the FREEDM 32A1024L device.

SBI\_MODE[2:0]:

This field must be set to the same value as Bits3:1 in Register 0x104.

TRIB[4:0], SPE[1:0] and SBI:

The TRIB[4:0], SPE[1:0] and SBI fields are used to fully specify to which SBI tributary the context RAM write or read operation will apply.

TRIB[4:0] specifies the SBI tributary number within the SBI SPE as specified by the SPE[1:0] and SBI fields. Legal values for TRIB[4:0] are b'00001' through b'11100'. Legal values for SPE[1:0] are b'01' through b'11'. SBI must be written to a logic one in the FREEDM 32A1024L device.

**Register 0x10C: RCAS Indirect Channel Provision RAM Timeslot and Control Select**

Bit	Type	Function	Default
Bit 31 To Bit 7		Unused	X
Bit 6	R	BUSY	0
Bit 5	R/W	RWB	0
Bit 4	R/W	TSLOT[4]	0
Bit 3	R/W	TSLOT[3]	0
Bit 2	R/W	TSLOT[2]	0
Bit 1	R/W	TSLOT[1]	0
Bit 0	R/W	TSLOT[0]	0

This register provides the link timeslot number and control bits used to access the channel provision RAM. The RCAS Indirect Channel Provision RAM Link Select register must be valid before writing this register. Writing to this register triggers an indirect register access.

**TSLOT[4:0]**

The indirect timeslot number bits (TSLOT[4:0]) indicate the timeslot to be configured or interrogated in the indirect access. For a channelized T1/J1 link, timeslots 0 to 23 are valid. For a channelized E1 link, timeslots 0 to 31 are valid. For unchannelized links, only timeslot 0 is valid.

**RWB**

The indirect access control bit (RWB) selects between a configure (write) or interrogate (read) access to the RCAS channel provision RAM. The address to the channel provision RAM is constructed by combining the TSLOT[4:0] and LINK number. Writing a logic zero to RWB triggers an indirect write operation. Data to be written is taken from the PROV, and the CHAN[9:0] bits of the Indirect Channel Data and Loop back enable register. Writing a logic one to RWB triggers an indirect read operation. Addressing of the RAM is the same as in an indirect write operation. The data read can be found in the PROV, and the CHAN[9:0] bits of the RCAS Indirect Channel Data register.

**BUSY**

The indirect access status bit (BUSY) reports the progress of an indirect access. BUSY is set high when this register is written, to trigger an indirect access, and will stay high until the access is complete. At which point, BUSY will be set low. This register should be polled to determine when data from an indirect read operation is available in the RCAS Indirect Data register or to determine when a new indirect write operation may commence.

**Register 0x110: RCAS Indirect Channel Data and Loop Back Enable**

Bit	Type	Function	Default
Bit 31 To Bit 12		Unused	X
Bit 11	R/W	CDLBEN	0
Bit 10	R/W	PROV	0
Bit 9	R/W	CHAN [9]	0
Bit 8	R/W	CHAN [8]	0
Bit 7	R/W	CHAN [7]	0
Bit 6	R/W	CHAN [6]	0
Bit 5	R/W	CHAN [5]	0
Bit 4	R/W	CHAN [4]	0
Bit 3	R/W	CHAN [3]	0
Bit 2	R/W	CHAN [2]	0
Bit 1	R/W	CHAN [1]	0
Bit 0	R/W	CHAN [0]	0

This register contains the data read from the RCAS channel provision RAM after an indirect read operation or the data to be inserted into the RCAS channel provision RAM in an indirect write operation.

One channel must be reserved for timeslots that are unprovisioned in an active tributary.

**CHAN[9:0]**

The indirect data bits (CHAN[9:0]) report the channel number read from the channel provision RAM after an indirect read operation has completed. Channel number to be written to the RCAS channel provision RAM in an indirect write operation must be set up in this register before triggering the write. CHAN[9:0] reflects the value written until the completion of a subsequent indirect read operation.

**PROV**

The indirect provision enable bit (PROV) reports the channel provision enable flag read from the RCAS channel provision RAM after an indirect read operation has completed. The provision enable flag to be written to the RCAS channel provision RAM in an indirect write operation must be set up in this register before triggering the write. When PROV is set high, the current receive data byte is processed as part of the channel as indicated by CHAN[9:0]. When PROV is set low, the current timeslot does not belong to any channel and the received data byte ignored. PROV reflects the value written until the completion of a subsequent indirect read operation.

## CDLBEN

The indirect channel based diagnostic loop back enable bit (CDLBEN) indicates that for this channel, data is looped back from the Tx path (THDL-12) instead of being received from the receive links. If enabled, the channel can not be used for SBI traffic. In addition, the equivalent bandwidth must be disabled in normal mode operation.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:02:11 PM

**Register 0x200: RHDL Indirect Channel Select**

Bit	Type	Function	Default
Bit 31 To Bit 16		Unused	X
Bit 15	R	CBUSY	0
Bit 14	R/W	CRWB	0
Bit 13 To Bit 10		Unused	X
Bit 9	R/W	CHAN[9]	0
Bit 8	R/W	CHAN[8]	0
Bit 7	R/W	CHAN[7]	0
Bit 6	R/W	CHAN[6]	0
Bit 5	R/W	CHAN[5]	0
Bit 4	R/W	CHAN[4]	0
Bit 3	R/W	CHAN[3]	0
Bit 2	R/W	CHAN[2]	0
Bit 1	R/W	CHAN[1]	0
Bit 0	R/W	CHAN[0]	0

This register provides the channel number used to access the receive channel provision RAM. Writing to this register triggers an indirect channel register access. During indirect write operations, there must be no incoming data present on the HDLC channel being configured. Prior to commencing any indirect write operation to a particular HDLC channel, any timeslots mapped in the RCAS channel provision RAM (Register 0x110) to that HDLC channel must be re-mapped to the HDLC channel reserved for unused time slots.

**CHAN[9:0]**

The indirect channel number bits (CHAN[9:0]) indicate the receive channel to be configured or interrogated in the indirect access.

**CRWB**

The channel indirect access control bit (CRWB) selects between a configure (write) or interrogate (read) access to the receive channel provision RAM. Writing a logic zero to CRWB triggers an indirect write operation. Data to be written is taken from the Indirect Channel Data registers. Writing a logic one to CRWB triggers an indirect read operation. The data read can be found in the Indirect Channel Data registers.

## CBUSY

The indirect access status bit (CBUSY) reports the progress of an indirect access. CBUSY is set high when this register is written to trigger an indirect access, and will stay high until the access is complete. At which point, CBUSY will be set low. This register should be polled to determine when data from an indirect read operation is available in the RHDL Indirect Channel Data #1 and #2 registers or to determine when a new indirect write operation may commence.

Downloaded [controlled] by he hai of nelep on Friday, 29 August, 2008 10:21 AM

**Register 0x204: RHDL Indirect Channel Data Register #1**

Bit	Type	Function	Default
Bit 31 To Bit 16		Unused	X
Bit 15	W*	PROV	X
Bit 14	R/W	STRIP	X
Bit 13	W*	Reserved	X
Bit 12	R	TAVAIL	X
Bit 11	W	FPTR[11]	X
Bit 10	W	FPTR[10]	X
Bit 9	W	FPTR[9]	X
Bit 8	W	FPTR[8]	X
Bit 7	W	FPTR[7]	X
Bit 6	W	FPTR[6]	X
Bit 5	W	FPTR[5]	X
Bit 4	W	FPTR[4]	X
Bit 3	W	FPTR[3]	X
Bit 2	W	FPTR[2]	X
Bit 1	W	FPTR[1]	X
Bit 0	W	FPTR[0]	X

This register contains data read from the channel provision RAM after an indirect read operation or data to be inserted into the channel provision RAM in an indirect write operation.

\* These registers are also readable if no traffic is enabled in the device.

**FPTR[11:0]**

The indirect FIFO block pointer (FPTR[11:0]) identifies one of the blocks of the circular linked list in the partial packet buffer used in the logical FIFO of the current channel. The FIFO pointer to be written to the channel provision RAM, in an indirect write operation, must be set up in this register before triggering the write. The FIFO pointer value can be any one of the blocks provisioned to form the circular buffer.

**TAVAIL**

The indirect Transaction Available bit (TAVAIL) indicates whether the FIFO for the channel currently contains at least one transaction, defined as either a complete packet or a transaction sized number of blocks, available for transfer over the receive DMA interface. When TAVAIL is a logic 1, a transaction is available for transfer. When TAVAIL is a logic 0, a transaction is not available. TAVAIL is a read-only bit.

**Reserved**

The Reserved bit must be set to 1 for correct operation of the FREEDM 32A1024L device.

## STRIP

The indirect frame check sequence discard bit (STRIP) configures the HDLC processor to remove the CRC from the incoming frame when writing the data to the channel FIFO. The FCS discard bit to be written to the channel provision RAM, in an indirect channel write operation, must be set up in this register before triggering the write. When STRIP is set high and CRC[1:0] is not equal to “00”, the received CRC value is not written to the FIFO. When STRIP is set low, the received CRC value is written to the FIFO. The bytes in buffer field of the RPD correctly reflect the presence/absence of CRC bytes in the buffer. STRIP reflects the value written until the completion of a subsequent indirect channel read operation.

## PROV

The indirect provision enable bit (PROV) reports the channel provision enable flag read from the channel provision RAM after an indirect channel read operation has completed. The provision enable flag to be written to the channel provision RAM, in an indirect write operation, must be set up in this register before triggering the write. When PROV is set high, the HDLC processor will process data on the channel specified by CHAN[9:0]. When PROV is set low, the HDLC processor will ignore data on the channel specified by CHAN[9:0]. PROV reflects the value written until the completion of a subsequent indirect channel read operation.

**Register 0x208: RHDL Indirect Channel Data Register #2**

Bit	Type	Function	Default
Bit 31 To Bit 16		Unused	X
Bit 15	W*	7BIT	X
Bit 14	W*	PRIORITY	X
Bit 13	W*	INVERT	X
Bit 12		Unused	X
Bit 11	W*	CRC[1]	X
Bit 10	W*	CRC[0]	X
Bit 9	R/W	Reserved	X
Bit 8	R/W	Reserved	X
Bit 7		Unused	X
Bit 6		Unused	X
Bit 5		Unused	X
Bit 4		Unused	X
Bit 3	R/W	Reserved	0
Bit 2	R/W	Reserved	0
Bit 1	R/W	Reserved	0
Bit 0	R/W	Reserved	0

This register contains data read from the channel provision RAM after an indirect read operation or it contains data to be inserted into the channel provision RAM in an indirect write operation.

\* These register bits are also readable if no traffic is enabled in the device.

Reserved

The reserved bits must be set to the following values for correct operation of the FREEDM 32A1024L device.

**Table 15 Reserved Bit Settings**

Bit	Setting
9	0
8	0
3	0
2	0
1	0
0	1

## CRC[1:0]

The CRC algorithm bits (CRC[1:0]) configures the HDLC processor to perform CRC verification on the incoming data stream. The value of CRC[1:0] to be written to the channel provision RAM, in an indirect channel write operation, must be set up in this register before triggering the write. CRC[1:0] reflects the value written until the completion of a subsequent indirect channel read operation.

**Table 16 CRC[1:0] Settings**

CRC[1]	CRC[0]	Operation
0	0	No Verification
0	1	CRC-CCITT
1	0	CRC-32
1	1	Reserved

## INVERT

The HDLC data inversion bit (INVERT) configures the HDLC processor to logically invert the incoming HDLC stream from the RCAS-12 before processing it. The value of INVERT to be written to the channel provision RAM, in an indirect channel write operation, must be set up in this register before triggering the write. When INVERT is set to one, the HDLC stream is logically inverted before processing. When INVERT is set to zero, the HDLC stream is not inverted before processing. INVERT reflects the value written until the completion of a subsequent indirect channel read operation. Before tearing down a channel, this bit must be set to 0.

## PRIORITY

The channel FIFO priority bit (PRIORITY) informs the partial packet processor that the channel has precedence over other channels when being serviced by upstream blocks. The value of PRIORITY to be written to the channel provision RAM, in an indirect channel write operation, must be set up in this register before triggering the write. Channel FIFOs with PRIORITY set to one are serviced before channel FIFOs with PRIORITY set to zero. Channels with an HDLC data rate to FIFO size ratio that is significantly higher than other channels should have PRIORITY set to one. PRIORITY reflects the value written until the completion of a subsequent indirect channel read operation.

## 7BIT

The 7BIT enable bit (7BIT) configures the HDLC processor to ignore the least significant bit of each octet in the incoming channel stream. The value of 7BIT to be written to the channel provision RAM, in an indirect channel write operation, must be set up in this register before triggering the write. When 7BIT is set high, the least significant bit (last bit of each octet received), is ignored. When 7BIT is set low, the entire receive data stream is processed. 7BIT reflects the value written until the completion of a subsequent indirect channel read operation.

**Register 0x210: RHDL Indirect Block Select**

Bit	Type	Function	Default
Bit 31 To Bit 16		Unused	X
Bit 15	R	BBUSY	0
Bit 14	R/W	BRWB	0
Bit 13 To Bit 12		Unused	X
Bit 11	R/W	BLOCK[11]	0
Bit 10	R/W	BLOCK[10]	0
Bit 9	R/W	BLOCK[9]	0
Bit 8	R/W	BLOCK[8]	0
Bit 7	R/W	BLOCK[7]	0
Bit 6	R/W	BLOCK[6]	0
Bit 5	R/W	BLOCK[5]	0
Bit 4	R/W	BLOCK[4]	0
Bit 3	R/W	BLOCK[3]	0
Bit 2	R/W	BLOCK[2]	0
Bit 1	R/W	BLOCK[1]	0
Bit 0	R/W	BLOCK[0]	0

This register provides the block number used to access the block pointer RAM. Writing to this register triggers an indirect block register access.

**BLOCK[11:0]**

The indirect block number (BLOCK[11:0]) indicates the block to be configured or interrogated in the indirect access.

**BRWB**

The block indirect access control bit (BRWB) selects between a configure (write) or interrogate (read) access to the block pointer RAM. Writing a logic zero to BRWB triggers an indirect block write operation. Data to be written is taken from the Indirect Block Data register. Writing a logic one to BRWB triggers an indirect block read operation. The data read can be found in the Indirect Block Data register.

**BBUSY**

The indirect access status bit (BBUSY) reports the progress of an indirect access. BBUSY is set high when this register is written to trigger an indirect access, and will stay high until the access is complete. At which point, BBUSY will be set low. This register should be polled to determine when data from an indirect read operation is available in the RHDL Indirect Block Data register or to determine when a new indirect write operation may commence.

**Register 0x214: RHDL Indirect Block Data**

Bit	Type	Function	Default
Bit 31 To Bit 12		Unused	X
Bit 11	R/W	BPTR[11]	X
Bit 10	R/W	BPTR[10]	X
Bit 9	R/W	BPTR[9]	X
Bit 8	R/W	BPTR[8]	X
Bit 7	R/W	BPTR[7]	X
Bit 6	R/W	BPTR[6]	X
Bit 5	R/W	BPTR[5]	X
Bit 4	R/W	BPTR[4]	X
Bit 3	R/W	BPTR[3]	X
Bit 2	R/W	BPTR[2]	X
Bit 1	R/W	BPTR[1]	X
Bit 0	R/W	BPTR[0]	X

This register contains data read from the block pointer RAM after an indirect block read operation or data to be inserted into the block pointer RAM in an indirect block write operation.

**BPTR[11:0]**

The indirect block pointer (BPTR[11:0]) configures the block pointer of the block specified by the Indirect Block Select register. The block pointer to be written to the block pointer RAM, in an indirect write operation, must be set up in this register before triggering the write. The block pointer value is the block number of the next block in the linked list. A circular list of blocks must be formed in order to use the block list as a receive channel FIFO buffer. BPTR[11:0] reflects the value written until the completion of a subsequent indirect block read operation. When provisioning a channel FIFO, all block pointers must be re-written to properly initialize the FIFO.

**Register 0x220: RHDL Configuration**

Bit	Type	Function	Default
Bit 31 To Bit 10		Unused	X
Bit 9	R/W	LENCHK	0
Bit 8	R/W	TSTD	0
Bit 7		Unused	X
Bit 6		Unused	X
Bit 5		Unused	X
Bit 4		Unused	X
Bit 3		Unused	X
Bit 2		Unused	X
Bit 1		Unused	X
Bit 0		Unused	X

This register configures all provisioned receive channels.

**TSTD**

The telecom standard bit (TSTD) controls the bit ordering of the HDLC data transferred across the receive APPI. When TSTD is set low, the least significant bit of each byte on the receive APPI bus (AD[0] and AD[8]) is the first HDLC bit received and the most significant bit of each byte (AD[7] and AD[15]) is the last HDLC bit received (datacom standard). When TSTD is set high, AD[0] and AD[8] are the last HDLC bits received and AD[7] and AD[15] are the first HDLC bits received (telecom standard).

**LENCHK**

The packet length error check bit (LENCHK) controls the checking of receive packets that are longer than the maximum programmed length. When LENCHK is set high, receive packets are aborted and the remainder of the frame discarded when the packet exceeds the maximum packet length given by MAX[15:0]. When LENCHK is set low, receive packets are not checked for maximum size and MAX[15:0] must be set to hFFFF.

**Note: It is recommended to set this bit to 1. If not set, a string of all 0's will be interpreted as an infinite length packet and will cause chunk buffer exhaustion.**

**Register 0x224: RHDL Maximum Packet Length**

Bit	Type	Function	Default
Bit 31 To Bit 16		Unused	X
Bit 15	R/W	MAX[15]	1
Bit 14	R/W	MAX[14]	1
Bit 13	R/W	MAX[13]	1
Bit 12	R/W	MAX[12]	1
Bit 11	R/W	MAX[11]	1
Bit 10	R/W	MAX[10]	1
Bit 9	R/W	MAX[9]	1
Bit 8	R/W	MAX[8]	1
Bit 7	R/W	MAX[7]	1
Bit 6	R/W	MAX[6]	1
Bit 5	R/W	MAX[5]	1
Bit 4	R/W	MAX[4]	1
Bit 3	R/W	MAX[3]	1
Bit 2	R/W	MAX[2]	1
Bit 1	R/W	MAX[1]	1
Bit 0	R/W	MAX[0]	1

This register configures the maximum legal HDLC packet byte length.

**MAX[15:0]**

The maximum HDLC packet length (MAX[15:0]) configures the FREEDM 32A1024L to reject HDLC packets longer than a maximum size when LENCHK is set high. Receive packets with total length, including address, control, information and FCS fields, greater than MAX[15:0] bytes are aborted. When LENCHK is set low aborts are not generated regardless of packet length and MAX[15:0] must be set to 'hFFFF.

**Register 0x380: THDL Indirect Channel Select**

Bit	Type	Function	Default
Bit 31 To Bit 16		Unused	X
Bit 15	R	CBUSY	0
Bit 14	R/W	CRWB	0
Bit 13 To Bit 10		Unused	X
Bit 9	R/W	CHAN[9]	0
Bit 8	R/W	CHAN[8]	0
Bit 7	R/W	CHAN[7]	0
Bit 6	R/W	CHAN[6]	0
Bit 5	R/W	CHAN[5]	0
Bit 4	R/W	CHAN[4]	0
Bit 3	R/W	CHAN[3]	0
Bit 2	R/W	CHAN[2]	0
Bit 1	R/W	CHAN[1]	0
Bit 0	R/W	CHAN[0]	0

This register provides the channel number used to access the transmit channel provision RAM. Writing to this register triggers an indirect channel register access.

**CHAN[9:0]**

The indirect channel number bits (CHAN[9:0]) indicate the channel to be configured or interrogated in the indirect access.

**CRWB**

The channel indirect access control bit (CRWB) selects between a configure (write) or interrogate (read) access to the channel provision RAM. Writing a logic zero to CRWB triggers an indirect write operation. Data to be written is taken from the Indirect Channel Data registers. Writing a logic one to CRWB triggers an indirect read operation. The data read can be found in the Indirect Channel Data registers.

**CBUSY**

The indirect access status bit (CBUSY) reports the progress of an indirect access. CBUSY is set high when this register is written to trigger an indirect access, and will stay high until the access is complete. At which point, CBUSY will be set low. This register should be polled to determine when data from an indirect read operation is available in the THDL Indirect Channel Data #1, #2 and #3 registers or to determine when a new indirect write operation may commence.

**Register 0x384: THDL Indirect Channel Data #1**

Bit	Type	Function	Default
Bit 31 To Bit 16		Unused	X
Bit 15	R/W	PROV	X
Bit 14	R/W	CRC[1]	X
Bit 13	R/W	CRC[0]	X
Bit 12	R/W	DELIN	X
Bit 11	R/W	FPTR[11]	X
Bit 10	R/W	FPTR[10]	X
Bit 9	R/W	FPTR[9]	X
Bit 8	R/W	FPTR[8]	X
Bit 7	R/W	FPTR[7]	X
Bit 6	R/W	FPTR[6]	X
Bit 5	R/W	FPTR[5]	X
Bit 4	R/W	FPTR[4]	X
Bit 3	R/W	FPTR[3]	X
Bit 2	R/W	FPTR[2]	X
Bit 1	R/W	FPTR[1]	X
Bit 0	R/W	FPTR[0]	X

This register contains data read from the channel provision RAM after an indirect channel read operation or data to be inserted into the channel provision RAM in an indirect channel write operation.

**FPTR[11:0]**

The indirect FIFO block pointer (FPTR[11:0]) informs the partial packet buffer processor about the circular linked list of blocks to use for a FIFO for the channel. The FIFO pointer to be written to the channel provision RAM, in an indirect write operation, must be set up in this register before triggering the write. The FIFO pointer value can be any one of the block numbers provisioned, by indirect block write operations, to form the circular buffer.

**DELIN**

The indirect delineate enable bit (DELIN) configures the HDLC processor to perform flag sequence insertion and bit stuffing on the outgoing data stream. The delineate enable bit to be written to the channel provision RAM, in an indirect channel write operation, must be set up in this register before triggering the write. When DELIN is set high, flag sequence insertion, bit stuffing and ,optionally, CRC generation is performed on the outgoing HDLC data stream. When DELIN is set low, the HDLC processor does not perform any processing (flag sequence insertion, bit stuffing nor CRC generation) on the outgoing stream. DELIN reflects the value written until the completion of a subsequent indirect channel read operation.

## CRC[1:0]

The CRC algorithm (CRC[1:0]) configures the HDLC processor to perform CRC generation on the outgoing HDLC data stream. The value of CRC[1:0] to be written to the channel provision RAM, in an indirect channel write operation, must be set up in this register before triggering the write. CRC[1:0] is ignored when DELIN is low. CRC[1:0] reflects the value written until the completion of a subsequent indirect channel read operation.

**Table 17 CRC[1:0] Settings**

CRC[1]	CRC[0]	Operation
0	0	No CRC
0	1	CRC-CCITT
1	0	CRC-32
1	1	Reserved

## PROV

The indirect provision enable bit (PROV) reports the channel provision enable flag read from the channel provision RAM after an indirect channel read operation has completed. The provision enable flag to be written to the channel provision RAM, in an indirect write operation, must be set up in this register before triggering the write. When PROV is set high, the HDLC processor will service requests for data from the TCAS-12 block. When PROV is set low, the HDLC processor will ignore requests from the TCAS-12 block. PROV reflects the value written until the completion of a subsequent indirect channel read operation.

**Register 0x388: THDL Indirect Channel Data #2**

Bit	Type	Function	Default
Bit 31 To Bit 16		Unused	X
Bit 15	R/W	7BIT	X
Bit 14	R/W	INHIBIT	X
Bit 13	R/W	INVERT	X
Bit 12	R/W	DFCS	X
Bit 11	R/W	Reserved	0
Bit 10	R/W	FLEN[10]	X
Bit 9	R/W	FLEN[9]	X
Bit 8	R/W	FLEN[8]	X
Bit 7	R/W	FLEN[7]	X
Bit 6	R/W	FLEN[6]	X
Bit 5	R/W	FLEN[5]	X
Bit 4	R/W	FLEN[4]	X
Bit 3	R/W	FLEN[3]	X
Bit 2	R/W	FLEN[2]	X
Bit 1	R/W	FLEN[1]	X
Bit 0	R/W	FLEN[0]	X

This register contains data to be inserted into the channel provision RAM in an indirect write operation.

**FLEN[10:0]**

The indirect FIFO length (FLEN[10:0]) is the number of blocks, less one, that is provisioned to the circular channel FIFO specified by the FPTR[10:0] block pointer. The FIFO length to be written to the channel provision RAM, in an indirect channel write operation, must be set up in this register before triggering the write.

**Reserved**

The reserved bits must be set low for correct operation of the FREEDM 32A1024L device.

**DFCS**

The diagnose frame check sequence bit (DFCS) controls the inversion of the FCS field inserted into the transmit packet. The value of DFCS to be written to the channel provision RAM, in an indirect channel write operation, must be set up in this register before triggering the write. When DFCS is set to one, the FCS field in the outgoing HDLC stream is logically inverted allowing diagnosis of downstream FCS verification logic. The outgoing FCS field is not inverted when DFCS is set to zero. DFCS reflects the value written until the completion of a subsequent indirect channel read operation.

## INVERT

The HDLC data inversion bit (INVERT) configures the HDLC processor to logically invert the outgoing HDLC stream. The value of INVERT to be written to the channel provision RAM, in an indirect channel write operation, must be set up in this register before triggering the write. When INVERT is set to one, the outgoing HDLC stream is logically inverted. The outgoing HDLC stream is not inverted when INVERT is set to zero. INVERT reflects the value written until the completion of a subsequent indirect channel read operation.

## INHIBIT

The channel FIFO expedite inhibit bit (INHIBIT) informs the partial packet processor that the channel has less priority than other channels when requesting data from the EQM-12. The value of INHIBIT to be written to the channel provision RAM, in an indirect channel write operation, must be set up in this register before triggering the write. Channel FIFOs with INHIBIT set to one cannot make expedited requests for data to the EQM-12. When INHIBIT is set to zero, both normal and expedited requests can be made to the EQM-12. Channels with HDLC data rates significantly slower than other channels should have INHIBIT set to one. INHIBIT reflects the value written until the completion of a subsequent indirect channel read operation.

## 7BIT

The least significant stuff enable bit (7BIT) configures the HDLC processor to stuff the least significant bit of each octet in the outgoing channel stream. The value of 7BIT to be written to the channel provision RAM, in an indirect channel write operation, must be set up in this register before triggering the write. When 7BIT is set high, the least significant bit (last bit of each octet transmitted) does not contain channel data and is forced to the value configured by the BIT8 register bit. When 7BIT is set low, the entire octet contains valid data and BIT8 is ignored. 7BIT reflects the value written until the completion of a subsequent indirect channel read operation.

**Register 0x38C: THDL Indirect Channel Data #3**

Bit	Type	Function	Default
Bit 31 To Bit 16		Unused	X
Bit 15	R/W	TRANS	X
Bit 14	R/W	IDLE	X
Bit 13		Unused	X
Bit 12		Unused	X
Bit 11	R/W	LEVEL[3]	X
Bit 10	R/W	LEVEL[2]	X
Bit 9	R/W	LEVEL[1]	X
Bit 8	R/W	LEVEL[0]	X
Bit 7	R/W	FLAG[2]	X
Bit 6	R/W	FLAG[1]	X
Bit 5	R/W	FLAG[0]	X
Bit 4		Unused	X
Bit 3	R/W	XFER[3]	X
Bit 2	R/W	XFER[2]	X
Bit 1	R/W	XFER[1]	X
Bit 0	R/W	XFER[0]	X

This register contains data read from the channel provision RAM after an indirect read operation or data to be inserted into the channel provision RAM in an indirect write operation.

**XFER[3:0]**

The indirect channel transfer size (XFER[3:0]) specifies the minimum FIFO free space, less 1, before the partial packet processor begins requesting data from the DMA port. The channel transfer size to be written to the channel provision RAM, in an indirect write operation, must be set up in this register before triggering the write. When the channel FIFO free space reaches the limit specified by XFER[3:0], the partial packet processor will make a request to the DMA port for one XFER[3:0] amount of data. FIFO free space is measured in the number of blocks with each block being 16 bytes in size. XFER[3:0] reflects the value written until the completion of a subsequent indirect channel read operation.

XFER[3:0] must be less than or equal to the start transmission level specified by LEVEL[3:0] and TRANS.

## FLAG[2:0]

The flag insertion control (FLAG[2:0]) configures the minimum number of flags or bytes of idle bits the HDLC processor inserts between HDLC packets. The value of FLAG[2:0] to be written to the channel provision RAM, in an indirect channel write operation, must be set up in this register before triggering the write. The minimum number of flags or bytes of idle (8 bits of 1's) inserted between HDLC packets is shown in the table below. FLAG[2:0] reflects the value written until the completion of a subsequent indirect channel read operation.

**Table 18 FLAG[2:0] Settings**

FLAG[2:0]	Minimum Number of Flag/Idle Bytes
000	1 flag / 0 Idle byte
001	2 flags / 0 idle byte
010	4 flags / 2 idle bytes
011	8 flags / 6 idle bytes
100	16 flags / 14 idle bytes
101	32 flags / 30 idle bytes
110	64 flags / 62 idle bytes
111	128 flags / 126 idle bytes

## LEVEL[3:0]

The indirect channel FIFO trigger level (LEVEL[3:0]), in concert with the TRANS bit, configure the various channel FIFO free space levels which trigger the HDLC processor to start transmission of a HDLC packet as well as trigger the partial packet buffer to request data from the upstream device as shown in the following table. The channel FIFO trigger level to be written to the channel provision RAM, in an indirect write operation, must be set up in this register before triggering the write. LEVEL[3:0] reflects the value written until the completion of a subsequent indirect channel read operation.

The HDLC processor starts transmitting a packet when the channel FIFO free space is less than or equal to the level specified in the appropriate Start Transmission Level column of the following table or when an end of a packet is stored in the channel FIFO. When the channel FIFO free space is greater than or equal to the level specified in the Starving Trigger Level column of the following table and the HDLC processor is transmitting a packet and an end of a packet is not stored in the channel FIFO, the partial packet buffer makes expedited requests to the upstream device to retrieve XFER[3:0] + 1 blocks of data.

## IDLE

The inter-frame time fill bit (IDLE) configures the HDLC processor to use flag bytes or HDLC idle as the inter-frame time fill between HDLC packets. The value of IDLE to be written to the channel provision RAM, in an indirect channel write operation, must be set up in this register before triggering the write. When IDLE is set low, the HDLC processor uses flag bytes as the inter-frame time fill. When IDLE is set high, the HDLC processor uses HDLC idle (all one's bit with no bit-stuffing pattern is transmitted) as the inter-frame time fill. IDLE reflects the value written until the completion of a subsequent indirect channel read operation.

TRANS

The indirect transmission start bit (TRANS), in concert with the LEVEL[3:0] bits, configure the various channel FIFO free space levels which trigger the HDLC processor to start transmission of a HDLC packet as well as trigger the partial packet buffer to request data from the upstream device as shown in the following table. The transmission start mode to be written to the channel provision RAM, in an indirect write operation, must be set up in this register before triggering the write. TRANS reflects the value written until the completion of a subsequent indirect channel read operation.

The HDLC processor starts transmitting a packet when the channel FIFO free space is less than or equal to the level specified in the appropriate Start Transmission Level column of the following table or when an end of a packet is stored in the channel FIFO. When the channel FIFO free space is greater than or equal to the level specified in the Starving Trigger Level column of the following table and the HDLC processor is transmitting a packet and an end of a packet is not stored in the channel FIFO, the partial packet buffer makes expedited requests to the upstream device to retrieve XFER[3:0] + 1 blocks of data.

To prevent lockup, the channel transfer size (XFER[3:0]) can be configured to be less than or equal to the start transmission level set by LEVEL[3:0] and TRANS. Alternatively, the channel transfer size can be set, such that, the total number of blocks in the logical channel FIFO minus the start transmission level is an integer multiple of the channel transfer size. The starving trigger level must always be set to a number of blocks greater than or equal to the channel transfer size.

**Table 19 Level[3:0]/TRANS Settings**

LEVEL[3:0]	Starving Trigger Level	Start Transmission Level (TRANS=0)	Start Transmission Level (TRANS=1)
0010	4 Blocks (64 bytes free)	Invalid	2 Blocks (32 bytes free)
0011	6 Blocks (96 bytes free)	4 Blocks (64 bytes free)	Invalid
0100	8 Blocks (128 bytes free)	6 Blocks (96 bytes free)	4 Blocks (64 bytes free)
0101	12 Blocks (192 bytes free)	8 Blocks (128 bytes free)	6 Blocks (96 bytes free)
0110	16 Blocks (256 bytes free)	12 Blocks (192 bytes free)	8 Blocks (128 bytes free)
0111	24 Blocks (384 bytes free)	16 Blocks (256 bytes free)	12 Blocks (192 bytes free)
1000	32 Blocks (512 bytes free)	24 Blocks (384 bytes free)	16 Blocks (256 bytes free)
1001	48 Blocks (768 bytes free)	32 Blocks (512 bytes free)	24 Blocks (384 bytes free)
1010	64 Blocks (1 Kbytes free)	48 Blocks (768 bytes free)	32 Blocks (512 bytes free)
1011	96 Blocks (1.5 Kbytes free)	64 Blocks (1 Kbytes free)	48 Blocks (768 bytes free)

LEVEL[3:0]	Starving Trigger Level	Start Transmission Level (TRANS=0)	Start Transmission Level (TRANS=1)
1100	192 Blocks (3 Kbytes free)	128 Blocks (2 Kbytes free)	96 Blocks (1.5 Kbytes free)

**Register 0x390: THDL Indirect Channel Data Register #4**

Bit	Type	Function	Default
Bit 31 To Bit 16		Unused	X
Bit 15	R	DMAEXP	X
Bit 14	R	DMAREQ	X
Bit 13	R	AVAIL	X
Bit 12	R	EOP[12]	X
Bit 11	R	EOP[11]	X
Bit 10	R	EOP[10]	X
Bit 9	R	EOP[9]	X
Bit 8	R	EOP[8]	X
Bit 7	R	EOP[7]	X
Bit 6	R	EOP[6]	X
Bit 5	R	EOP[5]	X
Bit 4	R	EOP[4]	X
Bit 3	R	EOP[3]	X
Bit 2	R	EOP[2]	X
Bit 1	R	EOP[1]	X
Bit 0	R	EOP[0]	X

This register contains data read from the channel provision RAM after an indirect read operation.

**EOP[12:0]**

The indirect channel FIFO end of packet count (EOP[12:0]) specifies the number of end of packets stored in the channel FIFO. The value of EOP[12:0] is expressed in a signed 2's complement form with EOP[12] as the sign bit. EOP[12:0] reflects the value of the last indirect channel read operation.

The EOP[12:0] register bits are used for test purposes only.

## AVAIL

The indirect channel data available flag (AVAIL) indicates when sufficient packet data is store in the channel FIFO for the HDLC processor to start transmission. When AVAIL is high, the channel FIFO free space is less than or equal to the level specified by the TRANS and LEVEL[3:0] register bits or at least one end of packet is store in the channel FIFO. In this case, the HDLC processor starts transmission when AVAIL is high and sufficient flags/idle specified by FLAG[2:0] have been transmitted. When AVAIL is low, the channel FIFO free space is greater than the level specified by the TRANS and LEVEL[3:0] register bits and no end of packets are store in the channel FIFO. In this case, the HDLC processor will not start transmitting a new packet or will finish transmitting the current packet. AVAIL reflects the value of the last indirect channel read operation.

The AVAIL register bit is used for test purposes only.

## DMAREQ

The indirect channel service request flag (DMAREQ) indicates when sufficient free space exists in the channel FIFO to perform a DMA operation. When DMAREQ is high, the channel free space is greater than or equal to 32 bytes. When DMAREQ is low, the channel free space is less than 32 bytes. DMAREQ reflects the value of the last indirect channel read operation.

The DMAREQ register bit is used for test purposes only.

## DMAEXP

The indirect channel expedite service request flag (DMAEXP) indicates when the channel FIFO requires an expedited DMA operation. When DMAEXP is high, the channel free space is greater than or equal to the level specified by LEVEL[3:0] and the HDLC processor is transmitting a packet and the end of a packet is not store in the channel FIFO. When DMAEXP is low, the channel free space is less than the level specified by LEVEL[3:0], or the HDLC processor is not transmitting or an end of a packet is store in the channel FIFO. DMAEXP reflects the value of the last indirect channel read operation.

The DMAEXP register bit is used for test purposes only.

**Register 0x394: THDL Indirect Channel Data Register #5**

Bit	Type	Function	Default
Bit 31 To Bit 16		Unused	X
Bit 15		Unused	X
Bit 14		Unused	X
Bit 13		Unused	X
Bit 12	R	FREE[12]	X
Bit 11	R	FREE[11]	X
Bit 10	R	FREE[10]	X
Bit 9	R	FREE[9]	X
Bit 8	R	FREE[8]	X
Bit 7	R	FREE[7]	X
Bit 6	R	FREE[6]	X
Bit 5	R	FREE[5]	X
Bit 4	R	FREE[4]	X
Bit 3	R	FREE[3]	X
Bit 2	R	FREE[2]	X
Bit 1	R	FREE[1]	X
Bit 0	R	FREE[0]	X

This register contains data read from the channel provision RAM after an indirect read operation.

**FREE[12:0]**

The indirect channel FIFO free space (FREE[12:0]) indicates the number of empty or free blocks in the channel FIFO. The value of FREE[12:0] is expressed in a signed 2's complement form with FREE[12] as the sign bit. FREE[12:0] reflects the value of the last indirect channel read operation.

The FREE[12:0] register bits are used for test purposes only.

**Register 0x398: THDL Indirect Channel Data Register #6**

Bit	Type	Function	Default
Bit 31 To Bit 16		Unused	X
Bit 15		Unused	X
Bit 14		Unused	X
Bit 13		Unused	X
Bit 12		Unused	X
Bit 11	R	WPTR[11]	X
Bit 10	R	WPTR[10]	X
Bit 9	R	WPTR[9]	X
Bit 8	R	WPTR[8]	X
Bit 7	R	WPTR[7]	X
Bit 6	R	WPTR[6]	X
Bit 5	R	WPTR[5]	X
Bit 4	R	WPTR[4]	X
Bit 3	R	WPTR[3]	X
Bit 2	R	WPTR[2]	X
Bit 1	R	WPTR[1]	X
Bit 0	R	WPTR[0]	X

This register contains data read from the channel provision RAM after an indirect read operation.

**WPTR[11:0]**

The channel FIFO writer pointer (WPTR[11:0]) is the block number in the channel FIFO to which the write processor is storing packet data. WPTR[11:0] reflects the value of the last indirect channel read operation.

The WPTR[11:0] register bits are used for test purposes only.

**Register 0x3A0: THDL Indirect Block Select**

Bit	Type	Function	Default
Bit 31 To Bit 16		Unused	X
Bit 15	R	BBUSY	0
Bit 14	R/W	BRWB	0
Bit 13 To Bit 12		Unused	X
Bit 11	R/W	BLOCK[11]	0
Bit 10	R/W	BLOCK[10]	0
Bit 9	R/W	BLOCK[9]	0
Bit 8	R/W	BLOCK[8]	0
Bit 7	R/W	BLOCK[7]	0
Bit 6	R/W	BLOCK[6]	0
Bit 5	R/W	BLOCK[5]	0
Bit 4	R/W	BLOCK[4]	0
Bit 3	R/W	BLOCK[3]	0
Bit 2	R/W	BLOCK[2]	0
Bit 1	R/W	BLOCK[1]	0
Bit 0	R/W	BLOCK[0]	0

This register provides the block number used to access the block pointer RAM. Writing to this register triggers an indirect block register access.

**BLOCK[11:0]**

The indirect block number (BLOCK[11:0]) indicates the block to be configured or interrogated in the indirect access.

**BRWB**

The block indirect access control bit (BRWB) selects between a configure (write) or interrogate (read) access to the block pointer RAM. Writing a logic zero to BRWB triggers an indirect block write operation. Data to be written is taken from the Indirect Block Data register. Writing a logic one to BRWB triggers an indirect block read operation. The data read can be found in the Indirect Block Data register.

**BBUSY**

The indirect access status bit (BBUSY) reports the progress of an indirect access. BBUSY is set high when this register is written to trigger an indirect access, and will stay high until the access is complete. At which point, BBUSY will be set low. This register should be polled to determine when data from an indirect read operation is available in the THDL Indirect Block Data register or to determine when a new indirect write operation may commence.

**Register 0x3A4: THDL Indirect Block Data**

Bit	Type	Function	Default
Bit 31 To Bit 16		Unused	X
Bit 15	R/W	Reserved	0
Bit 14 To Bit 12		Unused	X
Bit 11	R/W	BPTR[11]	0
Bit 10	R/W	BPTR[10]	0
Bit 9	R/W	BPTR[9]	0
Bit 8	R/W	BPTR[8]	0
Bit 7	R/W	BPTR[7]	0
Bit 6	R/W	BPTR[6]	0
Bit 5	R/W	BPTR[5]	0
Bit 4	R/W	BPTR[4]	0
Bit 3	R/W	BPTR[3]	0
Bit 2	R/W	BPTR[2]	0
Bit 1	R/W	BPTR[1]	0
Bit 0	R/W	BPTR[0]	0

This register contains data read from the transmit block pointer RAM after an indirect block read operation or data to be inserted into the transmit block pointer RAM in an indirect block write operation.

**BPTR[11:0]**

The indirect block pointer (BPTR[11:0]) configures the block pointer of the block specified by the Indirect Block Select register. The block pointer to be written to the transmit block pointer RAM, in an indirect write operation, must be set up in this register before triggering the write. The block pointer value is the block number of the next block in the linked list. A circular list of blocks must be formed in order to use the block list as a channel FIFO buffer. BPTR[11:0] reflects the value written until the completion of a subsequent indirect block read operation.

When provisioning a channel FIFO, all blocks pointers must be re-written to properly initialize the FIFO.

**Register 0x3B0: THDL Configuration**

Bit	Type	Function	Default
Bit 31 To Bit 10		Unused	X
Bit 9	R/W	BIT8	0
Bit 8	R/W	TSTD	0
Bit 7	R/W	Reserved	0
Bit 6 To Bit 4		Unused	X
Bit 3 To Bit 0	R/W	Reserved	0

This register configures all provisioned channels.

**Reserved**

The reserved bits must be set low for correct operation of the FREEDM 32A1024L device.

**TSTD**

The telecom standard bit (TSTD) controls the bit ordering of the HDLC data transferred on the transmit APPI. When TSTD is set low, the least significant bit of the each byte on the transmit APPI bus (AD[0] and AD[8]) is the first HDLC bit transmitted and the most significant bit of each byte (AD[7] and AD[15]) is the last HDLC bit transmitted (datacom standard). When TSTD is set high, AD[0] and AD[8] are the last HDLC bit transmitted and AD[7] and AD[15] are the first HDLC bit transmitted (telecom standard).

**BIT8**

The least significant stuff control bit (BIT8) carries the value placed in the least significant bit of each octet when the HDLC processor is configured (7BIT set high) to stuff the least significant bit of each octet in the corresponding transmit link (TD[n]). When BIT8 is set high, the least significant bit (last bit of each octet transmitted) is forced high. When BIT8 is set low, the least significant bit is forced low. BIT8 is ignored when 7BIT is set low.

**Register 0x400: TCAS Indirect Context RAM Link Select**

Bit	Type	Function	Default
Bit 31 To Bit 12		Unused	X
Bit 11	R	BUSY	X
Bit 10	R/W	RWB	0
Bit 9	R/W	Reserved	0
Bit 8	R/W	Reserved	0
Bit 7	R/W	SBI	0
Bit 6	R/W	SPE[1]	0
Bit 5	R/W	SPE[0]	0
Bit 4	R/W	TRIB[4]	0
Bit 3	R/W	TRIB[3]	0
Bit 2	R/W	TRIB[2]	0
Bit 1	R/W	TRIB[1]	0
Bit 0	R/W	TRIB[0]	0

This register provides the link number used to access the TCAS Context RAM. Writing to this register triggers an indirect register access.

Reserved:

The reserved bits must be set low for correct operation of the FREEDM 32A1024L device.

TRIB[4:0], SPE[1:0] and SBI

The TRIB[4:0], SPE[1:0] and SBI fields are used to fully specify to which SBI tributary the context RAM write or read operation will apply.

TRIB[4:0] specifies the SBI tributary number within the SBI SPE as specified by the SPE[1:0] and SBI fields. Legal values for TRIB[4:0] are b'00001' through b'11100'. Legal values for SPE[1:0] are b'01' through b'11'. SBI must be written to a logic one in the FREEDM 32A1024L device.

RWB

The indirect access control bit (RWB) selects between a configure (write) or interrogate (read) access to the context RAM. Writing a logic zero to RWB triggers an indirect write operation. Data to be written is taken from the LEN and SBI\_MODE[2:0] bits of the TCAS Indirect Context RAM Data register. Writing a logic one to RWB triggers an indirect read operation. The data read can be found in the LEN and SBI\_MODE[2:0] bits of the TCAS Indirect context RAM Data register.

**BUSY**

The indirect access status bit (BUSY) reports the progress of an indirect access. BUSY is set high when this register is written, to trigger an indirect access, and will stay high until the access is complete. At which point, BUSY will be set low. This register should be polled to determine when data from an indirect read operation is available in the TCAS Indirect Data register or to determine when a new indirect write operation may commence.

Downloaded [controlled] by he hai of nelep on Friday, 29 August, 2008 05:11:11 PM

**Register 0x404: TCAS Indirect Context RAM Data**

Bit	Type	Function	Default
Bit 31 To Bit 5		Unused	X
Bit 4	R/W	SYNC	0
Bit 3	R/W	SBI_MODE[2]	0
Bit 2	R/W	SBI_MODE[1]	0
Bit 1	R/W	SBI_MODE[0]	0
Bit 0	R/W	Reserved	0

This register provides the link enable bit and the frame mode or data type associated to this particular link in the TCAS context RAM.

**SYNC**

The SYNC bit determines whether the link is operating in synchronous mode or asynchronous mode. When set low the link is set to asynchronous mode. When set high the TCAS will to synchronize the link output data according to the synchronous mode requirements of the SBI bus. This bit only applies to framed T1 or E1 links.

**SBI\_MODE[2:0]**

The Frame Mode bits (SBI\_MODE [2:0]), report the type of data to a specific link to be configured accordingly according to the table below.

**Table 20 SBI Mode**

SBI_MODE [2:0]	Configuration
000	Unused
001	28 Unframed T1/J1 links
010	21 Unframed E1 links
011	Unused
100	Unused
101	28 Framed Channelized T1/J1 links
110	21 Framed Channelized E1 links
111	Unused

**Register 0x408: TCAS Indirect Channel Provision RAM Select**

Bit	Type	Function	Default
Bit 31 To Bit 13		Unused	X
Bit 12	R/W	SBI_MODE[2]	0
Bit 11	R/W	SBI_MODE[1]	0
Bit 10	R/W	SBI_MODE[0]	0
Bit 9	R/W	Reserved	0
Bit 8	R/W	Reserved	0
Bit 7	R/W	SBI	0
Bit 6	R/W	SPE[1]	0
Bit 5	R/W	SPE[0]	0
Bit 4	R/W	TRIB[4]	0
Bit 3	R/W	TRIB[3]	0
Bit 2	R/W	TRIB[2]	0
Bit 1	R/W	TRIB[1]	0
Bit 0	R/W	TRIB[0]	0

This register provides the link number used to access the TCAS channel provision RAM.

Reserved:

The reserved bits must be set low for correct operation of the FREEDM 32A1024L device.

SBI\_MODE[2:0]:

This field must be set to the same value as Bits3:1 in Register 0x404.

TRIB[4:0], SPE[1:0] and SBI:

The TRIB[4:0], SPE[1:0] and SBI fields are used to fully specify to which SBI tributary the context RAM write or read operation will apply.

TRIB[4:0] specifies the SBI tributary number within the SBI SPE as specified by the SPE[1:0] and SBI fields. Legal values for TRIB[4:0] are b'00001' through b'11100'. Legal values for SPE[1:0] are b'01' through b'11'. SBI must be written to a logic one in the FREEDM 32A1024L device.

**Register 0x40C: TCAS Indirect Channel Provision RAM Timeslot and Control Select**

Bit	Type	Function	Default
Bit 31 To Bit 7		Unused	X
Bit 6	R	BUSY	0
Bit 5	R/W	RWB	0
Bit 4	R/W	TSLOT[4]	0
Bit 3	R/W	TSLOT[3]	0
Bit 2	R/W	TSLOT[2]	0
Bit 1	R/W	TSLOT[1]	0
Bit 0	R/W	TSLOT[0]	0

This register provides the link timeslot number and control bits used to access the TCAS channel provision RAM. Writing to this register triggers an indirect register access.

**TSLOT[4:0]**

The indirect timeslot number bits (TSLOT[4:0]) indicate the timeslot to be configured or interrogated in the indirect access. For a channelized T1/J1 link, timeslots 0 to 23 are valid. For a channelized E1 link, timeslots 0 to 31 are valid. For unchannelized links, only timeslot 0 is valid.

**RWB**

The indirect access control bit (RWB) selects between a configure (write) or interrogate (read) access to the TCAS channel provision RAM. The address to the TCAS channel provision RAM is constructed by combining the TSLOT[4:0] and LINK[9:0] bits. Writing a logic zero to RWB triggers an indirect write operation. Data to be written is taken from the PROV, and the CHAN[9:0] bits of the TCAS Indirect Channel Data register. Writing a logic one to RWB triggers an indirect read operation. Addressing of the RAM is the same as in an indirect write operation. The data read can be found in the PROV, and the CHAN[9:0] bits of the TCAS Indirect Channel Data register.

**BUSY**

The indirect access status bit (BUSY) reports the progress of an indirect access. BUSY is set high when this register is written, to trigger an indirect access, and will stay high until the access is complete. At which point, BUSY will be set low. This register should be polled to determine when data from an indirect read operation is available in the Indirect Data register or to determine when a new indirect write operation may commence.

**Register 0x410: TCAS Indirect Channel Data enable**

Bit	Type	Function	Default
Bit 31 To Bit 11		Unused	X
Bit 10	R/W	PROV	0
Bit 9	R/W	CHAN [9]	0
Bit 8	R/W	CHAN [8]	0
Bit 7	R/W	CHAN [7]	0
Bit 6	R/W	CHAN [6]	0
Bit 5	R/W	CHAN [5]	0
Bit 4	R/W	CHAN [4]	0
Bit 3	R/W	CHAN [3]	0
Bit 2	R/W	CHAN [2]	0
Bit 1	R/W	CHAN [1]	0
Bit 0	R/W	CHAN [0]	0

This register contains the data read from the TCAS channel provision RAM after an indirect read operation or the data to be inserted into the TCAS channel provision RAM in an indirect write operation.

**CHAN[9:0]**

The indirect data bits (CHAN[9:0]) report the channel number read from the channel provision RAM after an indirect read operation has completed. Channel number to be written to the channel provision RAM in an indirect write operation must be set up in this register before triggering the write. CHAN[9:0] reflects the value written until the completion of a subsequent indirect read operation.

**PROV**

The indirect provision enable bit (PROV) reports the channel provision enable flag read from the TCAS channel provision RAM after an indirect read operation has completed. The provision enable flag to be written to the TCAS channel provision RAM in an indirect write operation must be set up in this register before triggering the write. When PROV is set high, the current request is processed as part of the channel as indicated by CHAN[9:0]. When PROV is set low, the current timeslot does not belong to any channel and the request is ignored. PROV reflects the value written until the completion of a subsequent indirect read operation. For unchannelized links, a read of any TSLOT will report the value in TSLOT[4:0]=00000.

**Register 0x418: TCAS Idle Time-slot Fill Data**

Bit	Type	Function	Default
Bit 31 To Bit 8		Unused	X
Bit 7	R/W	FDATA[7]	1
Bit 6	R/W	FDATA[6]	1
Bit 5	R/W	FDATA[5]	1
Bit 4	R/W	FDATA[4]	1
Bit 3	R/W	FDATA[3]	1
Bit 2	R/W	FDATA[2]	1
Bit 1	R/W	FDATA[1]	1
Bit 0	R/W	FDATA[0]	1

This register contains the data to be written to disabled time-slots of a channelized link.

**FDATA[7:0]**

The fill data bits (FDATA[7:0]) are transmitted during disabled (PROV set low) time-slots of channelized links.

**Register 0x580: RAPI Control Register**

Bit	Type	Function	Default
Bit 31 To Bit 16		Unused	X
Bit 15	R/W	ENABLE	0
Bit 14	R/W	STATEN	0
Bit 13	R/W	Reserved	0
Bit 12 To Bit 6		Unused	X
Bit 5	R/W	ANYPHYL	0
Bit 4		Unused	X
Bit 3	R/W	ALL1ENB	1
Bit 2 To Bit 0		Unused	X

The Control Register is used to set the operating mode of RAPI-12. It is used to configure the final word of a packet in APPI. It is also used to enable the RAPI-12.

**ALL1ENB**

The All Ones Enable bit (ALL1ENB) is used to configure the device address space of the RAPI-12 in level-2 APPI. It is not used in level-3 APPI. When ALL1ENB is high in level-2 APPI, the all ones address (RXADDR[3:0] = “1111”) is reserved as null address to resolve contention for Any-PHY bus, and it can not be assigned to any RAPI-12. When ALL1ENB is low in level-2 APPI, the all ones address is not treated as null address, and it can be assigned to one RAPI-12; contention for Any-PHY bus must be resolved by external logic.

**ANYPHYL**

The ANY PHY Level select bit allows selection between ANY PHY Level 2 and ANY PHY Level 3.

**Table 21 Any-PHY Encoding**

Any-PHY	Any-PHY Level
0	Level 2
1	Level 3

**Reserved**

The reserved bit must be set low for correct operation of the FREEDM 32A1024L device.

## STATEN

The status enable bit (STATEN) enables the RAPI-12 to provide the status of an erred packet on RXDATA[7:0] during transfer of the final word of that packet on the receive APPI (REOP and RERR high). When STATEN is set high, the RAPI-12 overwrites RXDATA[7:0] of the final word of an erred packet with status information for that packet. When STATEN is set low, the RAPI-12 does not report detailed status information for an erred packet. The RXDATA[15:0] connector description details the erred packet status reporting when STATEN is set high.

## ENABLE

The Enable bit (ENABLE) enables normal operation of the RAPI-12. When ENABLE is set low, the RAPI-12 will complete the current data transfer and will respond to any further transactions on the APPI but not send any new data. When ENABLE is set high, the RAPI-12 operates normally.

Downloaded [controlled] by he hai of nelep on Friday, 29 August, 2008 10:28 AM

**Register 0x584: RAPI Device Base Address Register**

Bit	Type	Function	Default
Bit 31 To Bit 4		Unused	X
Bit 3	R/W	DBADDR[3]	0
Bit 2	R/W	DBADDR[2]	0
Bit 1	R/W	DBADDR[1]	0
Bit 0	R/W	DBADDR[0]	0

The Device Base Address Register is used to configure the address space occupied by the FREEDM 32A1024L device for device selection.

**DBADDR[3:0]**

The Device Base Address bits (DBADDR[3:0]) configure the address space occupied by the FREEDM 32A1024L device for purposes of responding to receive polling and receive device selection. During polling in Level-2 APPI, the DBADDR[3:0] bits are used to respond to polling via the RXADDR[3:0] pins. Polling is not used in Level-3 APPI. During device selection, the DBADDR[3:0] bits are used to select a FREEDM 32A1024L device, enabling it to output data on the receive APPI.

**Register 0x588: RAPI Channel Base Address Register**

Bit	Type	Function	Default
Bit 31 To Bit 16		Unused	X
Bit 15	R/W	CBADDR[15]	0
Bit 14	R/W	CBADDR[14]	0
Bit 13	R/W	CBADDR[13]	0
Bit 12	R/W	CBADDR[12]	0
Bit 11	R/W	CBADDR[11]	0
Bit 10	R/W	CBADDR[10]	0
Bit 9	R/W	CBADDR[9]	0
Bit 8	R/W	CBADDR[8]	0
Bit 7	R/W	CBADDR[7]	0
Bit 6	R/W	CBADDR[6]	0
Bit 5	R/W	CBADDR[5]	0
Bit 4	R/W	CBADDR[4]	0
Bit 3	R/W	CBADDR[3]	0
Bit 2	R/W	CBADDR[2]	0
Bit 1	R/W	CBADDR[1]	0
Bit 0	R/W	CBADDR[0]	0

The Channel Base Address Register is used to configure the address space occupied by the FREEDM 32A1024L device for receive polling.

**CBADDR[15:0]**

The Channel Base Address bits (CBADDR[15:0]) configure the FREEDM 32A1024L to support channel numbers starting from the channel Base Address. The channel numbers used by the FREEDM 32A1024L will be CBADDR[15:0] to CBADDR[15:0]+1023.

**Register 0x58C: RAPI Status Register**

Bit	Type	Function	Default
Bit 31 To Bit 2		Unused	X
Bit 1	R	UDRUN	1
Bit 0	R	Reserved	0

The Status Register is used to record the status of RAPI-12.

**UDRUN**

The underrun bit (UDRUN) is used to record events when the circular FIFO in RAPI-12 is empty.

**Reserved**

The reserved bit must be set low for correct operation of the FREEDM 32A1024L device.

Downloaded [controlled] by he hai of nelep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x5C0: SBI EXTRACT Control**

Bit	Type	Function	Default
Bit 31 To Bit 4		Unused	X
Bit 3	R/W	Reserved	0
Bit 2	R/W	Unused	X
Bit 1	R/W	Reserved	0
Bit 0	R/W	SBI_PAR_CTL	1

This register controls the operation of the SBI EXTRACT block.

**SBI\_PAR\_CTL**

The SBI\_PAR\_CTL bit is used to configure the Parity mode for checking of the SBI parity signal, DDP as follows: When SBI\_PAR\_CTL is '0' parity is even. When SBI\_PAR\_CTL is '1' parity is odd.

**Reserved**

The reserved bits must be set according to the table below for correct operation of the FREEDM 32A1024L device.

**Table 22 Reserved/Unused Bit Settings**

Bit	Setting
3	1
2	0
1	0

**Register 0x5D4: SBI EXTRACT Tributary Indirect Access Address**

Bit	Type	Function	Default
Bit 31 To Bit 16	—	Unused	X
Bit 15	R	BUSY	0
Bit 14	R/W	RWB	0
Bit 13	R/W	Reserved	0
Bit 12	R/W	Reserved	0
Bit 11	R/W	Unused	X
Bit 10	R/W	Reserved	0
Bit 9	R/W	Reserved	0
Bit 8	R/W	Reserved	0
Bit 7	R/W	SBI	0
Bit 6	R/W	SPE[1]	0
Bit 5	R/W	SPE[0]	0
Bit 4	R/W	TRIB[4]	0
Bit 3	R/W	TRIB[3]	0
Bit 2	R/W	TRIB[2]	0
Bit 1	R/W	TRIB[1]	0
Bit 0	R/W	TRIB[0]	0

This register provides the receive SBI, SPE and link number used to access the SBI EXTRACT tributary control configuration RAM.

TRIB[4:0], SPE[1:0] and SBI:

The TRIB[4:0], SPE[1:0] and SBI fields are used to fully specify to which SBI tributary the Control register write or read operation will apply.

TRIB[4:0] specifies the SBI tributary number within the SBI SPE as specified by the SPE[1:0] and SBI fields. Legal values for TRIB[4:0] are b'00001' through b'11100'. Legal values for SPE[1:0] are b'01' through b'11'. SBI must be written to a logic one in the FREEDM 32A1024L device.

Reserved

The reserved bits must be set low for correct operation of the FREEDM 32A1024L device.

RWB

The indirect access control bit (RWB) selects between a configure (write) or interrogate (read) access to the tributary control configuration RAM. Writing a '0' to RWB triggers an indirect write operation. Data to be written is taken from the SBI EXTRACT Tributary Indirect Access Data Register. Writing a '1' to RWB triggers an indirect read operation. The data read can be found in the SBI EXTRACT Tributary Indirect Access Data Register.

**BUSY**

The indirect access status bit (BUSY) reports the progress of an indirect access. BUSY is set high when a write to the Extract RAM Indirect Access Address Register triggers an indirect access and will stay high until the access is complete. This bit should be polled to determine when data from an indirect read operation is available in the Extract RAM Indirect Access Control Data Register. In a write access this bit should be polled to determine when a new operation may commence.

Downloaded [controlled] by he hai of nelep on Friday, 29 August, 2008 10:21 AM

**Register 0x5DC: SBI EXTRACT Tributary RAM Indirect Access Data**

Bit	Type	Function	Default
Bit 31 To Bit 7	—	Unused	X
Bit 6	R/W	Reserved	0
Bit 5	R/W	Reserved	0
Bit 4	R/W	Reserved	0
Bit 3	R/W	TRIB_TYP[1]	0
Bit 2	R/W	TRIB_TYP[0]	0
Bit 1	R/W	Reserved	0
Bit 0	R/W	ENBL	0

This register contains data read from the SBI EXTRACT tributary control configuration RAM after an indirect read operation or data to be written to the tributary control configuration RAM in an indirect write operation.

**ENBL**

The ENBL bit is used to enable the EXSBI to take tributary data from an SBI tributary and transmit that data to the SBIIP link.

**Reserved**

The reserved bits must be set low for correct operation of the FREEDM 32A1024L device.

**TRIB\_TYP[1:0]**

The TRIB\_TYP[1:0] field is used to specify the characteristics of the SBI tributary as shown in Table 23 below:

**Table 23 TRIB\_TYP Encoding**

TRIB_TYP[1:0]	Tributary type
00	Reserved
01	Framed
10	Unframed
11	Reserved

**Register 0x5E0H: SBI EXTRACT SBI SPE Configuration Register**

Bit	Type	Function	Default
Bit 31 To Bit 12	R	Unused	0
Bit 11	R/W	SPE3_EN	0
Bit 10	R/W	SPE3_TYP[2]	0
Bit 9	R/W	SPE3_TYP [1]	0
Bit 8	R/W	SPE3_TYP [0]	0
Bit 7	R/W	SPE2_EN	0
Bit 6	R/W	SPE2_TYP[2]	0
Bit 5	R/W	SPE2_TYP [1]	0
Bit 4	R/W	SPE2_TYP [0]	0
Bit 3	R/W	SPE1_EN	0
Bit 2	R/W	SPE1_TYP[2]	0
Bit 1	R/W	SPE1_TYP [1]	0
Bit 0	R/W	SPE1_TYP [0]	0

SPE1\_EN, SPE2\_EN, SPE3\_EN

Enables SPE1, SPE2 and SPE3 respectively. When these bits are set to 0 the respective SPE is disabled. When these bits are set to 1 the respective SPE is enabled. When an SPE is enabled each individual tributary within an SPE can be selectively enabled via the Extract Tributary RAM Indirect Access Control Data register. These bits must be written in a second write after the SPE\*\_TYP[2:0] bits have been set.

SPE1\_TYP[2:0], SPE2\_TYP[2:0], SPE3\_TYP[2:0]

SPE1\_TYP[2:0], SPE2\_TYP[2:0] and SPE3\_TYP[2:0] select the SPE type for the three SPEs respectively. The types for each SPE are independently configured with possible types being T1 or E1. The setting for SPEx\_TYP[2:0] are:

**Table 24 SBI EXTRACT SPE\_TYP[2:0]**

SPEx_TYP[2:0]	Payload Type
X00	28 T1/J1 links
X01	21 E1links
010	Unused
011	Unused
11X	Unused

**Register 0x600H: TAPI Control Register**

Bit	Type	Function	Default
Bit 31 To Bit 16	—	Unused	X
Bit 15	R/W	ENABLE	0
Bit 14	R/W	Reserved	0
Bit 13	R/W	Reserved	0
Bit 12 To Bit 6	—	Unused	X
Bit 5	R/W	ANYPHYL	0
Bit 4	R/W	MODE	0
Bit 3 To Bit 2	—	Unused	X
Bit 1	R/W	ONE_TPA	0
Bit 0	R/W	NO_TPA_MASK	0

The Control Register is used to set TAPI-12 mode. The Control Register is also used to enable the TAPI-12.

**NO\_TPA\_MASK**

The no TPA mask mode bit (NO\_TPA\_MASK) is used to disable TPA masking that occurs when data on a channel is being received at the same time this channel is being polled. When NO\_TPA\_MASK=0 and an attempt is made to poll an Any-PHY channel for which the TAPI is in the process of receiving a burst data transfer, TAPI will mask the poll response for that polled channel by returning a response of '0' (i.e. no space available). When NO\_TPA\_MASK=1, poll masking is disabled.

**ONE\_TPA**

The single poll response bit (ONE\_TPA) enables a mode of operation in which poll responses for the high and low priority queues are combined on one output pin. When ONE\_TPA is set high, TPA\_LO indicates the fill status of both high and low priority queues (TPA\_LO is high only if both queues have space available) and TPA\_HI is undefined.

**MODE**

The mode bit (MODE) is used to configure operating modes of TAPI-12. When MODE is set high, TAPI-12 operates in non-blocking mode; that is, TAPI-12 will only deassert TRDY if it cannot accept 64 bytes (1 FIFO block) of data. When MODE is set low, TAPI-12 operates in blocking mode; that is, TAPI-12 will deassert TRDY if the free space in the circular FIFO is less than the data transfer burst length when TSX is sampled high. This bit should always be set to a 0 for guaranteed operation.

ANYPHYL

The ANY PHY Level select bit allows selection between ANY PHY L2 and ANY PHY L3.

**Table 25 Any-PHY Encoding**

Any-PHY	Any-PHY Level
0	Level 2
1	Level 3

Reserved

The reserved bits must be set low for correct operation of the FREEDM 32A1024L device

ENABLE

The Enable bit (ENABLE) enables normal operation of the TAPI-12. When ENABLE is set low, the TAPI-12 will complete the current data transfer and will respond to any further transactions on the APPI normally (by setting TRDY high), but will ignore any data. When ENABLE is set high, the TAPI-12 operates normally.

Downloaded [controlled] by he hai of neiep on 29 August, 2008 05:02:17 AM

**Register 0x604: TAPI Indirect Channel Provisioning Register**

Bit	Type	Function	Default
Bit 31 To Bit 16	—	Unused	X
Bit 15	R	BUSY	X
Bit 14	R/W	RWB	0
Bit 13 To Bit 10	—	Unused	X
Bit 9	R/W	CHAN[9]	0
Bit 8	R/W	CHAN[8]	0
Bit 7	R/W	CHAN[7]	0
Bit 6	R/W	CHAN[6]	0
Bit 5	R/W	CHAN[5]	0
Bit 4	R/W	CHAN[4]	0
Bit 3	R/W	CHAN[3]	0
Bit 2	R/W	CHAN[2]	0
Bit 1	R/W	CHAN[1]	0
Bit 0	R/W	CHAN[0]	0

The Indirect Channel Provisioning Register provides the channel number used to access the TAPI-12 channel provisioning RAM. Writing to this register triggers an indirect channel register access.

**CHAN[9:0]**

The indirect channel number bits (CHAN[9:0]) indicate the channel to be configured or interrogated in the indirect access.

**RWB**

The Read/Write Bar (RWB) bit selects between a provisioning/unprovisioning operation (write) or a query operation (read). Writing a logic 0 to RWB triggers the provisioning or unprovisioning of the channel specified by CHAN[9:0]. Writing a logic 1 to RWB triggers a query of the channel specified by CHAN[9:0].

**BUSY**

The indirect access status bit (BUSY) reports the progress of an indirect access. BUSY is set high when this register is written to trigger an indirect access, and will stay high until the access is complete. At which point, BUSY will be set low. This register should be polled to determine when data from an indirect read operation is available or to determine when a new indirect write operation may commence.

**Register 0x608: TAPI Indirect Channel Data Register**

Bit	Type	Function	Default
Bit 31 To Bit 16	—	Unused	X
Bit 15	R/W	PROV	0
Bit 14 To Bit 8	—	Unused	X
Bit 7	R/W	BLEN[7]	X
Bit 6	R/W	BLEN[6]	X
Bit 5	R/W	BLEN[5]	X
Bit 4	R/W	BLEN[4]	X
Bit 3	R/W	BLEN[3]	X
Bit 2	R/W	BLEN[2]	X
Bit 1	R/W	BLEN[1]	X
Bit 0	R/W	BLEN[0]	X

The TAPI Indirect Channel Data Register contains data read from the TAPI-12 channel provision RAM after an indirect read operation or data to be written to channel provision RAM in an indirect write operation.

**BLEN[7:0]**

The channel burst length (BLEN[7:0]) bits report the data transfer burst length read from the TAPI-12 channel provision RAM after an indirect read operation has completed. The data transfer burst length specifies the length (in bytes, less one) of burst data transfers on the transmit APPI that are not terminated by the assertion of TEOP. The data transfer burst length can be specified on a per-channel basis. The data transfer burst length to be written to the channel provision RAM in an indirect write operation must be set up in this register before triggering the write. BLEN[7:0] reflects the value written until the completion of a subsequent indirect read operation. The following values of BLEN[7:0] are valid:

**Table 26 Valid BLEN**

BLEN[7:0]	APPI Transfer Burst Length
00111111	64
01111111	128
11111111	256

## PROV

The indirect provision enable bit (PROV) reports the channel provision enable flag read from the TAPI-12 channel provision RAM after an indirect read operation has completed. The provision enable flag to be written to the TAPI-12 channel provision RAM, in an indirect write operation, must be set up in this register before triggering the write. When PROV is set high, the channel as indicated by CHAN[9:0] is provisioned. When PROV is set low, the channel indicated by CHAN[9:0] is unprovisioned. PROV reflects the value written until the completion of a subsequent indirect read operation. Traffic to the FREEDM 32A1024L must be stopped on a channel before that channel is unprovisioned.

**Register 0x60C: TAPI Reserved Register**

Bit	Type	Function	Default
Bit 31 To Bit 8	—	Unused	X
Bit 7	R/W	Reserved	0
Bit 6	R/W	Reserved	0
Bit 5	R/W	Reserved	1
Bit 4	R/W	Reserved	0
Bit 3	R/W	Reserved	1
Bit 2	R/W	Reserved	0
Bit 1	R/W	Reserved	0
Bit 0	R/W	Reserved	0

Reserved

The reserved bits must be left at their default value or set to 28H for correct operation of the FREEDM 32A1024L device.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x610: TAPI Status Register**

Bit	Type	Function	Default
Bit 31 To Bit 2	—	Unused	X
Bit 1	R	Reserved	0
Bit 0	R	FULL	0

The Status Register contains flag bits reflecting the current status of TAPI-12. This register does not remain set when the condition is not present.

**FULL**

The full bit (FULL) reports the instantaneous full status of the circular FIFO. It is set high when free space in the circular FIFO is smaller than a complete data segment and TSX is sampled high. When the full bit is high, it shows that the reader controller has not been able to empty the circular FIFO fast enough to keep pace with the writer controller. When TAPI-12 operates in non-blocking mode, the writer controller risks overflowing the circular FIFO when the full bit is set high.

**Reserved**

This bit should be ignored.

**Register 0x614: TAPI Base Address Register**

Bit	Type	Function	Default
Bit 31 To Bit 16	—	Unused	X
Bit 15	R/W	BADDR[15]	0
Bit 14	R/W	BADDR[14]	0
Bit 13	R/W	BADDR[13]	0
Bit 12	R/W	BADDR[12]	0
Bit 11	R/W	BADDR[11]	0
Bit 10	R/W	BADDR[10]	0
Bit 9	R/W	BADDR[9]	0
Bit 8	R/W	BADDR[8]	0
Bit 7	R/W	BADDR[7]	0
Bit 6	R/W	BADDR[6]	0
Bit 5	R/W	BADDR[5]	0
Bit 4	R/W	BADDR[4]	0
Bit 3	R/W	BADDR[3]	0
Bit 2	R/W	BADDR[2]	0
Bit 1	R/W	BADDR[1]	0
Bit 0	R/W	BADDR[0]	0

The Base Address Register specifies the minimum valid Any-PHY channel address for TAPI-12.

**BADDR[15:0]**

The base address bits (BADDR[15:0]) specifies the minimum valid Any-PHY channel address residing in TAPI-12. A channel prepend address provided on TXDATA or a polling address provided on TXADDR is deemed out of range if it is greater than the sum of RADDR[15:0] and BADDR[15:0] or less than BADDR[15:0]. BADDR[15:0] must be a multiple of RADDR[15:0]+1 (see TAPI Range Address Register).

**Note** – Since bit 10 of the channel prepend address provided on TXDATA is used to indicate the priority of the data being transferred, the base address must be chosen such that BADDR[10] is equal to 0.

**Register 0x618: TAPI Range Address Register**

Bit	Type	Function	Default
Bit 31 To Bit 16	—	Unused	X
Bit 15	R/W	RADDR[15]	0
Bit 14	R/W	RADDR[14]	0
Bit 13	R/W	RADDR[13]	0
Bit 12	R/W	RADDR[12]	0
Bit 11	R/W	RADDR[11]	0
Bit 10	R/W	RADDR[10]	0
Bit 9	R/W	RADDR[9]	0
Bit 8	R/W	RADDR[8]	0
Bit 7	R/W	RADDR[7]	0
Bit 6	R/W	RADDR[6]	0
Bit 5	R/W	RADDR[5]	0
Bit 4	R/W	RADDR[4]	0
Bit 3	R/W	RADDR[3]	0
Bit 2	R/W	RADDR[2]	0
Bit 1	R/W	RADDR[1]	0
Bit 0	R/W	RADDR[0]	0

The Range Address Register specifies the valid range of Any-PHY channel address for TAPI-12.

**RADDR[15:0]**

The range address bits (RADDR[15:0]) specifies the (valid range-1) of Any-PHY channel address residing in TAPI-12. A channel prepend address provided on TXDATA or a polling address on TXADDR is deemed out of range if it is greater than the sum of RADDR[15:0] and BADDR[15:0] or less than BADDR[15:0] but must be rounded to a power of 2 – 1. I.e.. For a range of 672 or 1024 channels, RADDR[15:0] must be set to the value 0000001111111111.

Note – Since the maximum number of channels supported by the FREEDM 32A1024L device is 1024, RADDR[15:10] must be set to 0.

**Register 0x680: SBI INSERT Control**

Bit	Type	Function	Default
Bit 31 To Bit 4	—	Unused	X
Bit 3	R/W	Reserved	0
Bit 2	R/W	Reserved	0
Bit 1	R/W	Reserved	0
Bit 0	R/W	SBI_PAR_CTL	1

This register controls the operation of the SBI INSERT block.

**SBI\_PAR\_CTL**

The SBI\_PAR\_CTL bit is used to configure the Parity mode for generation of the SBI parity signal, ADP as follows: When SBI\_PAR\_CTL is '0' parity is even. When SBI\_PAR\_CTL is '1' parity is odd.

**Reserved**

The reserved bits must be set low for correct operation of the FREEDM 32A1024L device.

**Register 0x68C: SBI INSERT T1 Frame Pulse Offset Register**

Bit	Type	Function	Default
Bit 15	R	Unused	0
Bit 14	R	Unused	0
Bit 13	R	Unused	0
Bit 12	R/W	Reserved	1
Bit 11	R/W	OFFSET_T1[11]	0
Bit 10	R/W	OFFSET_T1[10]	0
Bit 9	R/W	OFFSET_T1[9]	1
Bit 8	R/W	OFFSET_T1[8]	1
Bit 7	R/W	OFFSET_T1[7]	1
Bit 6	R/W	OFFSET_T1[6]	0
Bit 5	R/W	OFFSET_T1[5]	0
Bit 4	R/W	OFFSET_T1[4]	0
Bit 3	R/W	OFFSET_T1[3]	0
Bit 2	R/W	OFFSET_T1[2]	1
Bit 1	R/W	OFFSET_T1[1]	0
Bit 0	R/W	OFFSET_T1[0]	0

This register controls the T1 Frame pulse offset. This register is only required when operating in synchronous mode (SYNCH\_TRIB=1).

**OFFSET\_T1[11:0]**

This parameter must be programmed to OFFSET T1[11:0] = 1400 (decimal) or 0101 0111 1000 (binary) for correct operation of the device.

**Reserved**

The reserved bit must be left high for correct operation of the FREEDM 32A1024L device.

**Register 0x690: SBI INSERT E1 Frame Pulse Offset**

Bit	Type	Function	Default
Bit 15	R	Unused	0
Bit 14	R	Unused	0
Bit 13	R	Unused	0
Bit 12	R/W	Reserved	0
Bit 11	R/W	OFFSET_E1[11]	0
Bit 10	R/W	OFFSET_E1[10]	0
Bit 9	R/W	OFFSET_E1[9]	1
Bit 8	R/W	OFFSET_E1[8]	1
Bit 7	R/W	OFFSET_E1[7]	1
Bit 6	R/W	OFFSET_E1[6]	0
Bit 5	R/W	OFFSET_E1[5]	0
Bit 4	R/W	OFFSET_E1[4]	0
Bit 3	R/W	OFFSET_E1[3]	0
Bit 2	R/W	OFFSET_E1[2]	1
Bit 1	R/W	OFFSET_E1[1]	0
Bit 0	R/W	OFFSET_E1[0]	0

This register controls the E1 Frame pulse offset. This register is only required when operating in synchronous mode (SYNCH\_TRIB=1).

**OFFSET\_E1[11:0]**

This parameter must be programmed to OFFSET E1[11:0] = 1654 (decimal) or 0110 0111 0110 (binary) for correct operation of the device.

**Reserved**

The reserved bit must be set low for correct operation of the FREEDM 32A1024L device.

**Register 0x694: SBI INSERT Tributary Indirect Access Address**

Bit	Type	Function	Default
Bit 31 To Bit 16	—	Unused	X
Bit 15	R	BUSY	0
Bit 14	R/W	RWB	0
Bit 13	R/W	Reserved	0
Bit 12	R/W	Reserved	0
Bit 11	R/W	Unused	X
Bit 10	R/W	Reserved	0
Bit 9	R/W	Reserved	0
Bit 8	R/W	Reserved	0
Bit 7	R/W	SBI	0
Bit 6	R/W	SPE[1]	0
Bit 5	R/W	SPE[0]	0
Bit 4	R/W	TRIB[4]	0
Bit 3	R/W	TRIB[3]	0
Bit 2	R/W	TRIB[2]	0
Bit 1	R/W	TRIB[1]	0
Bit 0	R/W	TRIB[0]	0

This register provides the transmit SPE and link number used to access the SBI INSERT tributary control configuration RAM.

**TRIB[4:0], SPE[1:0] and SBI**

The TRIB[4:0], SPE[1:0] and SBI fields are used to fully specify to which SBI tributary the Control register write or read operation will apply.

TRIB[4:0] specifies the SBI tributary number within the SBI/SPE as specified by the SPE[1:0] and SBI fields. Legal values for TRIB[4:0] are b'00001' through b'11100'. Legal values for SPE[1:0] are b'01' through b'11'. SBI must be written to a logic one in the FREEDM 32A1024L device.

**Reserved**

The reserved bits must be set low for correct operation of the FREEDM 32A1024L device.

**RWB**

The indirect access control bit (RWB) selects between a configure (write) or interrogate (read) access to the tributary control configuration RAM. Writing a '0' to RWB triggers an indirect write operation. Data to be written is taken from the SBI INSERT Tributary Indirect Access Data Register. Writing a '1' to RWB triggers an indirect read operation. The data read can be found in the SBI INSERT Control Tributary RAM Indirect Access Data Register.

**BUSY**

The indirect access status bit (BUSY) reports the progress of an indirect access. BUSY is set high when a write to the SBI INSERT Tributary Indirect Access Address Register triggers an indirect access and will stay high until the access is complete. This register should be polled to determine when data from an indirect read operation is available in the SBI INSERT Tributary Indirect Access Data Register or to determine when a new indirect write operation may commence.

Downloaded [controlled] by he hai of nelep on Friday, 29 August, 2008 10:08 AM

**Register 0x69C: SBI INSERT Tributary Indirect Access Data**

Bit	Type	Function	Default
Bit 31 To Bit 7	—	Unused	X
Bit 6	R/W	SBIIP_LB	0
Bit 5	R/W	SYNCH_TRIB	0
Bit 4	R/W	CLK_MSTR	0
Bit 3	R/W	TRIB_TYP[1]	0
Bit 2	R/W	TRIB_TYP[0]	0
Bit 1	R/W	Reserved	0
Bit 0	R/W	ENBL	0

This register contains data read from the SBI INSERT tributary control configuration RAM after an indirect read operation or data to be written to the tributary control configuration RAM in an indirect write operation.

**ENBL**

The ENBL bit is used to enable the Tributary. Writing to an Insert Tributary Control and Status RAM location with the ENBL bit set enables the INSBI to take tributary data from an SBIIP link and transmit that data to the SBI tributary for that link.

**Reserved**

The reserved bit must be set low for correct operation of the FREEDM 32A1024L device.

**TRIB\_TYP[1:0]**

The TRIB\_TYP[1:0] field is used to specify the characteristics of the SBI tributary as shown in Table 27 below:

**Table 27 TRIB\_TYP Encoding**

TRIB_TYP[1:0]	Tributary type
00	Reserved
01	Framed
10	Unframed
11	Reserved

**CLK\_MSTR**

The CLK\_MSTR bit configures the SBI tributary to operate as a timing master or slave. Setting CLK\_MSTR to 1 configures the tributary as a timing master (AJUST\_REQ input ignored). Setting CLK\_MSTR to 0 configures the tributary as a timing slave (requests on AJUST\_REQ honored).

## SYNCH\_TRIB

The SYNCH\_TRIB bit is used to indicate whether the tributary is locked to the SBI SPE (i.e. is in synchronous mode). If this bit is set then the tributary is locked. If this bit is not set, then the tributary is free to float. This bit will default to off.

## SBIIP\_LB

The SBIIP loop back bit selects the SBIIP extract loop back bus as the source for this tributary. When SBIIP\_LB is set to 1 LB\_EXT\_DATA, LB\_EXT\_LINKRATE, etc. are used as the input data stream for the selected tributary. When SBIIP\_LB is set to 0 the insert SBIIP bus is the source for the selected tributary. Loop backs are only possible with floating tributaries, i.e. cannot be used with synchronous T1 and E1 tributaries.

Note: Any write to a Tributary Control RAM location for a tributary will generate a configuration reset on that tributary, irrespective of whether the data written to the tributary control RAM location is unchanged from the previous value.

Downloaded [controlled] by he hai of nelep on Friday, August 18, 2017 05:02:11 PM

**Register 0x6A0: SBI INSERT SBI SPE Configuration Register**

Bit	Type	Function	Default
Bit 31 To Bit 12	R	Unused	0
Bit 11	R/W	SPE3_EN	0
Bit 10	R/W	SPE3_TYP[2]	0
Bit 9	R/W	SPE3_TYP [1]	0
Bit 8	R/W	SPE3_TYP [0]	0
Bit 7	R/W	SPE2_EN	0
Bit 6	R/W	SPE2_TYP[2]	0
Bit 5	R/W	SPE2_TYP [1]	0
Bit 4	R/W	SPE2_TYP [0]	0
Bit 3	R/W	SPE1_EN	0
Bit 2	R/W	SPE1_TYP[2]	0
Bit 1	R/W	SPE1_TYP [1]	0
Bit 0	R/W	SPE1_TYP [0]	0

SPE1\_EN, SPE2\_EN, SPE3\_EN

Enables SPE1, SPE2 and SPE3 respectively. When these bits are set to 0 the respective SPE is disabled. When these bits are set to 1 the respective SPE is enabled. When an SPE is enabled each individual tributary within an SPE can be selectively enabled via the Insert Tributary Control Indirect Access Data register.

SPE1\_TYP[2:0], SPE2\_TYP[2:0], SPE3\_TYP[2:0]

SPE1\_TYP[2:0], SPE2\_TYP[2:0] and SPE3\_TYP[2:0] select the SPE type for the three SPEs respectively. The types for each SPE are independently configured with possible types being T1 or E1. The settings for SPE<sub>x</sub>\_TYP[2:0] are:

**Table 28 SBI INSERT SPE\_TYP[2:0]**

SPE <sub>x</sub> _TYP[2:0]	Payload Type
X00	28 T1/J1 Links
X01	21 E1 Links
010	Reserved
011	Reserved
11x	Reserved

**Register 0x800: Memory Port Control**

Bit	Type	Function	Default
Bit 31	R	MPBusy	0
Bit 30 To Bit 29	R/W	MPCCommand[1:0]	0
Bit 28 To Bit 27	R/W	MPBurstLength[1:0]	0
Bit 26 To Bit 24	R/W	MPMemSelect[2:0]	0
Bit 23 To Bit 0	R/W	MPQuadAddr[23:0]	0

Writes to this register will start a BUMP2 access to the internal aperture defined by MPMemSelect. The completion of one access is signaled by BUMP2 asserting MPBusy to state low. During an internal access, while MPBusy is high, all BUMP2 Control Registers are accessible by the microprocessor.

**MPQuadAddr[23:0]**

Indicates the beginning quad long word address for the operation in memory. Up to 96 megabytes of memory is supported in each aperture by this address (or 4M 16-byte or 24-byte regions).

For Chunk Buffer DRAM accesses, only even number addresses are valid.

**MPMemSelect[2:0]**

Selects the memory aperture. The aperture is chosen according to the following table.

**Table 29 MPMEMSelect Function**

MPMemSelect[2:0]	Aperture Selected
000	Connection Context SRAM
001	Chunk Buffer DRAM
010	Resequencing DRAM
011	Statistics Counters
100	EQM-12 Memory
101	TFRAG Any-PHY Channel RAM
110	RFRAG Memory
111	Unused

MPBurstLength[1:0]

Indicates how many long words of data will be written to or read from memory in one burst access. Data read from the memory goes to the Memory Read Data N registers. After a burst of 1 word only the Memory Read Data 1 register is updated, a burst of two words will update this register and Memory Read Data 2, and so on for bursts of 3 and 4 words. Similarly for write bursts when data from the Memory Write Data registers is written to the memory.

**Table 30 MPBurstLength Function**

MPBurstLength[1:0]	Long Words Selected
00	1
01	2
10	3
11	4

For accesses to the Chunk Buffer DRAM, only the values 01 and 11 are valid. For accesses to the TFRAG Any-PHY Channel RAM and the RFRAG RAM only the value of 00 is valid.

MPCCommand[1:0]

Selects the type of access.

**Table 31 MPCCommand functions**

MPCCommand[1:0]	Command Selected
00	Reserved
01	Write
10	Read
11	Unused

MPBusy

When a command is executed, this bit will automatically be set to a 1. When the command is complete, this bit will be cleared to zero. This signal is the inverse of MPISTATI found in the Interrupt Status Register.

**Register 0x804-0x810: Memory Write Data N, N=0..3 (Burstable)**

Bit	Type	Function	Default
Bit 31 To Bit 0	R/W	MPWrDataN[31:0]	0

Writes to these registers are not allowed while MPBusy is active high and MPCCommand[1:0]="01" (write).

MPWrDataN[31:0], N = 0..3

A 32 bit slice of the 128 bits of write data to be directed to the address and aperture as specified in the memory port control register. MPWrData0[31:0] corresponds to bits [31:0] of the write data. MPWrData1[31:0] corresponds to bits [63:32] of the write data. MPWrData2[31:0] corresponds to bits [95:64] of the write data. MPWrData3[31:0] corresponds to bits [127:96] of the write data.

Downloaded [controlled] by he hai of nelep on Friday, 11/11/2010 15:02:17 PM

**Register 0x814: Memory Write Data Overflow 1 (Burstable)**

Bit	Type	Function	Default
Bit 31 To Bit 16	R/W	MPWrData1[47:32]	0
Bit 15 To Bit 0	R/W	MPWrData0[47:32]	0

Writes to this register are not allowed while MPBusy is active high and MPCCommand[1:0]="01" (write). This register is only used for writes to the Chunk Buffer Memory.

MPWrData0[47:32]

The most significant 16 bits of MPWrData0.

MPWrData1[47:32]

The most significant 16 bits of MPWrData1.

Downloaded [controlled] by he hai of nelep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x818: Memory Write Data Overflow 2 (Burstable)**

Bit	Type	Function	Default
Bit 31 To Bit 16	R/W	MPWrData3[47:32]	0
Bit 15 To Bit 0	R/W	MPWrData2[47:32]	0

Writes to this register are not allowed while MPBusy is active high and MPCCommand[1:0]="01" (write). This register is only used for writes to the Chunk Buffer Memory.

MPWrData2[47:32]

The most significant 16 bits of MPWrData2.

MPWrData3[47:32]

The most significant 16 bits of MPWrData3.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x81C-0x828: Memory Read Data N, N=0..3 (Burstable)**

Bit	Type	Function	Default
Bit 31 To Bit 0	R	MPRdDataN[31:0]	0

When a read command (MPCCommand[1:0]="10") is asserted, the data in these registers will be valid after MPBusy goes low and will stay valid until the end of the next read command.

MPRdDataN[31:0], N = 0..3

The least significant 32 bits of read data from the address and aperture as specified in the memory port control register. MPRdDataN corresponds to MPLWordEn[N].

Downloaded [controlled] by he hai of nelep on Friday, 29 April 2011, 20:05:02:17 PM

**Register 0x82C: Memory Read Data Overflow 1 (Burstable)**

Bit	Type	Function	Default
Bit 31 To Bit 16	R	MPRdData1[47:32]	0
Bit 15 To Bit 0	R	MPRdData0[47:32]	0

When a read command (MPCommand[1:0]="10") is asserted, the data in this register will be valid after MPBusy goes low and will stay valid until the end of the next read command. This register is only updated after reads from the Chunk buffer memory.

MPRdData0[47:32]

Indicates the most significant 16 bits of the first word of read data from memory.

MPRdData1[47:32]

Indicates the most significant 16 bits of the second word of read data from memory.

**Register 0x830: Memory Read Data Overflow 2 (Burstable)**

Bit	Type	Function	Default
Bit 31 To Bit 16	R	MPRdData3[47:32]	0
Bit 15 To Bit 0	R	MPRdData2[47:32]	0

When a read command (MPCommand[1:0]="10") is asserted, the data in this register will be valid after MPBusy goes low and will stay valid until the end of the next read command. This register is only updated after reads from the Chunk Buffer Memory.

MPRdData2[47:32]

Indicates the most significant 16 bits of the third word of read data from memory.

MPRdData3[47:32]

Indicates the most significant 16 bits of the fourth word of read data from memory.

**Register 0x884: Unexpected SN CI (USNCI)**

Bit	Type	Function	Default
Bit 31 To Bit 14	—	Unused	X
Bit 13 To Bit 0	R/W	CI	0

CI

The Connection Identifier (CI) of the connection that last experienced an unexpected SN.

Downloaded [controlled] by he hai of nelep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x888: Lost SN CI (LSNCI)**

Bit	Type	Function	Default
Bit 31 To Bit 14	—	Unused	X
Bit 13 To Bit 0	R/W	CI	0

CI

The Connection Identifier (CI) of the connection that last triggered the LSNEI interrupt.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x88C: SRAM Parity Error Address (SPERRADD)**

Bit	Type	Function	Default
Bit 31 To Bit 18	—	Unused	X
Bit 17 To Bit 0	R/W	SPERRADD	0

**SPERRADD**

The last SRAM Address that was being accessed when a parity error occurred.

Downloaded [controlled] by he hai of nelep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x890: Excessive number of Fragments CI (ENFCI)**

Bit	Type	Function	Default
Bit 31 To Bit 14	—	Unused	X
Bit 13 To Bit 0	R/W	CI	0

CI

The Connection Identifier (CI) of the last connection on which a frame/packet was received with an excessive number of fragments. Maximum acceptable limit of fragments per packet is 82.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x894: Chunk Buffer Lower Threshold Exceeded Channel (CBLTEXCH)**

Bit	Type	Function	Default
Bit 31 To Bit 10	—	Unused	X
Bit 9 To Bit 0	R/W	AP_CHAN	0

**AP\_CHAN**

The Any-PHY Channel number of the last channel to exceed the Chunk Buffer Lower Threshold (as indicated by the CBLTEXI interrupt bit).

Downloaded [controlled] by he hai of nelep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x898: Auto Do Not Re-Sequence CI (AUTODRICI)**

Bit	Type	Function	Default
Bit 31 To Bit 16	—	Unused	X
Bit 15	R2C	MTO	0
Bit 14	R/W	Reserved	0
Bit 13 To Bit 0	R/w	CI	0

**CI**

The Connection Identifier (CI) of the last connection whose DO\_NOT\_RESEQ bit in the connection context memory was set automatically as a result of experiencing a large number of lost sequenced datagrams in a short time period. (The AUTODRI interrupt bit is set when a DO\_NOT\_RESEQ bit is set automatically.)

**MTO**

The More Than One (MTO) bit is set if AUTODRI interrupts which pertain to two or more different connections occur between reads of this register. The bit is cleared each time this register is read.

**Register 0x900 CB\_DRAMC Status and Control Register**

Bit	Type	Function	Default
Bit 31 To Bit 7	—	UNUSED	X
Bit 6	R/W	Reserved	0
Bit 5	R/W	DECC	0
Bit 4	R/W	ECC_OFF	0
Bit 3	R/W	FUNC_MODE	0
Bit 2	R/W	FPP_INIT	0
Bit 1	R/W	PROV_MODE	0
Bit 0	R	SDRAM_INIT	1

This register provides status information regarding the state of the CB\_DRAMC. Only one of SDRAM\_INIT, PROV\_MODE or FUNC\_MODE at any given time is allowed to be set “high” in this register. Unpredicted behavior may result otherwise. The ECC\_OFF bit should be set to 1 prior to or at the same time FPP\_INIT is set to 1 for hardware initialization of the FPP\_FIFO. For microprocessor initialization, these bits should be set to 1 prior to the initialization process.

**SDRAM\_INIT**

Indicates that the initialization sequence of the Chunk Buffer SDRAMs is in progress. Since this sequence is executing immediately following power-up, this bit is set to “1” by default. This bit is automatically cleared when the SDRAM initialization procedure is completed.

**PROV\_MODE**

This bit is automatically set by the CB\_DRAMC when it finishes executing the initialization sequence required by the SDRAMs. When set, this bit indicates that the CB\_DRAMC is in “Provision” mode and only the microprocessor can perform memory transactions. This bit should be cleared by the microprocessor when all SDRAM transactions are complete. In addition, note that setting this bit while the CB\_DRAMC is in “Functional Mode” (with FUNC\_MODE set) will cause undetermined results.

**FPP\_INIT**

When set, this bit indicates that the DRAMC is in the process of initializing the Free Pool Pointer (FPP) FIFO residing in the Chunk Buffer. Two options exist for initializing the FPP FIFO: The first requires the microprocessor to set the FPP\_INIT bit. This will prompt a CB\_DRAMC based initialization procedure of the FIFO. The other method is to initialize the FPP FIFO by direct microprocessor accesses. In that case there is no need to set this bit.

## FUNC\_MODE

When set, this bit indicates that the CB\_DRAMC is in “Functional Mode”, i.e., it is ready to perform access to the Chunk Buffer on behalf of the various functional units of the chip. When the Free Pool Pointer (FPP) FIFO is initialized by the CB\_DRAMC this bit will be automatically set by the CB\_DRAMC at the end of the FPP FIFO initialization procedure. Otherwise this bit needs to be set by the microprocessor (when it finishes initializing the FPP FIFO).

## ECC\_OFF

Setting this bit turns ECC off. ECC will not be added or corrected. When using the microprocessor interface to access the SDRAMs, this bit must be set to 1.

## DECC

The diagnostic ECC bit (DECC) configures TFRAG to logically invert the ECC for diagnostic purposes. When DECC is a logic one, ECC generated will be inverted. When DECC is a logic zero, a correct ECC will be generated.

## Reserved

The reserved bit must be set low for correct operation of the FREEDM 32A1024L device.

**Register 0x904: CB\_DRAMC\_COECCE Register**

Bit	Type	Function	Default
Bit 31 To Bit 24	—	Unused	X
Bit 23 To Bit 0	R/W	COADDR[23:0]	0

Correctable ECC Error Register. This register stores the last address of the chunk or FPP that caused an ECC error that was corrected.

**COADDR[23:0]**

It stores the address of the latest ECC error detected and corrected, (i.e., if two consecutive chunks read from the memory caused a correctable ECC error, only the address of the last chunk is kept).

Downloaded [controlled] by he hai of nelep on Friday, 19 August, 2008 05:02:17 PM

**Register 0x908: CB\_DRAMC\_UNCOECCE Register**

Bit	Type	Function	Default
Bit 31 To Bit 24	—	Unused	X
Bit 23 To Bit 0	R/W	UNCOADDR[23:0]	0

Uncorrectable ECC Error Register. This register stores the last address of the chunk or FPP that caused 2 ECC errors, one of which cannot be corrected.

**UNCOADDR[23:0]**

It stores the address of the latest uncorrectable ECC error, (i.e., if two consecutive chunks read from the memory caused an uncorrectable ECC error, only the address of the last chunk is kept).

Downloaded [controlled] by he hai of nelep on Friday, 19 August, 2008 05:02:17 PM

**Register 0x918 RS\_DRAMC Status and Control Register**

Bit	Type	Function	Default
Bit 31 To Bit 7	—	Unused	X
Bit 6	R/W	Reserved	0
Bit 5	R/W	DECC	0
Bit 4	R/W	ECC_OFF	0
Bit 3	R/W	FUNC_MODE	0
Bit 2	R/W	FPP_INIT	0
Bit 1	R/W	PROV_MODE	0
Bit 0	R	SDRAM_INIT	1

This register provides status information regarding the state of the RS\_DRAMC. Only one of SDRAM\_INIT, PROV\_MODE or FUNC\_MODE at any given time is allowed to be set “high” in this register. Unpredicted behavior may result otherwise. The ECC\_OFF bit should be set to 1 prior to or at the same time FPP\_INIT is set to 1 for hardware initialization of the FPP\_FIFO. For microprocessor initialization, these bits should be set to 1 prior to the initialization process.

**SDRAM\_INIT**

Indicates that the initialization sequence of the Resequencing Buffer SDRAMs is in progress. Since this sequence is executing immediately following power-up, this bit is set to “1” by default. This bit is automatically cleared when the SDRAM initialization procedure is completed.

**PROV\_MODE**

This bit is automatically set by the RS\_DRAMC when it finishes executing the initialization sequence required by the SDRAMs. When set, this bit indicates that the RS\_DRAMC is in “Provision” mode and only the microprocessor can perform memory transactions. This bit should be cleared by the microprocessor when all SDRAM transactions are complete. In addition, note that setting this bit while the RS\_DRAMC is in “Functional Mode” (with FUNC\_MODE set) will cause undetermined results.

**FPP\_INIT**

When set, this bit indicates that the RS\_DRAMC is in the process of initializing the Free Pool Pointer (FPP) FIFO used by the resequencing logic (realized in the Resequencing Buffer). Two options exist for initializing the FPP FIFO: The first requires the microprocessor to set the FPP\_INIT bit. This will prompt a RS\_DRAMC based initialization procedure of the FIFO. The other method is to initialize the FPP FIFO by direct microprocessor accesses. In that case there is no need to set this bit.

#### FUNC\_MODE

When set, this bit indicates that the RS\_DRAMC is in “Functional Mode”, i.e., it is ready to perform accesses to the Resequencing Buffer. When the Free Pool Pointer (FPP) FIFO is initialized by the RS\_DRAMC this bit will be automatically set by the RS\_DRAMC at the end of the FPP FIFO initialization procedure. Otherwise this bit needs to be set by the microprocessor (when it finishes initializing the FPP FIFO).

#### ECC\_OFF

Setting this bit turns ECC off. ECC will not be added or corrected. When using the microprocessor interface to access the SDRAMs, this bit must be set to 1.

#### DECC

The diagnostic ECC bit (DECC) configures DRAMC to logically invert the ECC for diagnostic purposes. When DECC is a logic one, ECC generated will be inverted. When DECC is a logic zero, a correct ECC will be generated.

#### Reserved

The reserved bit must be set low for correct operation of the FREEDM 32A1024L device.

**Register 0x91C: RS\_DRAMC\_COECCE Register**

Bit	Type	Function	Default
Bit 31 To Bit 24	—	Unused	X
Bit 23 To Bit 0	R/W	COADDR[23:0]	0

Correctable ECC Error Register. This register stores the last address that caused an ECC error that was corrected.

**COADDR[23:0]**

It stores the address of the latest ECC error detected and corrected, (i.e., if two consecutive memory transactions caused a correctable ECC error, only the last address is kept).

Downloaded [controlled] by he hai of nelep on Friday, 19 August, 2008 05:02:17 PM

**Register 0x920: RS\_DRAMC\_UNCOECCE Register**

Bit	Type	Function	Default
Bit 31 To Bit 24	—	Unused	X
Bit 23 To Bit 0	R/W	UNCOADDR[23:0]	0

Uncorrectable ECC Error Register. This register stores the last address that caused 2 ECC errors, one of which can not be corrected.

**UNCOADDR[23:0]**

It stores the address of the latest uncorrectable ECC error, (i.e., if two consecutive memory transactions caused an uncorrectable ECC error, only the last address is kept).

Downloaded [controlled] by he hai of neiep on Friday, 19 August, 2008 05:02:17 PM

**Register 0x9A0: BIST Controller**

This control register is common to all BIST sequencers in the FREEDM 32A1024L.

Bit	Type	Function	Default
Bit 31 To Bit 12	—	Unused	X
Bit 11	R/W	BISTPATTERN[7]	0
Bit 10	R/W	BISTPATTERN[6]	0
Bit 9	R/W	BISTPATTERN[5]	0
Bit 8	R/W	BISTPATTERN[4]	0
Bit 7	R/W	BISTPATTERN[3]	0
Bit 6	R/W	BISTPATTERN[2]	0
Bit 5	R/W	BISTPATTERN[1]	0
Bit 4	R/W	BISTPATTERN[0]	0
Bit 3	R/W	BISTMODE[2]	1
Bit 2	R/W	BISTMODE[1]	0
Bit 1	R/W	BISTMODE[0]	0
Bit 0	R/W	BISTSIDE	0

The BIST Enable register must be set up prior to setup of this register.

**BISTSIDE**

The BIST sequencer input BISTSIDE determines which port of dual-port RAMs is tested when the BIST logic is operating.

**BISTMODE[2:0]**

The BIST sequencer input BISTMODE should be set to “010” to run BIST. Other values are reserved for use during PMC production test.

**BIST\_PATTERN[7:0]**

The BIST test data pattern that is applied to the RAMs during BIST.

**Register 0x9A4: BIST Enable**

Bit	Type	Function	Default
Bit 31 To Bit 16	—	Unused	X
Bit 15	R/W	TAPI-12_EN	0
Bit 14	R/W	RAPI-12_EN	0
Bit 13	R/W	FRMBLD_EN	0
Bit 12	R/W	EQM-12_EN	0
Bit 11	R/W	IQM-12_EN	0
Bit 10	R/W	CB_DRAMC_EN	0
Bit 9	R/W	RS_DRAMC_EN	0
Bit 8	R/W	TFRAG_EN	0
Bit 7	R/W	RFRAG_EN	0
Bit 6	R/W	PM-12_EN	0
Bit 5	R/W	THDL-12_EN	0
Bit 4	R/W	RHDL-12_EN	0
Bit 3	R/W	TCAS-12_EN	0
Bit 2	R/W	RCAS-12_EN	0
Bit 1	R/W	INSBI_EN	0
Bit 0	R/W	EXSBI_EN	0

Each control bit in this register enables the BIST test of all memories controlled by the selected BIST sequencer. All memories in a selected block will be tested at the same time. It should be noted that for BIST to work, all clocks must be the same frequency (SYSCLK, RXCLK, TXCLK) and the maximum frequency of operation is 40MHz. Of the BIST sequencers above, RAPI-12 is run off RXCLK. All other BIST sequencers are run off SYSCLK. This feature is intended for production testing as opposed to on board testing. If this feature is desired for on board testing, the simplest solution is to set TAPI-12\_EN and RAPI-12\_EN to 0 (i.e. don't BIST test these memories) and set SYSCLK=52MHz.

**Register 0x9A8: BIST Result**

Bit	Type	Function	Default
Bit 31 To Bit 16	—	Unused	X
Bit 15	R	TAPI-12_RE	X
Bit 14	R	RAPI-12_RE	X
Bit 13	R	FRMBLD_RE	0
Bit 12	R	EQM-12_RE	0
Bit 11	R	IQM-12_RE	0
Bit 10	R	CB_DRAMC_RE	0
Bit 9	R	RS_DRAMC_RE	0
Bit 8	R	TFRAG_RE	0
Bit 7	R	RFRAG_RE	0
Bit 6	R	PM-12_RE	0
Bit 5	R	THDL-12_RE	0
Bit 4	R	RHDL-12_RE	0
Bit 3	R	TCAS-12_RE	0
Bit 2	R	RCAS-12_RE	0
Bit 1	R	INSBI_RE	0
Bit 0	R	EXSBI_RE	0

Each control bit in this register informs the result of the BIST test of all memories controlled by the selected BIST sequencer. An active high bit means that at least one of the tested memories in the specified block has an error. The reported result is only valid for BIST sequencers that are enabled in the BIST Enable register, once the corresponding “End” bits in register 0x9AC become set.

**Register 0x9AC: BIST End**

Bit	Type	Function	Default
Bit 31 To Bit 16	—	Unused	X
Bit 15	R	TAPI-12_ED	0
Bit 14	R	RAPI-12_ED	0
Bit 13	R	FRMBLD_ED	0
Bit 12	R	EQM-12_ED	0
Bit 11	R	IQM-12_ED	0
Bit 10	R	CB_DRAMC_ED	0
Bit 9	R	RS_DRAMC_ED	0
Bit 8	R	TFRAG_ED	0
Bit 7	R	RFRAG_ED	0
Bit 6	R	PM-12_ED	0
Bit 5	R	THDL-12_ED	0
Bit 4	R	RHDL-12_ED	0
Bit 3	R	TCAS-12_ED	0
Bit 2	R	RCAS-12_ED	0
Bit 1	R	INSBI_ED	0
Bit 0	R	EXSBI_ED	0

Each control bit in this register informs the end of the BIST test of all memories controlled by the selected BIST sequencer.

**Register 0x9B0: EXSBI BIST ERROR**

Bit	Type	Function	Default
Bit 31 To Bit 8	X	Unused	X
Bit 7 To Bit 0	R	ERRORN[7:0]	0

Each of these bits reports a possible error in one of the internal RAMs in EXSBI TSB.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x9B4: INSBI BIST ERROR**

Bit	Type	Function	Default
Bit 31 To Bit 10	X	Unused	X
Bit 9 To Bit 0	R	ERRORN[9:0]	0

Each of these bits reports a possible error in one of the internal RAMs in the INSBI TSB.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x9B8: RCAS-12 BIST ERROR**

Bit	Type	Function	Default
Bit 31 To Bit 3	X	Unused	X
Bit 2 To Bit 0	R	ERRORN[2:0]	0

Each of these bits reports a possible error in one of the internal RAMs in the RCAS-12 TSB.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x9BC: TCAS-12 BIST ERROR**

Bit	Type	Function	Default
Bit 31 To Bit 4	X	Unused	X
Bit 3 To Bit 0	R	ERRORN[3:0]	0

Each of these bits reports a possible error in one of the internal RAMs in the TCAS-12 TSB.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x9C0: RHDL-12 BIST ERROR**

Bit	Type	Function	Default
Bit 31 To Bit 21	X	Unused	X
Bit 20 To Bit 0	R	ERRORN[20:0]	0

Each of these bits reports a possible error in one of the internal RAMs in the RHDL-12 TSB.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x9C4: THDL-12 BIST ERROR**

Bit	Type	Function	Default
Bit 31 To Bit 22	X	Unused	X
Bit 21 To Bit 0	R	ERRORN[21:0]	0

Each of these bits reports a possible error in one of the internal RAMs in the THDL-12 TSB.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x9C8: PM-12 BIST ERROR**

Bit	Type	Function	Default
Bit 31 To Bit 6	X	Unused	X
Bit 5 To Bit 0	R	ERRORN[5:0]	0

Each of these bits reports a possible error in one of the internal RAMs in the PM-12 TSB.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x9CC: RFRAG BIST ERROR**

Bit	Type	Function	Default
Bit 31 To Bit 3	X	Unused	X
Bit 2 To Bit 0	R	ERRORN[2:0]	0

Each of these bits reports a possible error in one of the internal RAMs in the RFRAG TSB.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x9D0: TFRAG BIST ERROR**

Bit	Type	Function	Default
Bit 31 To Bit 4	X	Unused	X
Bit 3 To Bit 0	R	ERRORN[3:0]	0

Each of these bits reports a possible error in one of the internal RAMs in the TFRAG TSB.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x9D4: RS\_DRAMC BIST ERROR**

Bit	Type	Function	Default
Bit 31 To Bit 1	X	Unused	X
Bit 0	R	ERRORN[0]	0

Each of these bits reports a possible error in one of the internal RAMs in the RS\_DRAMC TSB.

Downloaded [controlled] by he hai of nelep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x9D8: CB\_DRAMC BIST ERROR**

Bit	Type	Function	Default
Bit 31 To Bit 2	X	Unused	X
Bit 1 To Bit 0	R	ERRORN[1:0]	0

Each of these bits reports a possible error in one of the internal RAMs in the CB\_DRAMC TSB.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x9DC: IQM-12 BIST ERROR**

Bit	Type	Function	Default
Bit 31 To Bit 5	X	Unused	X
Bit 4 To Bit 0	R	ERRORN[4:0]	0

Each of these bits reports a possible error in one of the internal RAMs in the IQM-12 TSB.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x9E0: EQM-12 BIST ERROR**

Bit	Type	Function	Default
Bit 31 To Bit 7	X	Unused	X
Bit 6 To Bit 0	R	ERRORN[6:0]	0

Each of these bits reports a possible error in one of the internal RAMs in the EQM-12 TSB.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x9E4: FRMBLD BIST ERROR**

Bit	Type	Function	Default
Bit 31 To Bit 3	X	Unused	X
Bit 2 To Bit 0	R	ERRORN[2:0]	0

Each of these bits reports a possible error in one of the internal RAMs in the FRMBLD TSB.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x9E8: RAPI-12 BIST ERROR**

Bit	Type	Function	Default
Bit 31 To Bit 2	X	Unused	X
Bit 1 To Bit 0	R	ERRORN[1:0]	X

Each of these bits reports a possible error in one of the internal RAMs in the RAPI-12 TSB.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:02:17 PM

**Register 0x9EC: TAPI-12 BIST ERROR**

Bit	Type	Function	Default
Bit 31 To Bit 3	X	Unused	X
Bit 2 To Bit 0	R	ERRORN[2:0]	X

Each of these bits reports a possible error in one of the internal RAMs in the TAPI-12 TSB.

Downloaded [controlled] by he hai of neiep on Friday, 29 August, 2008 05:02:17 PM

## 11.2 Microprocessor Accessible Memories

Certain regions of the internal and external memories are used to configure and monitor the operation of the FREEDM 32A1024L.

Unlike the Normal Mode registers, these entries are not cleared upon read unless specified. Specified setups are required for correct operation of the chip. The default value for these memory bits is X unless specified.

### 11.2.1 PM-12 Memory Map

This internal memory is used for storing statistics counters. This memory is accessed through the Memory Port Control register and is burst accessible. This memory is initialized to 0 on reset although on start up, small erred packets may pass through the chip causing the counts to be non-zero. The contents of the memory must be read every 2 seconds in order to ensure counters do not overflow. Counters will be reset to 0 once read. If the counter is allowed to overflow, it will not rollover but will hold the maximum count value until read.

**Note 1:** Byte count includes 2-bytes per event for the CI prepend. Byte count (not including CI prepend) can be determined using corresponding event count.

**Note 2:** Byte count includes 2-bytes per frame/packet for the error CI prepend.

**Note 3:** Byte count is invalid for HDLC channels which have ‘cut-through’ enabled. (I.e. when the CUT\_THRU[1:0] bits in RFRAG memory are set to a value other than “00”.)

**Table 32 PM-12 Memory Map**

Address	Record	Bits	Description
0000	Unused	31:26	X
RX_HDLC_CH (1K) 03FF	RX_BYTE_CNT	25:0	Rx byte count per HDLC channel
0400	Unused	31:26	X

2C05	RX_GMX_BYTE_CNT	31:0	Rx byte count of datagrams with packet length greater than maximum allowed*note1,3
2C06	RX_FOR_BYTE_CNT	31:0	Rx byte count of datagrams with unexpected sequence number*note1
2C07	RX_ABR_BYTE_CNT	31:0	Rx byte count of datagrams with abort errors*note1,3
2C08	RX_UHF_BYTE_CNT	31:0	Rx byte count of datagrams with unsupported header format*note2
2C09	RX_LOST_EV	31:0	Rx lost SN event interrupts
2C0A	RX_PKLT_LMIN	31:0	Rx packet length less than minimum allowed
2C0B	RX_EXC_FR_NBR	31:0	Rx excessive number of fragments events
2C0C	TX_FIFO_UF	31:0	Tx FIFO underflow
2C0D-2C13	Reserved	31:0	X

### 11.2.2 EQM-12 Memory

This internal memory is used to setup configuration and read status per Egress HDLC Channel and Multi-group. The default value of this memory is 0. All Reserved bits must be set to the value defined for correct operation.

**Table 33 EQM-12 Memory Map**

Addresses 000 to 3FF contain, for each HDLC channel, configuration data pertaining to that channel's low-priority chunk buffer queue and/or data used when that HDLC channel is a member of a multi-link bundle. (HDLC channels which are members of a multi-link bundle do not have two levels of priority.)

Address	Record	Word:Bits	Description
000  HDLC CHANNEL # (1024)  each address = 4x32bits  3FF	Unused	127:123	X
	Reserved	122:121	Reserved. Must be set to 0 for correct operation.
	SPC_THR[18:0]	120:102	Space threshold. Must be setup to control HDLC Channel availability indications over the ANY PHY I/F. SPC_THR multiplied by 32 represents the maximum number of bytes below which an HDLC channel will indicate that it has space to accept a new datagram. When TPA_MODE is set to 0, SPC_THR should be set to {OV_THR – LO_PRI_MTU}
	Reserved	101	Reserved. Must be set to 0 for correct operation.
	OV_THR[18:0]	100:82	Overflow Threshold. This value must be set larger than the SPC_THR value to indicate at which point and overflow interrupt is generated.
	MLG[7:0]	81:74	Multi-link Group Number.
	AP_CHAN[9:0]	73:64	Any-PHY Channel number.
	SPACE	63	Indicates space available to accept a datagram. Must be set to 1 when written.
	OVERFLOW	62	Indicates chunk buffer queue has overflowed. Must be set to 0 when written.
	ML	61	Must be set for HDLC channels that belong to a multi-link bundle.
	V_TP	60	Valid Tail Pointer. See Note below.
	SZ	59:40	Size. Must be set to 0 for correct operation.
	TP	39:20	Tail Pointer. See Note below.
	HP	19:0	Head Pointer. See Note below.

Note: HP and TP must be set to 0 after reset. For subsequent initializations of the HDLC channel, traffic must be stopped and when SZ=0, a read modify write must be performed on the new configuration. V-TP, TP, and HP should be written such that their value is preserved.

Addresses 400 to 54F contain configuration data for each multi-link bundle. The same data may also be accessed at addresses C00 to D4F. The only difference is that, when data is written to via

addresses C00 to D4F, only bits [189:150] (i.e. fields ML\_SPC\_THR, ML\_OV\_THR and the 2 reserved bits next to them) are modified. The other fields in the record retain their existing values. (When data is written to via addresses 400 to 54F, all fields in the record are over-written.) In other words, using addresses C00 to D4F allow the multi-link space and overflow thresholds to be updated in real time without corrupting the other fields.

Address	Record	Word:Bits	Description
400 or C00	Unused	199:195	X
	Round Robin	194	Sets lowest fill queue arbitration to round robin mode. The lowest fill queue is always selected as the next HDLC channel to be serviced. When multiple queues contain the same number of bytes and Round Robin is set, priority is given to the HDLC channel in the group following the one that was just serviced. When set to 0, priority is always given to the lowest channel in the group with lowest fill.
	RR Start Index	193:190	Round Robin starting index. This context indicates the channel in a ML group that will have highest priority if multiple channels have lowest fill. This index can be used to dictate which channel will first be used when a bundle is started up. Alternatively, this can be set to 0 and the first fragment will be sent down the first link in the bundle.
	Reserved	189	Reserved. Must be set to 0 for correct operation.
	ML_OV_THR[18:0]	188:170	Multi-link Overflow Threshold. Defined as for OV_THR above. This value overrides the HDLC channel threshold value.
	Reserved	169	Reserved. Must be set to 0 for correct operation.
	ML_SPC_THR[18:0]	168:150	Multi-link Space Threshold. Defined as for SPC_THR above. This value overrides the HDLC channel threshold value.
	OVERFLOW	149	Indicates chunk buffer queue has overflowed. Must be set to 0 when written.
	SPACE	148	Indicates space available to accept a datagram. Must be set to 1 when written.
	ML_SIZE	147:128	Queue size in chunks. Must be set to 0.
	Unused	127:124	X
	54F or D4F	NUM_HCH[3:0]	123:120
HDLC_CHAN[119:0]		119:0	The multi-link members (max of 12 HDLC channels). The first member is HDLC_CHAN[9:0] and the last member is HDLC_CHAN[119:110].

Addresses 800 to BFF contain, for each HDLC channel, configuration data pertaining to that channel's high-priority chunk buffer queue.

Address	Record	Word:Bits	Description
800	Unused	127:123	X
	Reserved	122:121	Reserved. Must be set to 0 for correct operation.

Address	Record	Word:Bits	Description
HDLC CHANNEL # (1024)  each address = 4x32bits  BFF	SPC_THR[18:0]	120:102	Space threshold. Must be setup to control HDLC Channel availability indications over the ANY PHY I/F. SPC_THR multiplied by 32 represents the maximum number of bytes below which an HDLC channel will indicate that it has space to accept a new datagram. When TPA_MODE is set to 0, SPC_THR should be set to {OV_THR – HI_PRI_MTU}
	Reserved	101	Reserved. Must be set to 0 for correct operation.
	OV_THR[18:0]	100:82	Overflow Threshold. This value must be set larger than the SPC_THR value to indicate at which point and overflow interrupt is generated.
	Unused	81:74	X
	AP_CHAN[9:0]	73:64	Any-PHY Channel number.
	SPACE	63	Indicates space available to accept a datagram. Must be set to 1 when written.
	OVERFLOW	62	Indicates chunk buffer queue has overflowed. Must be set to 0 when written.
	Reserved	61	Reserved. Must be set to 0 for correct operation.
	V_TP	60	Valid Tail Pointer. See Note below.
	SZ	59:40	Size. Must be set to 0 for correct operation.
	TP	39:20	Tail Pointer. See Note below.
	HP	19:0	Head Pointer. See Note below.

Note: HP and TP must be set to 0 after reset. For subsequent initializations of the HDLC channel, traffic must be stopped and when SZ=0, a read modify write must be performed on the new configuration. V-TP, TP, and HP should be written such that their value is preserved.

### 11.2.3 TFRAG Any-PHY Channel RAM Memory Map

This internal memory must be written to setup Egress ANY PHY Channel configuration. The default value of this memory is 0, except for the contents of address 405. MPBurstLength[1:0] must = 00 for access to this memory.

**Table 34 TFRAG Any-PHY Channel RAM Memory Map**

Address	Record	Bits	Description
000  Any-PHY CHANNEL # (1024)	Unused	31:24	X.
	PPP_PID_COMP	23	PID Compression enabled.
	PPP_ADDR_CTRL_COMP	22	Address/Control Compression enable.
	ML_GROUP[7:0]	21:14	Multi-link Group. This must be set to the Multi-link bundle number. Does not apply if in Single Link Mode.
	ML_CH	13	1 indicates that this channel is Multi-link.
	DATA_TYPE[2:0]	12:10	Indicates data type as follows: 000 – PPP 001 – FR (UNI/NNI format) 010 – Transparent Mode 011 – FR (End-to-End format) 1XX – Unused
	3FF	HDLC_CHAN[9:0]	9:0
400	Unused	31:5	X
	TPA_MODE	4	TPA reporting mode. If 0, TPA reports whether or not an entire MTU can be accepted. If 1, TPA reports whether EQM FIFO size is below or above the space threshold (SPC_THR or ML_SPC_THR).
	Reserved	3:2	Reserved. Must be left at default or set to 00 for correct operation.
	DET_EOP_LOSS	1	1 – Enable detection of EOP Loss. If the Any-PHY channel number changes before end-of-packet is received, the next segment will be interpreted as end-of-packet.
	Reserved	0	Reserved. Must be left at default or set to 0 for correct operation.
403, 402, 401	Reserved	31:0	X. Read only.
404	Unused	31:9	X
404	HI_PRI_MTU	8:0	MTU size in chunks for high-priority traffic. Defaults to 0. Only used when TPA_MODE is set to 0. Must be left at default or set to 0 if TPA_MODE is set to 1.
405	Unused	31:9	X
405	LO_PRI_MTU	8:0	MTU size in chunks for low-priority traffic. Defaults to 0x12C (i.e. 300 decimal, corresponding to 9600 bytes). Only used when TPA_MODE is set to 0. Must be set to 0 if TPA_MODE is set to 1.

### 11.2.4 RFRAG Memory Map

This internal memory must be written to setup Ingress HDLC Channel configuration. The default value of this memory is 0. MPBurstLength[1:0] must = 00 for access to this memory.

**Table 35 RFRAG Memory Map**

Address	Record	Bits	Description
000       HDLC CHANNEL # (1024)	Reserved	31:24	Must be written to 0 for correct operation.
	CUT_THRU	23:22	Enables a cut-through mode in which data is output on the Any-PHY bus as series of channel-interleaved partial packets. 00 – Cut-through disabled, full packet output 01 – Output partial packet every 1*AP_SEGSIZE bytes. 10 – Output partial packet every 2*AP_SEGSIZE bytes. 11 – Output partial packet every 3*AP_SEGSIZE bytes. When cut-through is enabled, PTCL_PPP[1:0] must be set to "10".
	SDDSCRD_OVR	21	Small datagram discard threshold override. Set this bit to 1 to override the default 40-byte small datagram discard threshold with the value programmed into the SDDSCRD_THR[5:0] register.
	SDDSCRD_THR[5:0]	20:15	Small datagram discard threshold. When the SDDSCRD_OVR control bit is set to 1, program this register to the byte size (0 to 56) under which small datagrams will be discarded when an excessive number of datagrams are waiting to be processed by the resequencing engine.
	PTCL_PPP[1:0]	14:13	Protocol definition. 00 – PPP 01 – Frame Relay (only recognise UNI/NNI fragmentation format) 10 – Transparent Mode 11 – Frame Relay (only recognise End-to-End fragmentation format)
	ACF_CPRS	12	Address-and-Control field compression. Set this bit to 1 to allow the reception of Address-and-Control field compressed PPP headers. Uncompressed headers may also be received when this bit is set, but must carry the standard 0xFF and 0x03 values. This control bit is only used in PPP mode.
	PF_CPRS	11	Protocol field compression. Set this bit to 1 to allow the reception of Protocol field compressed PPP headers. Uncompressed headers may also be received when this bit is set. This control bit is only used in PPP mode.
	SEQFMT_12	10	Sequence number format. This control bit is only used in PPP mode. 0 – 12 bits 1 – 24 bits

Address	Record	Bits	Description
3FF	AP_CHAN[9:0]	9:0	Any-PHY channel number. Program this register to the Any-PHY channel number associated with this HDLC Channel. Prior to tearing down an Any-PHY channel, all CI's associated with that ANY_PHY channel must first be torn down following the specified tear down procedure.
400     Any-PHY CHANNEL # (1024)     7FF	Reserved	31:29	Must be written to 0 for correct operation.
	DONT_RESEQ	28	When set to 1, causes sequenced datagrams to be processed as if they were non-sequenced, i.e. they are not re-sequenced or re-assembled, but rather are immediately queued for output on the Any-PHY interface. When output on the Any-PHY interface, such datagrams will be marked as erred.  Note 1. This bit does not affect CI lookup in the RS Memory. Sequenced datagrams will still be mapped to a sequenced CI.  Note 2. If DONT_RESEQ has been set on a particular Any-PHY channel and it is then desired to clear the bit to re-enable normal processing of sequenced traffic on the channel, steps 2 thru 6 of the CI teardown procedure detailed in section 10.7 must be performed for each sequenced CI pertaining to the Any-PHY channel prior to changing DONT_RESEQ from 1 to 0.
	LT_LEVEL[1:0]	27:26	Lower discard threshold, above which certain classes of datagram may be configured to be passed and all other datagrams will be discarded. 00 – AP_ALLOC_THR - 512 chunks 01 – AP_ALLOC_THR * 0.875 10 – AP_ALLOC_THR * 0.75 11 – AP_ALLOC_THR * 0.5  The CBLTEXI interrupt is asserted when a datagram is discarded due to this lower threshold being exceeded.  The lower discard threshold is only activated if one or more of the EN_LT_MLCTRL, EN_LT_LMI or EN_LT_NONSEQ bits is set to 1. If all three bits are set to 0, datagrams are only discarded if AP_ALLOC_THR is exceeded.
	EN_LT_MLCTRL	25	When set to 1, activates lower discard threshold but allows through control datagrams (those with the C bit set in ML-FR or the MSB of PID(H) set in PPP) until AP_ALLOC_THR is reached.
	EN_LT_LMI	24	When set to 1, activates lower discard threshold but allows through Frame Relay datagrams which have a DLCI of 0 or 1023 until AP_ALLOC_THR is reached. (Also allows through FR control datagrams, although these do not have a DLCI.)
	EN_LT_NONSEQ	23	When set to 1, activates lower discard threshold but allows through non-sequenced datagrams (including control datagrams) until AP_ALLOC_THR is reached.

Address	Record	Bits	Description
Any-PHY CHANNEL # (1024)	400	22:4	Any-PHY storage allocation threshold. Program this register to the allowed number of chunks of storage above which datagrams received for this Any-PHY channel will be discarded. Note that this threshold will be verified only at the start of every datagram (i.e., no datagram will be discarded if its first chunk was accepted, even though subsequent chunks may cause the Any-PHY storage allocation threshold to be exceeded). Care must therefore be taken when defining Any-PHY storage allocation thresholds to reserve (subtract) enough headroom for storage of one additional datagram.
	OUTFMT_FRPK	3	Output format (frame/packet or fragment). 0 – Frame/Packet 1 – Fragment
	AP_CIOUT	2	Any-PHY connection identifier output. Set this bit to 1 to indicate that the connection identifier is to be pre-pended to all datagram transfers across a downstream Any-PHY interface. This bit will be overridden and forced to 1 when an erred datagram is received. It will be overridden and forced to 0 when CUT_THRU is enabled on the Any-PHY channel's corresponding HDLC channel, even for erred datagrams.  This bit should never be cleared when sequenced datagrams are expected as this will cause an unexpected presence of sequence number error.
	AP_SEGSIZE [1:0]	1:0	Ingress Any-PHY channel output segment size (64, 128, or 256 bytes). Each channel must be programmed with the same value. 00 – 64 bytes 01 – 128 bytes 10 – 256 bytes 11 – Unused
7FF			
800 BFF		31:0	Reserved. Must be left at default or written to 0 for correct operation.
C00		31:19	Unused
FFF	AP_NCHNKS [18:0]	18:0	Number of chunks stored in external chunk buffer

### 11.2.5 Re-Sequence Structures (RS) Memory Map

This external memory can be read or written with any value for test purposes before Functional Mode (FUNC\_MODE) in the RS\_DRAMC Status and Control Register is enabled. The contents of the memory must be left in the state described below for correct operation. ECC Protection can be enabled in the RS\_DRAMC Status and Control Register. If ECC is enabled, bits 31-24 are overwritten with the ECC value. If ECC is disabled, bits 31-24 are written with the data presented.

**Table 36 RS Memory Map**

Address	Record	Bits	Description
000000	CI_LOOKUP	31:0	<p><b>Connection Identifier Lookup record.</b> This record must be populated according to the record description below. All unused locations must be set to a default connection identifier. Whenever a connection is de-commissioned, the location must be written with a default connection identifier. A Unique CI must be used for each Any-PHY channel. All CI's in an Any-PHY channel must be torn down before an Any-PHY channel is torn down. The connection Identifier lookup address is generated as follows:</p> <p>Bits 23:22 – 0  Bits 21:12 – HDLC CH number or Any-PHY CH number  Bits 11:10 – 00 – Sequenced or Transparent Mode            01 – Non-sequenced            10 – Control (ML_FR, ML_PPP, SL_PPP)            11 – Corrupt  Bits 9:0 – 0 for Corrupt, Control or Transparent Mode.            DLCI or COS otherwise (although COS=0 if non-sequenced).</p> <p>A sequenced CI lookup record consists of up to 1024 entries per HDLC or Any-PHY channel. In frame relay, 1024 unique DLCI numbers can be mapped to 1-to-1024 CI numbers. In PPP, 16 COS numbers can be mapped to 1-to-16 CI numbers. The choice of whether to use HDLC or Any-PHY channel numbers for the CI lookup is at the discretion of the user and is controlled by the CI_LOOKUP_CHAN bit in register 0x020. If HDLC channel-based lookup is selected, then for each sequenced connection in an HDLC bundle, the same CI must be set up for each HDLC#. See Table 37 for details. This format is also used for transparent mode operation, in which case the address bits 9:0 must be set to 0.</p> <p>A non-sequenced CI lookup record consists of up to 1024 entries per HDLC channel. (For non-sequenced CI lookup, bits [21:12] of the lookup key are interpreted as an HDLC channel number regardless of the setting of the CI_LOOKUP_CHAN bit.) In frame relay, 1024 unique DLCI numbers can be mapped to 1-to-1024 CI numbers. In PPP, each channel is mapped to 1 non-sequenced CI number. See Table 38 for details.</p> <p>A control CI lookup record consists of 1 entry per HDLC channel. (For control CI lookup, bits [21:12] of the lookup key are interpreted as an HDLC channel number regardless of the setting of the CI_LOOKUP_CHAN bit.) In multi-link frame relay an active control bit in the frame header results in an index to the CI present in this record. In single or multi-link PPP an active NCP or LCP bit in the packet header results in an index to the CI present in this record. For Single Link FR, control packets are identified by DLCI and these packets must be identified by putting a unique CI in the non-sequenced table based on DLCI. See Table 39 for details.</p>

(HDLC#  
x 4096  
= 4M)

Address	Record	Bits	Description
3FFFFFF			A corrupt CI lookup record consists of 1 entry per HDLC channel. (For corrupt CI lookup, bits [21:12] of the lookup key are interpreted as an HDLC channel number regardless of the setting of the CI_LOOKUP_CHAN bit.) A datagram marked as corrupted will result in an index to the corrupt CI lookup record. See Table 40 for details.
400000 (256k) 43FFFF	Reserved	31:0	<b>LSB Record Status.</b> Upon initialization, S/W must write this field to 0 for correct operation of the chip. <b>Note –</b> ECC must be disabled when these locations are read from and written to by S/W.
440000 (3.75M) 7FFFFFF	Unused	31:0	X
800000 (2M) 9FFFFFF	Reserved	31:0	<b>MSB Record.</b> Upon initialization, S/W must write this field to 0 for correct operation of the chip.
A00000 (512k entries x 2 locations per entry) AFFFFFF	Reserved	31:0	Used by hardware.
B00000 (32k-40h) B07FBF	LSB_RCD_FREELIST	31:0	<b>LSB Record Freelist record.</b> Each entry points to the location of an unoccupied LSB record with each LSB record comprising 128 address locations. When the RS_DRAMC status register bit FPP_INIT is set, internal logic writes a unique 15-bit pointer value to each of the 32k freelist locations (pointer values ranging from 40h to 7FFFh). If the RS_DRAMC status register bit FPP_INIT is not set, and has not been set since initialization of the device, then the microprocessor must populate the LSB record freelist as the internal logic will not have been invoked to do so. See Table 43 for details.
B07FC0 (0.96875M) BFFFFFF	Unused	31:0	X
C00000 (4M) FFFFFFF	Reserved	31:0	Used by hardware.

**Table 37 Sequenced Connection Identifier Lookup Record**

Relative Address	Record	Bits	Description
000000 (1k)	Reserved	31:24	These bits are ignored and overwritten with an ECC value via logic within the device.

Relative Address	Record	Bits	Description
index via DLCI or COS number 0003FF	Unused	23:14	X

### 11.2.7 Connection Context (CC) Memory Map

This memory holds connection configuration for both Ingress (RX) and Egress (Tx). This external memory can be read or written with any value for test purposes before Traffic is enabled. The contents of the memory must be left in the state described below for correct operation. A connection's data may be read but not written to once traffic is present on the connection. Each connection contains of 16 32-bit records (W15-W0). When writing to word 0 to set up a Rx connection, words 1-3 must also be written to the value 0. Addressing per CI is described as follows:

**Table 45 Connection Context Memory Addressing**

RAM Address	CI #	Word
00000	0000	W0
00001	0000	W1
...	...	...
0000F	0000	W15
00010	0001	W0

...	...	...
0001F	0001	W15
3FFF0	3FFF	W0
3FFF1	3FFF	W1
...	...	...
3FFFF	3FFF	W15

**Table 46 CC Memory Map**

Address	Record	Word:Bits	Description
00000  CI#*16words (16x16K)	Tx Unused	W15:31:10	X
	TX_HDR_SZ[1:0]	W15:9:8	Transmit Fragmentation Header 00 - Short sequence 01 - Short sequence with class(PPP) 10 - Long sequence (PPP) 11 - Long sequence with class (PPP)
	TX_FRAG_MODE[1:0]	W15:7:6	Tx Fragmentation Mode 00 – Add Fragment Header 01 – Reserved 10 – Non sequenced 11 - Unused
	TX_FRAG_SIZE[1:0]	W15:5:4	Fragmentation size 00 – 128 01 – 256 10 – 512 11 – packet
(con't)	TX_SUB_CH_NUM[3:0]	W15:3:0	Tx Sub-channel number. Defines the offset/index of a member channel within a multi-link group that is to be selected.

Address	Record	Word:Bits	Description	
(con't)	TX_SEQ_NUM [23:0]	W14:31:8	Transmit Sequence Number. Note: Only the least significant 12 bits are valid for 12 bit sequence number modes.	
	Unused	W14:7	X	
	TX_ML_OVRD	W14:6	Transmit Multi-link override 0 – No override 1 – Multi-link override. The sub channel number is used to select from the multi-link bundle.	
	TX_COS[3:0]	W14:5:2	Tx Class of Service. Used only for PPP/ML_PPP.	
	TX Reserved	W14:1:0	These bits must be set to 0 for correct operation.	
	Unused	W13:31:0	X	
	Unused	W12:31:0	X	
	Unused	W11:31:0	X	
	Unused	W10:31:0	X	
	Unused	W9:31:0	X	
	Unused	W8:31:0	X	
	Unused	W7:31:0	X	
	Rx Reserved	W6:31:0	These bits must be set to 0 for correct operation.	
	Rx Reserved	W5:31:0	These bits must be set to 0 for correct operation.	
	Rx Reserved	W4:31:0	These bits must be set to 0 for correct operation.	
	Rx Reserved	W3:31:13	These bits must be set to 0 for correct operation.	
	FIFO_ACT	W3:12	FIFO Active. 1 – Active 0 – Inactive	
	CI#*16words (16x16K)	Rx Reserved	W3:11:9	These bits must be set to 0 for correct operation.
		DO_NOT_RESEQ	W3:8	When set to 1, treat all datagrams as non-sequenced. (Any sequenced datagrams will not be re-sequenced and will be output on the Any-PHY interface marked as erred.) This bit should be set if sequenced traffic is not expected on the connection. It should also be set for default CIs corresponding to unprovisioned Frame Relay DCLIs or unexpected PPP COS values.
		EN_AUTO_DNR	W3:7	When set to 1, enable automatic setting of DO_NOT_RESEQ when DNR_LOST_CNT saturates.
DNR_LOST_CNT[2:0]		W3:6:4	Do-Not-Resequence Lost Counter. Increments by 3 when a LOST event occurs and decrements by 1 when a sequenced datagram is successfully dequeued. Saturates and locks upon reaching the value 7, whereupon the DO_NOT_RESEQ bit will be set if EN_AUTO_DNR is set. (The condition for saturation approximates to the occurrence of 3 LOST events in a sliding window of 5 received datagrams.)  If the DO_NOT_RESEQ bit is set auto-matically by this saturating counter, the CI tear down procedure described in section 10.7 must be followed before S/W clears this bit and re-starts the connection.	
(con't)	Rx Reserved	W3:3:0	These bits must be set to 0 for correct operation.	
	Rx Reserved	W2:31:0	These bits must be set to 0 for correct operation.	
(con't)	Rx Reserved	W1:31:16	These bits must be set to 0 for correct operation.	

Address	Record	Word:Bits	Description													
CI#*16words (16x16K)	RESEQ_ACT	W1:15	Resequencing Active. 1 – Active 0 - Inactive													
	Rx Reserved	W1:14	This bit must be set to 0 for correct operation.													
	CNT_INTVL_F LAG	W1:13	Count interval flag. This bit is compared with the CC_CNT_INTVL register bit to determine whether LSNE_CNT, USNE_CNT and DE_CNT should be reset to zero.

### Operation of the LSNE, USNE and DE Counters

Each Connection Context Memory record contains 3 counters which record the number of Lost Sequence Number events, Unexpected Sequence Number events and Frame Relay datagrams received with the DE bit set. The 13-bit counters saturate upon reaching 1FFF hex and are reset by toggling the CC\_CNT\_INTVL register bit. For example, if the CC\_CNT\_INTVL register bit is zero and the counters saturate, they will remain saturated until CC\_CNT\_INTVL is set to one. If CC\_CNT\_INTVL is one and the counters saturate, they will remain saturated until

CC\_CNT\_INTVL is set to zero. It is recommended that the counters be read at regular intervals and, each time after they are read, that CC\_CNT\_INTVL be toggled to initiate a new counting interval.

The CNT\_INTVL\_FLAG bit in the Connection Context Memory record is used to detect changes of the CC\_CNT\_INTVL bit and to reset the counters accordingly. Each time an incoming datagram is processed, and its Connection Context Memory record read, the value of CNT\_INTVL\_FLAG is compared with CC\_CNT\_INTVL. If the bits are different, it is assumed that CC\_CNT\_INTVL has been toggled and the counts are therefore reset. CNT\_INTVL\_FLAG is inverted when the counts are reset, so that it is equal to CC\_CNT\_INTVL after each datagram is processed.

Note that a Connection Context Memory record is only read when an incoming datagram corresponding to the connection in question is being processed. It is possible, therefore, that during a particular counting interval, no datagram is received on a particular connection. Should this occur, that connection's Context Memory record will not be read and the counts will not be zeroed, even though the CC\_CNT\_INTVL bit was toggled by the user. Such a situation can be detected by checking whether or not CNT\_INTVL\_FLAG has toggled since it was last read.

The following procedure can be used to determine a correct count value even if a counter is not reset properly due to no datagrams being received on a particular connection during a count interval:

```

At the end of each count interval:

FOR each active connection {
    Read Connection Context Memory record

    Extract the LSNE_CNT, USNE_CNT, DE_CNT and CNT_INTVL_FLAG fields

    IF {all 3 counters = value read last time AND
        CNT_INTVL_FLAG = value read last time} THEN
        # No datagram was received during poll interval.
        Ignore counter values.
        Correct counter values = all zeros.
    ELSE IF (any counter <> value read last time AND
        CNT_INTVL_FLAG = value read last time) THEN
        # Datagrams were received during poll interval, but CNT_INTVL_FLAG
        # did not invert. This happens when no datagram is received in the
        # preceding poll interval. The user toggled CC_CNT_INTVL twice
        # (or any even number of times) since a datagram was last received
        # on this connection so it looked like it hadn't toggled. The
        # counters therefore did not zero.
        Correct counter values = values just read minus values read
        last time.
    ELSE
        # Counters zeroed properly.
        Correct counter values = values just read.
    END IF
} # end FOR

Toggle CC_CNT_INTVL to initiate new counting interval.

```

Note that these counters only give an approximate count of the number of LSNE, USNE and DE bit set events, since there is window between the count values being read and the CC\_CNT\_INTVL bit being toggled, during which count events may be missed.

## 12 Test Features Description

The FREEDM 32A1024L also supports a standard IEEE 1149.1 five signal JTAG boundary scan test port for use in board testing. All device inputs may be read and all device outputs may be forced via the JTAG test port.

### 12.1 Test Mode Registers

Test mode registers are used to apply test vectors to the DLL during production testing of the FREEDM 32A1024L. Production testing is enabled by asserting the PMCTEST pin. During production tests, FREEDM 32A1024L registers are selected by the TA[12:0] pins. Read accesses are enabled by asserting TRDB low while write accesses are enabled by asserting TWRB low. Test mode register data is conveyed on the TDAT[15:0] pins. Test mode registers (as opposed to normal mode registers) are selected when TA[12]/TRS is set high.

**Table 47 Test Mode Register Memory Map**

Address TA[12:0]	Register
0x0000 - 0x0EFF	Normal Mode Registers
0x0F00 - 0x0F1F	Reserved
0x1F20 - 0x1F2C	DLL Test Registers
0x1F2D - 0x1FFF	Reserved

**Notes on Test Mode Register Bits:**

1. Writing values into unused register bits has no effect. However, to ensure software compatibility with future, feature-enhanced versions of the product, unused register bits must be written with logic zero. Reading back unused bits can produce either a logic one or a logic zero; hence unused register bits should be masked off by software when read.
2. Writeable test mode register bits are not initialized upon reset unless otherwise noted.

### 12.2 JTAG Test Port

The FREEDM 32A1024L JTAG Test Access Port (TAP) allows access to the TAP controller and the 4 TAP registers: instruction, bypass, device identification and boundary scan. Using the TAP, device input logic levels can be read, device outputs can be forced, the device can be identified and the device scan path can be bypassed. For more details on the JTAG port, please refer to the Operations section.

**Table 48 Instruction Register (Length - 3 Bits)**

Instructions	Selected Register	Instruction Code IR[2:0]
EXTEST	Boundary Scan	000
IDCODE	Identification	001
SAMPLE	Boundary Scan	010
BYPASS	Bypass	011
BYPASS	Bypass	100
STCTEST	Boundary Scan	101
BYPASS	Bypass	110
BYPASS	Bypass	111

### 12.2.1 Register

Length - 32 bits

Version number - 0H

Part Number - 7310H

Manufacturer's identification code - 0CDH

Device identification - 073100CDH

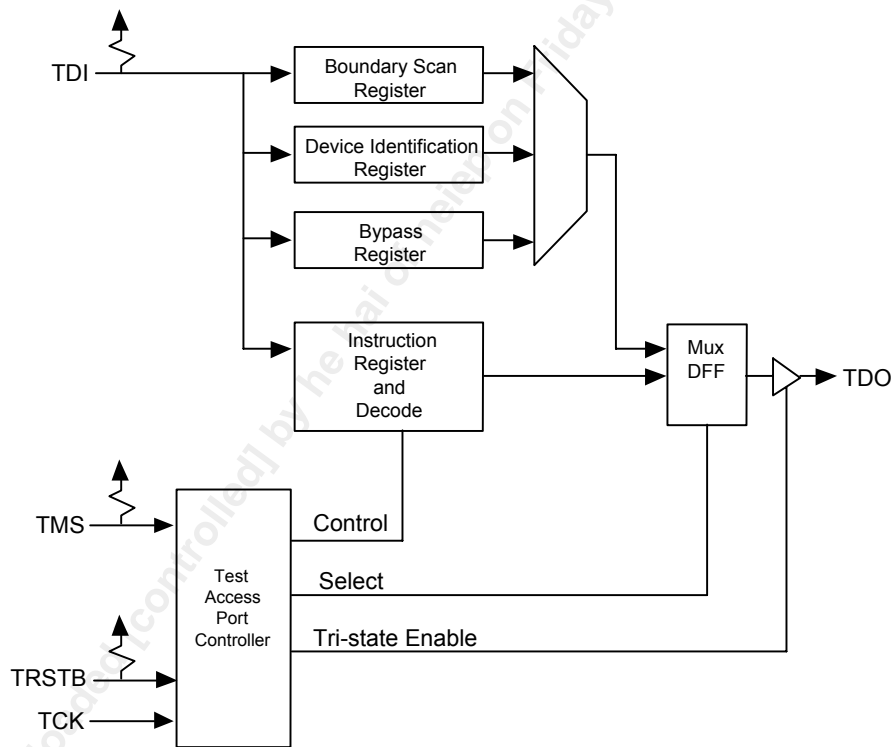

## 13 Operation

This section presents operating details for the JTAG boundary scan feature.

### 13.1 JTAG Support

The FREEDM 32A1024L supports the IEEE Boundary Scan Specification as described in the IEEE 1149.1 standards. The Test Access Port (TAP) consists of the five standard pins, TRSTB, TCK, TMS, TDI and TDO used to control the TAP controller and the boundary scan registers. The TRSTB input is the active low reset signal used to reset the TAP controller. TCK is the test clock used to sample data on input, TDI and to output data on output, TDO. The TMS input is used to direct the TAP controller through its states. The basic boundary scan architecture is shown below.

**Figure 35 Boundary Scan Architecture**

The boundary scan architecture consists of a TAP controller, an instruction register with instruction decodes, and a bypass register, a device identification register and a boundary scan register. The TAP controller interprets the TMS input and generates control signals to load the instruction and data registers. The instruction register with instruction decode block is used to select the test to be executed and/or the register to be accessed. The bypass register offers a single bit delay from primary input, TDI to primary output, TDO. The device identification register contains the device identification code.

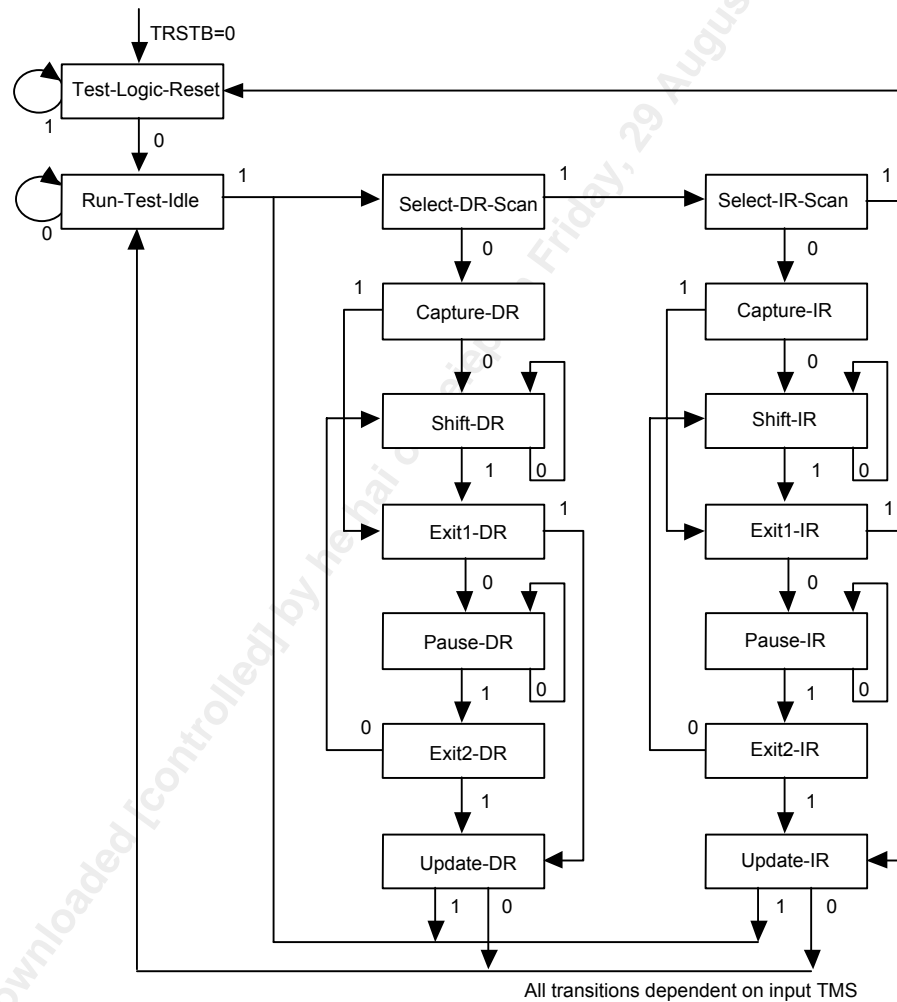

The boundary scan register allows testing of board inter-connectivity. The boundary scan register consists of a shift register placed in series with device inputs and outputs. Using the boundary scan

register, all digital inputs can be sampled and shifted out on primary output TDO. In addition, patterns can be shifted in on primary input, TDI and forced onto all digital outputs.

### TAP Controller

The TAP controller is a synchronous finite state machine clocked by the rising edge of primary input, TCK. All state transitions are controlled using primary input, TMS. The finite state machine is described below.

**Figure 36 TAP Controller Finite State Machine**

### Test-Logic-Reset

The test logic reset state is used to disable the TAP logic when the device is in normal mode operation. The state is entered asynchronously by asserting input, TRSTB. The state is entered synchronously regardless of the current TAP controller state by forcing input, TMS high for 5 TCK clock cycles. While in this state, the instruction register is set to the IDCODE instruction.

### Run-Test-Idle

The run test/idle state is used to execute tests.

### Capture-DR

The capture data register state is used to load parallel data into the test data registers selected by the current instruction. If the selected register does not allow parallel loads or no loading is required by the current instruction, the test register maintains its value. Loading occurs on the rising edge of TCK.

### Shift-DR

The shift data register state is used to shift the selected test data registers by one stage. Shifting is from MSB to LSB and occurs on the rising edge of TCK.

### Update-DR

The update data register state is used to load a test register's parallel output latch. In general, the output latches are used to control the device. For example, for the EXTEST instruction, the boundary scan test register's parallel output latches are used to control the device's outputs. The parallel output latches are updated on the falling edge of TCK.

### Capture-IR

The capture instruction register state is used to load the instruction register with a fixed instruction. The load occurs on the rising edge of TCK.

### Shift-IR

The shift instruction register state is used to shift both the instruction register and the selected test data registers by one stage. Shifting is from MSB to LSB and occurs on the rising edge of TCK.

### Update-IR

The update instruction register state is used to load a new instruction into the instruction register. The new instruction must be scanned in using the Shift-IR state. The load occurs on the falling edge of TCK.

The Pause-DR and Pause-IR states are provided to allow shifting through the test data and/or instruction registers to be momentarily paused.

## Boundary Scan Instructions

The following is a description of the standard instructions. Each instruction selects a serial test data register path between input, TDI and output, TDO.

### BYPASS

The bypass instruction shifts data from input, TDI to output, TDO with one TCK clock period delay. The instruction is used to bypass the device.

## EXTEST

The external test instruction allows testing of the interconnection to other devices. When the current instruction is the EXTEST instruction, the boundary scan register is placed between input, TDI and output, TDO. Primary device inputs can be sampled by loading the boundary scan register using the Capture-DR state. The sampled values can then be viewed by shifting the boundary scan register using the Shift-DR state. Primary device outputs can be controlled by loading patterns shifted in through input TDI into the boundary scan register using the Update-DR state.

## SAMPLE

The sample instruction samples all the device inputs and outputs. For this instruction, the boundary scan register is placed between TDI and TDO. Primary device inputs and outputs can be sampled by loading the boundary scan register using the Capture-DR state. The sampled values can then be viewed by shifting the boundary scan register using the Shift-DR state.

## IDCODE

The identification instruction is used to connect the identification register between TDI and TDO. The device's identification code can then be shifted out using the Shift-DR state.

## STCTEST

The single transport chain instruction is used to test out the TAP controller and the boundary scan register during production test. When this instruction is the current instruction, the boundary scan register is connected between TDI and TDO. During the Capture-DR state, the device identification code is loaded into the boundary scan register. The code can then be shifted out output, TDO using the Shift-DR state.

## INTEST

The internal test instruction is used to exercise the device's internal core logic. When this instruction is the current instruction, the boundary scan register is connected between TDI and TDO. During the Update-DR state, patterns shifted in on input, TDI are used to drive primary inputs. During the Capture-DR state, primary outputs are sampled and loaded into the boundary scan register.

## 14 Functional Timing

### 14.1 SBI Drop Bus Interface Timing

Figure 37 T1/E1 Drop Bus Functional Timing

Figure 37 illustrates the operation of the SBI DROP BUS, using a negative justification on the second to last V3 octet as an example. The justification is indicated by asserting DPL high during the V3 octet. The timing diagram also shows the location of one of the tributaries by asserting DV5 high during the V5 octet.

### 14.2 SBI Add Bus Interface Timing

Figure 38 T1/E1 Add Bus Adjustment Request Functional Timing

Figure 38 illustrates the operation of the SBI Add Bus, using positive and negative justification requests as an example. (The responses to the justification requests would take effect during the next multi-frame. The APL signal illustrates the response to a positive justification request for DS1 #1 and a negative justification request for DS1 #2 in the previous multiframe). The negative justification request occurs on the DS1 #1 tributary when AJUST\_REQ is asserted high during the V3 octet. The positive justification occurs on the DS1 #2 tributary when AJUST\_REQ is asserted high during the first DS1 #2 octet after the V3 octet.

### 14.3 Receive APPI Timing (Any-PHY Level 2)

The receive Any-PHY packet interface (APPI) timing is shown in Figure 39 through Figure 42 when the Any-PHY interface operates at 52 MHz, 16 bits of RXDATA are valid. The FREEDM 32A1024L device provides data to an external controller using the receive APPI. The following discussion surrounding the receive APPI functional timing assumes that multiple FREEDM 32A1024L devices share a single external controller. All Rx APPI signals are shared between the FREEDM 32A1024L devices

**Figure 39 Receive APPI Timing (Normal Transfer 16 bit 52 MHz)**

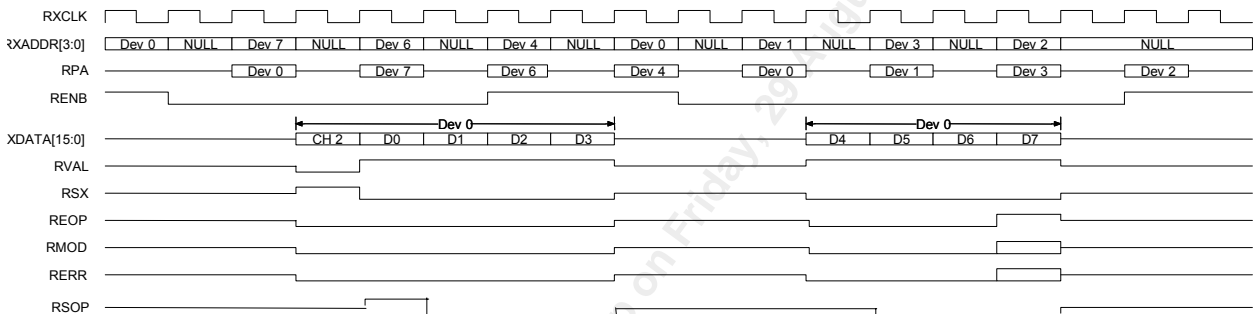

Figure 39 shows the transfer of an 8 word packet across the Rx APPI from FREEDM 32A1024L device 0, Any-PHY channel 2. In this example, seven FREEDM 32A1024L devices are sharing the Rx APPI, with device 5 being the null address.

The data transfer begins when the external controller selects FREEDM 32A1024L device 0 by placing that address on the RXADDR[3:0] inputs and setting RENB high. The external controller sets RENB low in the next RXCLK cycle to commence data transfer across the Rx APPI. The FREEDM 32A1024L samples RENB low and responds by asserting RSX one RXCLK cycle later. The start of all burst data transfers is qualified with RSX and an in-band Any-PHY channel address on RXDATA[15:0] to associate the data to follow with an Any-PHY channel.

During the cycle when D2 is placed on RXDATA[15:0], the external controller is unable to accept any further data and sets RENB high. Two RXCLK cycles later, the FREEDM 32A1024L tristates the Rx APPI. The external controller may hold RENB high for an indeterminate number of RXCLK cycles. The FREEDM 32A1024L will wait until the external controller returns RENB low. Because the FREEDM 32A1024L does not support interrupted data transfers on the Rx APPI, the external controller must reselect FREEDM 32A1024L device 0 or output a null address during the clock cycle before it returns RENB low. However, while RENB remains high, the address on the RXADDR[3:0] signals may change. When the FREEDM 32A1024L device 0 samples RENB low, it continues data transfer by providing D4 on RXDATA[15:0]. Note that if D3 were the final word of the packet (Status), in response to sampling REOP high, the external controller does not have to reselect FREEDM 32A1024L device 0. This is shown in Figure 42.

The FREEDM 32A1024L will not pause burst data transfers across the Rx APPI.

The FREEDM 32A1024L automatically deselected at the end of all burst data transfers. The FREEDM 32A1024L must be reselected before any further data will be transferred across the Rx APPI.

The RVAL and REOP signals indicate the presence and end of valid packet data respectively. The RERR and RMOD signals are only valid at the end of a packet and are qualified with the REOP signal. When a packet is erred, the FREEDM 32A1024L may be programmed to overwrite RXDATA[15:0] in the final word of packet transfer with status information indicating the cause of the error. RXDATA[15:0] is not modified if a packet is error free.

The RXADDR[3:0] signals serve to poll FREEDM 32A1024L devices as well as for selection. During data transfer, the RXADDR[3:0] signals continue to poll the FREEDM 32A1024L devices sharing the Rx APPI. Polled results are returned on the RPA signal. Note that each poll address is separated by a NULL address to generate tristate turn-around cycle in order to prevent multiple FREEDM 32A1024L devices from briefly driving RPA. If RPA is a point-to-point signal for each FREEDM 32A1024L device on the board, then the tristate turn-around cycle is not required, thereby effectively doubling the polling bandwidth at the expense of extra signals.

Polled results reflect the status of the Rx APPI. Polled responses always refer to the next segment transfer. In other words, polled responses during or after the RXCLK cycle where RSX is set high refer to a segment that is not involved in the current data transfer. This allows the external controller to gather knowledge about the segment not involved in the current segment transfer so that it can anticipate reselecting that FREEDM 32A1024L device (via RENB) to maximize bandwidth on the Rx APPI (shown in Figure 41).

**Figure 40 Receive APPI Timing (Auto Deselection)**

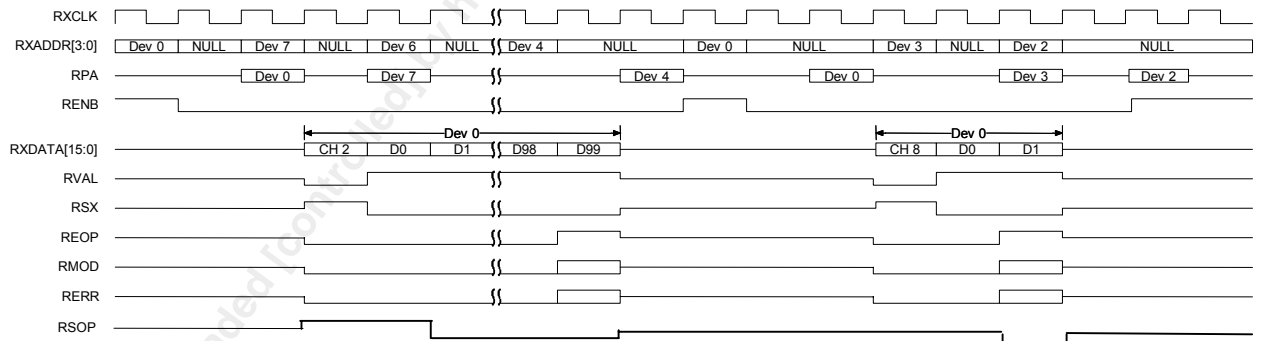

Figure 40 shows the transfer of a 100 word packet across the Rx APPI from FREEDM 32A1024L device 0, channel 2 followed by the transfer of a 2 word packet from FREEDM 32A1024L device 0, channel 8. More importantly, Figure 40 illustrates that, for back-to-back transfers from the same FREEDM 32A1024L (device 0), it must be reselected before any further data is provided on the Rx APPI.

At the end of the first 100 word packet transfer across the Rx APPI, the FREEDM 32A1024L automatically deselected and must be reselected before the second two word packet is transferred. When the external controller samples REOP high, it recognizes that the burst transfer has completed. Two RXCLK cycles later, the external controller reselects FREEDM 32A1024L device

0 by setting RENB high and placing address 0 on the RXADDR[3:0] signals. When the FREEDM 32A1024L samples RENB low, it begins the next data transfer as before.

**Figure 41 Receive APPI Timing (Optimal Reselection)**

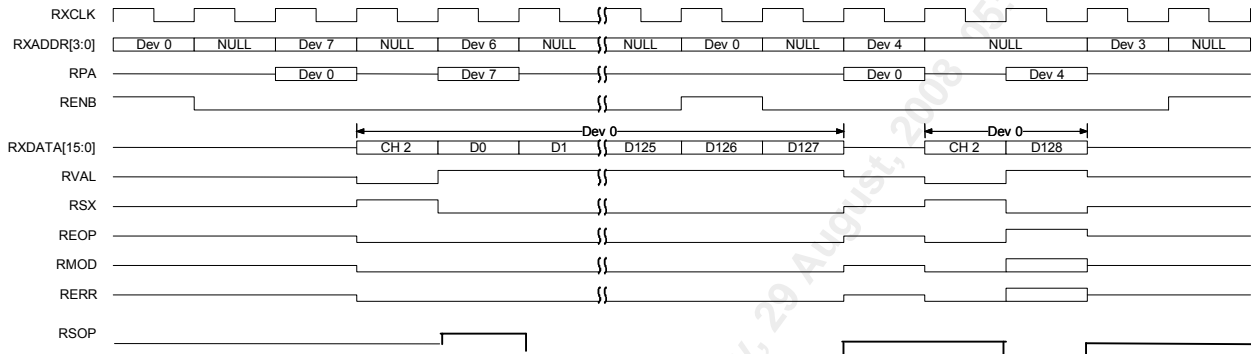

Figure 41 shows optimal bandwidth utilization across the Rx APPI.

With knowledge that the maximum burst data transfer (excluding Any-PHY channel address prepend) is 256 bytes, i.e. 128 words, the external controller sets RENB high when the 127<sup>th</sup> word (D126) is placed on RXDATA[15:0] in anticipation of the end of a burst transfer. The FREEDM 32A1024L completes the burst data transfer and tristates the Rx APPI one RXCLK cycle after RENB is sampled high. Because the burst data transfer is complete and RENB is immediately returned low following selection, the FREEDM 32A1024L immediately begins the next data transfer following the single turn-around cycle.

The protocol dictates that at least one tristate turn-around cycle be inserted between data transfers, even if the external controller is reselecting the same FREEDM 32A1024L device. In other words, Figure 41 shows the earliest possible time that the external controller could have set RENB high to reselect FREEDM 32A1024L device 0.

**Figure 42 Receive APPI Timing (Boundary Condition)**

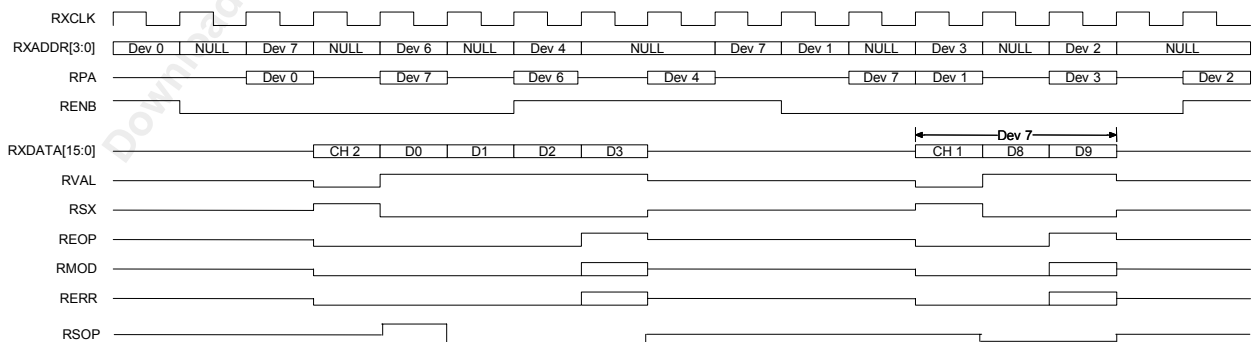

Figure 42 shows the boundary condition where a packet transfer completes shortly after the external controller has set RENB high to pause the FREEDM 32A1024L device. The second data transfer is the final two words of a packet for FREEDM 32A1024L device 7, channel 1.

When FREEDM 32A1024L device 0 places D2 on RXDATA[15:0], the external controller sets RENB high to pause the FREEDM 32A1024L device. In the following RXCLK cycle, the FREEDM 32A1024L provides D3 on RXDATA[15:0] and sets REOP high to conclude packet transfer. The external controller samples REOP high while RENB is high and recognizes that the packet transfer is complete. The external controller now knows that it doesn't need to reselect FREEDM 32A1024L device 0, but can select another FREEDM 32A1024L device sharing the Rx APPI. The external controller decides to select FREEDM 32A1024L device 7 by placing this address on the RXADDR[3:0] signals. The external controller sets RENB low to commence data transfer from FREEDM 32A1024L device 7.

## 14.4 Transmit APPI Timing (Any-PHY Level 2)

The transmit Any-PHY packet interface (APPI) timing is shown in Figure 43. An external controller provides data to the FREEDM 32A1024L device using the transmit APPI. The following discussion surrounding the transmit APPI functional timing assumes that multiple FREEDM 32A1024L devices share a single external controller. The FREEDM 32A1024L compares the TXADDR[15:0] to the base and range address registers to determine if the poll request is destined for the particular FREEDM 32A1024L. All Tx APPI signals are shared between the FREEDM 32A1024L devices.

**Figure 43 Transmit APPI Timing (Normal Transfer)**

Figure 43 shows transfer of a 256 word packet on the Tx APPI for Any-PHY channel 0. The maximum burst data transfer (excluding channel address prepend) is 128 words, so two data transfers are required to complete the transfer of the 256 word packet. The start of all burst data transfers is qualified with the TSX signal and an in-band channel address on TXDATA[15:0] to associate the data to follow with an Any-PHY channel. The TEOP signal indicates the end of valid packet data. The TMOD and TERR signals are held low except at the end of a packet (TEOP set high).

The FREEDM 32A1024L starts driving the TRDY signal one TXCLK cycle after TSX is sampled high. Upon sampling the TRDY signal high, the external controller completes the current burst data transfer. The FREEDM 32A1024L tristates the TRDY signal one TXCLK cycle after it has been

driven high. This is the case for the first burst data transfer in Figure 43. In the second burst data transfer, the FREEDM 32A1024L drives the TRDY signal low to indicate that the FIFO in the Tx APPI is full and no further data may be transferred. Upon sampling the TRDY signal low, the external controller must hold the last valid word of data on TXDATA[15:0]. The FREEDM 32A1024L may drive TRDY low for an indeterminate number of TXCLK cycles. During this time, the external controller must wait and is not permitted to begin another burst data transfer until TRDY is sampled high. When there is space in the Tx APPI FIFO, the FREEDM 32A1024L drives the TRDY signal high. Upon sampling the TRDY signal high, the external controller completes the current burst data transfer. The FREEDM 32A1024L tristates the TRDY signal one TXCLK cycle after it has been driven high.

The external controller must sample the TRDY signal high and must then wait one clock cycle before it can begin the next burst data transfer. This prevents the external controller from bombarding the FREEDM 32A1024L device with small packets and allows the FREEDM 32A1024L to perform the necessary housekeeping and clean up associated with the ending of burst data transfers. In addition, the rule that TSX must be a minimum of 4 clock cycles apart must be adhered to. This protocol also ensures that transitions between burst data transfers do not require any extra per Any-PHY channel storage, thereby simplifying implementation of both the external controller and the FREEDM 32A1024L device. Figure 44 illustrates this condition.

**Figure 44 Transmit APPI Timing (Special Conditions)**

Figure 44 shows two special conditions – (1) the transfer of a one word packet, illustrating how the external controller must wait until TRDY has been sampled high before the next data transfer can begin, and (2) the transfer of a packet that completes when TRDY is set low, illustrating that although the packet has been completely transferred, the external controller must still wait until TRDY has been sampled high before the next data transfer can begin.

The first data transfer is a single word packet for Any-PHY channel 0. The FREEDM 32A1024L asserts TRDY high one TXCLK cycle after TSX is sampled high. The Tx APPI protocol dictates that the external controller must wait until one clock after TRDY is sampled high before beginning the next data transfer for Any-PHY channel 3. The external controller must hold the last valid word on TXDATA[15:0] until TRDY is sampled high. In this case, that data is a don't care. The FREEDM 32A1024L tristates the TRDY signal one TXCLK cycle after it has been driven high.

The second transfer is a three word packet, which completes transfer in the same TXCLK cycle that TRDY is sampled low by the external controller. Again, the external controller must hold the last valid word on TXDATA[15:0] until TRDY is sampled high. In this case, that data is D2, the last word of the packet. The FREEDM 32A1024L may drive TRDY low for an indeterminate number of TXCLK cycles. During this time, the external controller must wait and is not permitted to begin

another burst data transfer until TRDY is sampled high. When the external controller samples TRDY high, the current burst transfer is deemed to be complete and the external controller may begin the next data transfer. The FREEDM 32A1024L tristates the TRDY signal one TXCLK cycle after it has been driven high.

**Figure 45 Transmit APPI Poll Timing**

When supporting Any-PHY Level 2, polling is completely decoupled from device and Any-PHY channel selection on the Tx APPI (Figure 45). Accordingly, the TXADDR[15:0] signals continue to provide only a poll address for any of the FREEDM 32A1024L devices sharing the Tx APPI. The FREEDM 32A1024L compares the TXADDR[15:0] to the base and range address registers to determine if the channel being polled resides within the device. Poll results are returned on the TPA signals. The meaning of the TPA responses depends on the setting of the TPA\_MODE bit in the TFRAG Any-PHY Channel RAM. The user may configure TPA\_HI/ TPA\_LO to report whether or not space exists in the Any-PHY channel FIFO to accept a further MTU-sized packet. Alternatively, TPA\_HI/TPA\_LO may be configured to report whether the FIFO fill level is above or below a user-defined threshold.

## 14.5 Receive APPI Timing (Any-PHY Level 3)

The receive Any-PHY packet interface (APPI) timing is shown in Figure 46 when the Any-PHY interface operates at 104 MHz, RXDATA[7:0] are valid. The FREEDM 32A1024L device provides data to an external controller using the receive APPI.

**Figure 46 Receive APPI Timing (Normal Transfer 8 bit 104 MHz)**

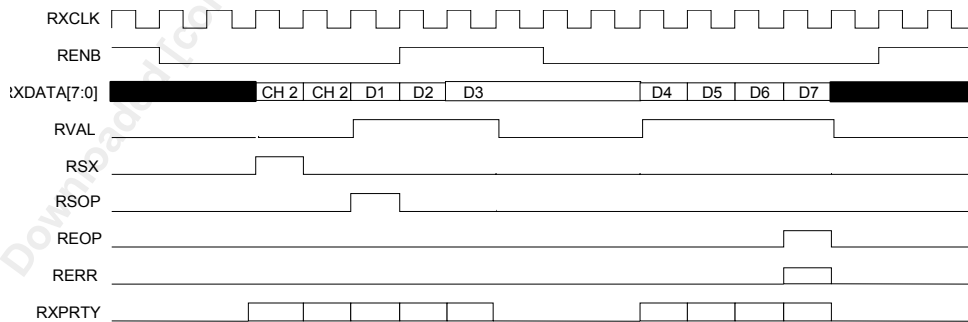

Figure 46 shows the transfer of an 8 byte packet across the Rx APPI from FREEDM 32A1024L. The external controller sets RENB low to commence data transfer across the Rx APPI. The FREEDM 32A1024L samples RENB low and responds by asserting RSX one RXCLK cycle later. The start of all burst data transfers is qualified with RSX and an in-band Any-PHY channel address on RXDATA[7:0] to associate the data to follow with an Any-PHY channel. The RSOP signal is

asserted 2 cycles after the RSX allowing the controller to identify the start of packet. The first two bytes indicate the Any-PHY channel (CH 2) while the next two bytes contain either a connection identifier or the first two bytes of the packet.

During the cycle when D2 is placed on RXDATA[7:0], the external controller is unable to accept any further data and sets RENB high. Two RXCLK cycles later, the FREEDM 32A1024L pauses the Rx APPI. The external controller may hold RENB high for an indeterminate number of RXCLK cycles. The FREEDM 32A1024L will wait until the external controller returns RENB low.

The FREEDM 32A1024L will not pause burst data transfers across the Rx APPI.

The RVAL and REOP signals indicate the presence and end of valid packet data respectively. The RERR and RMOD signals are only valid at the end of a packet and are qualified with the REOP signal. When a packet is erred, the FREEDM 32A1024L may be programmed to overwrite RXDATA[7:0] in the final word of packet transfer with status information indicating the cause of the error. RXDATA[7:0] is not modified if a packet is error free

## 14.6 Transmit APPI Timing (Any-PHY Level 3)

The transmit Any-PHY packet interface (APPI) timing is shown in Figure 47 through Figure 49. An external controller provides data to the FREEDM 32A1024L device using the transmit APPI. The following discussion surrounding the transmit APPI functional timing assumes that point to point interfaces exist between FREEDM 32A1024L and the external controller. The FREEDM 32A1024L compares the TXADDR[15:0] to the base and range address registers to determine if the address is destined for the FREEDM 32A1024L.

**Figure 47 Transmit APPI Timing Any-PHY Level 3 (Normal Transfer)**

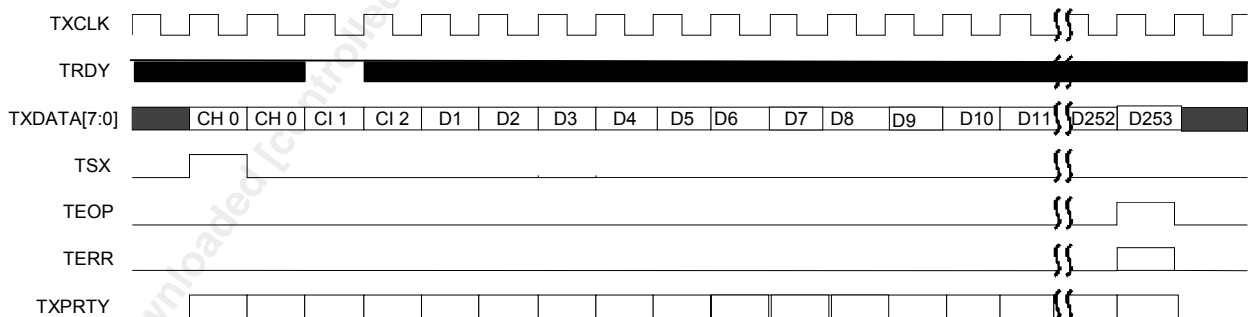

Figure 47 shows transfer of a 254 byte packet on the Tx APPI of FREEDM 32A1024L. The start of all burst data transfers is qualified with the TSX signal and an in-band Any-PHY channel address on TXDATA[7:0] to associate the data to follow with an Any-PHY channel. The TEOP signal indicates the end of valid packet data. The TERR signal is held low except at the end of a packet (TEOP set high).

The TRDY signal is valid one TXCLK cycle after TSX is sampled high. Upon sampling the TRDY signal high, the external controller completes the current burst data transfer. This is the case for the

first burst data transfer in Figure 47. In Figure 48, the FREEDM 32A1024L drives the TRDY signal low to indicate that the FIFO in the Tx APPI are full and no further data may be transferred. Upon sampling the TRDY signal low, the external controller must hold the last valid word of data on TXDATA[7:0]. The FREEDM 32A1024L may drive TRDY low for an indeterminate number of TXCLK cycles. During this time, the external controller must wait and is not permitted to begin another burst data transfer until TRDY is sampled high. Upon sampling the TRDY signal high, the external controller completes the current burst data transfer.

The external controller can sample the TRDY signal high before it can begin the next burst data transfer. TRDY is provided to prevent the external controller from bombarding the FREEDM 32A1024L device with small packets and allows the FREEDM 32A1024L to perform the necessary housekeeping and clean up associated with the ending of burst data transfers. In addition, the rule that TSX must be a minimum of 4 clock cycles apart must be adhered. This protocol also ensures that transitions between burst data transfers do not require any extra per Any-PHY channel storage, thereby simplifying implementation of both the external controller and the FREEDM 32A1024L device. Figure 48 illustrates this condition.

**Figure 48 Transmit APPI Timing Any-PHY Level 3 (Special Condition)**

Figure 48 shows a special condition where the transfer of a packet that completes when TRDY is set low, illustrating that although the packet has been completely transferred, the external controller must still wait until TRDY has been sampled high before the next data transfer can begin.

The illustrated transfer is a two byte packet, which completes transfer in the same TXCLK cycle that TRDY is sampled low by the external controller. The external controller must hold the last valid byte on TXDATA[7:0] until TRDY is valid and sampled high. In this case, that data is D1, the last byte of the packet. The FREEDM 32A1024L may drive TRDY low for an indeterminate number of TXCLK cycles. During this time, the external controller must wait and is not permitted to begin another burst data transfer until TRDY is valid and sampled high. When the external controller samples TRDY high, the current burst transfer is deemed to be complete and the external controller may begin the next data transfer.

**Figure 49 Transmit APPI Polling Timing (Any-PHY Level 3)**

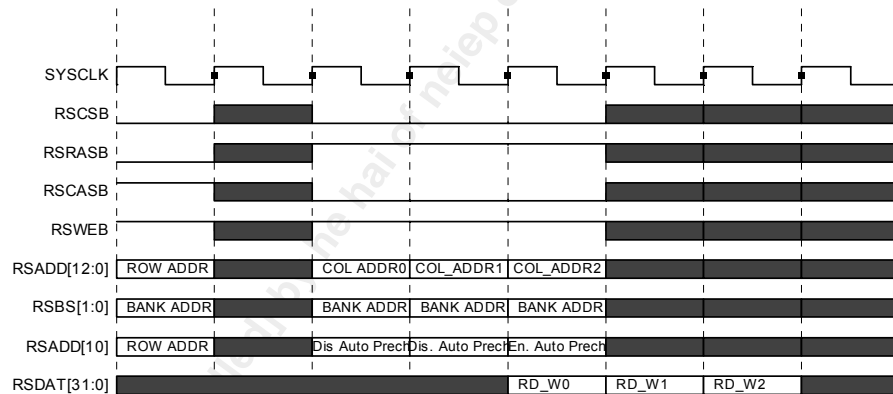

When supporting Any-PHY Level 3 mode polling is completely decoupled from data transfer on the Tx APPI (Figure 49) with the restriction that the TPA poll result is invalid for all channels if it corresponds to a TXADDR poll coincident with the start of transfer (i.e. the cycle in which TSX is driven high). Accordingly, the TXADDR[15:0] signals continue to provide only a poll address for the FREEDM 32A1024L device. The FREEDM 32A1024L compares the TXADDR[15:0] to the base and range address registers to determine if the Any-PHY channel being polled resides within the device. Poll results are returned on the TPA signal. The meaning of the TPA responses depends on the setting of the TPA\_MODE bit in the TFRAG Any-PHY Channel RAM. The user may configure TPA\_HI/TPA\_LO to report whether or not space exists in the Any-PHY channel FIFO to accept a further MTU-sized packet. Alternatively, TPA\_HI/ TPA\_LO may be configured to report whether the FIFO fill level is above or below a user-defined threshold.

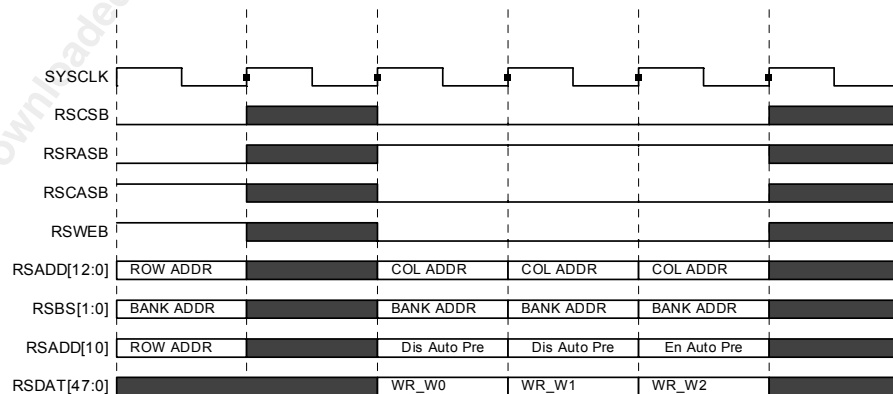

## 14.7 Re-Sequencing SDRAM Interface

The following two diagrams depict the timing for signals destined for the pins of the Re-sequencing SDRAM during the Activate-Read (with Auto-precharge), and Activate-Write (with Auto-precharge) sequences.

**Figure 50 Read Timing for Re-Sequencing Memory**

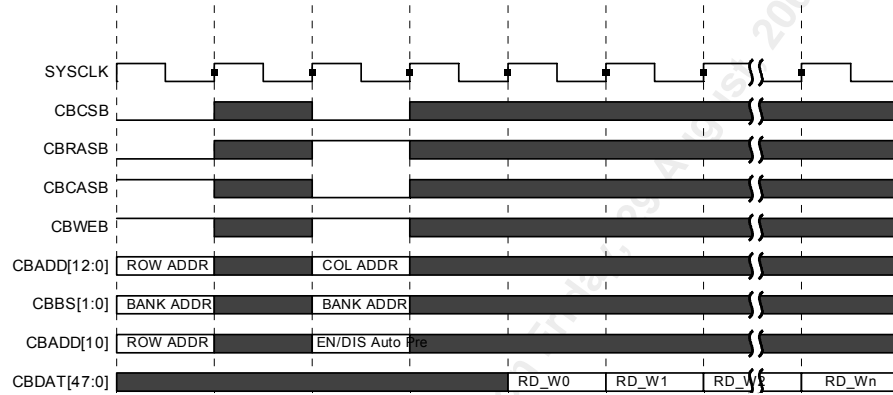

**Figure 51 Write Timing Re-Sequencing Memory**

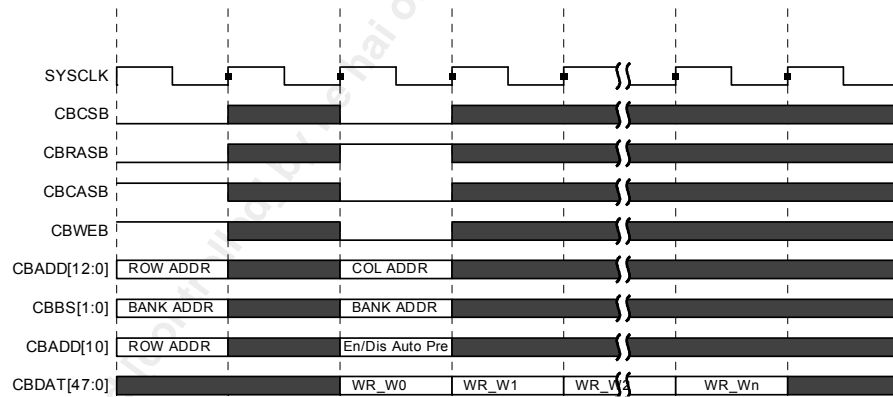

## 14.8 Chunk Buffer SDRAM Interface

The following two diagrams depict the timing for signals destined for the pins of the Chunk Buffer SDRAM during the Activate-Read (with Auto-precharge), and Activate-Write (with Auto-precharge) sequences.

**Figure 52 Read Timing for Chunk Buffer Memory**

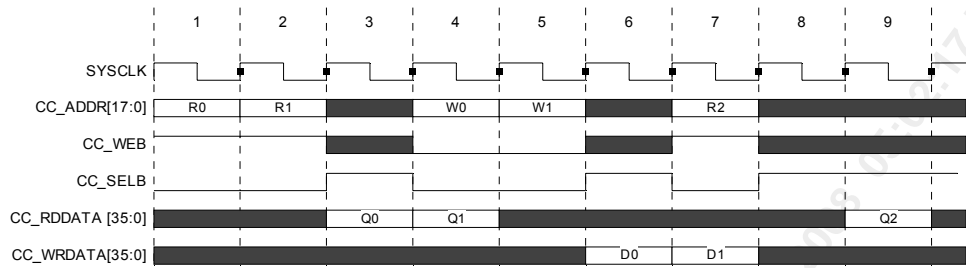

**Figure 53 Write Timing for Chunk Buffer Memory**

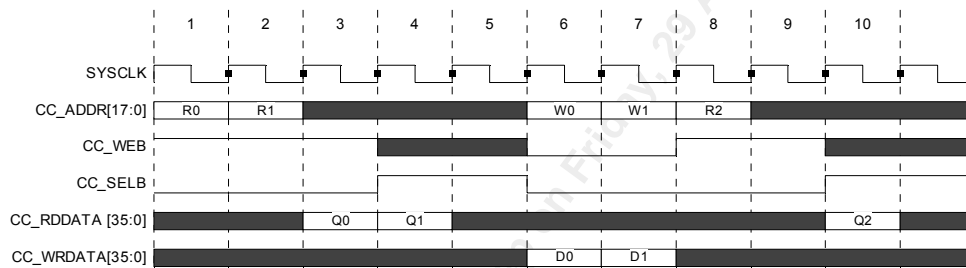

## 14.9 Context SSRAM Interface (ZBT SSRAM mode)

The following diagrams depict the timing for the pipelined ZBT SSRAM and Standard SSRAM during a read followed by a write cycle.

**Figure 54 Read Followed by Write Timing for ZBT Mode**

**Figure 55 Read Followed by Write Timing for Standard SSRAM Mode**

## 14.10 Microprocessor Interface

The following diagrams illustrate the various handshaking required for microprocessor reads and writes.

Figure 56 shows a single read and write operation to the non-burstable register space with bus polarity set to 1. On the first cycle, BURSTB is sampled inactive; therefore, it is expected that the cycle is a single data transfer, and the BLAST signal is of no significance. The subsequent 2 cycles have BURSTB sampled active hence the transfer cycle is terminated when both BLAST and READYB are asserted. Note that between each transfer, there is a turn around cycle provided by the external interface to ensure that there is no bus contention on back to back transfers on the AD bus.

**Figure 56 Read and Write to Non-burstable Register Space**

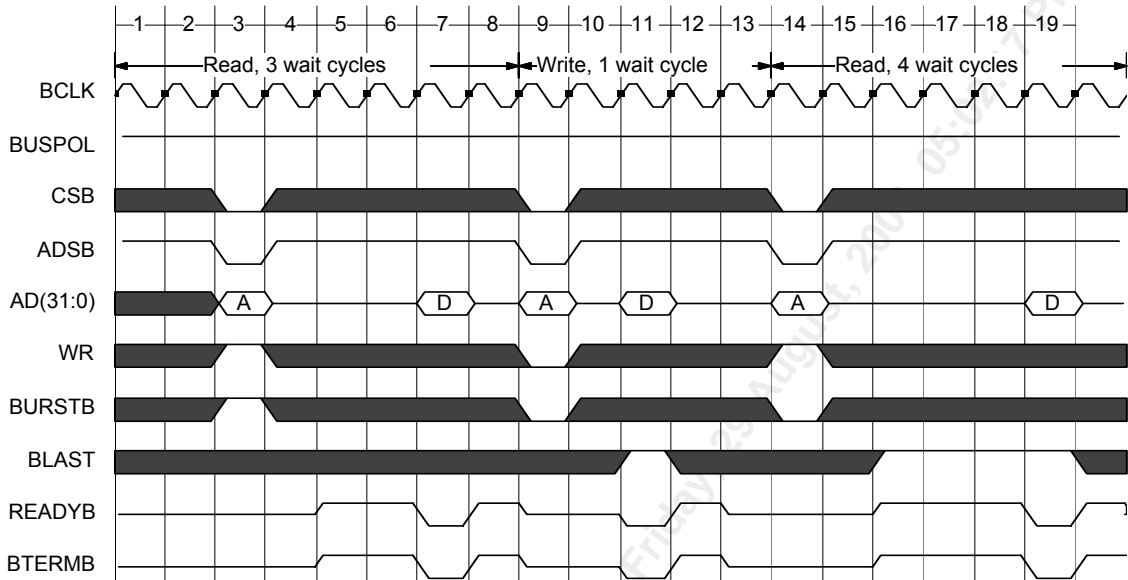

Figure 57 shows a burst read and write operation (only valid for burstable registers) with bus polarity set to 0. The first and third accesses illustrate transfers that are terminated by the FREEDM 32A1024L via the assertion of BTERMB. The second and fourth accesses illustrate transfers that are terminated by the external interface via the assertion of BLAST. Note that between each transfer, there is no turn around cycle. Care must be taken to examine the AC timing to ensure that there is no bus contention on the AD bus between a read followed by a write transfer. BTERMB is only asserted when the burst access is 4 cycles long. It is not asserted if the burst cycle is terminated by BLAST or for non-burst accesses (BURSTB=1).

**Figure 57 Read and Write to Burstable Address Space**

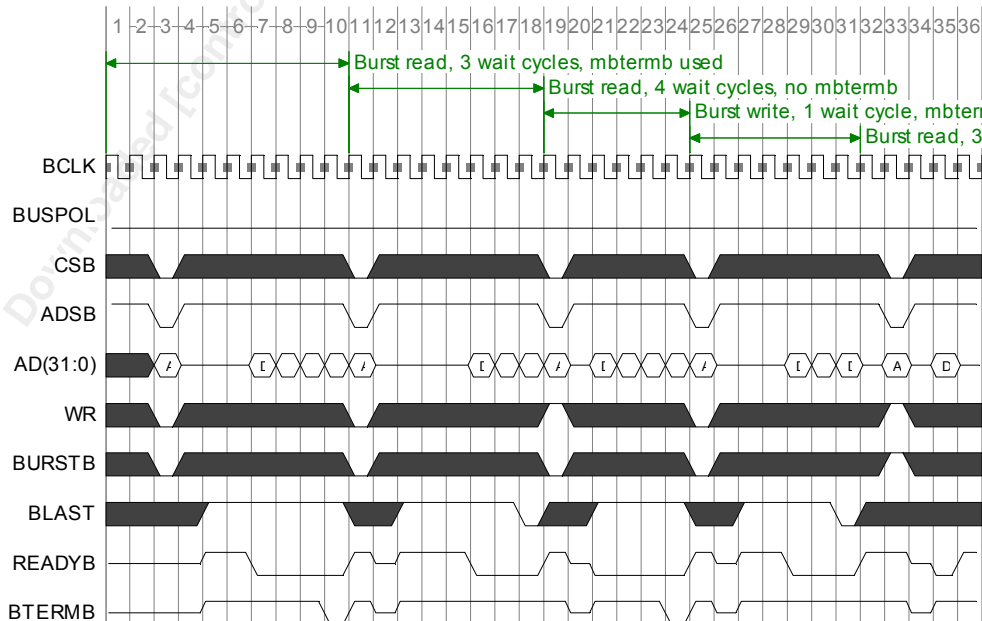

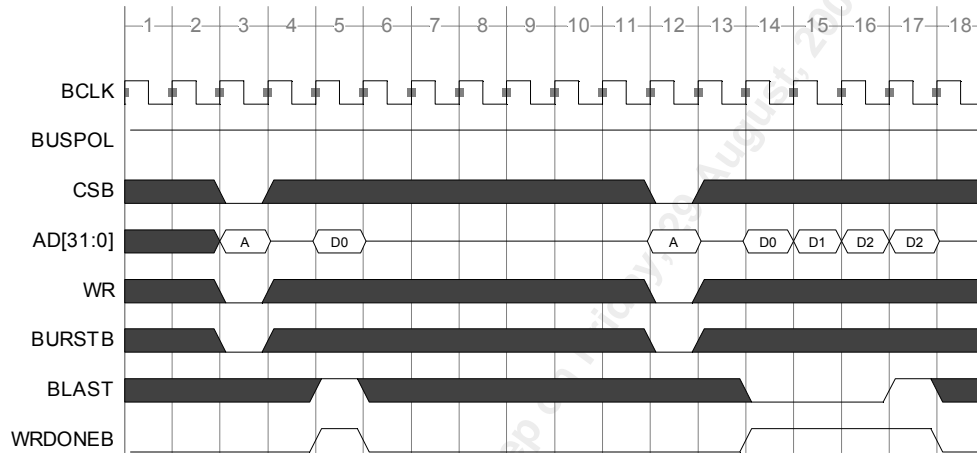

Figure 58 shows consecutive write operations using the WRDONEB signal without the READYB. Write operations may only begin when WRDONEB is sampled low by the external interface. On the first data transfer, the cycle is terminated normally. Subsequent access does not begin until WRDONEB is sampled low by the external interface. This interface is used when the external processor is incapable of dealing with wait states during write

**Figure 58 Consecutive Write Accesses Using WRDONEB**

## 15 Absolute Maximum Ratings

Maximum ratings are the worst-case limits that the device can withstand without sustaining permanent damage. They are not indicative of normal operating conditions.

**Table 49 FREEDM 32A1024L Absolute Maximum Ratings**

Storage Temperature	-40°C to +125°C
Supply Voltage (+3.3 Volt $V_{DD3.3}$ )	-0.3V to +4.6V
Supply Voltage (+1.8 Volt $V_{DD1.8}$ )	-0.3V to +2.5 V
Voltage on Any Pin	-0.3V to $V_{DD3.3} + 0.3V$
Static Discharge Voltage	$\pm 1000$ V
Latch-Up Current	$\pm 100$ mA
DC Input Current	$\pm 20$ mA
Lead Temperature	+230°C
Absolute Maximum Junction Temperature	+120° C

## 16 Normal Operating Conditions

Unless otherwise specified, all DC and AC specifications in this data sheet are valid for the following voltage and temperature ranges. These ranges show the typical VDD per supply, for the major operating modes, with outputs loaded, for vector sets and/or boards functioning normally.

**Table 50 Normal Operating Conditions**

	Operating Range <sup>1</sup>		Typical <sup>2</sup>
<b>Operating Temperature</b>	T <sub>A</sub> = -40 °C to T <sub>A</sub> =85 °C		T <sub>J</sub> = 60 °C
<b>Supply Voltages</b>	<b>Minimum (V)</b>	<b>Typical (V)</b>	<b>Maximum (V)</b>
1.8V Supply Voltage (V <sub>DD1.8</sub> )	1.71	1.80	1.94
3.3V Supply Voltage (V <sub>DD3.3</sub> )	3.0	3.3	3.6

**Notes**

1. Power supply, D.C. characteristics, and A.C. timing are characterized across these operating ranges, unless otherwise stated
2. Where typical measurements are given, these parameter values will be used, unless otherwise stated

Downloaded [controlled] by he hai of neiep on Friday, 29 Jun 2018 05:11 PM

## 17 Power Information

### 17.1 Power Requirements

**Table 51 Power Requirements**

Conditions	Parameter	Typ <sup>1,3</sup>	High <sup>4</sup>	Max <sup>2</sup>	Units
32 T1/E1 Operation	IDDOP (1.8V)	0.78	0.85	—	A
	IDDOP (3.3 V)	0.07	0.08	—	A
	Total Power	1.64	1.94	—	W

**Notes:**

1. Typical IDD values are calculated as the mean value of current under the following conditions: typically processed silicon, nominal supply voltage, T<sub>J</sub>=60 °C, outputs loaded with 30 pF (if not otherwise specified), and a normal amount of traffic or signal activity. These values are suitable for evaluating typical device performance in a system
2. Max IDD values are currents guaranteed by the production test program and/or characterization over process for operating currents at the maximum operating voltage and operating temperature that yields the highest current (including outputs loaded to 30 pF, unless otherwise specified)
3. Typical power values are calculated using the formula:

$$\text{Power} = \sum_i (\text{VDDNomi} \times \text{IDDTypi})$$

Where i denotes all the various power supplies on the device, VDDNomi is the nominal voltage for supply i, and IDDTypi is the typical current for supply i (as defined in note 1 above). These values are suitable for evaluating typical device performance in a system

4. High power values are a “normal high power” estimate and are calculated using the formula:

$$\text{Power} = \sum_i (\text{VDDMaxi} \times \text{IDDHighi})$$

Where i denotes all the various power supplies on the device, VDDMaxi is the maximum operating voltage for supply i, and IDDHighi is the current for supply i. IDDHigh values are calculated as the mean value plus two sigmas (2σ) of measured current under the following conditions: T<sub>J</sub>=105° C, outputs loaded with 30 pF (if not otherwise specified). These values are suitable for evaluating board and device thermal characteristics

### 17.2 Power Sequencing

Due to ESD protection structures in the pads it is necessary to exercise caution when powering a device up or down. ESD protection devices behave as diodes between power supply pins and from I/O pins to power supply pins. Under extreme conditions, incorrect power sequencing may damage these ESD protection devices or trigger latch up.

The recommended power supply sequencing is as follows:

1. VDD<sub>3,3</sub> power must be supplied either before VDD<sub>1,8</sub> or simultaneously with VDD<sub>1,8</sub>.
2. I/Os get driven after all the supplies have been powered. Otherwise, the I/Os must be current limited to 20 mA.
3. Power down the device in the reverse sequence.

### 17.3 Power Supply Filtering

Ferrite beads are not advisable in digital switching circuits because inductive spiking ( $di/dt$  noise) is introduced into the power rail. Simple RC filtering is probably the best approach provided care is taken to ensure the IR drop in the resistance does not lower the supply voltage below the recommended operating voltage.

## 18 D.C. Characteristics

Table 52 FREEDM 32A1024L D.C. Characteristics

Symbol	Parameter	Min	Typ	Max	Units	Conditions
V <sub>IL</sub>	Input Low Voltage	-0.3		0.8	Volts	
V <sub>IH</sub>	Input High Voltage	2.0		V <sub>DD3,3</sub> + 0.3	Volts	
V <sub>OL</sub>	Output or Bi-directional Low Voltage			0.4	Volts	I <sub>OL</sub> = -9 mA for all outputs except TDO where I <sub>OL</sub> = -6 mA, and AD[31:0], READYB, BTERMB, WRDONEB where I <sub>OL</sub> = -12 mA. Note 3.
V <sub>OH</sub>	Output or Bi-directional High Voltage	2.4			Volts	I <sub>OH</sub> = 9 mA for all outputs except TDO where I <sub>OH</sub> = 6 mA, and AD[31:0], READYB, BTERMB, WRDONEB where I <sub>OH</sub> = 12 mA. Note 3.
I <sub>ILPU</sub>	Input Low Current	+10	+150	+200	μA	V <sub>IL</sub> = GND, Notes 1, 3, 5.
I <sub>IHPU</sub>	Input High Current	-10	0	+10	μA	V <sub>IH</sub> = VDD, Notes 1, 3
I <sub>IL</sub>	Input Low Current	-10	0	+10	μA	V <sub>IL</sub> = GND, Notes 2, 3
I <sub>IH</sub>	Input High Current	-10	0	+10	μA	V <sub>IH</sub> = VDD, Notes 2, 3
C <sub>IN</sub>	Input Capacitance		5		pF	Excludes package. Package typically 2 pF. Note 5.
C <sub>OUT</sub>	Output Capacitance		5		pF	All pins. Excludes package. Package typically 2 pF. Note 5.
C <sub>IO</sub>	Bi-directional Capacitance		5		pF	All pins. Excludes package. Package typically 2 pF. Note 5.
L <sub>PIN</sub>	Pin Inductance		2		nH	All pins. Note 5.

**Notes on D.C. Characteristics:**

1. Input pin or bi-directional pin with internal pull-up resistor.
2. Input pin or bi-directional pin without internal pull-up resistor.
3. Negative currents flow into the device (sinking), positive currents flow out of the device (sourcing).
4. Input pin or bi-directional pin with internal pull-down resistor.
5. Typical values are given as a design aid. The product is not tested to the typical values given in the data sheet.

## 19 A.C. Timing Characteristics

### Notes on Input Timing:

1. When a set-up time is specified between an input and a clock, the set-up time is the time in nanoseconds from the 1.4 Volt point of the input to the 1.4 Volt point of the clock.
2. When a hold time is specified between an input and a clock, the hold time is the time in nanoseconds from the 1.4 Volt point of the clock to the 1.4 Volt point of the input.

### Notes on Output Timing:

1. Output propagation delay time is the time in nanoseconds from the 1.4 Volt point of the reference signal to the 1.4 Volt point of the output.
2. Loads used to measure maximum output propagation delays are specified with each table.
3. 0pF load is used to measure minimum output propagation delays.

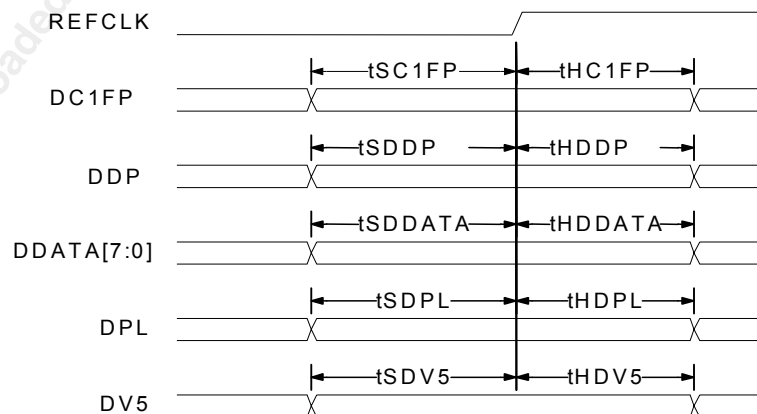

Output tristate delay is the time in nanoseconds from the 1.4 Volt point of the reference signal to the point where the total current delivered through the output is less than or equal to the leakage current transfer.

### 19.1 SBI Bus Interface Timing

**Table 53 REFCLK Timing**

Symbol	Description	Min	Max	Units
f <sub>CLK</sub>	Frequency, REFCLK =77.76MHz (SBI336) OR Frequency, REFCLK =19.44MHz (SBI)	-20	+20	ppm
DCLK	Duty Cycle, REFCLK	40	60	%

**Figure 59 SBI336 Drop Bus Input Interface Timing**

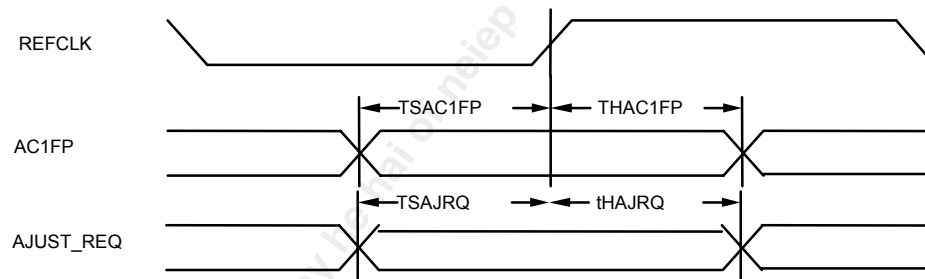

**Table 54 SBI336 Drop Bus Input Timing (Referenced to Figure 59)**

Symbol	Parameter	Min	Max	Units
tSC1FP	REFCLK to Valid DC1FP Set-up Time	2		ns
tHC1FP	REFCLK to Valid DC1FP Hold Time	0		ns
tSDDATA	REFCLK to Valid DDATA Set-up Time	2		ns
tHDDATA	REFCLK to Valid DDATA Hold Time	0.3		ns
tSDPL	REFCLK to Valid DPL Set-up Time	2		ns
tHDPL	REFCLK to Valid DPL Hold Time	0.3		ns
tSDV5	REFCLK to Valid DV5 Set-up Time	2		ns
tHDV5	REFCLK to Valid DV5 Hold Time	0.3		ns
tSDDP	REFCLK to Valid DDP Set-up Time	2		ns
tHDDP	REFCLK to Valid DDP Hold Time	0.3		ns

## 19.2 SBI Add Bus Interface Timing

**Figure 60 SBI336 Add Bus Input Interface Timing**

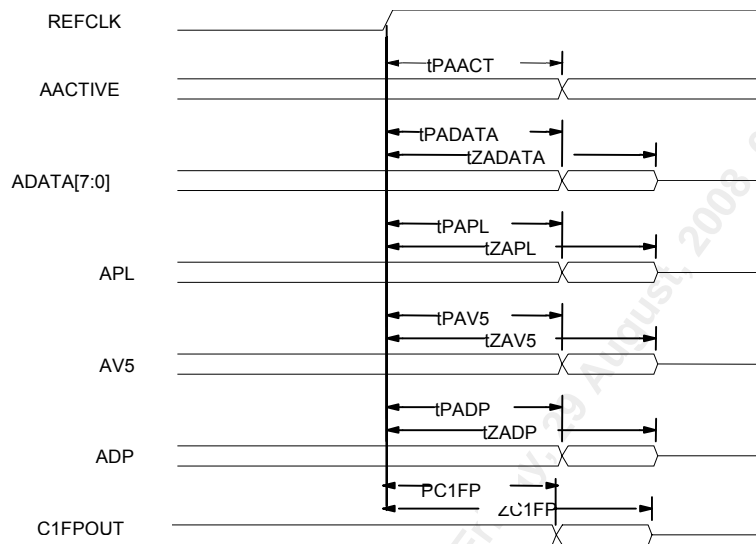

**Table 55 SBI336 Add Bus Input Timing (Referenced to Figure 60 )**

Symbol	Parameter	Min	Max	Units
TSAC1FP	REFCLK to Valid AC1FP Set-up Time	2		ns
THAC1FP	REFCLK to Valid AC1FP Hold Time	0		ns
TSAJRQ	REFCLK to Valid AJUST_REQ Set-up Time	2		ns
THAJRQ	REFCLK to Valid AJUST_REQ Hold Time	0		ns

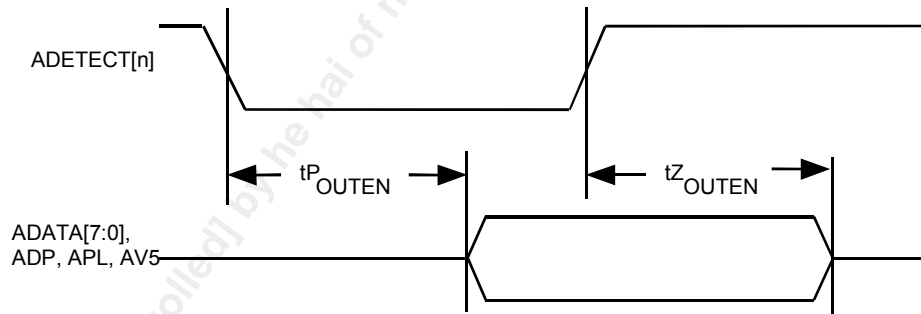

**Notes:**

- Input setup and hold times do not apply to ADETECT[1:0].

**Figure 61 SBI336 Add Bus Output Interface Timing**

**Figure 62 SBI ADD BUS Collision Avoidance Timing**

**Table 56 SBI336 Add Bus Output Timing (Referenced to Figure 61 and Figure 62)**

Symbol	Parameter	Min	Max	Units
tPAACT	REFCLK Edge to AACTIVE Prop Delay	1	8	ns
tPADATA	REFCLK Edge to ADATA Prop Delay	1	8.3	ns
tZADATA	REFCLK Edge to ADATA Output Tri-state (see note 3)	1	9	ns
tPAPL	REFCLK Edge to APL Prop Delay	1	8	ns
tZAPL	REFCLK Edge to APL Output Tri-state (see note 3)	1	9	ns
tPAV5	REFCLK Edge to AV5 Prop Delay	1	8.3	ns
tZAV5	REFCLK Edge to AV5 Output Tri-state (see note 3)	1	9	ns
tPADP	REFCLK Edge to ADP Prop Delay	1	8	ns
tZADP	REFCLK Edge to ADP Output Tri-state (see note 3)	1	9	ns
TPC1FP	REFCLK Edge to C1FPOUT Prop Delay	1	9	ns
TPOUTEN	ADETECT[1] and ADETECT[0] low to All SBI ADD BUS Outputs (except AACTIVE) Valid	2	13	ns

Symbol	Parameter	Min	Max	Units
TZOUTEN	ADETECT[1] or ADETECT[0] high to All SBI ADD BUS Outputs (except AACTIVE) Tristate	2	13	ns

**Notes:**

1. Although the AJUST\_REQ is referenced to the Drop bus DC1FP alignment the timing from REFCLK is independent of the Add or Drop side of the SBI336 bus.
2. Maximum output propagation delays are measured with a 50pF load on the outputs except C1FPOUT, which is measured with a 100pF load.
3. This number is only relevant when the DEFAULT\_DRV register bit in SBI ADD BUS Master Configuration register is low indicating the bus is not always driven.

## 19.3 Any-PHY Timing

**Table 57 Any-PHY Level 2 Interface (Figure 63 and Figure 64)**

Symbol	Description	Min	Max	Units
	RXCLK Frequency	25	52	MHz
	RXCLK Duty Cycle	40	60	%
	TXCLK Frequency	25	52	MHz
	TXCLK Duty Cycle	40	60	%
tSAPPI	All APPI Input Set-up time to RXCLK, TXCLK	4		ns
tHAPPI	All APPI Input Hold time to RXCLK, TXCLK	1.1		ns
tPAPPI	RXCLK, TXCLK to all APPI Outputs Valid	1	12	ns
tZAPPI	RXCLK, TXCLK to APPI Outputs Tristate	1	12	ns
tZDAPPI	RXCLK, TXCLK to APPI Outputs Driven	0		ns

**Notes:**

- Maximum output propagation delays are measured with a 50pF load on the output.

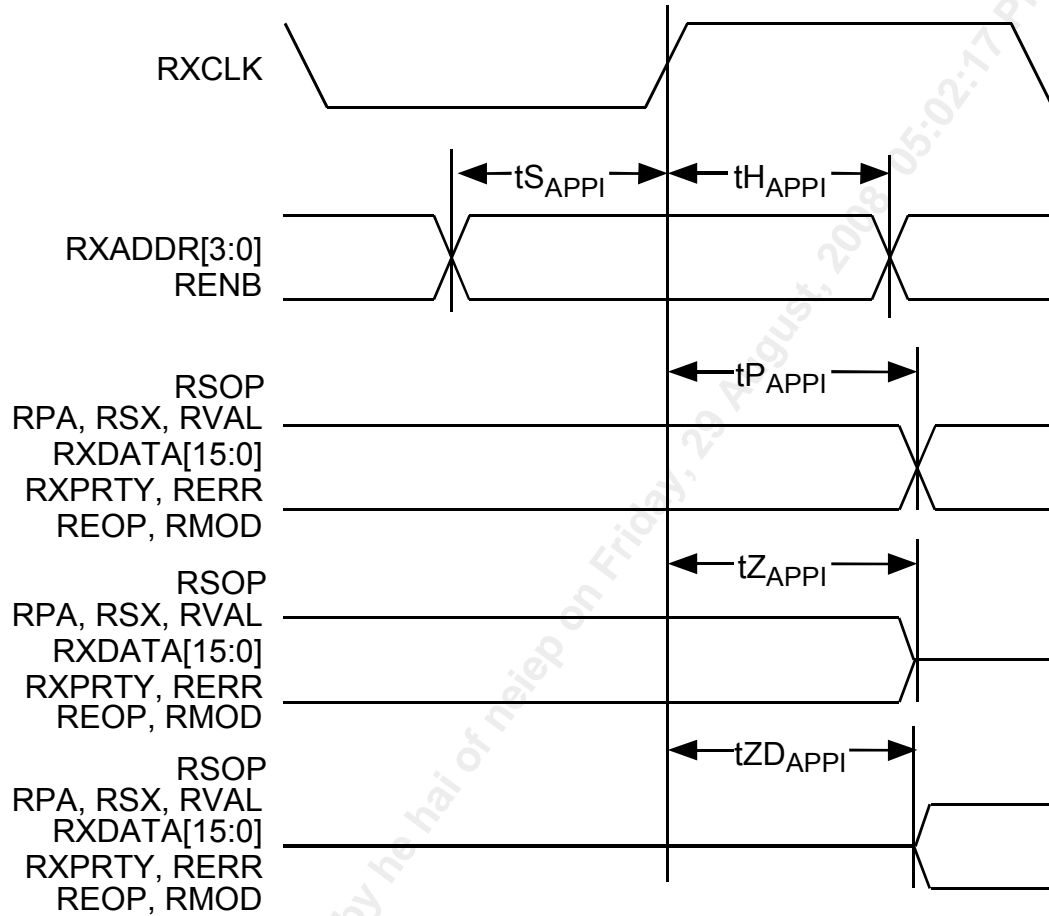

**Table 58 Any-PHY Level 3 Interface (Figure 63 and Figure 64)**

Symbol	Description	Min	Max	Units
	RXCLK Frequency	52	104	MHz
	RXCLK Duty Cycle	40	60	%
	TXCLK Frequency	52	104	MHz
	TXCLK Duty Cycle	40	60	%
tSAPPI	All APPI Input Set-up time to RXCLK, TXCLK	2		ns
tHAPPI	All APPI Input Hold time to RXCLK, TXCLK	1.1		ns
tPAPPI	RXCLK, TXCLK to all APPI Outputs Valid	1.1	6.5	ns

**Notes:**

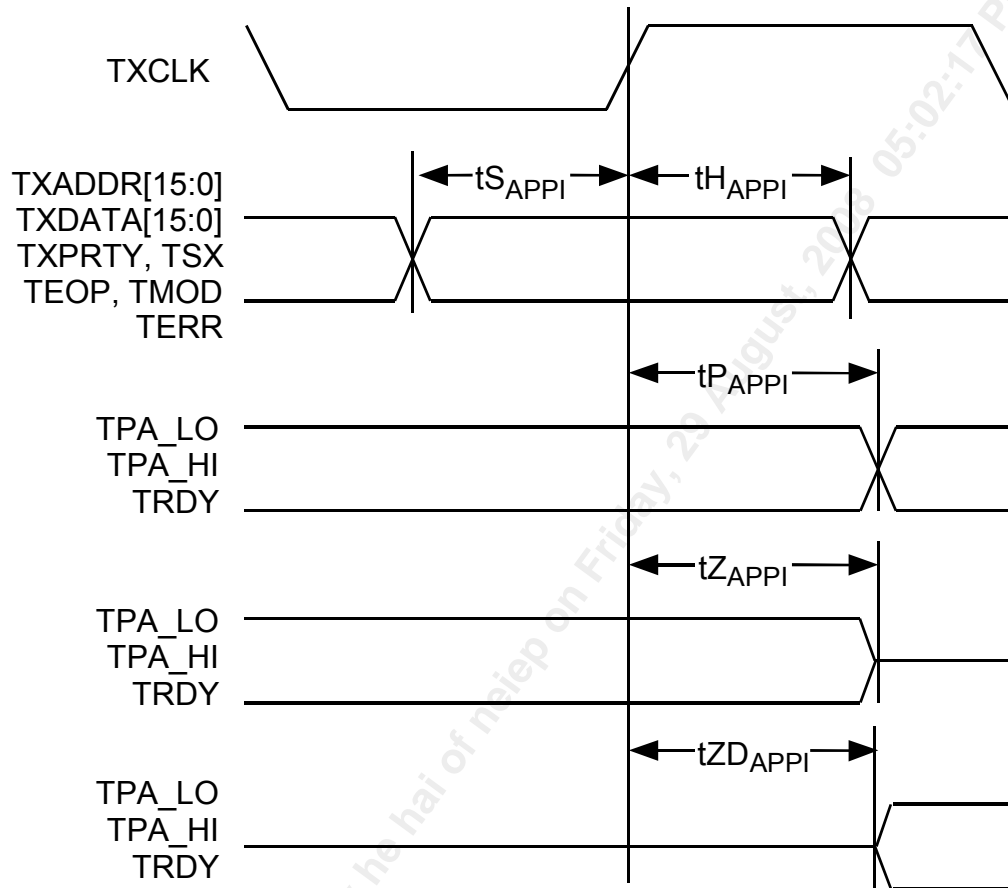

- Maximum output propagation delays are measured with a 20pF load on the output.

Figure 64 Transmit Any-PHY Interface Timing

## 19.4 Microprocessor Timing

Table 59 Microprocessor Interface (Figure 65)

Symbol	Description	Min	Max	Units
f <sub>CLK</sub>	Frequency, BCLK	33	66	MHz
D <sub>CLK</sub>	Duty Cycle, BCLK	40	60	%
T <sub>s</sub>	Input Set-up time to BCLK	4.0		ns
T <sub>h</sub>	Input Hold time to BCLK	1.1		ns
T <sub>p</sub>	BCLK High to Output Valid	2.0	9.5	ns
T <sub>z</sub>	BCLK High to Output High-Impedance	2.0	9.5	ns
T <sub>zb</sub>	BCLK High to Output Driven	2.0		ns

**Notes:**

1. Maximum output propagation delays are measured with a 50pF load on the output.
2. Input setup and hold times do not apply to BUSPOL.
3. Output Valid delays do not apply to INTHIB and INTLOB.

Figure 65 Synchronous I/O Timing

## 19.5 Memory Timing

Table 60 SYSCLK Timing

Symbol	Description	Min	Max	Units
fCLK	Frequency, SYSCLK	90	100	MHz
DCLK	Duty Cycle, SYSCLK	40	60	%

Table 61 Resequencing SDRAM Interface (Figure 65)

Symbol	Description	Min	Max	Units
Ts	Input Set-up time to SYSCLK	2.5		ns
Th	Input Hold time to SYSCLK	0		ns
Tp	SYSCLK High to Output Valid	0.5	6.0	ns
Tz	SYSCLK High to Output High-Impedance	0.5	6.0	ns

**Notes:**

1. Maximum output propagation delays are measured with a 30pF load on the output.
2. Output Valid delay does not apply to DQM.

Table 62 Chunk Buffer SDRAM Interface (Figure 65)

Symbol	Description	Min	Max	Units
Ts	Input Set-up time to SYSCLK	2.5		ns
Th	Input Hold time to SYSCLK	0		ns
Tp	SYSCLK High to Output Valid	0.5	6.0	ns
Tz	SYSCLK High to Output High-Impedance	0.5	6.0	ns

**Notes:**

- Maximum output propagation delays are measured with a 30pF load on the output.

Table 63 Connection Context Memory SSRAM Interface (Figure 65)

Symbol	Description	Min	Max	Units
Ts	Input Set-up time to SYSCLK	3.5		ns
Th	Input Hold time to SYSCLK	0		ns

Symbol	Description	Min	Max	Units
Tp	SYSCLK High to Output Valid	0.5	6.5	ns
Tz	SYSCLK High to Output High-Impedance	0.5	6.5	ns
Tzb	SYSCLK High to Output Driven	0.5		ns

**Notes:**

- Maximum output propagation delays are measured with a 20pF load on the output.

## 19.6 JTAG Timing

**Table 64 JTAG Port Interface (Figure 66)**

Symbol	Description	Min	Max	Units
	TCK Frequency		1	MHz
	TCK Duty Cycle	40	60	%
t <sub>S</sub> TMS	TMS Set-up time to TCK	50		ns
t <sub>H</sub> TMS	TMS Hold time to TCK	50		ns
t <sub>S</sub> TDI	TDI Set-up time to TCK	50		ns
t <sub>H</sub> TDI	TDI Hold time to TCK	50		ns
t <sub>P</sub> TDO	TCK Low to TDO Valid	2	50	ns

**Notes:**

- Maximum output propagation delays are measured with a 50pF load on the output.

**Figure 66 JTAG Port Interface Timing**

## 20 Thermal Information

### 20.1 Central Office Environment – No Heatsink

This product is designed to operate over a wide temperature range and is suited for central office equipment<sup>1</sup>.

**Table 65 Central Office Thermal Information**

Maximum long-term operating junction temperature ( $T_J$ ) to ensure adequate long-term life	105°C
Maximum junction temperature ( $T_J$ ) for short-term excursions with guaranteed continued functional performance <sup>2</sup> . This condition will typically be reached when local ambient reaches 70 °C.	125°C
Minimum ambient temperature ( $T_A$ )	-5°C

**Table 66 Thermal Resistance vs. Air Flow<sup>3</sup>**

Airflow	Natural Convection	200 LFM	400 LFM
$\theta_{JA}$ (°C/W)	10.68	7.39	6.63

**Table 67 Device Compact Model<sup>4</sup>**

Junction-to-Top Thermal Resistance, $\theta_{JT}$	0.25°C/W
Junction-to-Board Thermal Resistance, $\theta_{JB}$	4.5 °C/W

Power depends upon the operating mode. To obtain power information, refer to ‘High’ power values in section 17.1 Power Requirements.

#### Notes

1. The minimum ambient temperature requirement for Central Office Equipment approximates the minimum ambient temperature requirement for Commercial Equipment
2. Short-term is used as defined in Telcordia Technologies Generic Requirements GR-63-Core Core; for more information about this standard, see [3]
3.  $\theta_{JA}$  is the total junction to ambient thermal resistance as measured according to JEDEC Standard JESD51 (2S2P); for more information about this standard, see [4.1]
4.  $\theta_{JB}$ , the junction-to-board thermal resistance, is obtained by simulating conditions described in JEDEC Standard JESD 51-8 (for more information about this standard, see [2]) and  $\theta_{JT}$ , the junction-to-top thermal resistance, is obtained by simulating conditions described in SEMI Standard G30-88 (for more information about this standard, see [4])

## 20.2 Outside Plant Environment

This product is designed to operate over a wide temperature range when used with a heat sink and is suited for outside plant equipment<sup>1</sup>.

**Table 68 Outside Plant Thermal Information**

Maximum long-term operating junction temperature ( $T_J$ ) to ensure adequate long-term life.	105°C
Maximum junction temperature ( $T_J$ ) for short-term excursions with guaranteed continued functional performance <sup>2</sup> . This condition will typically be reached when the local ambient temperature reaches 85 °C.	125°C
Minimum ambient temperature ( $T_A$ )	-40°C

**Table 69 Device Compact Model<sup>3</sup>**

Junction-to-Case Thermal Resistance, $\theta_{JC}$	0.25°C/W
Junction-to-Board Thermal Resistance, $\theta_{JB}$	4.5 °C/W

**Table 70 Heat Sink Requirements**

$\theta_{SA} + \theta_{CS}$ <sup>4</sup>	The sum of $\theta_{SA} + \theta_{CS}$ must be less than or equal to: $[(105 - T_A) / P_D] - \theta_{JC}$ °C/W where: $T_A$ is the ambient temperature at the heat sink location $P_D$ is the operating power dissipated in the package $\theta_{SA}$ and $\theta_{CS}$ are required for long-term operation
--	---

Power depends upon the operating mode. To obtain power information, refer to ‘High’ power values in section 17.1 Power Requirements.

### Notes

1. The minimum ambient temperature requirement for Outside Plant Equipment meets the minimum ambient temperature requirement for Industrial Equipment
2. Short-term is used as defined in Telcordia Technologies Generic Requirements GR-63-Core Core; for more information about this standard, see [3]
3.  $\theta_{JC}$ , the junction-to-case thermal resistance, is a measured nominal value plus two sigma.  $\theta_{JB}$ , the junction-to-board thermal resistance, is obtained by simulating conditions described in JEDEC Standard JESD 51-8; for more information about this standard, see [2]
4.  $\theta_{SA}$  is the thermal resistance of the heat sink to ambient.  $\theta_{CS}$  is the thermal resistance of the heat sink attached material. The maximum  $\theta_{SA}$  required for the airspeed at the location of the device in the system with all components in place

## 21 Mechanical Information
