# TDA7412

CARRADIO SIGNAL PROCESSOR

- 3 STEREO INPUTS
- 3 MONO INPUTS
- DYNAMIC-COMPRESSION-STAGE FOR CD
- SOFTSTEP-VOLUME
- BASS, TREBLE AND LOUDNESS CONTROL
- VOICE-BAND-FILTER
- DIRECT MUTE AND SOFTMUTE
- INTERNAL BEEP
- FOUR INDEPENDENT SPEAKER-OUTPUTS
- STEREO SUBWOOFER OUTPUT
- INDEPENDENT SECOND SOURCE-SELECTOR
- FULL MIXING CAPABILITY
- PAUSE DETECTOR

Stereodecoder:

- RDS MUTE
- NO EXTERNAL ADJUSTMENTS
- AM/FM NOISEBLANKER WITH SEVERAL TRIGGER CONTROLS
- PROGRAMMABLE MULTIPATH DETECTOR
- QUALITY DETECTOR OUTPUT

TQFP44
ORDERING NUMBER: TDA7412
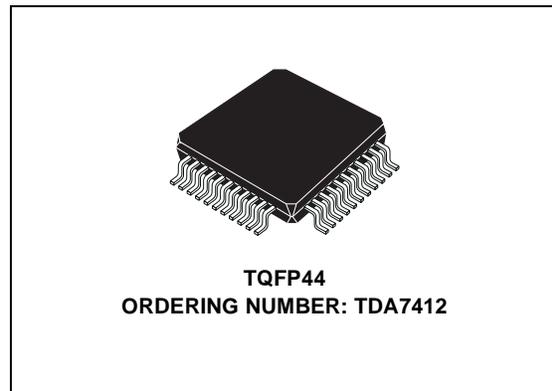

Digital Control:

I^2C-BUS INTERFACE

DESCRIPTION

The device includes a high performance audioprocessor and a stereodecoder-noiseblanker combination with the whole low frequency signal processing necessary for state-of-the-art as well as future carradios. The digital control allows a programming in a wide range of all the filter characteristics. Also the stereodecoder part offers several possibilities of programming especially for the adaptation to different IF-devices.

October 2003

PIN CONNECTION (Top view)

Top pins (left to right): 44 MD2G, 43 MD2, 42 MD1G/SE4L, 41 MD1/SE4R, 40 MUX/PAUSE, 39 CREF, 38 ACOUTL, 37 ACOUTR, 36 SWINL, 35 SWINR, 34 ACINLF

Left pins (top to bottom):
1 SE1L
2 SE1R
3 FD1L+/SE3L
4 FD1L-/SE2L
5 FD1R+/SE3R
6 FD1R-/SE2R
7 FD2L+
8 FD2L-
9 FD2R+
10 FD2R-
11 AM

Right pins (top to bottom):
33 ACINLR
32 ACINRF
31 ACINRR
30 OUTLF
29 OUTLR
28 OUTRF
27 OUTRR
26 OUTSWL
25 OUTSWR
24 OUTSSL
23 OUTSSR

Bottom pins (left to right): 12 AM IF, 13 MPX, 14 LEVEL, 15 MPIN, 16 MPOUT, 17 QUAL, 18 SM, 19 GND, 20 SDA, 21 SCL, 22 VDD

D00AU1131

ESD:

All pins are protected against ESD according to the MIL883 standard.

ABSOLUTE MAXIMUM RATINGS

| Symbol	Parameter	Value	Unit
V_S	Operating Supply Voltage	10.5	V
T_{amb}	Operating Temperature Range	-40 to 85	°C
T_{stg}	Storage Temperature Range	-55 to +150	°C

THERMAL DATA

Symbol	Parameter	Value	Unit

		Stereodecoder + Audioprocessor		55		dB

BLOCK DIAGRAM
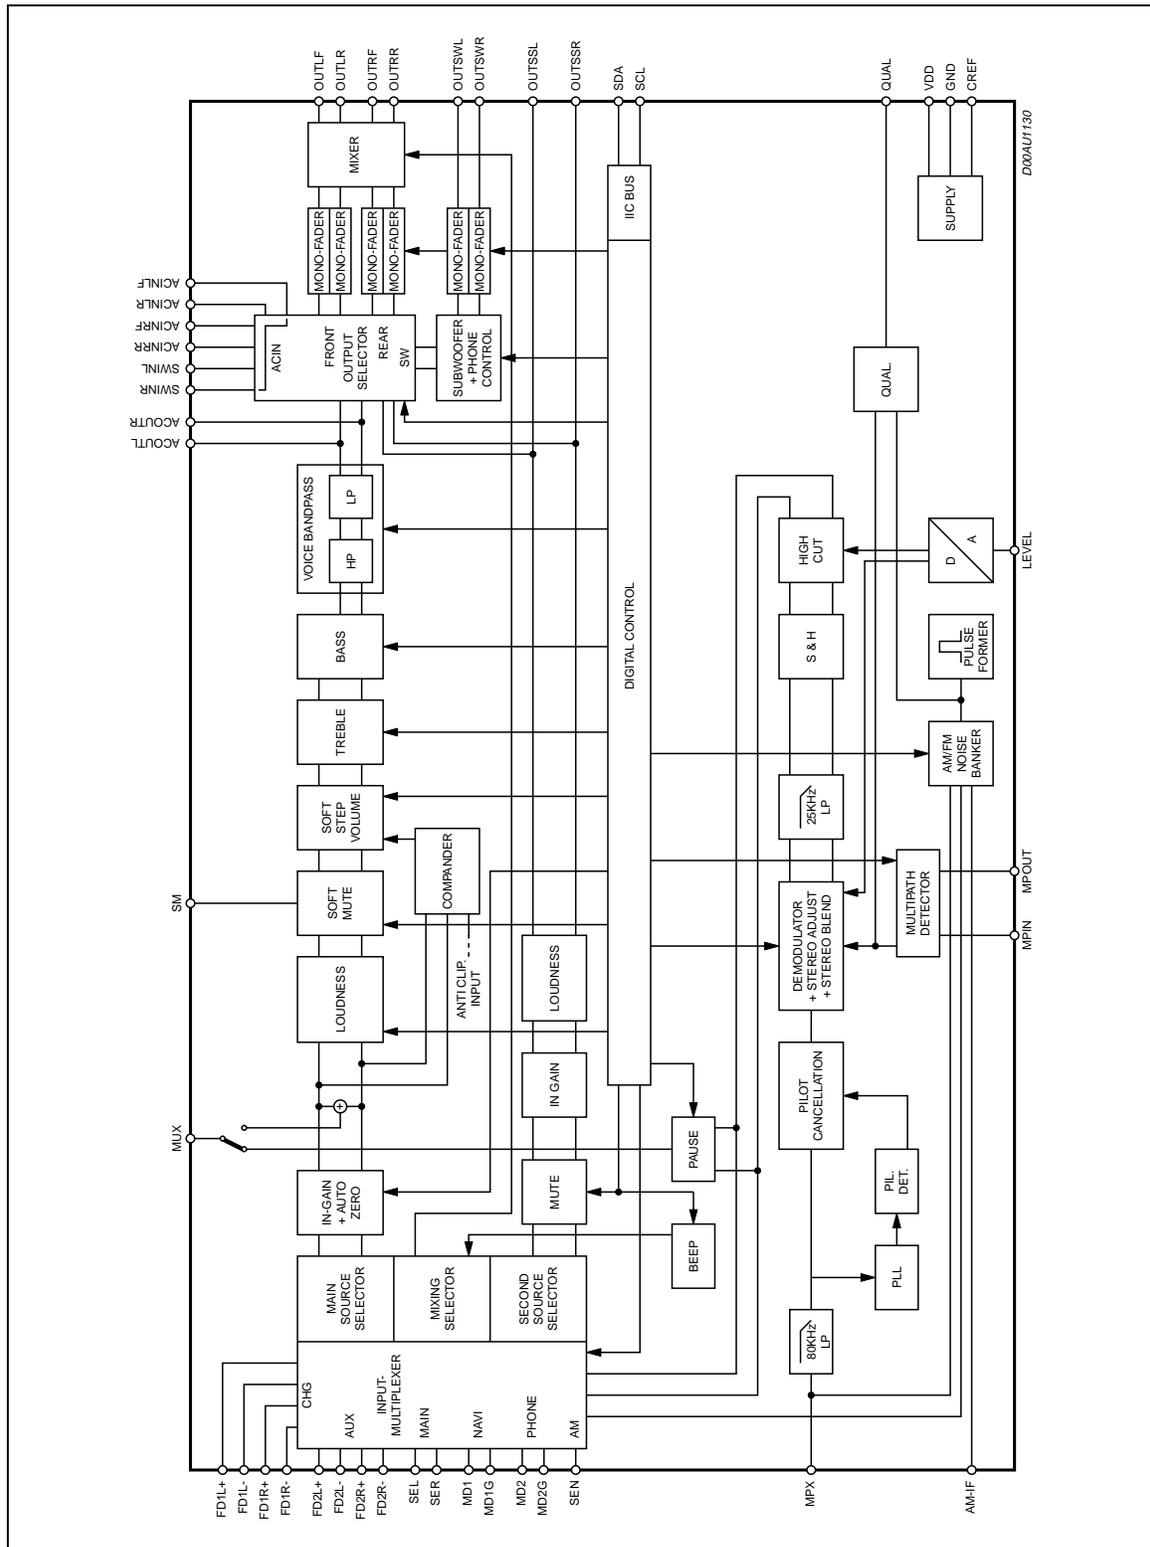

Audioprocessor Part Features:

Input Multiplexer	2 fully differential CD stereo inputs with programmable attenuation
	1 single-ended stereo input
	2 differential mono input
	1 single-ended mono input
	In-Gain 0..15dB, 1dB steps
	internal Offset-cancellation (AutoZero)
	separate second source-selector
Beep	internal Beep with 4 frequencies
Mixing stage	Beep, Phone and Navigation mixable to all speaker-outputs
Loudness	programmable center frequency and frequency response
	15 x 1dB steps
	selectable flat-mode (constant attenuation)
Volume	0.5dB attenuator
	100dB range
	soft-step control with programmable times
Compander	dynamic range compression for use with CD
	2:1 compression rate
	programmable max. gain
Bass	2nd order frequency response
	center frequency programmable in 8 steps
	DC gain programmable
	$\pm$ 15 x 1dB steps
Treble	2nd order frequency response
	center frequency programmable in 4 steps
	$\pm$15 x 1dB steps
Voice Bandpass	2nd order butterworth highpass filter with programmable cut-off frequency
	2nd order butterworth lowpass filter with programmable cut-off frequency
	selectable flat-mode
Speaker	4 independent speaker controls in 1dB steps
	control range 95dB
	separate Mute
Subwoofer	single-ended stereo output
	independent stereo level controls in 1dB steps
	control range 95dB
	separate Mute
Mute Functions	direct mute
	digitally controlled SoftMute with 4 programmable mute-times
Pause Detector	programmable threshold

ELECTRICAL CHARACTERISTICS

V_S = 9V; T_{amb} = 25°C; R_L = 10kΩ; all gains = 0dB; f = 1kHz; unless otherwise specified

1.0 DESCRIPTION OF THE AUDIOPROCESSOR PART

1.1 Input stages

In the basic configuration two full-differential, two mono-differential, one single ended stereo and one single-ended mono input are available. In addition a dedicated input for the stereodecoder MPX-signal is present.

Figure 1. Input-stages
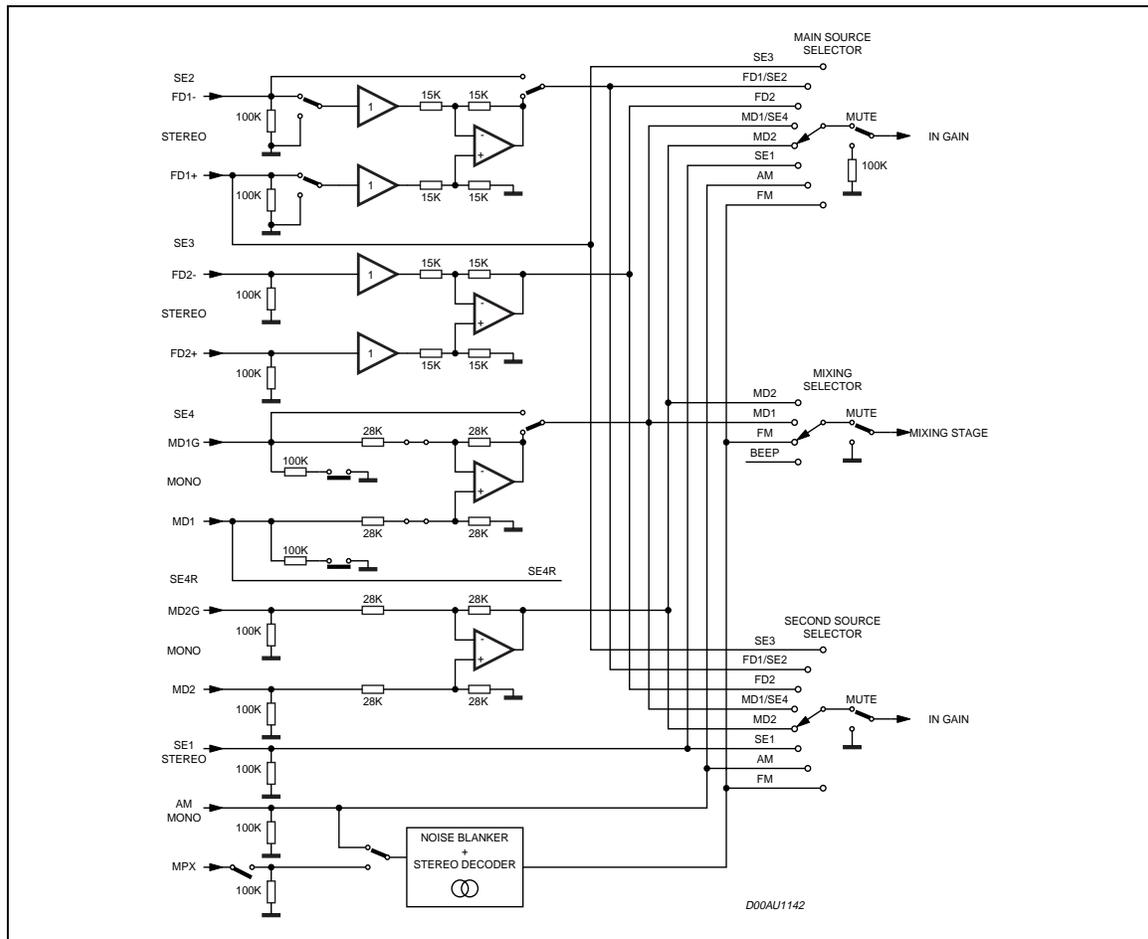

Full-differential stereo Input 1 (FD1)

The FD1-input is implemented as a buffered full-differential stereo stage with 100kΩ input-impedance at each input. The attenuation is programmable in 3 steps from 0 to -12dB in order to adapt the incoming signal level. A 6dB attenuation is included in the differential stage, the additional 6dB are done by a following resistive divider. This input is also configurable as two single-ended stereo inputs (see pin-out).

Full-differential stereo Input 2 (FD2)

The FD2-input has the same general structure as FD1, but with a programmable attenuation of 0 or 6dB embedded in the differential stage.

Mono-differential Input 1 (MD1)

The MD1-input is designed as a basic differential stage with 56kΩ input-impedance. This input is configurable as a single-ended stereo input (see pin-out).

Mono-differential Input 2 (MD2)

The MD2-input has the same topology as MD1, but without the possibility to configure it to single ended.

Single-ended stereo Input (SE1), single-ended mono input (AM) and FM-MPX input

All single ended inputs offer an input impedance of 100kΩ. The AM-pin can be connected by software to the input of the stereo-decoder in order to use the AM-noiseblanker and AM-High-Cut feature.

1.2 AutoZero

The AutoZero allows a reduction of the number of pins as well as external components by canceling any offset generated by or before the In-Gain-stage (Please notice that externally generated offsets, e.g. generated through the leakage current of the coupling capacitors, are not canceled).

The auto-zeroing is started every time the DATA-BYTE 0 is selected and needs max. **0.3ms** for the alignment. To avoid audible clicks the Audioprocessor is muted before the loudness stage during this time. The AutoZero-feature is only present in the main signal-path.

AutoZero for Stereodecoder-Selection

A special procedure is recommended for selecting the stereodecoder at the **main** input-selector to guarantee an optimum offset-cancellation:

(Step 0: SoftMute or Mute the signal-path)

Step 1: Temporary deselect the stereodecoder at all input-selectors

Step 2: Configure the stereodecoder via IIC-Bus

Step 3: Wait 1ms

Step 4: Select the stereodecoder at the main input-selector first

The root cause of this procedure is, that after muting the stereodecoder (Step 1), the internal stereodecoder filters have to settle in order to perform a proper offset-cancellation.

AutoZero-Remain

In some cases, for example if the µP is executing a refresh cycle of the IIC-Bus-programming, it is not useful to start a new AutoZero-action because no new source is selected and an undesired mute would appear at the outputs. For such applications the A679 could be switched in the **AutoZero-Remain-Mode** (Bit 6 of the subaddress-byte). If this bit is set to high, the DATABYTE 0 could be loaded without invoking the AutoZero and the old adjustment-value remains.

1.3 Pause Detector / MUX-Output

The pin number 40(Pause/MUX) is configurable for two different functions:

1. During Pause-Detector OFF this pin is used as a mono-output of the main input-selector. This signal is often used to drive a level-/equalizer-display on the carradio front-panel.

2. During Pause-Detector ON the pin is used to define the time-constant of the detector by an external capacitor. The pause-detector is driven by the internal stereodecoder-outputs in order to use pauses in the FM-signal for alternate-frequency-jumps. If the signal-level of both stereodecoder channels is outside the programmed voltage-window, the external capacitor is abruptly discharged. Inside the pause-condition the capacitor is slowly recharged by a constant current of 25µA. The pause information is also available via IIC-Bus (see IIC-Bus programming).
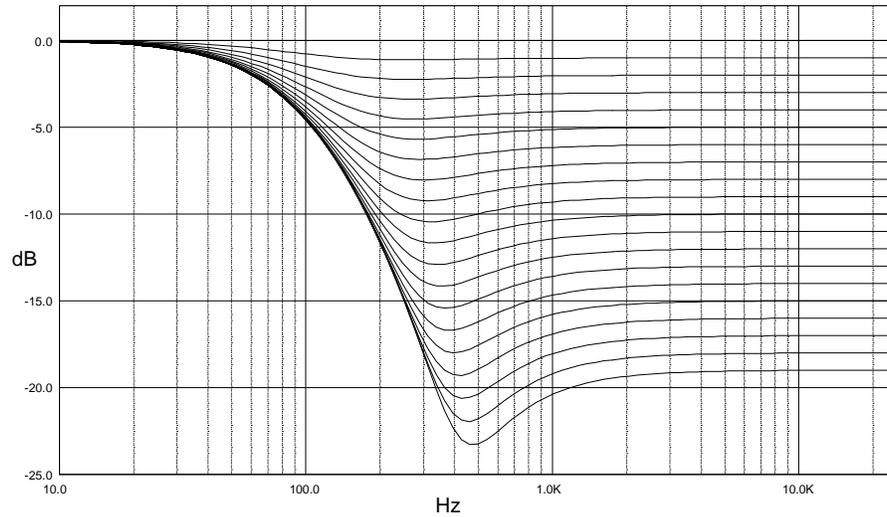

1.4 Loudness

There are four parameters programmable in the loudness stage:

1.4.1 Attenuation

Figure 2 shows the attenuation as a function of frequency at f_P = 400Hz

Figure 2. Loudness Attenuation @ f_P = 400Hz.

1.4.2 Peak Frequency

Figure 3 shows the four possible peak-frequencies at 200, 400, 600 and 800HzFigure 3: Loudness Center frequencies @ Attn. = 15dB
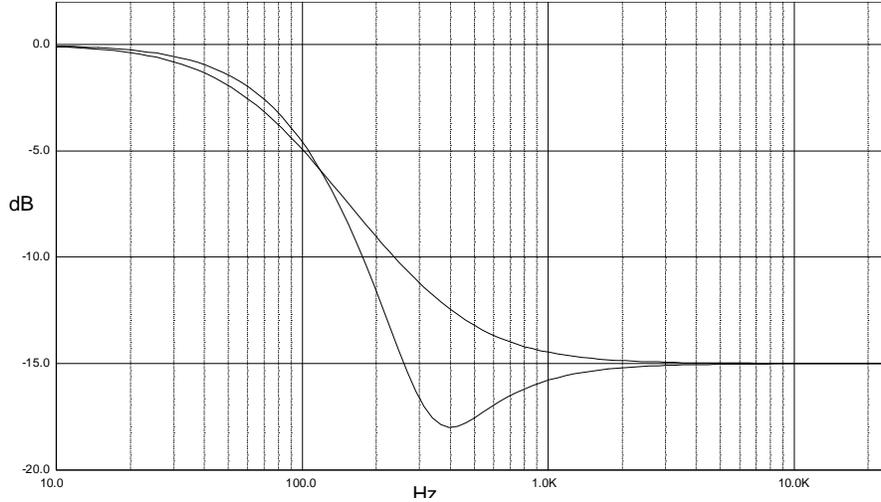

Figure 3. Loudness Center frequencies @ Attn. = 15dB.

1.4.3 Loudness Order

Different shapes of 1st and 2nd-Order Loudness

Figure 4. 1st and 2nd Order Loudness @ Attn. = 15dB, f_P=400Hz

1.4.4 Flat Mode

In flat mode the loudness stage works as a 0dB to -19dB attenuator.

1.5 SoftMute

The digitally controlled SoftMute stage allows muting/demuting the signal with a I^2C-bus programmable slope. The mute process can either be activated by the SoftMute pin or by the I^2C-bus. This slope is realized in a special S-shaped curve to mute slow in the critical regions (see Figure 5).

For timing purposes the Bit0 of the I^2C-bus output register is set to 1 from the start of muting until the end of de-muting.

Figure 5. Softmute-Timing
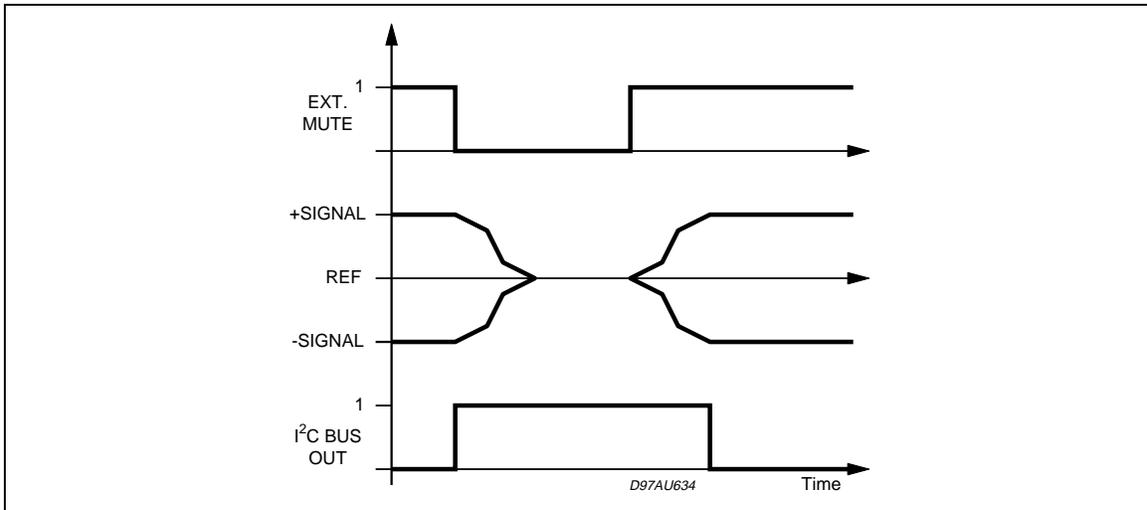

Note: Please notice that a started Mute-action is always terminated and could not be interrupted by a change of the mute -signal.

1.6 SoftStep-Volume and Speaker

When the volume-level is changed audible clicks could appear at the output. The root cause of those clicks could either be a DC-Offset before the volume-stage or the sudden change of the envelope of the audiosignal. With the SoftStep-feature both kinds of clicks could be reduced to a minimum and are no more audible. The blend-time from one step to the next is programmable in four steps.

Figure 6. SoftStep-Timing
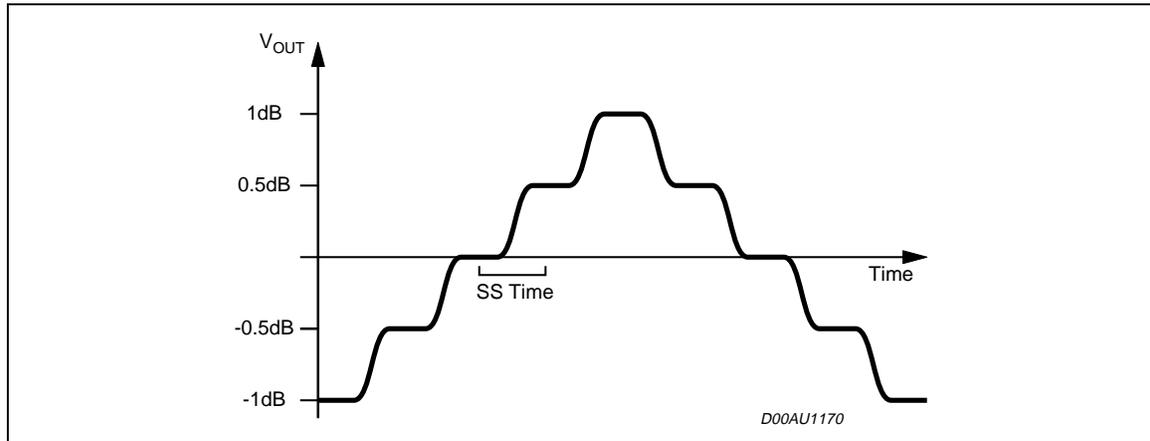

Note: For steps more than 0.5dB (Volume) /1dB (speaker) the SoftStep mode should be deactivated because it could generate a hard 1dB step during the blend-time.

1.7 Bass

There are four parameters programmable in the bass stage:

1.7.1 Attenuation

Figure 7 shows the attenuation as a function of frequency at a center frequency of 80Hz.

Figure 7. Bass Control @ f_C = 80Hz, Q = 1
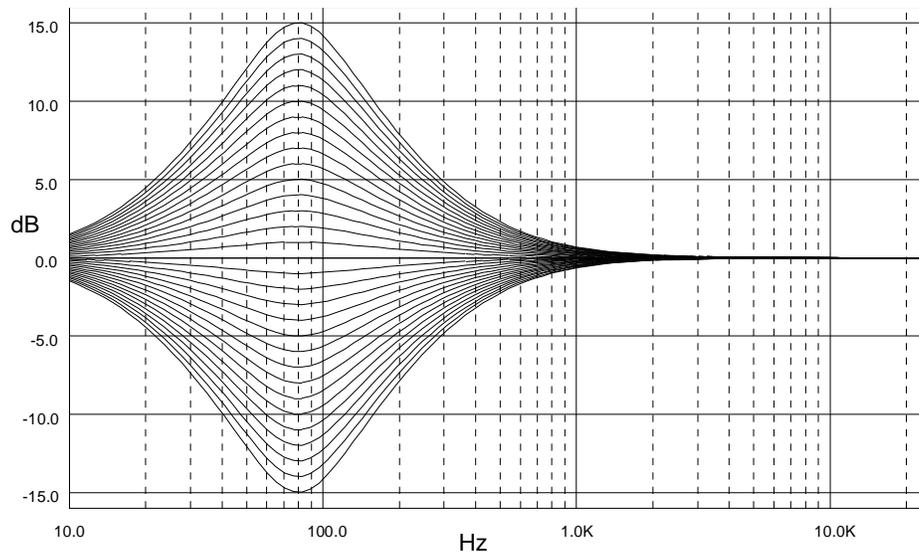

1.7.2 Center Frequency

Figure 8 shows the eight possible center frequencies 60, 70, 80, 90, 100, 130, 150 and 200Hz.

Figure 8. Bass center Frequencies @ Gain = 14dB, Q = 1
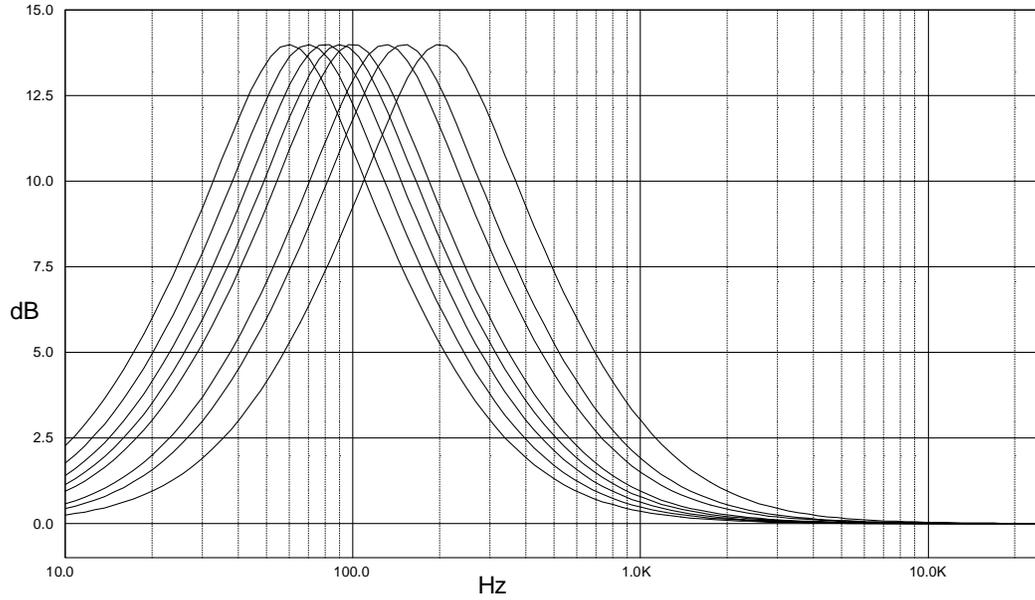

1.7.3 Quality Factors

Figure 9 shows the four possible quality factors 1, 1.25, 1.5 and 2.

Figure 9. Bass Quality factors @ Gain = 14dB, f_C = 80Hz
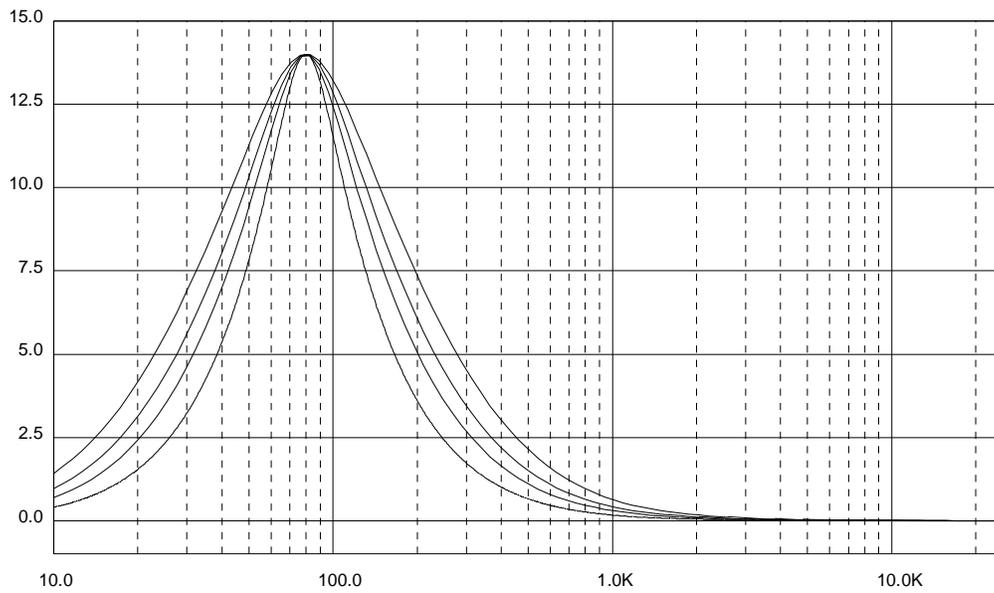

1.7.4 DC Mode

In this mode the DC-gain is increased by 4.4dB. In addition the programmed center frequency and quality factor is decreased by 25% which can be used to reach alternative center frequencies or quality factors.

Figure 10. Bass normal and DC Mode @ Gain = 14dB, f_C = 80Hz
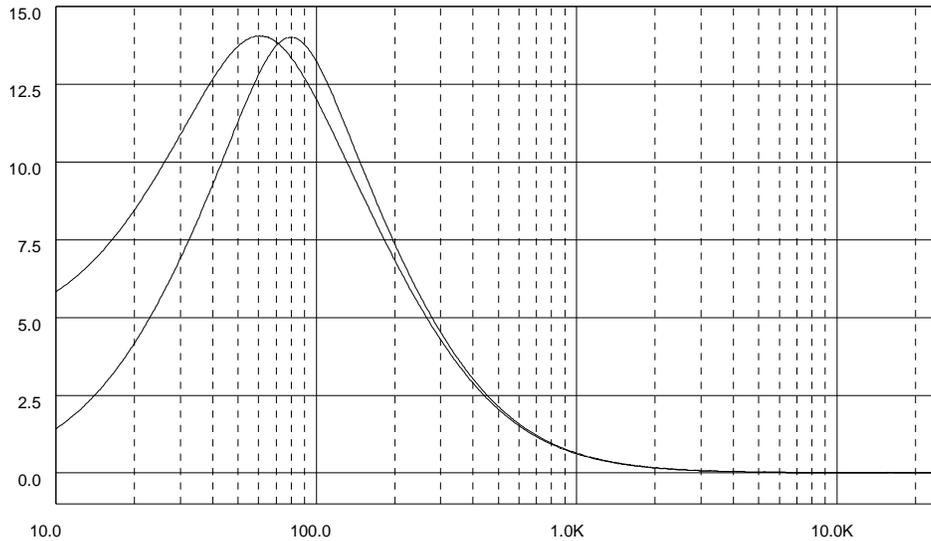

Note: The center frequency, Q and DC-mode can be set fully independently.

1.8 Treble

There are two parameters programmable in the treble stage:

1.8.1 Attenuation

Figure 11 shows the attenuation as a function of frequency at a center frequency of 17.5kHz.

Figure 11. Treble Control @ f_C = 17.5kHz
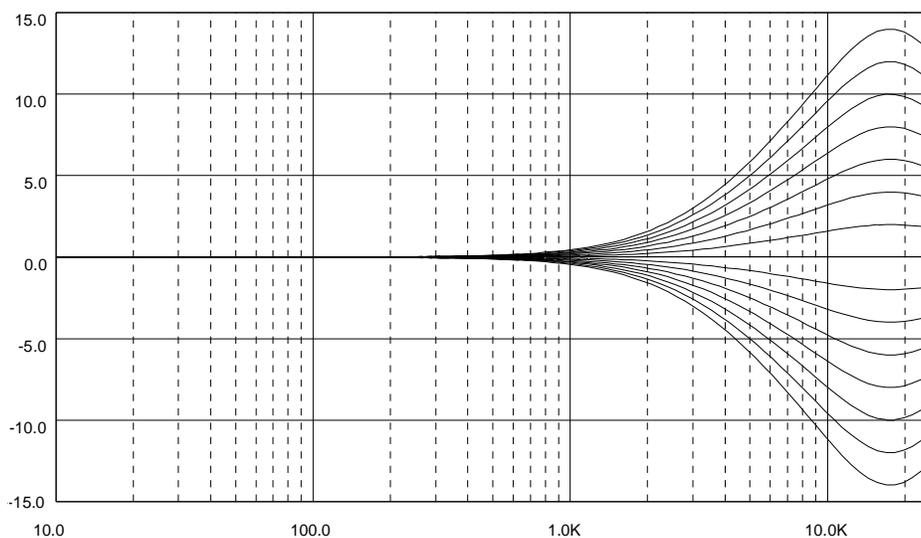

1.8.2 Center Frequency

Figure 12 shows the four possible center frequencies 10k, 12.5k, 15k and 17.5kHz.

Figure 12. Treble Center Frequencies @ Gain = 14dB
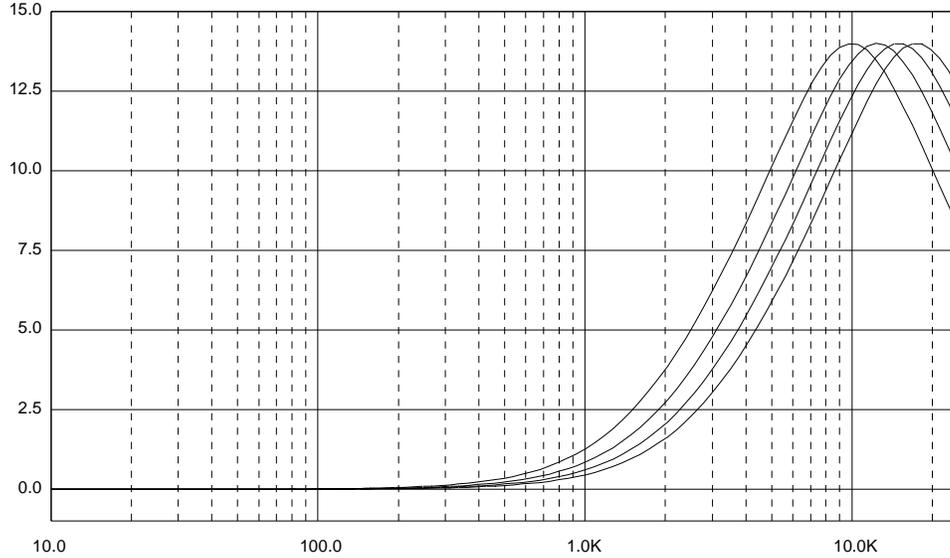

1.9 Subwoofer Application

Figure 13. Subwoofer Application with LPF 80/120/160Hz and HPF 90/135/180Hz
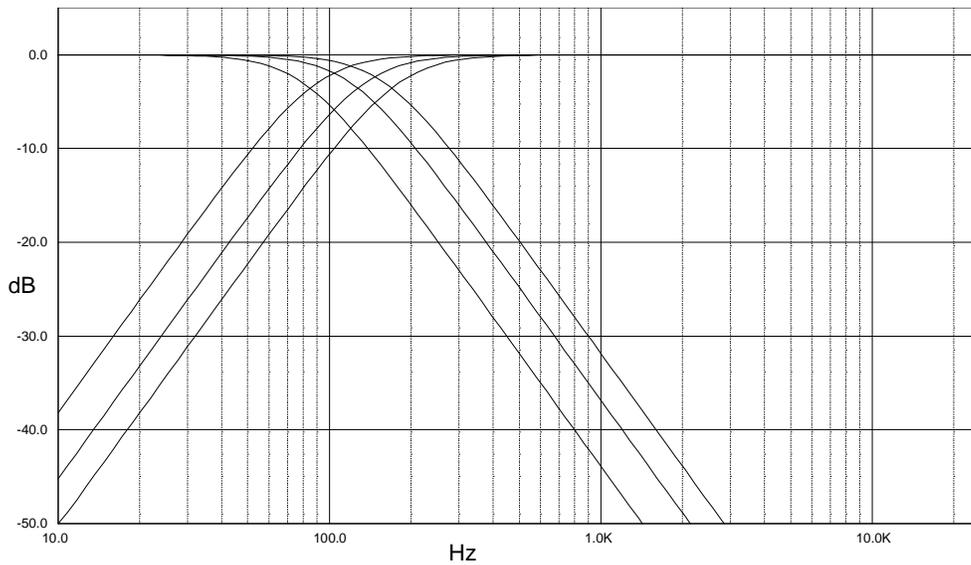

Both filters, the lowpass- as well as the highpass-filter, have butterworth characteristic so that their cut-off frequencies are not equal but shifted by the factor 1.125 to get a flat frequency response.

1.10 Voice-Band Application

Figure 14. VoiceBand Application with HPF 300/450/600/750Hz and LPF 3k/6kHz
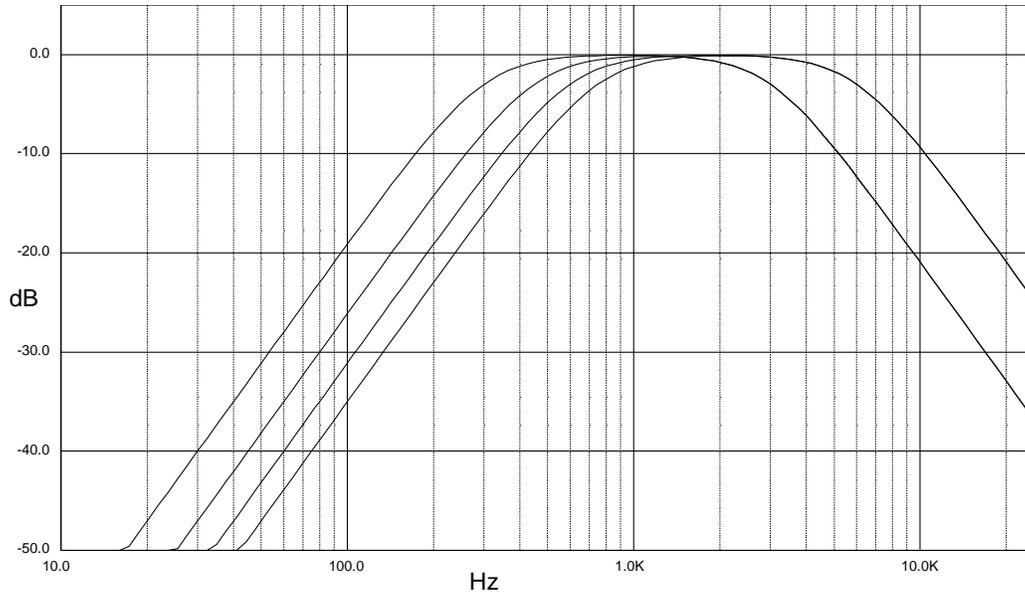

1.11 Output Selector

The output-selector allows to connect the main- or the second-source to the Front-, Rear and Subwoofer speaker-attenuator, respectively. As an example of this programming the device is able to connect via software the main-source to the back (rear) and the second-source to the front (see Figure 17). In addition to this stage allows to setup different applications by IIC-Bus programming. In figure 18 to 20 three examples are given.

Figure 15. Output Selector
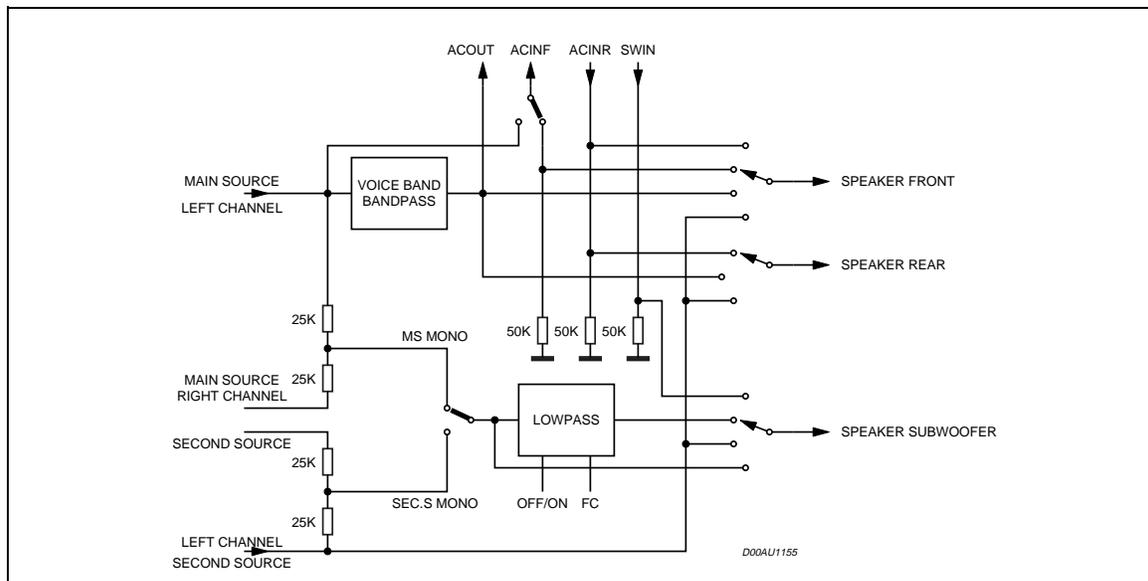

1.12 Subwoofer

Several different applications are possible with the Subwoofer-circuit:

1. Subwoofer-Filter OFF

   a. Main-source stereo (AC-coupled)

   b. Second-source stereo (DC-coupled)

   c. Main-source mono-differential (DC-coupled)

   d. Second-source mono-differential (DC-coupled)

2. Subwoofer-Filter ON

   a. Main-source mono-differential (DC-coupled)

   b. Second-source mono-differential (DC-coupled)

   c. Center-Speaker-Mode (filtered mono signal at SWL, unfiltered mono signal at SWR)

In all applications the phase of the output-signal can be configured to be 0° or 180° . In the Center-Speaker-Mode only at the filtered output the phase is changed.

Figure 16. Application1 using internal Highpass- and mono Low-pass-Filter
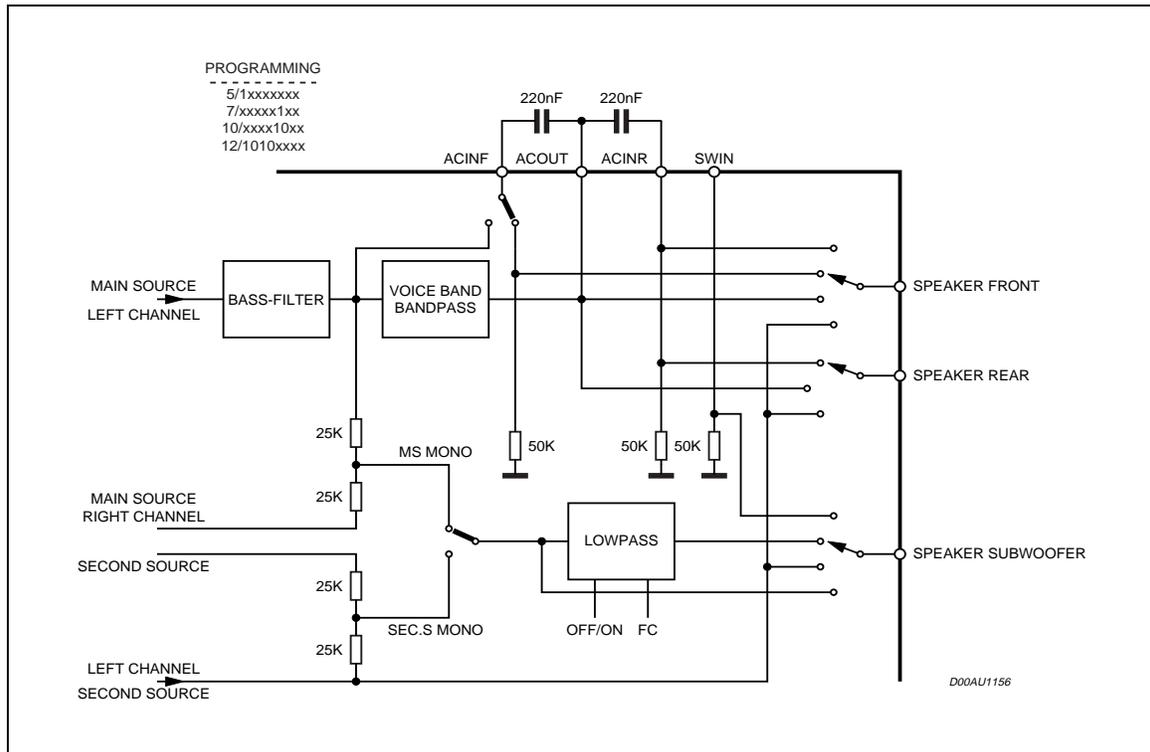

Figure 17. Application2 using internal Highpass- and external stereo Low-pass-Filter
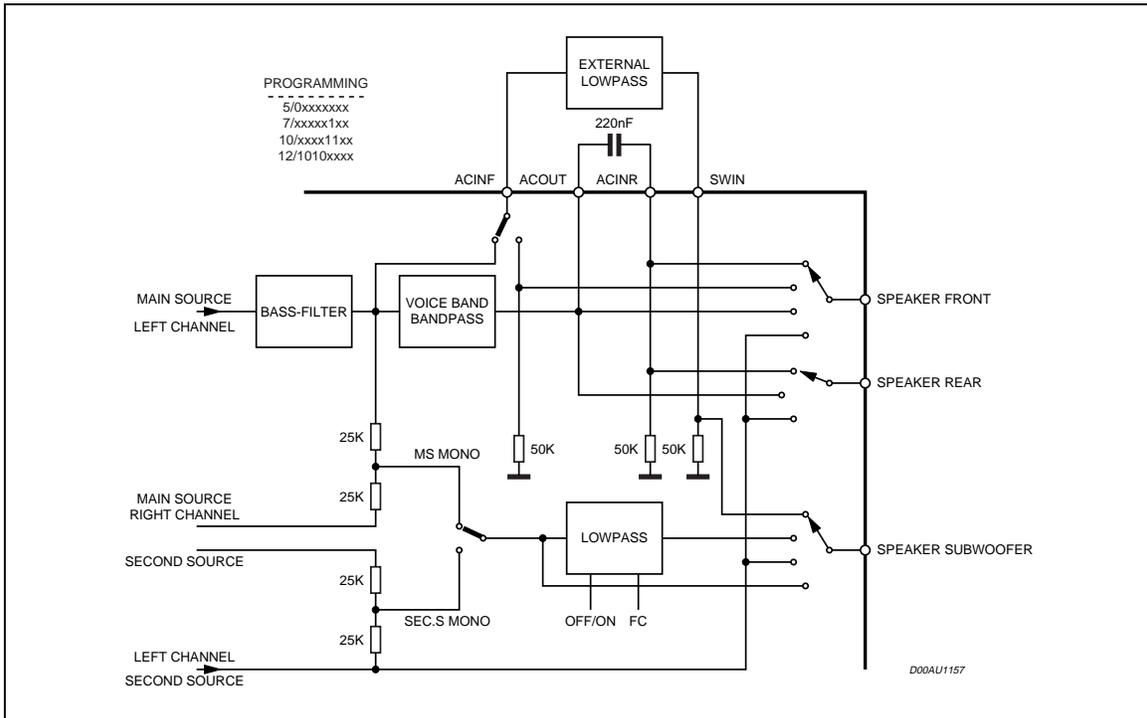

Figure 18. Application3 using pure external Filtering (e.g. DSP)
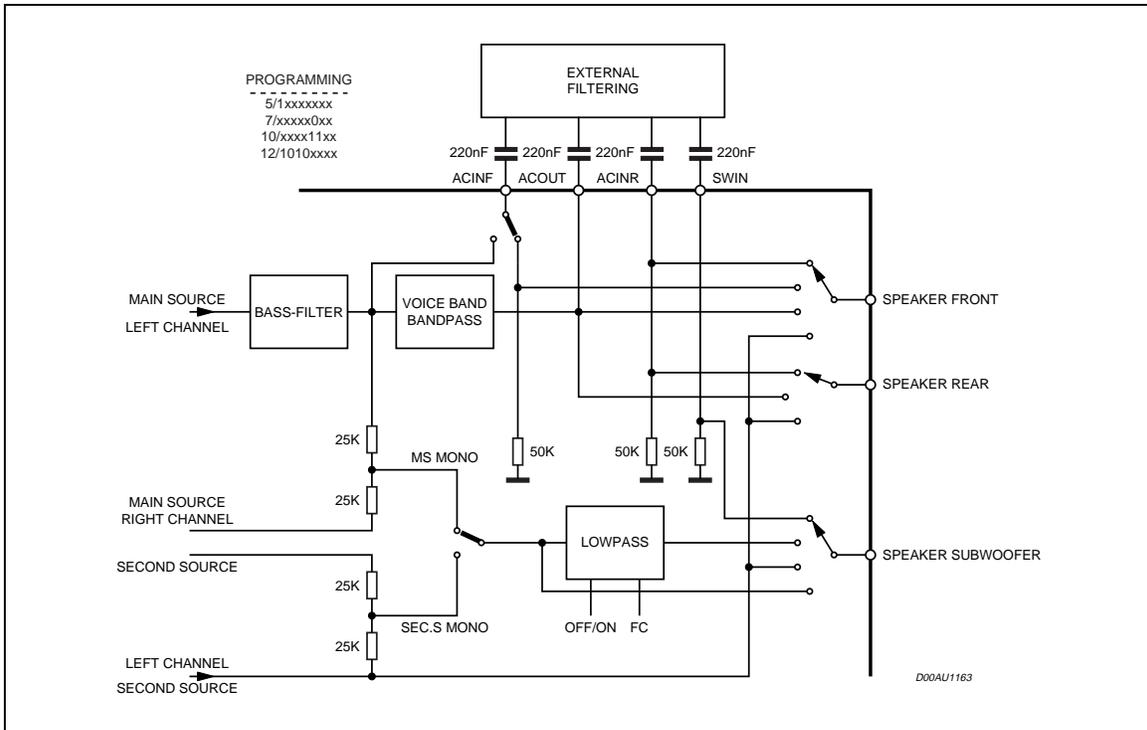

1.13 Speaker-Attenuator and Mixing

A Mixing-stage is placed after each speaker-attenuator and can be set independly to mixing-mode. Having a full volume for the Mix-signal the stage offers a wide flexibility to adapt the mixing levels.

Figure 19. Output Selector
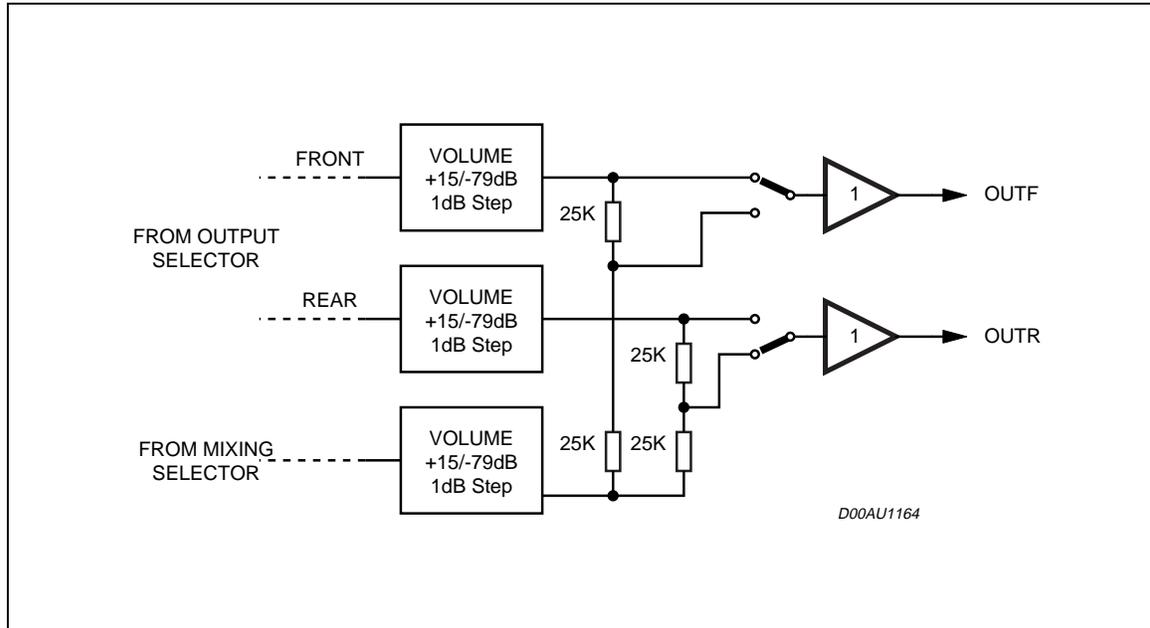

1.14 Audioprocessor Testing

During the Testmode, which can be activated by setting bit D_0 of the stereodecoder testing-byte **and** the audio-processor testing byte, several internal signals are available at the FD2R- pin. During this mode the input resistance of 100kOhm is disconnected from the pin. The internal signals available are shown in the Data-byte specification.

2.0 STEREODECODER PART

2.1 FEATURES:

■ no external components necessary

■ PLL with adjustment free, fully integrated VCO

■ automatic pilot dependent MONO/STEREO switching

■ very high suppression of intermodulation and interference

■ programmable Roll-Off compensation

■ dedicated RDS-Softmute

■ Highcut- and Stereoblend-characterisctics programmable in a wide range

■ FM/AMNoiseblanker with several threshold controls

■ Multipath-detector with programmable internal/external influence

■ I^2C-bus control of all necessary functions

2.2 ELECTRICAL CHARACTERISTICS

V_S = 9V, deemphasis time constant = 50μs, MPX input voltage V_{MPX} = 500mV (75kHz deviation), modulation frequency = 1kHz, input gain = 6dB, T_{amb} = 27°C, unless otherwise specified.

Symbol	Parameter	Test Condition	Min.	Typ.	Max.	Unit

2.3 NOTES TO THE CHARACTERISTICS

2.3.1 Intermodulation Suppression

$$\alpha 2 \ = \ \frac{V_O(signal)(at1kHz)}{V_O(spurious)(at1kHz)} ; f_s \ = \ (2 \cdot 10kHz) - 19kHz$$

$$\alpha 3 \ = \ \frac{V_O(signal)(at1kHz)}{V_O(spurious)(at1kHz)} ; f_s \ = \ (3 \cdot 13kHz) - 38kHz$$

measured with: 91% pilot signal; fm = 10kHz or 13kHz.

2.3.2 Traffic Radio (V.F.) Suppression

$$\alpha 57(V.W.F) = \frac{V_O(signal)(at1kHz)}{V_O(spurious)(at1kHz \pm 23kHz)}$$

measured with: 91% stereo signal; 9% pilot signal; fm=1kHz; 5% subcarrier (f=57kHz, fm=23Hz AM, m=60%)

2.3.3 SCA (Subsidiary Communications Authorization)

$$\alpha 67 \ = \ \frac{V_O(signal)(at1kHz)}{V_O(spurious)(at1kHz)} ; f_s \ = \ (2 \cdot 38kHz) - 67kHz$$

measured with: 81% mono signal; 9% pilot signal; fm=1kHz; 10%SCA - subcarrier (f_s = 67kHz, unmodulated).

2.3.4 ACI (Adjacent Channel Interference)

$$\alpha 114 \ = \ \frac{V_O(signal)(at1kHz)}{V_O(spurious)(at4kHz)} ; f_s \ = \ 110kHz - (3 \cdot 38kHz)$$

$$\alpha 190 \ = \ \frac{V_O(signal)(at1kHz)}{V_O(spurious)(at4kHz)} ; f_s \ = \ 186kHz - (5 \cdot 38kHz)$$

measured with: 90% mono signal; 9% pilot signal; fm=1kHz; 1% spurious signal (f_s = 110kHz or 186kHz, un-modulated).

2.4 NOISE BLANKER PART

2.4.1 Features:

■ AM and FM mode
■ internal 2nd order 140kHz high-pass filter for MPX path
■ internal rectifier and filters for AM-IF path
■ programmable trigger thresholds
■ trigger threshold dependent on high frequency noise with programmable gain
■ additional circuits for deviation- and fieldstrength-dependent trigger adjustment

■ 4 selectable pulse suppression times for each mode

■ programmable noise rectifier charge/discharge current

2.4.2 ELECTRICAL CHARACTERISTICS

All parameters measured in FM mode if not otherwise specified.

3.0 FUNCTIONAL DESCRIPTION OF STEREODECODER

Figure 23. Block diagram of Stereodecoder
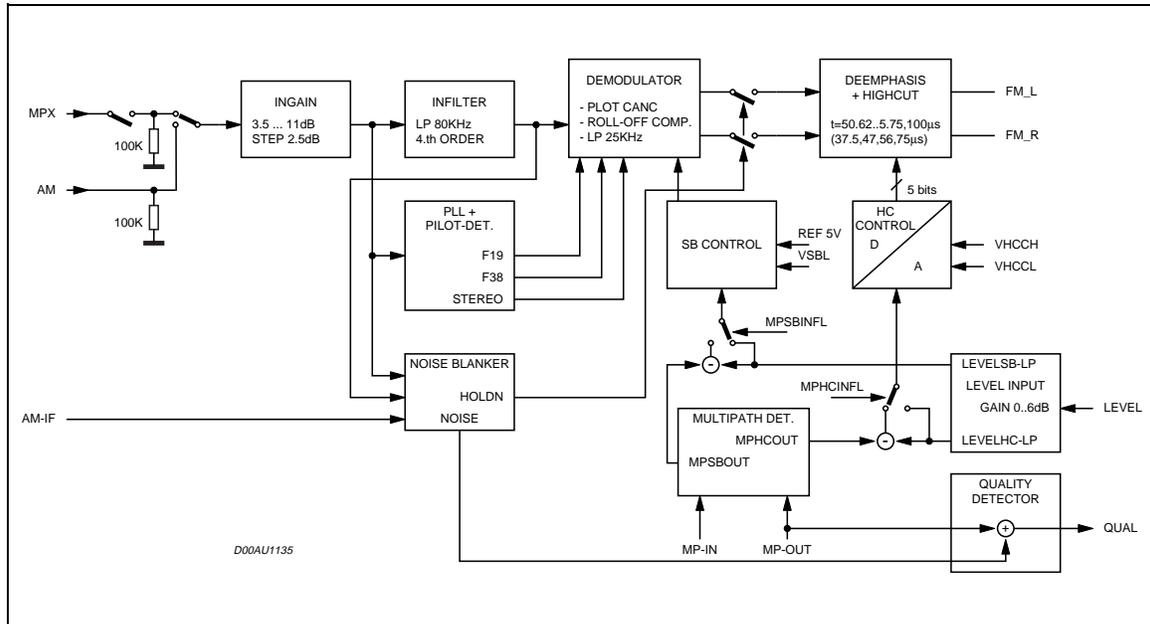

The stereodecoder-part of the A679 (see Fig. 23) contains all functions necessary to demodulate the MPX-signal like pilottone-dependent MONO/STEREO-switching as well as "stereoblend" and "highcut". Adaptations like programmable input gain, roll-off compensation, selectable deemphasis time constant and a programmable fieldstrength input allow to use different IF-devices.

3.1 Stereodecoder-Mute

The A679 has a fast and easy to control RDS-Mute function which is a combination of the audioprocessor's Soft-Mute and the high-ohmic mute of the stereodecoder. If the stereodecoder is selected and a SoftMute command is sent (or activated through the SM-pin) the stereodecoder will be set automatically to the high-ohmic mute condition after the audio-signal has been softmuted. Hence a checking of alternate frequencies could be performed. Additionally the PLL can be set to "Hold"-mode, which disables the PLL input during the mute time. To release the system from the mute condition simply the unmute-command must be sent: the stereodecoder is unmuted immediately and the audioprocessor is softly unmuted. Fig. 26 shows the output-signal V_O as well as the internal stereodecoder mute signal. This influence of SoftMute on the stereodecoder mute can be switched off by setting bit 3 of the SoftMute byte to "0". A stereodecoder mute command (bit 0, stereodecoder byte set to "1") will set the stereodecoder **in any case** independently to the high-ohmic mute state.

If any other source than the stereodecoder is selected the decoder remains muted and the MPX-pin is connected to V_{ref} to avoid any discharge of the coupling capacitor through leakage currents. No further mute command should be applied.

Figure 24. Signals during stereodecoder's SoftMute
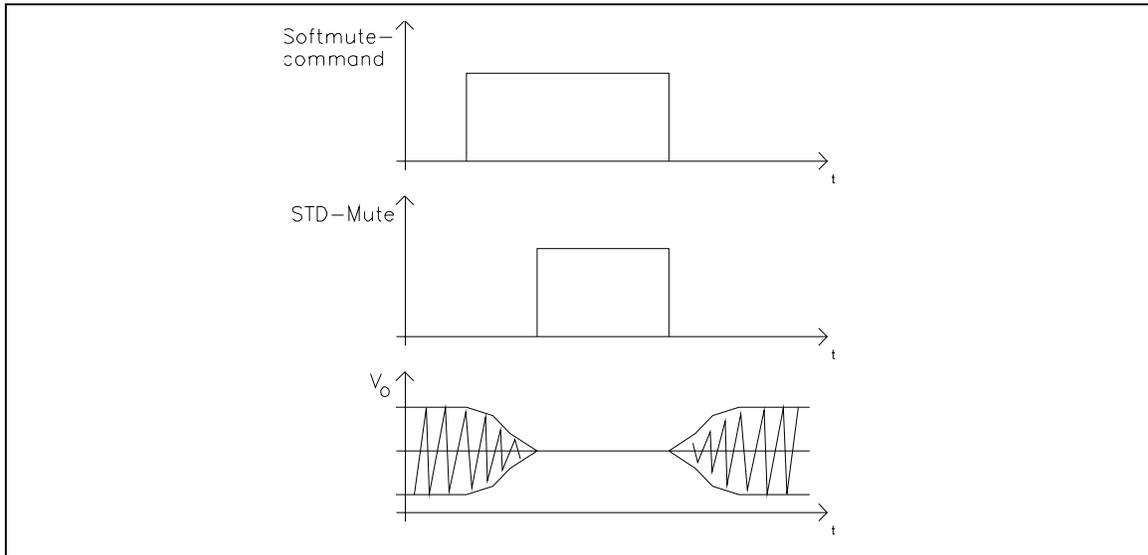

Figure 25. Signal-Control via SoftMute-Pin
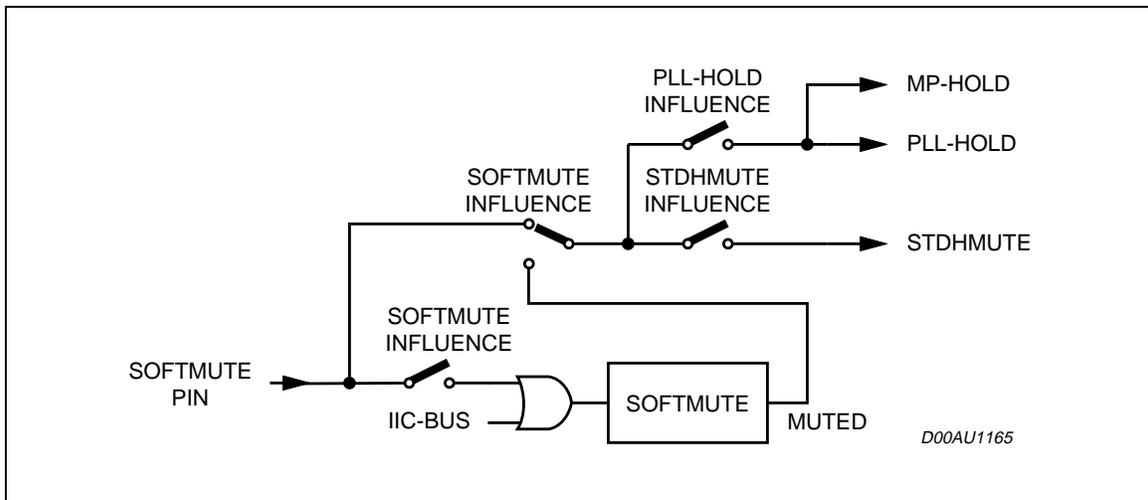

3.2 InGain + Infilter

The InGain stage allows to adjust the MPX-signal to a magnitude of about $1V_{rms}$ internally which is the recommended value. The 4.th order input filter has a corner frequency of 80kHz and is used to attenuate spikes and noise and acts as an anti-aliasing filter for the following switch capacitor filters.

3.3 Demodulator

In the demodulator block the left and the right channel are separated from the MPX-signal. In this stage also the 19-kHz pilottone is cancelled. For reaching a high channel separation the A679 offers an I^2C-bus programmable roll-off adjustment which is able to compensate the lowpass behavior of the tuner section. If the tuner's attenuation at 38kHz is in a range from 7.2% to 31.0% the A679 needs no external network in front of the MPX-pin. Within this range an adjustment to obtain at least 40dB channel separation is possible. The bits for this adjustment are located together with the fieldstrength adjustment in one byte. This gives the possibility to perform an

optimization step during the production of the carradio where the channel separation and the fieldstrength control are trimmed. The setup of the Stereoblend characteristics which is programmable in a wide range is described in 2.8.

3.4 Deemphasis and Highcut

The deemphasis-lowpass allows to choose a time constant between 37.5 and 100µs. The highcut control range will be 2 x τ_{Deemp} or 2.7 x τ_{Deemp} dependent on the selected time constant (see programming section). The bit D7 of the hightcut-byte will shift timeconstant and range.

Inside the highcut control range (between VHCH and VHCL) the LEVEL signal is converted into a 5 bit word which controls the lowpass time constant between τ_{Deemp}...3 (3.7) x τ_{Deemp}. Thereby the resolution will remain always 5 bits independently of the absolute voltage range between the VHCH- and VHCL-values. In addition the maximum attenuation can be fixed between 2 and 10dB.

The highcut function can be switched off by I^2C-bus (bit D_7, Highcut byte set to "0").

The setup of the highcut characteristics is described in 2.9.

3.5 PLL and Pilottone-Detector

The PLL has the task to lock on the 19kHz pilottone during a stereo-transmission to allow a correct demodulation. The included pilottone-detector enables the demodulation if the pilottone reaches the selected pilottone threshold V_{PTHST}. Two different thresholds are available. The detector output (signal STEREO, see Blockdiagram) can be checked by reading the status byte of the A679 via I^2C-bus. During a Softmute the PLL can be set into "Hold"-mode which freezes the PLL's state (bit D_4, Softmute byte). After releasing the Softmute the PLL will again follow the input signal only by correcting the phase error.

3.6 Fieldstrength Control

The fieldstrength input is used to control the highcut- and the stereoblend-function. In addition the signal can be also used to control the noiseblanker thresholds and as input for the multipath detector. These additional functions are described in sections 3.3 and 4.

3.7 EVEL-Input and -Gain

To suppress undesired high frequency modulation on the highcut- and stereoblend-control signal the LEVEL signal is lowpass filtered firstly. The filter is a combination of a 1.st-order RC-lowpass at 53kHz (working as anti-aliasing filter) and a 1.st-order switched-capacitor-lowpass at 2.2kHz. The second stage is a programmable gain stage to adapt the LEVEL signal internally to different IF-devices (see Testmode section 5: LEVELHCC). The gain is widely programmable in 16 steps from 0dB to 6dB (step=0.4dB). These 4 bits are located together with the Roll-Off bits in the "Stereodecoder-Adjustment"-byte to simplify a possible adjustment during the production of the carradio. This signal controls directly the Highcut stage whereas the signal is filtered again (fc=100Hz) before the stereoblend stage (see fig. 32).

3.8 Stereoblend Control

The stereoblend control block converts the internal LEVEL-voltage (LEVELSB) into an demodulator compatible analog signal which is used to control the channel separation between 0dB and the maximum separation. Internally this control range has a fixed upper limit which is the internal reference voltage REF5V. The lower limit can be programmed between 20 and 70% of REF5V in 3.3% steps (see figs.28, 29).

To adjust the external LEVEL-voltage to the internal range two values must be defined: the LEVEL gain L_G and VSBL (see fig. 29). At the point of full channel separation the external level signal has to be amplified that internally it becomes equal to REF5V. The second point (e.g. 10dB channel sep.) is then adjusted with the VSBL voltage.

Figure 26. Internal stereoblend characteristics
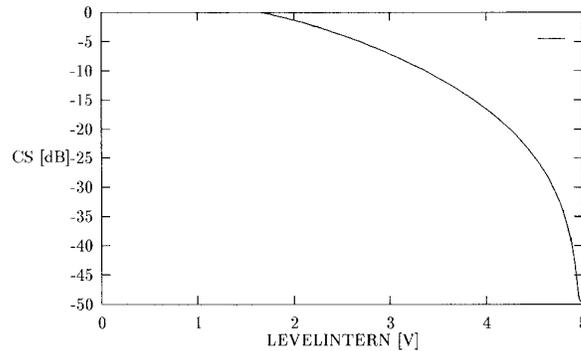

The gain can be programmed through 4 bits in the "Stereodecoder-Adjustment"-byte. All necessary internal reference voltages like REF5V are derived from a bandgap circuit. Therefore they have a temperature coefficient near zero.

Figure 27. Relation between internal and external LEVEL-voltages for setup of Stereoblend
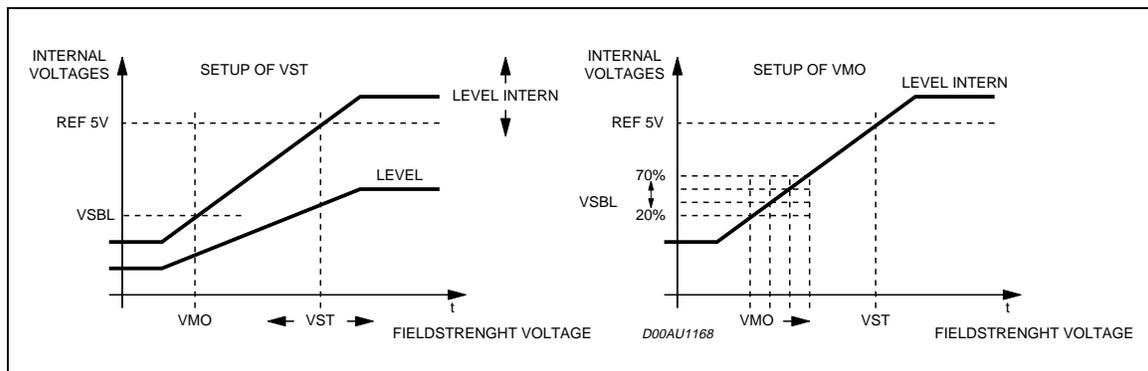

3.9 Highcut Control

The highcut control set-up is similar to the stereoblend control set-up : the starting point VHCH can be set with 2 bits to be 42, 50, 58 or 66% of REF5V whereas the range can be set to be 17, 22, 28 or 33% of VHCH (see fig. 30).

Figure 28. Highcut characteristics
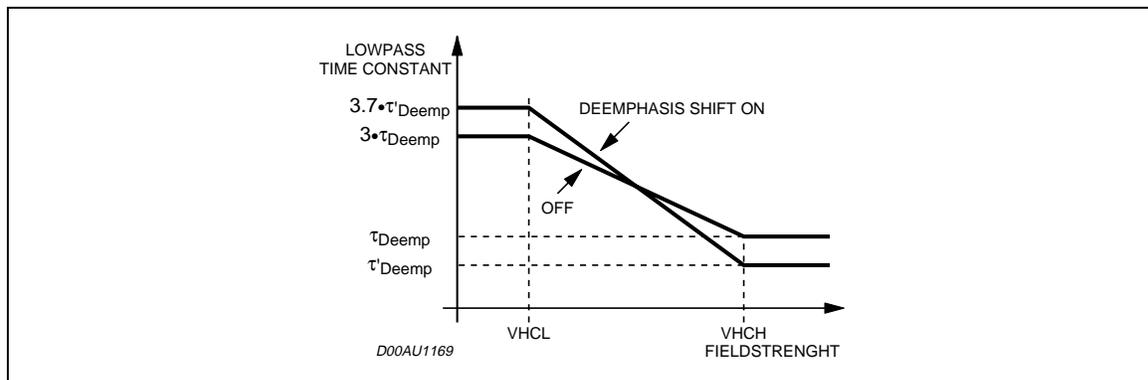

4.0 FUNCTIONAL DESCRIPTION OF THE NOISEBLANKER

In the automotive environment the MPX-signal as well as the AM-signal is disturbed by spikes produced by the ignition and other radiating sources like the wiper-motor. The aim of the noiseblanker part is to cancel the audible influence of the spikes. Therefore the output of the stereodecoder is held at the actual voltage for a time between 22 and 38µs in FM (370 and 645µs in AM-mode). The blockdiagram of the noiseblanker is given in fig.31.

Figure 29. Block diagram of the noiseblanker
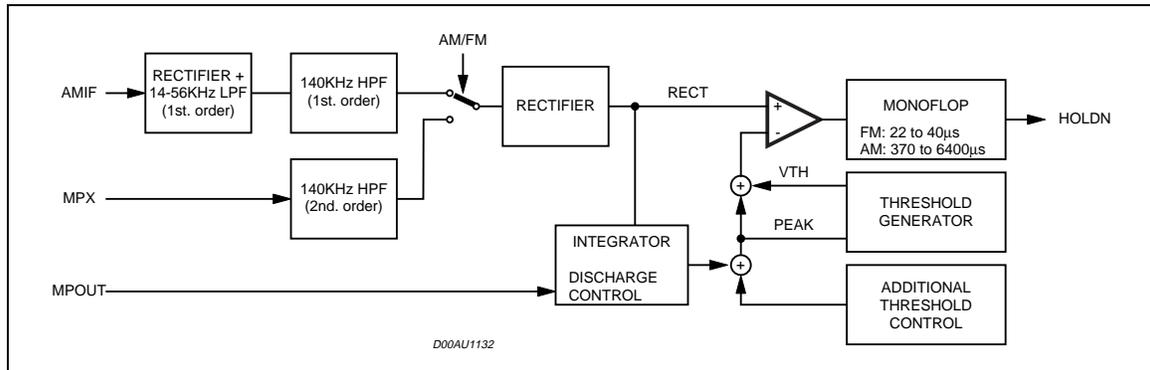

In a first stage the spikes must be detected but to avoid a wrong triggering on high frequency (white) noise a complex trigger control is implemented. Behind the triggerstage a pulse former generates the "blanking"-pulse.

4.1 Trigger Path FM

The incoming MPX signal is highpass-filtered, amplified and rectified. This second order highpass-filter has a corner-frequency of 140kHz. The rectified signal, RECT, is integrated (lowpass filtered) to generate a signal called PEAK. The DC-charge/discharge behaviour can be adjusted as well as the transient behaviour(MP-discharge control). Also noise with a frequency 140kHz increases the PEAK voltage. The PEAK voltage is fed to a threshold generator, which adds to the PEAK-voltage a DC-dependent threshold VTH. Both signals, RECT and PEAK+VTH are fed to a comparator which triggers a re-triggerable monoflop. The monoflop's output activates the sample-and-hold circuits in the signalpath for the selected duration.

4.2 Noise Controlled Threshold Adjustment (NCT)

There are mainly two independent possibilities for programming the trigger threshold:

1. the low threshold in 8 steps (bits D_1 to D_3 of the noiseblanker-byte I)

2. and the noise adjusted threshold in 4 steps (bits D_4 and D_5 of the noiseblanker-byte I, see fig. 19).

The low threshold is activ in combination with a good MPX signal without noise; the PEAK voltage is less than 1V. The sensitivity in this operation is high.

If the MPX signal is noisy (low fieldstrength) the PEAK voltage increases due to the higher noise, which is also rectified. With increasing of the PEAK voltage the trigger threshold increases, too. This gain is programmable in 4 steps (see fig. 22).

4.3 Additional Threshold Control Mechanism

4.3.1 Automatic Threshold Control by the Stereoblend voltage

Besides the noise controlled threshold adjustment there is an additional possibility for influencing the trigger threshold which depends on the stereoblend control.

The point where the MPX signal starts to become noisy is fixed by the RF part. Therefore also the starting point

of the normal noise-controlled trigger adjustment is fixed (fig. 24). In some cases the behavior of the noiseblanker can be improved by increasing the threshold even in a region of higher fieldstrength. Sometimes a wrong triggering occurs for the MPX signal often shows distortion in this range which can be avoided even if using a low threshold. Because of the overlap of this range and the range of the stereo/mono transition it can be controlled by stereoblend. This increase of the threshold is programmable in 3 steps or switched off.

4.3.2 Over Deviation Detector

If the system is tuned to stations with a high deviation the noiseblanker can trigger on the higher frequencies of the modulation or distortion. To avoid this behavior, which causes audible noise in the output signal, the noiseblanker offers a deviation-dependent threshold adjustment. By rectifying the MPX signal a further signal representing the actual deviation is obtained. It is used to increase the PEAK voltage. Offset and gain of this circuit are programmable in 3 steps with the bits D_6 and D_7 of the noiseblanker-byte I (bit combination '00' turns off the detector, see fig. 23).

4.3.3 Multipath-Level

To react on high repetitive spikes caused by a Multipath-situation, the discharge-time of the PEAK voltage can be decreased depending on the voltage-level at pin MPout. The A679 offers a linear as well as a threshold driven control. The linear influence of the Multipath-Level on the PEAK-signal (D_7 of Multipath-Control-Byte) gives a discharge slewrate of 1V/ms[1] . The second possibility is to activate the threshold driven discharge which switches on the 18kOhm discharge if the Multipath-Level is below 2.5V (D_7 of noiseblanker-byte II-byte).

[1] The slewrate is measured with $R_{Discharge}$=infinite and V_{MPout}=2.5V

AM mode of the Noiseblanker

The A679 noiseblanker is also suitable for AM noise cancelling. The detector uses in AM mode the 450kHz unfiltered IF-output of the tuner for spike detection. A combination of programmable gain-stage and lowpass-filter forms an envelope detector which drives the noiseblanker's input via a 120kHz 1.st order highpass. In order to blank the whole spike in AM mode the hold-times of the sample and hold circuit are much longer then in FM (640µs to 1.2ms). All threshold controls can be used like in FM mode.

5.0 FUNCTIONAL DESCRIPTION OF THE MULTIPATH-DETECTOR

Using the Multipath-Detector the audible effects of a multipath condition can be minimized. A multipath-condition is detected by rectifying the spectrum around 19kHz in the fieldstrength signal. An external capacitor is used to define the attack- and decay-times for the Stereoblend (see blockdiagram, fig. 32). Due to the very small charge currents this capacitor should be a low leakage current type (e.g ceramic). Using this configuration an adaptation to the user's requirement is possible without effecting the "normal" fieldstrength input (LEVEL) for the stereodecoder. This application is given in fig. 32. Another (internal) time constant is used to control the Highcut through the multipath detector

Selecting the "internal influence" in the configuration byte the Stereo-Blend and/or the Highcut is automatically invoked during a multipath condition according to the voltage appearing at the MP_OUT-pin.

Figure 30. Blockdiagram of the Multipath-Detector

6.0 QUALITY DETECTOR

The A679 offers a quality detector output which gives a voltage representing the FM-reception conditions. To calculate this voltage the MPX-noise and the multipath-detector output are summed according to the following formula :

$$V_{Qual} = 1.6 \, (V_{Noise} - 0.8 \, V) + a \, (REF5V - V_{Mpout}).$$

The noise-signal is the PEAK-signal without additional influences (see noiseblanker description). The factor 'a' can by programmed to 0.7 .... 1.15. The output is a low impedance output able to drive external circuitry as well as simply fed to an AD-converter for RDS applications.

7.0 TESTMODE

During the Testmode, which can be activated by setting bit D_0 and bit D_1 of the stereodecoder testing-byte, several internal signals are available at the FD2R+ pin. During this mode the input resistance of 100kOhm is disconnected from the pin. The internal signals available are shown in the Data-byte specification.

8.0 DUAL MPX USAGE

8.1 Feature Description

The A679 is able to support a twin tuner concept via the Dual-MPX-Mode. In this configuration the MPX-pin and the MD2G-pin are acting as MPX1 and MPX2 inputs. The DC-Voltage at the MD2-pin controls whether one or both MPX-signals are used to decode the stereo FM-signal. It is designed as a window-comparator with the characteristic shown in Figure 1 (Please note that the thresholds have a hysteresis of 500mV).

In this mode the stereodecoder highohmic-mute mutes both inputs in parallel.

Figure 31.
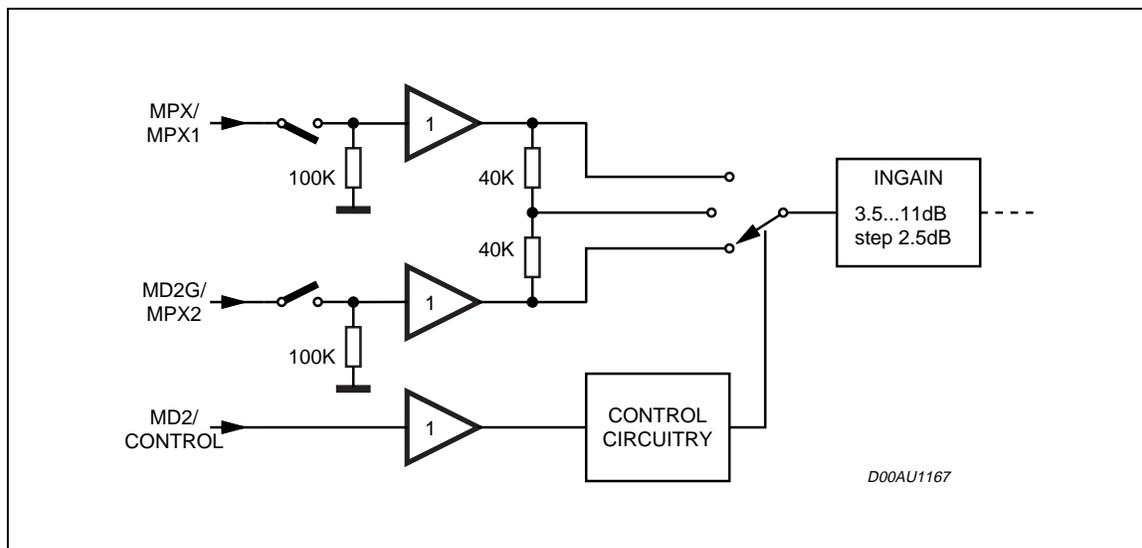

8.2 Configuration

The Dual-MPX-Mode can be easily configured by setting bit 3 of subaddress 30 to LOW (see Byte 30 description and Application Diagram of fig. 33).

9.0 I²C BUS INTERFACE

9.1 Interface Protocol

■ The interface protocol comprises:

■ a start condition (S)

■ a chip address byte (the LSB bit determines read / write transmission)

■ a subaddress byte

■ a sequence of data (N-bytes + acknowledge)

■ a stop condition (P)

CHIP ADDRESS									SUBADDRESS								DATA 1....DATA n					
MSB						LSB			MSB						LSB		MSB			LSB		
S	1	0	0	0	1	1	0	R/W	ACK	C	AZ	I	A	A	A	A	A	ACK			DATA			ACK	P
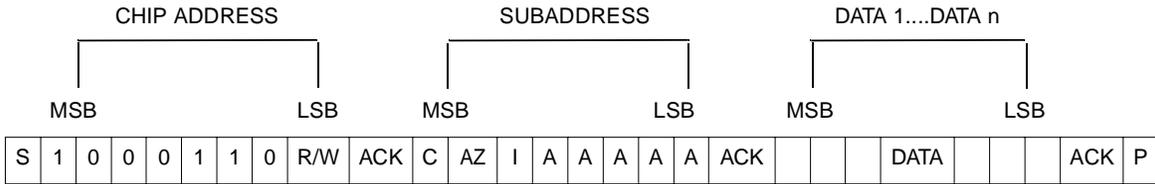

S = Start

R/W = "0" -> Receive-Mode (Chip could be programmed by µP)
　　　　 "1" -> Transmission-Mode (Data could be received by µP)
ACK = Acknowledge
P = Stop
MAX CLOCK SPEED 500kbits/s

9.2 Auto increment

If bit I in the subaddress byte is set to "1", the autoincrement of the subaddress is enabled.

9.3 TRANSMITTED DATA (send mode)

MSB							LSB
X	X	X	X	X	P	ST	SM

SM = Soft mute activated
ST = Stereo
P = Pause
X = Not Used

The transmitted data is automatically updated after each ACK.
Transmission can be repeated without new chipaddress.

9.4 Reset Condition

A Power-On-Reset is invoked if the Supply-Voltage is below than 3.5V. After that the following data is written automatically into the registers of all subaddresses :

MSB							LSB
1	1	1	1	1	1	1	0

The programming after POR is marked bold-face / underlined in the programming tables.
With this programming all the outputs are muted to V_{REF} ($V_{OUT} = V_{DD}/2$).

9.5 SUBADDRESS (receive mode)

MSB							LSB	FUNCTION
I_2	I_1	I_0	A_4	A_3	A_2	A_1	A_0
