## LOW VOLTAGE 14-BIT LINEAR CODEC

- 14-bit linear analog to digital and digital to analog converters
- 8-bit A-law or $\mu$-law companded analog to digital and digital to analog converters

## DESCRIPTION

The MAS9090 is a high performance low power PCM CODEC and filter device tailored to implement the audio front-end functions required by the low voltage/low power consumption digital terminals.

## FEATURES

- Single 2.7-3.6 V Power supply
- $-30^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$ temperature operation range
- 11 mW operating power (typ. at 2.7 V )
- 15 mW operating power (typ. at 3.0 V )
- $\quad 27 \mathrm{~mW}$ operating power (typ. at 3.6V)
- Digital bandpass filters
- $\pm 0.5 \mathrm{~dB}$ absolute gain accuracy (untrimmed)
- 28-pin SO and 44-pin TQFP packages
- Pin compatible with ST5090 and ST5092

PIN CONFIGURATION

## PIN DESCRIPTION

| Pin Name | Pin Number |  | Type | Function |
| :--- | :---: | :---: | :---: | :--- |
|  | SO28 | TQFP44 |  |  |
|  | 1,4 | $1,4,7,9$ <br> $11,12,13$ <br> $2,2,23,27$ <br> $28,29,32$ <br> $35,39,40$, <br> 43,44 |  |  |

| Pin Name | Pin Number |  | Type | Function |
| :--- | :---: | :---: | :---: | :--- |
| MCLK | 20 | 25 | DI | Master clock input. Must be $512,1536,2048 \mathrm{kHz}$ |
| LO | 21 | 26 | DO | Value of bit DO of CR1. |
| MIC2- | 22 | 30 | Al | Negative differential input for MIC2. |
| MIC2+ | 23 | 31 | Al | Positive differential input for MIC2. |
| MIC1- | 24 | 33 | Al | Negative differential input for MIC1. |
| MIC1+ | 25 | 34 | Al | Positive differential input for MIC1. |
| GNDA | 26 | 36 | G | GNDA analog ground. |
| MIC3- | 27 | 37 | Al | Negative differential input for MIC3. |
| MIC3+ | 28 | 38 | Al | Positive differential input for MIC3. |

## ABSOLUTE MAXIMUM RATINGS

| Parameter | Symbol | Conditions | Min | Max | Unit |
| :--- | :---: | :--- | :---: | :---: | :---: |
| Supply Voltage | $\mathrm{V}_{\mathrm{CC}}$ |  |  | 5.0 | V |
| Voltage at MIC |  | $\mathrm{V}_{\mathrm{CC}}<3.6 \mathrm{~V}$ | -1 | $\mathrm{~V}_{\mathrm{CC}}+1$ | V |
| Current at any digital output |  |  |  | 50 | mA |
| Voltage at any digital input |  | $\mathrm{V}_{\mathrm{CC}}<3.6 \mathrm{~V}$ | -1 | $\mathrm{~V}_{\mathrm{CC}}+1$ | V |
| Storage Temperature | $\mathrm{T}_{\mathrm{S}}$ |  | -55 | +125 | ${ }^{\circ} \mathrm{C}$ |

## RECOMMENDED OPERATION CONDITIONS

| Parameter | Symbol | Conditions | Min | Typ | Max | Unit |
| :--- | :---: | :--- | :---: | :---: | :---: | :---: |
| Supply Voltage | $\mathrm{V}_{\mathrm{CC}}$ | 3.0 V mode $(\mathrm{SV}=0)$ | 2.7 | 3.0 | 3.6 | V |
| Operating Temperature | $\mathrm{T}_{\mathrm{A}}$ |  | -30 |  | +85 | ${ }^{\circ} \mathrm{C}$ |

## ELECTRICAL CHARACTERISTICS

## - Digital Inputs/Outputs

$\left(\mathrm{V}_{\mathrm{CC}}=2.7-3.6 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=-30^{\circ} \mathrm{C}\right.$ to $+85^{\circ} \mathrm{C}$, unless otherwise specified)

| Parameter | Symbol | Conditions | Min | Typ | Max | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Input low voltage | VIL | All digital inputs DC All digital inputs AC |  |  | $\begin{aligned} & \hline 0.3 V_{c c} \\ & 0.2 V_{c c} \\ & \hline \end{aligned}$ | V |
| Input high voltage | VIH | All digital inputs DC All digital inputs AC | $\begin{aligned} & 0.7 \mathrm{~V}_{\mathrm{Cc}} \\ & 0.8 \mathrm{~V}_{\mathrm{CC}} \\ & \hline \end{aligned}$ |  |  | V |
| Output low voltage | VOL | All digital outputs, $\mathrm{IL}=10 \mu \mathrm{~A}$ <br> All digital outputs, $\mathrm{IL}=2 \mathrm{~mA}$ |  |  | $\begin{aligned} & 0.1 \\ & 0.4 \end{aligned}$ | V |
| Output high voltage | VOH | All digital outputs, $\mathrm{IL}=10 \mu \mathrm{~A}$ <br> All digital outputs, $\mathrm{IL}=2 \mathrm{~mA}$ | $\begin{aligned} & \mathrm{V}_{\mathrm{cc}}-0.1 \\ & \mathrm{~V}_{\mathrm{cc}}-0.4 \end{aligned}$ |  |  | V |
| Input low current | IIL | Any digital input, $G N D<V_{\mathbb{I N}}<\mathrm{V}_{\mathbb{I}}$ | -10 |  | 10 | $\mu \mathrm{A}$ |
| Input high current | IIH | Any digital input, $\mathrm{V}_{\mathrm{IH}}<\mathrm{V}_{\mathrm{IN}}<\mathrm{V}_{\mathrm{CC}}$ | -10 |  | 10 | $\mu \mathrm{A}$ |
| Output current in high impedance | IOZ | TX and CO | -10 |  | 10 | $\mu \mathrm{A}$ |

## - Analog Inputs/Outputs

| Parameter | Symbol | Conditions | Min | Typ | Max | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Input leakage | $\mathrm{I}_{\text {MIC }}$ | GND < $\mathrm{V}_{\text {MIC }}<\mathrm{V}_{\text {CC }}$ (active mic) | -100 | $\pm 20$ | +100 | $\mu \mathrm{A}$ |
| Input resistance | $\mathrm{R}_{\text {MIC }}$ | GND < $\mathrm{V}_{\text {MIC }}<\mathrm{V}_{\text {CC }}$ | 50 |  |  | $\mathrm{k} \Omega$ |
| Load resistance | $\mathrm{R}_{\text {LSP1 }}$ | SP1+ to SP1- | 30 |  |  | $\Omega$ |
| Load capacitance | $\mathrm{C}_{\text {LSP1 }}$ | SP1+ to SP1- |  | 50 |  | nF |
| Output resistance | RosP1 | Steady zero PCM code applied to $R X, I=1 \mathrm{~mA}$ |  | 1.0 |  | $\Omega$ |
| Differential offset voltage from SP1+ to SP1- | $\mathrm{V}_{\text {OSP1 }}$ | Alternating zero PCM code applied to $R X, R_{L}=30$ ohms | -100 | 0 | +100 | mV |
| Load resistance | $\mathrm{R}_{\text {LSP2 }}$ | SP2+ to SP2- | 30 |  |  | $\Omega$ |
| Load capacitance | $\mathrm{C}_{\text {LSP2 }}$ | SP2+ to SP2- |  | 50 |  | nF |
| Input resistance | $\mathrm{R}_{\text {MIC }}$ | GND < $\mathrm{V}_{\text {MIC }}<\mathrm{V}_{\text {CC }}$ | 50 |  |  | k $\Omega$ |
| Output resistance | $\mathrm{R}_{\text {OSP2 }}$ | Steady zero PCM code applied to $\mathrm{RX}, \mathrm{I}=1 \mathrm{~mA}$ |  | 1.0 |  | $\Omega$ |
| Differential offset voltage from SP2+ to SP2- | $\mathrm{V}_{\text {OSP2 }}$ | Alternating zero PCM code applied to $R X, R_{L}=30$ ohms | -100 | 0 | +100 | mV |

## - Power Dissipation

$\left(\mathrm{V}_{\mathrm{CC}}=2.7-3.6 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=-30^{\circ} \mathrm{C}\right.$ to $+85^{\circ} \mathrm{C}$, unless otherwise specified)

| Parameter | Symbol | Conditions | Min | Typ | Max | Unit |
| :--- | :---: | :--- | :---: | :---: | :---: | :---: |
| Power down current at 3.0V | $\mathrm{I}_{\mathrm{CC} 0}$ | $\mathrm{CCLK}, \mathrm{CI}=0.1 \mathrm{~V}$ <br> $\mathrm{CS}=\mathrm{VCC}-0.1 \mathrm{~V}$ |  | 0.08 | 10 | $\mu \mathrm{~A}$ |
| Power up current at 2.7V | $\mathrm{I}_{\mathrm{CC} 1}$ | SP1 and SP2 not loaded |  | 4 | 6 | mA |
| Power up current at 3.0V | $\mathrm{I}_{\mathrm{CC} 1}$ | SP1 and SP2 not loaded |  | 5 | 8 | mA |
| Power up current at 3.6V | $\mathrm{I}_{\mathrm{CC} 1}$ | SP1 and SP2 not loaded |  | 7.5 | 12 | mA |
| SP1 short circuit current | $\mathrm{I}_{\mathrm{SHORT}}$ |  |  | 130 |  | mA |

## TIMING SPECIFICATIONS

## - Master Clock Timing

| Parameter | Symbol | Conditions | Min | Typ | Max | Unit |
| :--- | :---: | :--- | :---: | :---: | :---: | :---: |
| Frequency of MCLK | $\mathrm{f}_{\text {MCLK }}$ | programmable |  | 512 <br> 1536 <br> 2048 |  | kHz |
| Period of MCLK high/low <br> $\mathrm{f}_{\text {MCK }}=512$ | $\mathrm{t}_{\text {WHM }}$ <br> $\mathrm{t}_{\text {WLM }}$ | Measured from $\mathrm{V}_{\mathrm{IH}}$ to $\mathrm{V}_{\mathrm{IH}}$ | 878 |  | 1074 | ns |
| Period of MCLK high <br> $\mathrm{f}_{\text {MCK }}=1536,2048$ | $\mathrm{t}_{\text {WHM }}$ | Measured from $\mathrm{V}_{\mathrm{IH}}$ to $\mathrm{V}_{\mathrm{IH}}$ | 80 |  |  | ns |
| Period of MCLK low <br> $\mathrm{f}_{\text {MCK }}=1536,2048$ | $\mathrm{t}_{\text {WLM }}$ | Measured from $\mathrm{V}_{\mathrm{IL}}$ to $\mathrm{V}_{\mathrm{IL}}$ | 80 |  |  | ns |
| Rise time of MCLK | $\mathrm{t}_{\text {RM }}$ | Measured from $\mathrm{V}_{\mathrm{IL}}$ to $\mathrm{V}_{\mathrm{IH}}$ |  |  | 30 | ns |
| Fall time of MCLK | $\mathrm{t}_{\text {FM }}$ | Measured from $\mathrm{V}_{\mathrm{IH}}$ to $\mathrm{V}_{\mathrm{IL}}$ |  |  | 30 | ns |

- PCM Interface Timing

| Parameter | Symbol | Conditions | Min | Typ | Max | Unit |
| :--- | :---: | :--- | :---: | :---: | :---: | :---: |
| Hold time, MCLK low to FS low | $\mathrm{t}_{\text {HMLF }}$ |  | 17 |  |  | ns |

## FUNCTIONAL DESCRIPTION

## - Operating Modes

When power is first applied, power-on reset circuit initializes control and data registers of MAS9090 and puts it into a power-down state. During powerdown state, control registers retain their initial state until they are written via the serial interface. Master clock (MCLK) can be inactive.

The power up/down control is accomplished by changing the P -bit of the address byte of the serial interface ("0" means active and "1" power-down) or by stopping the master clock.

## - Control Interface

Control information or data is written into or readback from the internal registers of MAS9090 via the serial control port. Serial control port consists of control output CO, control input CI, chip select CSand control clock CCLK and supports the MICROWIRE ${ }^{\text {тм }}$ ) communication protocol. All control instructions, except the single byte power up/down command require two bytes of data.

To shift the data into MAS9090, CCLK must be pulsed eight times (CS is low). Data on the Cl input is shifted into the serial input register on the rising edges of CCLK pulses. After 8 bit address data is shifted in, the content of the shift register is decoded and may indicate that 8 bit control word will follow. Control word may start immediately after the address byte or after a single CS pulse. It is not mandatory for the CS signal to return high in between the address and the data. After the second byte is shifted in, the CS signal must return to a high state.

The same process takes place for reading-back status information during the next CS low state. CS will remain low for eight CCLK pulses. The data is shifted out on the CO output from the serial output register on the falling edges of CCLK. When CS is high, the CO pin is in a high impedance state, which enables CO pins of other devices to be multiplexed together.

## - Digital Data Interface

Digital data is shifted in/out from RX/TX using master clock (MCLK) and Frame Sync (FS) signals. FS determines the beginning of frame and its duration can vary from single cycle of MCLK to squarewave.

Three different modes between FS and the first time slot of a data frame can be used: non-delayed normal data timing, non-delayed reverse data timing and delayed data timing. These modes are set with bits DM0 and DM1 of control register CR1.

In non-delayed timing modes the first time slot begins coincident with the rising edge of the FS. In delayed timing mode the FS must be active at least one half cycle of MCLK before the beginning of the first time slot.

Bit EN of control register CR1 enables the voice data transfer on TX and RX pins. Data is shifted out from TX output on the rising edge of MCLK and shifted into RX on falling edge of MCLK on assigned time slot. In non-delayed reverse mode the data is shifted with different edge of MCLK (on falling edge from TX and on rising edge into RX). TX output is in tristate condition during non selected time slots. The TX output transmits 8 bits of encoded data (A-law or $\mu$-law) or 16 bits (14 effective bits, 2 LSB bits zero) of linear data when compressor is bypassed.

Two time slots (B1 and B2) can be used in two formats: in Format 1, time slot B1 corresponds to eight MCLK cycles starting immediately after the rising edge of FS and time slot B2 starts immediately after the B1 is ended. A two-bit space is left after B 2 for insertion of possible D channel data. The position of this two-bit data is changed in Format 2 to the center of time slots B1 and B2. The data format is selected by bit FF in control register CR0 and time slots B1 and B2 are selected by bit TS in control register CR1.

## - Control Channel Access to PCM Interface

When companded code is selected it is possible to access the selected time slot (B1 or B2) by writing data bytes to internal registers CR2 and CR3. The byte written to CR3 is transmitted from TX with the following frame in place of PCM data if bit MX (3) of CR1 is selected. To implement a continuous data flow from interface to $B$ channel a control byte has to be sent on each PCM frame.

The byte written into CR2 is sent through the receive audio path ( $R X$ ) if bit $M R$ (4) of CR1 is selected. CR2 can also be used to read the RX input. In order to implement a continuous data flow from $B$ channel to the interface, register CR2 has to be read at each PCM frame.

## FUNCTIONAL DESCRIPTION

## - TX Audio Path

Analog front end provides three identical differential inputs (MIC1, MIC2, MIC3) for capacitive connection of microphones or auxiliary audio circuits. Desired input signal is selected with bits VS and TE (6 and 7) of register CR4 and forwarded to a low noise preamplifier.
Preamplifier has 16.1 dB gain and its output is fed to the programmable gain amplifier which provides an additional gain from 0 to 22.5 dB in 1.5 dB steps. Gain is controlled with bits 4-7 of register CR5.

An active RC anti alias filter is used to prevent signal folding during the sampling. Accurate analog to digital conversion is done by using a sigma-delta modulator followed by a decimation filter.
Digital multiplexer (bit DE (0) in CR 7) is used to select the input of a digital bandpass filter (3003400 Hz ). The input can be taken from the output of the decimator or from an internal ring/tone generator. The bandpass filter output contains hard clipping saturation logic for signals exceeding overload level $(+3.14 \mathrm{~dB})$. Highpass part of the bandpass filter can be bypassed with bit HPT of register CR10.

Output data can be compressed by using CCITT Alaw or $\mu 255-$ law coding. The compression code is selected with bits CM (5), MA (4) and IA (3) of register CRO.

## - RX Audio Path

Received signal is transferred into RX register in 8 bit encoded format or in 16 bit linear format. The data is expanded by using A-law or $\mu$-law signal encoding according to CCITT A and $\mu 255$ laws. The expansion code is selected with bits CM (5), MA (4) and IA (3) of register CRO. Signal is then passed through a bandpass filter (bandpass $300-3400 \mathrm{~Hz}$ ). The high pass section of the filter can be bypassed with bit HPR of register CR4.

The input signal of $R X$ gain3 is controlled with bits SI (5), RTE (2) and SE (0) of register CR4. Bit SI activates the transmit side tone signal, bit RTE activates the ring/tone generator and bit SE activates the received signal to be summed to the gain input. RX gain3 can be programmed with bits 4-7 of register CR6 from 0 dB to -30 dB with -2 dB steps. It contains also hard-clipping saturation logic.

After gain adjustment the signal is fed to a digital sigma-delta modulator followed by a switched capacitor (SC) reconstruction filter and a continuous time smoothing filter. Filtered analog signal can be directed to a speaker amplifier (SP1) or to an extra analog output amplifier (SP2) with bits OE1 (4) and OE2 (3) of register CR4. Gains can be set with register CR6 in the range of 0 to -30 dB in -2 dB steps.

Differential analog outputs (SP1, SP2) are capable of directly driving output load of $30 \Omega$ with power level up to 66 mW . Also ceramic receivers up to $50 n F$ can be used. Power up transient noise suppression is used in both outputs.

## - Ring and tone generator

Ring/tone generator is able to generate one or two sinewave or squarewave frequencies (including DTMF tones) to the transmit (TX) receive ( $R X$ ) or buzzer paths. Generated frequencies can be programmed with registers CR8 and CR9. One of the three frequency ranges can be selected with bits DFT and HFT of register CR10. Output signal level of the tone generator can be selected from 0 to -27 dB with -3 dB steps with bits $4-7$ of register CR7.

Single ended BZ output is used to drive a buzzer by using an external bipolar transistor with pulse width modulated (PWM) squarewave signal f1 (CR8). This PWM signal can also be amplitude modulated with signal f2 (CR9). Maximum load for BZ is $5 \mathrm{k} \Omega$ and 50 pF . Implementation of tone generator is fully digital. Therefore no amplitude or frequency response variations (at TX output) over temperature, power supply or from unit to unit exist.

## Address byte bits:

- Bit 0 reserved for future extensions
- Bit 1 indicates the presence of a second byte. If cleared indicates single byte power up/down command
- Bit 2 is write/read select bit
- Bits 6 to 3 contain the address of register
- Registers CR12, CR13, CR15 are not accessible
- MSB bit (bit 7) of the address and data byte is always clocked first into or out from Cl and CO pins
- Bit 7 ' $P$ ' controls the power up/down state of the chip. $P=1$ means power down

Data bits:

- All registers are cleared during power on reset or by writing to bit POR of CR10
- Default value for all bits is zero.

Notice the difference between power down and POR. Registers can be written in both power down/up states and they retain their values in power down. Both data and control registers are cleared when POR bit (in CR10) is written high or during power on reset (i.e. Vcc transition from 0 volts to $3-5$ volts).

Control register CR14 ( for testing purposes only)

* state at power on initialization

## REGISTER DESCRIPTION

## Control register CR0

## Master Clock Frequency Selection:

External MCLK frequency can be 512 kHz, $1.536 \mathrm{MHz}, 2.048 \mathrm{MHz}$ or 2.56 MHz . During initialization Bits F1 (7) and F0 (6) must be set to select correct value for internal clock divider. Default value for external MCLK is 512 kHz . Any other value must be selected before Power up command.

## Coding Selection

Bit CM (5) permits selection of 14-bit linear coding or companded coding. Default is linear mode.

In case of companded mode ( $\mathrm{CM}=1$ ) bits MA (4) and IA (3) select either $\mu-255$ or A law coding mode and the format for both.

In case of linear mode (CM=0) bits MA (4) and IA (3) select the linear data to be in 2's complement, 1's complement or sign and magnitude format.

## Digital Interface Format (1)

Bit FF (2) selects the format for TX and Rx data transfer. If $\mathrm{FF}=0$ Format 1 is selected and channels B 1 and B 2 are consecutive. $\mathrm{FF}=1$ selects Format 2 where channels B1 and B2 are separated by two bits.

## 56+8 Selection (1)

If bit B7 (1) is selected MAS9090 takes only seven most significant bits of the companded PCM data byte. LSB bit on RX is ignored and LSB bit on TX is in high impedance state. This allows direct connection of an external "in band" data generator to the digital interface.

## Digital Loopback

Bit DL (0) selects the digital loopback mode, where data written into RX data register (CR2) from received time slot is read-back from that register in the selected time-slot on TX.

No PCM decoding or encoding takes place in this mode.

## Control Register CR1

## Digital Interface Timing

Bit TM1 (7) selects the timing mode for digital interface. As a default ( $\mathrm{TM} 1=0$ ) delayed timing mode is selected. In delayed mode (TM1=1) bit TMO (6) selects the normal (TMO=0) or reversed timing mode ( $\mathrm{TMO}=1$ ).

## Latch output control

Bit DO (5) controls directly the LO output pin. Bit written to DO is seen inverted from the output LO.

## Microwire access on RX path (1)

When bit MR (4) is set high the data written into register CR2 is decoded each frame and sent to receive path. Data input $R X$ is ignored when $M R$ is high.

In other direction, current PCM data input received at $R X$ can be read from register CR2 each frame.

## Microwire access on TX path (1)

Bit MX (3) enables the access of write only register CR3 to TX output. When MX is set active data written to CR3 is send to TX output every frame. PCM encoder is ignored.

## Transmit/Receive enable/disable

Bit EN (2) enables or disables voice data transfer on TX and RX pins. When disabled PCM data from RX input is not decoded and TX output is on high impedance state. Default value is disabled.

## B-channel selection (1)

Bit TS (1) selects the active channel B1 or B2. Default (TS=0) is B1 channel. (See Fig on page 14)

## Power supply selection

Bit SV (0) selects the main supply voltage used. When SV is low a $2.7-3.6 \mathrm{~V}$ supply is assumed. It is not allowed to put SV bit high.

## Control Register CR2 (1)

Data sent to receive path or data received from RX input is seen in register CR2. See register CR1 bit MR (4).

## Control Register CR3 (1)

TX data transmitted. Refer to bit MX (3) in CR1.

DA9090B. 002
March 20, 1998

## REGISTER DESCRIPTION

## Control Register CR4

## Transmit Input Selection

Bits VS (7) and TE (6) select active input (MIC1, MIC2 or MIC3). Default is that all inputs are muted. Transmit (TX) gain can be adjusted from 0 to 22.5 dB in 1.5 dB steps with register CR5 bits (7:4).

## Sidetone Selection

Transmit signal after bandpass filter can be fed back to the receive amplifiers when bit $\mathrm{SI}(5)$ is set high.

## Output Driver Selection

Bits OE1 (4) and OE2 (3) select the active output of the RX gain to be SP1 or SP2. Both outputs can be muted.

## Ring/Tone Signal Selection

Bit RTE (2) connects the on-chip Ring/Tone generator to the RX gain input.

## Receive High Pass Filter Selection

Bit HPR (1) provides possibility to bypass high pass section of the receive bandpass filter.

## PCM receive data selection

Bit SE (0) enables the connection of the received signal to the RX gain input.

## Control Register CR5

## Transmit Gain Selection

TX gain can be programmed from 0 to 22.5 dB in 1.5 dB steps with bits (7:4).

## Sidetone Attenuation Selection

Transmit signal picked after digital bandpass filters can be fed back to RX gain. Attenuation of the sidetone signal can be programmed from -12.5 dB to -27.5 dB in 1 dB steps with bits (7:4). Attenuation is relative to the input signal level of bandpass filter.

## Control Register CR6

## Speaker 1 and 2 Gain Selection

The attenuation of both speaker gains can be programmed separately from 0 to -30 dB in 2 dB steps with bits (7:4) and (3:0).
$0 \mathrm{dBm0}$ voltage at the output of the RX gain on pins $\mathrm{SP} 1 / 2+$ and $\mathrm{SP} 1 / 2$ - is 1.965 Vrms when 0 dB gain is selected. When -30 dB gain is selected the 0 dBm 0 level is 61.85 mVrms .

## Control Register CR7

## Tone/Ring Gain Selection

Output of Tone/Ring generator can be attenuated from 0 to -27 dB in 3 dB steps with bits (7:4).

## Frequency Mode Selection

Bits f 1 (3) and f 2 (2) permit selection of f 1 and/or f 2 frequency generators. When f 1 (f2) is selected the output of the tone generator is signal at the frequency programmed by the register CR8 (CR9). If both f 1 and f 2 are selected the output is a sum of both signals. In case of squarewave the f1 is amplitude modulated by $\mathfrak{f}$. In order to meet DTMF specifications the level of $\mathfrak{f 2}$ is attenuated by 2 dB relative to f 1 .

## Waveform Selection

Bit SN (1) selects the output waveform of the tone generator to be square $(\mathrm{SN}=0)$ or sinewave $(\mathrm{SN}=1)$.

## DTMF Selection

Bit DE (0) permits the connection of the tone generator to the transmit path. Speaker output can also be provided by using sidetone circuit (bit SI of CR4) or directly connecting the tone generator to RX gain with bit RTE of CR4.

## REGISTER DESCRIPTION

## Control Registers CR8 and CR9

The frequency of both frequency generators is programmed by CR8 and CR9.

When standard frequency range is selected (CR10: $\mathrm{DFT}=0$, HFT=0) the frequency is defined by formulas: $\mathrm{f} 1=\mathrm{CR} 8 / 0.128 \mathrm{~Hz}$ and $\mathrm{f} 2=\mathrm{CR9} / 0.128$ Hz , where CR8 and CR9 are decimal equivalents of the register content. Thus any frequency between 7.8 Hz and 1992 Hz in 7.8 Hz step can be selected.

When halved frequency range is selected (CR10:DFT=0, HFT=1) the frequency is defined by formulas: $\mathfrak{f 1}=$ CR8 $/ 0.256 \mathrm{~Hz}$ and $\mathrm{f} 2=$ CR9 $/ 0.256$ Hz . Thus any frequency between 3.9 Hz and 996 Hz in 3.9 Hz step can be selected.

When doubled frequency range is selected (CR10:DFT=1, HFT=0) the frequency is defined by formulas: $\mathrm{f} 1=\mathrm{CR} 8 / 0.064 \mathrm{~Hz}$ and $\mathrm{f} 2=\mathrm{CR9} / 0.064$ Hz . Thus any frequency between 15.6 Hz and 3984 Hz in 15.6 Hz step can be selected.

## Control Register CR10

Writing bit POR (7) high puts the MAS9090 in power-on-reset state and all data and control registers are cleared (including the POR bit).

Logic low written to bit SCA (6) sets the chip to scan mode. During scan Cl is the input and TX is the output. Used only for device testing.

High written to bit HPT (5) bypasses the highpass part of the TX bandpass filter.

When Bit EXT (4) is set active the two bit output of the ADC is disabled and data is fed from pins CR and DR. Used only for device testing.

With bit LO (3) it is possible to loop internally from TX to RX. Bit L1 (2) permits looping from the expander output to the compressor input.

## Frequency Range Selection

Bits DFT (1) and HFT (0) define the frequency range of the tone generator output. Three modes are possible: halved, standard and doubled with output frequencies from $3.9 \ldots 996 \mathrm{~Hz}$ and $7.8 \ldots 1992 \mathrm{~Hz}$, $15.6 \ldots 3984 \mathrm{~Hz}$ respectively.

## Control Register CR11

When bit BE (7) is high it permits the connection of f1 squarewave pulse width modulated (PWM) ring signal to buzzer driver output pin BZ. Signal can be amplitude modulated (AM) with squarewave signal f2.
When bit BE is low (buzzer disabled) the state of the output pin BZ is logical inversion of bit $\mathrm{BI}(6)$. This works also in power-down state.

When buzzer output is enabled ( $\mathrm{BE}=1$ ) bit $\mathrm{BI}(6)$ controls the polarity of the duty cycle selection. $\mathrm{BI}=1$ means the duty cycle is calculated from the relative width of the logic one. When $\mathrm{BI}=0$ the duty cycle is calculated from the relative width of the logic zero.

Bits BZ5:BZ0 (5:0) define the duty cycle of the PWM squarewave, according to the following formula: duty cycle $=$ CR11(5:0) $\times 0.78125$ \%, where CR11 (5:0) is the decimal equivalent of binary value BZ5:BZ0.

## Control Register CR14 (for testing)

Bits AM2:AM0 (7:5) control the analog multiplexer. Different analog test signals can be fed to test pads. Test pads are not wire bonded in production packages.

Bits DM2:DM0 (4:2) control the digital multiplexer. Different test signals can be fed to the TX output pin.

Bit MUX (1) connects the test outputs to the TX output pin. It is for device testing.

Bit EDX (0) enables the TX output continuously. No pull-up resistor is needed when TX pin is the only output for the reading device and EDX is written High.
