BTS 775 G	Q67007-A9350	P-DSO-28-9

Description

The **BTS 775 G** is a **TrilithIC** contains one double high-side switch and two low-side switches in **one P-DSO-28-9** -Package.

**“Silicon instead of heatsink”
becomes true**

The ultra low $R_{DS\ ON}$ of this device avoids powerdissipation. It saves costs in mechanical construction and mounting and increases the efficiency.

The high-side switches are produced in the **SIEMENS SMART SIPMOS®** technology. It is fully protected and contains the signal conditioning circuitry for diagnosis. (The comparable standard high-side product is the **BTS 621L1**.)

For minimized $R_{DS\ ON}$ the two low-side switches are N channel vertical power FETs in the **SIEMENS SMART SIPMOS®** technology. Fully protected by embedded protection functions. (The comparable standard product is the **BSP 78**).

Each drain of these three chips is mounted on separated leadframes (see **P-DSO-28-9** pin configuration). The sources of all four power transistors are connected to separate pins.

So the **BTS 775 G** can be used in H-Bridge configuration as well as in any other switch configuration.

Moreover, it is possible to add current sense resistors.

All these features open a broad range of automotive and industrial applications.

Circuit Description

Input Circuit

The control inputs GH1,2 consist of TTL/CMOS compatible Schmitt-Triggers with hysteresis. Buffer amplifiers are driven by these stages and convert the logic signal into the necessary form for driving the power output stages.

The inputs GL1 and GL2 are connected to the internal gate-driving units of the fully protected N-channel vertical power-MOS-FETs.

Output Stages

The output stages consist of an ultra low $R_{DS\ ON}$ Power-MOS H-Bridge. Embedded protective circuits make the outputs short circuit proof to ground, to the supply voltage and load short circuit proof. Positive and negative voltage spikes, which occur when driving inductive loads, are limited by integrated power clamp diodes.

Short Circuit Protection

The outputs are protected against

- output short circuit to ground
- output short circuit to the supply voltage, and
- overload (load short circuit).

An internal OP-Amp controls the Drain-Source-Voltage by comparing the DS-Voltage-Drop with an internal reference voltage. Above this trippoint the OP-Amp reduces the output current depending on the junction temperature and the drop voltage.

In the case of overloaded high-side switches the status output is set to low.

If the HS-Switches are in OFF-state-Condition internal resistors $R_{O1,2}$ from SH1,2 to GND pull the voltage at SH1,2 to low values. On each output pin SH1 and SH2 an output examiner circuit compares the output voltages with the internal reference voltage VEO. This results in switching the status output to low. The fully protected low-side switches have no status output.

Overtemperature Protection

The highside and the lowside switch also incorporates an overtemperature protection circuit with hysteresis which switches off the output transistors and sets the status output to low.

Undervoltage-Lockout (UVLO)

When V_S reaches the switch-on voltage V_{UVON} the IC becomes active with a hysteresis. The High-Side output transistors are switched off if the supply voltage V_S drops below the switch off value V_{UVOFF} .

Overvoltage-Lockout (OVLO)

When V_S reaches the switch-off voltage $V_{OV\text{OFF}}$ the High-Side output transistors are switched off with a hysteresis. The IC becomes active if the supply voltage V_S drops below the switch-on value $V_{OV\text{ON}}$.

Open Load Detection

Open load is detected by current measurement. If the output current drops below an internal fixed level the error flag is set with a delay.

Status Flag

Various errors as listed in the table "Diagnosis" are detected by switching the open drain output ST to low.
