One-cell Lithium-ion battery protection with over/undercharge and overcurrent protection

NE57600

GENERAL DESCRIPTION

The NE57600 series is a family of small, high-precision lithium-ion battery protection devices that provide protection against the damaging effects of overcharging, overdischarging, short circuit, and excessive current consumption such as happens if the consumer uses the battery for an apparatus it was not meant to power. The NE57600 is a single-cell Li-ion protection IC.

The NE57600 over and under voltage accuracy is trimmed to within ± 25 mV (5%) and is available to match the requirements of all lithium-ion cells manufactured in the market today.

FEATURES

- Trimmed overvoltage trip point to within ± 25 mV
- Programmable overvoltage trip time delay
- Trimmed undervoltage trip point to within ± 25 mV
- Very Low undervoltage sleep quiescent current 0.05 mA
- Discharge overcurrent cutoff
- Low operating current (10 μ A)
- Very small SOT-26A package

APPLICATIONS

- Protecting one-cell Li-ion battery packs for mobile phones or palmtop devices

NE57600

ORDERING INFORMATION

TYPE NUMBER	PACKAGE		TEMPERATURE RANGE
	NAME	DESCRIPTION	
NE57600XD	SOT-26A	small outline plastic surface mount, 6-pin	-20 to +70 °C

NOTE:

The device has ten protection parameter options, indicated by the X on the order code, and defined in the following table.

TYPICAL PROTECTION PARAMETERS IN THE NE57600 FAMILY

Part Number	Overcharge detection voltage (V)	Overcharge detection hysteresis voltage (mV)	Over-discharge detection voltage (V)	Over-discharge resumption voltage (V)	Overcurrent detection voltage (mV)
NE57600Y	4.200	200	2.3	3.00	200
NE57600D	4.200	200	2.3	3.90	200
NE57600E	4.250	200	2.3	3.00	200
NE57600F	4.250	150	2.4	3.00	150
NE57600C	4.280	200	2.3	2.90	120
NE57600G	4.295	150	2.4	3.00	150
NE57600W	4.300	150	2.4	3.00	150
NE57600H	4.325	200	2.5	3.00	200
NE57600J	4.325	200	2.5	3.00	200
NE57600B	4.350	200	2.4	3.00	200

Part number marking

Each device is marked with a four letter code. The first three letters designate the product. The fourth letter, represented by "x", is a date tracking code.

Part Number	Marking
NE57600YD	A F A x
NE57600BD	A F B x
NE57600CD	A F C x
NE57600DD	A F D x
NE57600ED	A F E x
NE57600FD	A F F x
NE57600GD	A F G x
NE57600HD	A F H x
NE57600WD	A F J x
NE57600JD	A F K x

PIN CONFIGURATION

Figure 2. Pin configuration.

PIN DESCRIPTION

PIN	SYMBOL	DESCRIPTION
1	VM	Monitor pin. Detects overcurrent and the presence of a charger.
2	V _{CC}	Positive supply voltage input pin. Connect to positive terminal of the cell.
3	C _{DLY}	Charge Time Delay pin. The capacitor connected to this pin sets the delay.
4	CF	Charge FET pin. This drives the gate of the charge control N-ch FET.
5	GND	Ground pin. Connect to negative terminal of the cell.
6	DF	Discharge detection pin. This drives the gate of the discharge N-ch FET.

One-cell Lithium-ion battery protection with over/undercharge and overcurrent protection

NE57600

MAXIMUM RATINGS

SYMBOL	PARAMETER	MIN.	MAX.	UNIT
V_{IN}	Input voltage	-0.3	+18	V
$V_{CF(max)}$	CF pin voltage	-	$V_{CC} - 28$	V
$V_{VM(max)}$	VM pin voltage	-	$V_{CC} - 28$	V
T_{amb}	Operating ambient temperature range	-20	+70	°C
T_{stg}	Storage temperature	-40	+125	°C
P_D	Power dissipation	-	200	mW

ELECTRICAL CHARACTERISTICS

Characteristics measured with $T_{amb} = 25\text{ °C}$, unless otherwise specified.

SYMBOL	PARAMETER	CONDITIONS	Min.	Typ.	Max.	UNIT
I_{CC1}	Current consumption 1	$V_{CC} = 3.6\text{ V}$: Set between CF-GND: 910 k Ω connected		10.0	14.0	μA
I_{CC2}	Current consumption 2	$V_{CC} = 3.6\text{ V}$: IC only between CF-GND: 910 k Ω connected		6.0	10.0	μA
I_{CC3}	Current consumption 3	$V_{CC} = 3.6\text{ V}$: Discharge FET OFF between CF-GND: 910 k Ω not connected		TBD	TBD	μA
I_{CC4}	Current consumption 4	$V_{CC} = 1.9\text{ V}$: Discharge FET OFF between CF-GND: 910 k Ω not connected		0.05	0.3	μA
I_{CC5}	Current consumption 5	$V_{CC} = 4.5\text{ V}$: Set between CF-BG: 910 k Ω connected		35	60	μA
$V_{OV(th)}$	Over-charge voltage	$T_{amb} = 0\text{ °C} - 50\text{ °C}$ V_{CC} : L \rightarrow H	4.325	4.350	4.375	V
$V_{OV(hyst)}$	Over-charge hysteresis	V_{CC} : H \rightarrow L	100	200	300	mV
$V_{UV(th)}$	Over-discharge voltage	V_{CC} : H \rightarrow L	2.30	2.40	2.50	V
$V_{UV(rel)}$	Release over-discharge mode		2.88	3.00	3.12	V
$V_{OC(th)}$	Over-current detect level	V_{VM} : L \rightarrow H	174	200	226	mV
$V_{OC(rel)}$	Release over-current level	V_{VM} : H \rightarrow L		130		mV
	Condition of release over-current mode	Load condition		50		M Ω
V_{SC}	Short detect level			1.3		V
$t_{DLY(OD)}$	Over-discharge dead time		7.0	10.0	15.0	ms
$t_{OC(DT)}$	Over-current dead time	VM: 0 V \rightarrow 0.5 V	7.0	10.0	15.0	ms
$t_{DLY(SC)}$	Short detect delay time	VM: 0 V \rightarrow 2 V		0.02	0.20	ms
$t_{OLY(OV)}$	Over-charge dead time	$C_{TD} = 0.01\text{ }\mu\text{F}$	50	100	150	ms
V_{GDH}	DF pin LOW level	$V_{CC} = 3.6\text{ V}$	$V_{CC}-0.3$	$V_{CC}-0.1$	V_{CC}	V
I_{DFH1}	DF pin source current 1	$V_{DF} = V_{CC} - 1.0\text{ V}$		-100	-30	μA
I_{DFH2}	DF pin source current 2	$V_{DF} = V_{CC} - 0.3\text{ V}$		-0.40	-0.07	μA
I_{DFL1}	DF pin sink current 1	$V_{VM} > 1.0\text{ V}$; $V_{DF} = 1.0\text{ V}$	50	300		μA
I_{DFL2}	DF pin sink current 2	$V_{VM} > 1.0\text{ V}$; $V_{DF} = 0.3\text{ V}$	30	100		μA
I_{CF1}	CF pin source current 1	$V_{CF} = V_{CC} - 1.0\text{ V}$		-20	-10	μA
I_{CF2}	CF pin source current 2	$V_{CF} = V_{CC} - 0.3\text{ V}$		-15	-5	μA
V_{ST}	Start trigger voltage	V_{VM} : 0 V \rightarrow -0.5 V	-0.2	-0.1	0	V
V_{PRO}	Over-voltage charger protection	$V_{CC} = 3.6\text{ V}$, between GND-VM voltage	-1.5	-2.5	-3.0	V
V_{OV}	OV charge minimum voltage	$V_{CC} = 0\text{ V}$; Charger voltage		2.0	3.0	V

TECHNICAL DISCUSSION

Lithium Cell Safety

Lithium-ion and lithium-polymer cells have a higher energy density than that of nickel-cadmium or nickel metal hydride cells and have a much lighter weight. This makes the lithium cells attractive for use in portable products. However, lithium cells require a protection circuit within the battery pack because certain operating conditions can be hazardous to the battery or the operator, if allowed to continue.

Lithium cells have a porous carbon or graphite anode where lithium ions can lodge themselves in the pores. The lithium ions are separated, which avoids the hazards of metallic lithium.

If the lithium cell is allowed to become overcharged, metallic lithium plates out onto the surface of the anode and volatile gas is generated within the cell. This creates a **rapid-disassembly hazard** (the battery ruptures). If the cell is allowed to over-discharge (V_{cell} less than approximately 2.3 V), then the copper metal from the cathode goes into the electrolyte solution. This shortens the cycle life of the cell, but presents no safety hazard. If the cell experiences excessive charge or discharge currents, as happens if the wrong charger is used, or if the terminals short circuit, the internal series resistance of the cell creates heating and generates the volatile gas which could rupture the battery.

The protection circuit continuously monitors the cell voltage for an **overcharged condition** or an **overdischarged condition**. It also continuously monitors the output for an **overcurrent condition**. If any of these conditions are encountered, the protection circuit opens a series MOSFET switch to terminate the abnormal condition. The lithium cell protection circuit is placed within the battery pack very close to the cell.

Charging control versus battery protection

The battery pack industry does not recommend using the pack's internal protection circuit to end the charging process. The external battery charger should have a charge termination circuit in it, such as that provided by the SA57611. This provides two levels of overcharge protection, with the primary protection of the external charge control circuit and the backup protection from the battery pack's protection circuit. The charge termination circuit will be set to stop charging at a level around 50 mV less than the overvoltage threshold voltage of the battery pack's own protection circuit.

Lithium Cell Operating Characteristics

The internal resistance of lithium cells is in the 100 mΩ range, compared to the 5–20 mΩ of the nickel-based batteries. This makes the Lithium-ion and polymer cells better for lower battery current applications (less than 1 ampere) as found in cellular and wireless telephones, palmtop and laptop computers, etc.

The average operating voltage of a lithium-ion or polymer cell is 3.6 V as compared to the 1.2 V of NiCd and NiMH cells. The typical discharge curve for Lithium cell is shown in Figure 6.

Figure 6. Lithium discharge curve.

One-cell Lithium-ion battery protection with over/undercharge and overcurrent protection

NE57600

Charging Lithium Cells

The lithium cells must be charged with a dedicated charging IC such as the NE57600. These dedicated charging ICs perform a current-limited, constant-voltage charge, as shown in Figure 7.

The charger IC begins charging with a current that is typically the rating of the cell (1C) or the milliampere rating of the cell. As the cell approaches its full-charge voltage rating (V_{OV}), the current entering the cell decreases, and the charger IC provides a constant voltage. When the charge current falls below a preset amount, 50 mA for example, the charge is discontinued.

If charging is begun below the overdischarged voltage rating of the cell, it is important to slowly raise the cell voltage up to this overdischarged voltage level. This is done by a **reconditioning charge**. A small amount of current is provided to the cell (50 mA for example), and the cell voltage is allowed a period of time to rise to the overdischarged voltage. If the cell voltage recovers, then a normal charging sequence can begin. If the cell does not reach the overdischarged voltage level, then the cell is too damaged to charge and the charge is discontinued.

To take advantage of the larger energy density of lithium cells it is important to allow enough time to completely charge the cell. When the charger switches from constant current to constant voltage charge (Point B, Figure 7) the cell only contains about 80 percent of its full capacity. When the cell is 100 mV less than its full rated charge voltage the capacity contained within the cell is 95 percent. Hence, allowing the cell to slowly complete its charge takes advantage of the larger capacity of the lithium cells.

NE57600

APPLICATION INFORMATION

The NE57600 drives the series N-Channel MOSFETs to states determined by the cell's voltage and the battery pack load current. During normal operation, both the discharge and charge MOSFETs are ON, allowing bidirectional current flow.

If the battery pack is being charged, and the cell's voltage exceeds the overvoltage threshold, then the charge MOSFET is turned OFF. The cell's voltage must fall lower than the overvoltage hysteresis voltage ($V_{OV(Hyst)}$) before the charge MOSFET is again turned ON.

If the battery pack is being discharged and the undervoltage threshold ($V_{UV(TH)}$) is exceeded, then the discharge MOSFET is turned OFF. It will not turn back ON until a charger is applied to the pack's external terminals AND the cell's voltage rises above the undervoltage hysteresis voltage ($V_{UV(Hyst)}$).

When the battery pack is being discharged, if the load current causes the voltage across the discharge MOSFET to exceed the

overcurrent threshold voltage ($V_{OC(TH)}$), then the discharge MOSFET is turned OFF after a fixed 7–18 ms delay. If short-circuit is placed across the pack's terminals, then the discharge MOSFET is turned OFF after a 100–300 ms delay to avoid damaging the MOSFETs.

The R-C filter on the V_{CC} pin

An R-C filter is needed on the V_{CC} pin, primarily to shield the IC from electrostatic energy and spikes on the terminals of the battery pack. A secondary need is during the occurrence of a short-circuit across the battery pack terminals. Here, the Li-ion cell voltage could collapse and cause the IC to enter an unpowered state. The R-C filter provides power during the first instant of the short circuit, allowing the IC to turn OFF the discharge MOSFET before the IC loses power. The R-C filter also filters any voltage noise caused by noisy load current. The values shown in Figure 9 are adequate for these purposes.

Figure 9. Functional diagram.

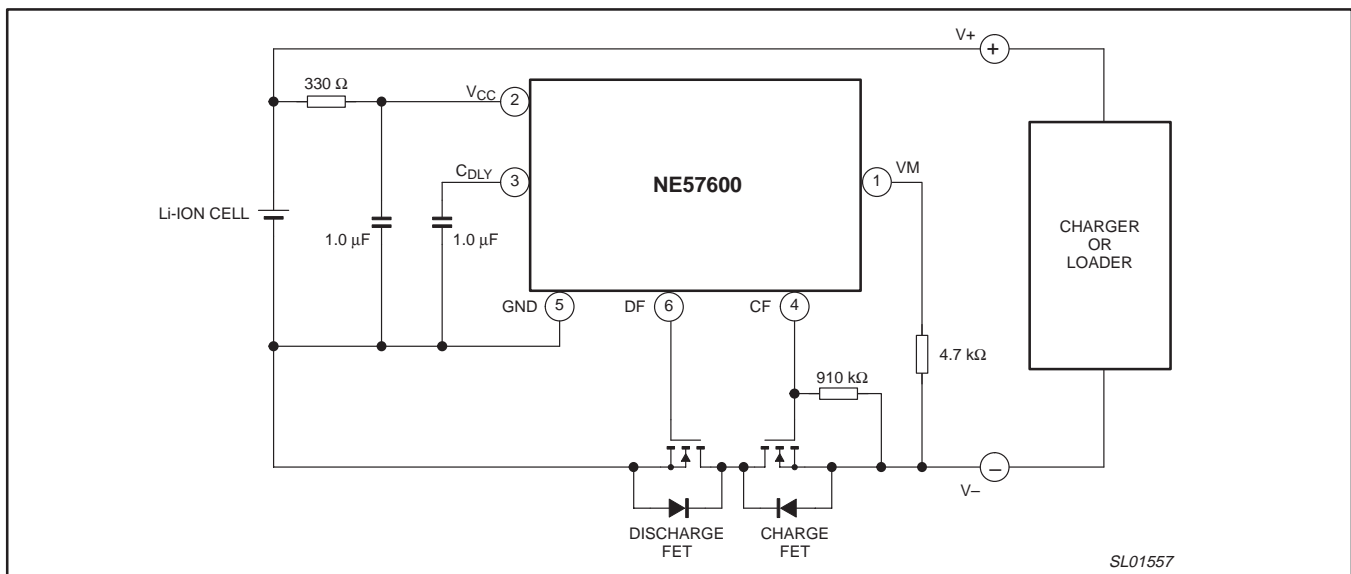

Figure 10. Typical application circuit.

One-cell Lithium-ion battery protection with over/undercharge and overcurrent protection

NE57600

FET STATUS FOR NORMAL AND ABNORMAL CONDITIONS

Operating Mode and Charging Condition	Charge FET (CF)	Discharge FET (DF)
Normal (charging or discharging)	ON	ON
Overcharge (charging)	OFF	ON
Overcharge (discharging)	ON	ON
Overdischarge (discharging)	OFF	OFF
Overdischarge (charging)	ON	ON
Overcurrent (charging or discharging)	OFF	OFF

- Normal mode:** Overdischarge detection voltage < battery voltage < overcharge detection voltage
Discharge current < overcurrent detection level
- Overcharge mode:** Battery voltage > overcharge detection voltage
- Overdischarge mode:** Overdischarge detection voltage > battery voltage
- Overcurrent mode:** Discharge current > overcurrent detection level
voltage between VM and GND = discharge current × FET ON resistance (discharge or charge FET)

Selecting the Optimum MOSFETs

For a single-cell battery pack, a logic-level MOSFET should be used. These MOSFETs have turn-on thresholds of 0.9 V and are considered full-on at 4.5 V VGS. Some problem may be encountered in not having enough gate voltage to fully turn-ON the series MOSFETs over the battery pack entire operating voltage. If one deliberately selects an N-Channel MOSFET with a much greater current rating, a lower RDS(on) over the entire range can be attained.

The MOSFETs should have a voltage rating greater than 20 V and should have a high avalanche rating to survive any spikes generated across the battery pack terminals.

The current rating of the MOSFETs should be greater than four times the maximum "C-rating" of the cells. The current rating, though, is more defined by the total series resistance of the battery pack. The total resistance of the battery pack is given by Equation 1.

$$R_{bat(tot)} = R_{DS(on)} + R_{cell} \quad (\text{Equation 1})$$

The total pack resistance is typically determined by the system requirements. The total pack resistance directly determines how much voltage droop will occur during pulses in load current.

Another consideration is the forward-biased safe operating area of the MOSFET. During a short-circuit, the discharge current can easily reach 10–15 times the "C-rating" of the cells. The MOSFET must survive this current prior to the discharge MOSFET can be turned OFF. So having an FBSOA envelope that exceeds 20 amperes for 5 ms would be safe.

Data sheet status

Data sheet status ^[1]	Product status ^[2]	Definitions
Objective data	Development	This data sheet contains data from the objective specification for product development. Philips Semiconductors reserves the right to change the specification in any manner without notice.
Preliminary data	Qualification	This data sheet contains data from the preliminary specification. Supplementary data will be published at a later date. Philips Semiconductors reserves the right to change the specification without notice, in order to improve the design and supply the best possible product.
Product data	Production	This data sheet contains data from the product specification. Philips Semiconductors reserves the right to make changes at any time in order to improve the design, manufacturing and supply. Changes will be communicated according to the Customer Product/Process Change Notification (CPCN) procedure SNW-SQ-650A.

[1] Please consult the most recently issued data sheet before initiating or completing a design.

[2] The product status of the device(s) described in this data sheet may have changed since this data sheet was published. The latest information is available on the Internet at URL <http://www.semiconductors.philips.com>.

Definitions

Short-form specification — The data in a short-form specification is extracted from a full data sheet with the same type number and title. For detailed information see the relevant data sheet or data handbook.

Limiting values definition — Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 60134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.

Application information — Applications that are described herein for any of these products are for illustrative purposes only. Philips Semiconductors make no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

Disclaimers

Life support — These products are not designed for use in life support appliances, devices or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips Semiconductors customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips Semiconductors for any damages resulting from such application.

Right to make changes — Philips Semiconductors reserves the right to make changes, without notice, in the products, including circuits, standard cells, and/or software, described or contained herein in order to improve design and/or performance. Philips Semiconductors assumes no responsibility or liability for the use of any of these products, conveys no license or title under any patent, copyright, or mask work right to these products, and makes no representations or warranties that these products are free from patent, copyright, or mask work right infringement, unless otherwise specified.
