

# Constant-Current/ Constant-Voltage 3A Battery Charger with Input Current Limiting

## FEATURES

- Simple Design to Charge NiCd, NiMH and Lithium Rechargeable Batteries—Charging Current Programmed by Resistors or DAC
- Adapter Current Loop Allows Maximum Possible Charging Current During Computer Use
- Precision 0.5% Accuracy for Voltage Mode Charging
- High Efficiency Current Mode PWM with 4A Internal Switch
- 5% Charging Current Accuracy
- Adjustable Undervoltage Lockout
- Automatic Shutdown When AC Adapter is Removed
- Low Reverse Battery Drain Current: 3 $\mu$ A
- Current Sensing Can Be at Either Terminal of the Battery
- Charging Current Soft-Start
- Shutdown Control

## APPLICATIONS

- Chargers for NiCd, NiMH, Lead-Acid, Lithium Rechargeable Batteries
- Switching Regulators with Precision Current Limit

## DESCRIPTION

The LT<sup>®</sup>1511 current mode PWM battery charger is the simplest, most efficient solution to fast charge modern rechargeable batteries including lithium-ion (Li-Ion), nickel-metal-hydride (NiMH) and nickel-cadmium (NiCd) that require constant-current and/or constant-voltage charging. The internal switch is capable of delivering 3A\* DC current (4A peak current). Full-charging current can be programmed by resistors or a DAC to within 5%. With 0.5% reference voltage accuracy, the LT1511 meets the critical constant-voltage charging requirement for Li-Ion cells.

A third control loop is provided to regulate the current drawn from the AC adapter. This allows simultaneous operation of the equipment and battery charging without overloading the adapter. Charging current is reduced to keep the adapter current within specified levels.

The LT1511 can charge batteries ranging from 1V to 20V. Ground sensing of current is not required and the battery's negative terminal can be tied directly to ground. A saturating switch running at 200kHz gives high charging efficiency and small inductor size. A blocking diode is not required between the chip and the battery because the chip goes into sleep mode and drains only 3 $\mu$ A when the wall adapter is unplugged.

LT, LTC and LT are registered trademarks of Linear Technology Corporation.  
 \*See LT1510 for 1.5A Charger

## PIN FUNCTIONS

**GND (Pins 1, 4, 5, 7, 16, 23, 24):** Ground Pin.

**SW (Pin 2):** Switch Output. The Schottky catch diode must be placed with very short lead length in close proximity to SW pin and GND.

**BOOST (Pin 3):** This pin is used to bootstrap and drive the switch power NPN transistor to a low on-voltage for low power dissipation. In normal operation,  $V_{BOOST} = V_{CC} + V_{BAT}$  when switch is on. Maximum allowable  $V_{BOOST}$  is 55V.

**UV (Pin 6):** Undervoltage Lockout Input. The rising threshold is at 6.7V with a hysteresis of 0.5V. Switching stops in undervoltage lockout. When the supply (normally the wall adapter output) to the chip is removed, the UV pin has to be pulled down to below 0.7V (a 5k resistor from adapter output to GND is required) otherwise the reverse battery current drained by the chip will be approximately 200 $\mu$ A instead of 3 $\mu$ A. Do not leave UV pin floating. If it is connected to  $V_{IN}$  with no resistor divider, the built-in 6.7V undervoltage lockout will be effective.

**OVP (Pin 8):** This is the input to the amplifier VA with a threshold of 2.465V. Typical input current is about 3nA out of pin. For charging lithium-ion batteries, VA monitors the battery voltage and reduces charging when battery voltage reaches the preset value. If it is not used, the OVP pin should be grounded.

**CLP (Pin 9):** This is the positive input to the supply current limit amplifier CL1. The threshold is set at 100mV. When used to limit supply current, a filter is needed to filter out the 200kHz switching noise.

**CLN (Pin 10):** This is the negative input to the amplifier CL1.

**COMP1 (Pin 11):** This is the compensation node for the amplifier CL1. A 200pF capacitor is required from this pin to GND if input current amplifier CL1 is used. At input adapter current limit, this node rises to 1V. By forcing COMP1 low with an external transistor, amplifier CL1 will be defeated (no adapter current limit). COMP1 can source 200 $\mu$ A.

**SENSE (Pin 12):** Current Amplifier CA1 Input. Sensing can be at either terminal of the battery.

**SPIN (Pin 13):** This pin is for the internal amplifier CA1 bias. It has to be connected to  $R_{S1}$  as shown in the 3A Lithium Battery Charger (Figure 1).

**BAT (Pin 14):** Current Amplifier CA1 Input.

**COMP2 (Pin 15):** This is also a compensation node for the amplifier CL1. It gets up to 2.8V at input adapter current limit and/or at constant-voltage charging.

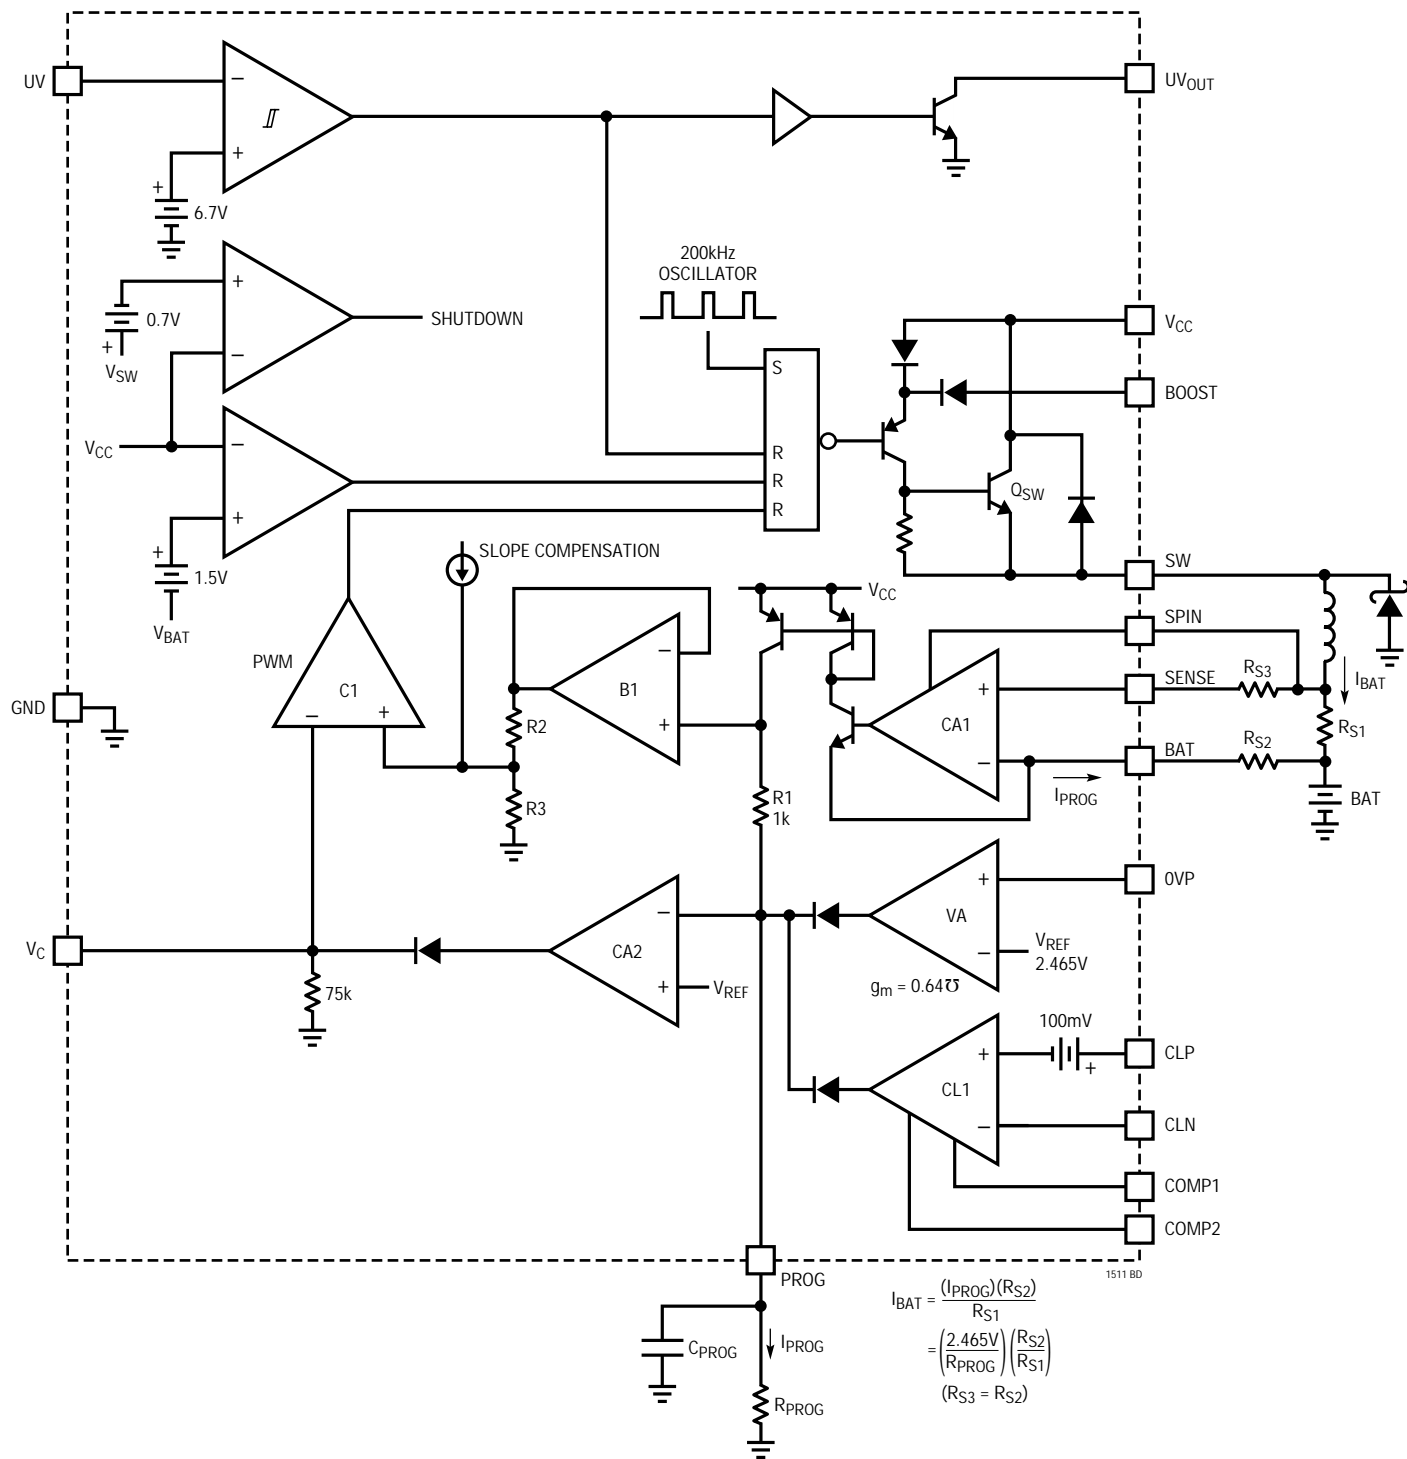

**UV<sub>OUT</sub> (Pin 17):** This is an open collector output for undervoltage lockout status. It stays low in undervoltage state. With an external pull-up resistor, it goes high at valid  $V_{CC}$ . Note that the base drive of the open collector NPN comes from CLN pin. UV<sub>OUT</sub> stays low only when CLN is higher than 2V. Pull-up current should be kept under 100 $\mu$ A.

**$V_C$  (Pin 18):** This is the control signal of the inner loop of the current mode PWM. Switching starts at 0.7V. Higher  $V_C$  corresponds to higher charging current in normal operation. A capacitor of at least 0.33 $\mu$ F to GND filters out noise and controls the rate of soft-start. To shut down switching, pull this pin low. Typical output current is 30 $\mu$ A.

**PROG (Pin 19):** This pin is for programming the charging current and for system loop compensation. During normal operation,  $V_{PROG}$  stays close to 2.465V. If it is shorted to GND the switching will stop. When a microprocessor controlled DAC is used to program charging current, it must be capable of sinking current at a compliance up to 2.465V.

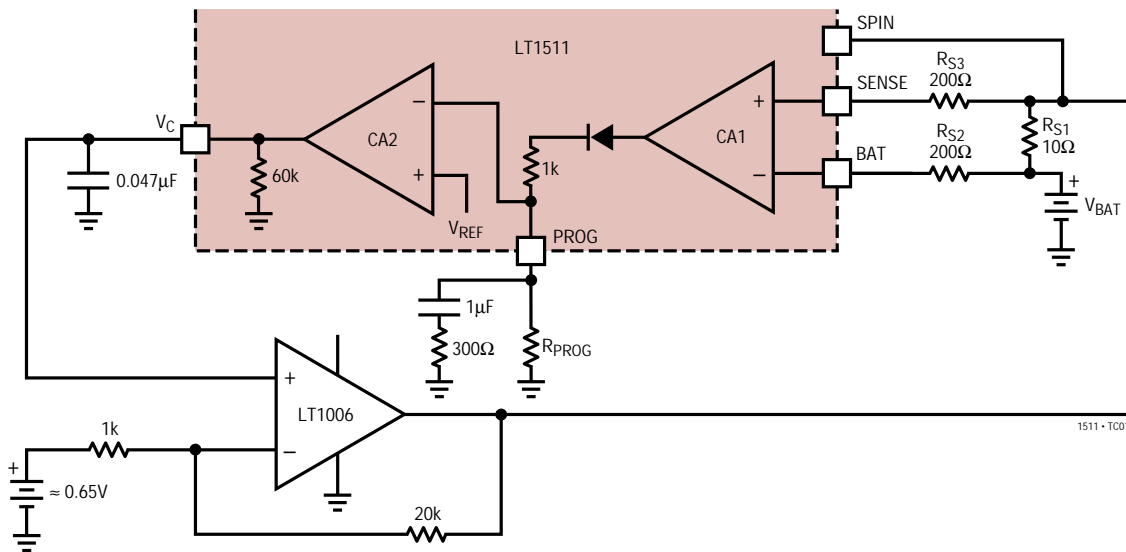

**$V_{CC}$  (Pins 20, 21, 22):** This is the supply of the chip. For good bypass, a low ESR capacitor of 20 $\mu$ F or higher is required, with the lead length kept to a minimum.  $V_{CC}$  should be between 8V and 28V and at least 3V higher than  $V_{BAT}$ . Undervoltage lockout starts and switching stops when  $V_{CC}$  goes below 7V. Note that there is a parasitic diode inside from SW pin to  $V_{CC}$  pin. Do not force  $V_{CC}$  below SW by more than 0.7V with battery present. All three  $V_{CC}$  pins should be shorted together close to the pins.

# BLOCK DIAGRAM

TEST CIRCUITS

Test Circuit 1

Test Circuit 2

OPERATION

The LT1511 is a current mode PWM step-down (buck) switcher. The battery DC charging current is programmed by a resistor  $R_{PROG}$  (or a DAC output current) at the PROG pin (see Block Diagram). Amplifier CA1 converts the charging current through  $R_{S1}$  to a much lower current  $I_{PROG}$  fed into the PROG pin. Amplifier CA2 compares the output of CA1 with the programmed current and drives the PWM loop to force them to be equal. High DC accuracy is achieved with averaging capacitor  $C_{PROG}$ . Note that  $I_{PROG}$  has both AC and DC components.  $I_{PROG}$  goes through R1 and generates a ramp signal that is fed to the PWM control comparator C1 through buffer B1 and level shift resistors

R2 and R3, forming the current mode inner loop. The Boost pin drives the switch NPN  $Q_{SW}$  into saturation and reduces power loss. For batteries like lithium-ion that require both constant-current and constant-voltage charging, the 0.5%, 2.465V reference and the amplifier VA reduce the charging current when battery voltage reaches the preset level. For NiMH and NiCd, VA can be used for overvoltage protection. When input voltage is not present, the charger goes into low current (3 $\mu$ A typically) sleep mode as input drops down to 0.7V below battery voltage. To shut down the charger, simply pull the  $V_C$  pin low with a transistor.

## APPLICATIONS INFORMATION

### Input and Output Capacitors

In the 3A Lithium Battery Charger (Figure 1), the input capacitor ( $C_{IN}$ ) is assumed to absorb all input switching ripple current in the converter, so it must have adequate ripple current rating. Worst-case RMS ripple current will be equal to one half of output charging current. Actual capacitance value is not critical. Solid tantalum capacitors such as the AVX TPS and Sprague 593D series have high ripple current rating in a relatively small surface mount package, but *caution must be used when tantalum capacitors are used for input bypass*. High input surge currents can be created when the adapter is hot-plugged to the charger and solid tantalum capacitors have a known failure mechanism when subjected to very high turn-on surge currents. Highest possible voltage rating on the capacitor will minimize problems. Consult with the manufacturer before use. Alternatives include new high capacity ceramic ( $5\mu\text{F}$  to  $20\mu\text{F}$ ) from Tokin or United Chemi-Con/Marcon, et al., and the old standby, aluminum electrolytic, which will require more microfarads to achieve adequate ripple rating. Sanyo OS-CON can also be used.

The output capacitor ( $C_{OUT}$ ) is also assumed to absorb output switching current ripple. The general formula for capacitor current is:

$$I_{RMS} = \frac{0.29 (V_{BAT}) \left(1 - \frac{V_{BAT}}{V_{CC}}\right)}{(L1)(f)}$$

For example,  $V_{CC} = 16\text{V}$ ,  $V_{BAT} = 8.4\text{V}$ ,  $L1 = 20\mu\text{H}$ , and  $f = 200\text{kHz}$ ,  $I_{RMS} = 0.3\text{A}$ .

EMI considerations usually make it desirable to minimize ripple current in the battery leads, and beads or inductors may be added to increase battery impedance at the 200kHz switching frequency. Switching ripple current splits between the battery and the output capacitor depending on the ESR of the output capacitor and the battery impedance. If the ESR of  $C_{OUT}$  is  $0.2\Omega$  and the battery impedance is rased to  $4\Omega$  with a bead or inductor, only 5% of the current ripple will flow in the battery.

### Soft-Start

The LT1511 is soft started by the  $0.33\mu\text{F}$  capacitor on the  $V_C$  pin. On start-up,  $V_C$  pin voltage will rise quickly to  $0.5\text{V}$ , then ramp at a rate set by the internal  $45\mu\text{A}$  pull-up current and the external capacitor. Battery charging current starts ramping up when  $V_C$  voltage reaches  $0.7\text{V}$  and full current is achieved with  $V_C$  at  $1.1\text{V}$ . With a  $0.33\mu\text{F}$  capacitor, time to reach full charge current is about  $10\text{ms}$  and it is assumed that input voltage to the charger will reach full value in less than  $10\text{ms}$ . The capacitor can be increased up to  $1\mu\text{F}$  if longer input start-up times are needed.

In any switching regulator, conventional timer-based soft starting can be defeated if the input voltage rises much slower than the time out period. This happens because the switching regulators in the battery charger and the computer power supply are typically supplying a fixed amount of power to the load. If input voltage comes up slowly compared to the soft start time, the regulators will try to deliver full power to the load when the input voltage is still well below its final value. If the adapter is current limited, it cannot deliver full power at reduced output voltages and the possibility exists for a quasi "latch" state where the adapter output stays in a current limited state at reduced output voltage. For instance, if maximum charger plus computer load power is  $30\text{W}$ , a  $15\text{V}$  adapter might be current limited at  $2.5\text{A}$ . If adapter voltage is less than ( $30\text{W}/2.5\text{A} = 12\text{V}$ ) when full power is drawn, the adapter voltage will be sucked down by the constant  $30\text{W}$  load until it reaches a lower stable state where the switching regulators can no longer supply full load. This situation can be prevented by utilizing *undervoltage lockout*, set higher than the minimum adapter voltage where full power can be achieved.

A fixed undervoltage lockout of  $7\text{V}$  is built into the  $V_{CC}$  pin, but an additional adjustable lockout is also available on the UV pin. Internal lockout is performed by clamping the  $V_C$  pin low. The  $V_C$  pin is released from its clamped state when the UV pin rises above  $6.7\text{V}$  and is pulled low when the UV pin drops below  $6.2\text{V}$  ( $0.5\text{V}$  hysteresis). At the same time  $UV_{OUT}$  goes high with an external pull-up resistor. This signal can be used to alert the system that charging is about to start. The charger will start delivering current about  $4\text{ms}$  after  $V_C$  is released, as set by the  $0.33\mu\text{F}$

## APPLICATIONS INFORMATION

capacitor. A resistor divider is used to set the desired  $V_{CC}$  lockout voltage as shown in Figure 2. A typical value for  $R_6$  is 5k and  $R_5$  is found from:

$$R_5 = \frac{R_6(V_{IN} - V_{UV})}{V_{UV}}$$

$V_{UV}$  = Rising lockout threshold on the UV pin

$V_{IN}$  = Charger input voltage that will sustain full load power

Example: With  $R_6 = 5k$ ,  $V_{UV} = 6.7V$  and setting  $V_{IN}$  at 12V;  
 $R_5 = 5k (12V - 6.7V)/6.7V = 4k$

The resistor divider should be connected directly to the adapter output as shown, not to the  $V_{CC}$  pin to prevent battery drain with no adapter voltage. If the UV pin is not used, connect it to the adapter output (not  $V_{CC}$ ) and connect a resistor no greater than 5k to ground. Floating the pin will cause reverse battery current to increase from  $3\mu A$  to  $200\mu A$ .

If connecting the unused UV pin to the adapter output is not possible for some reason, it can be grounded. Although it would seem that grounding the pin creates a permanent lockout state, the UV circuitry is arranged for phase reversal with low voltages on the UV pin to allow the grounding technique to work.

Figure 2. Adapter Current Limiting

### Adapter Limiting

An important feature of the LT1511 is the ability to automatically adjust charging current to a level which avoids overloading the wall adapter. This allows the product to operate at the same time that batteries are

being charged without complex load management algorithms. Additionally, batteries will automatically be charged at the maximum possible rate of which the adapter is capable.

This feature is created by sensing total adapter output current and adjusting charging current downward if a preset adapter current limit is exceeded. True analog control is used, with closed loop feedback ensuring that adapter load current remains within limits. Amplifier CL1 in Figure 2 senses the voltage across  $R_{S4}$ , connected between the CLP and CLN pins. When this voltage exceeds 100mV, the amplifier will override programmed charging current to limit adapter current to  $100mV/R_{S4}$ . A lowpass filter formed by  $500\Omega$  and  $1\mu F$  is required to eliminate switching noise. If the current limit is not used, both CLP and CLN pins should be connected to  $V_{CC}$ .

### Charging Current Programming

The basic formula for charging current is (see Block Diagram):

$$I_{BAT} = I_{PROG} \left( \frac{R_{S2}}{R_{S1}} \right) = \left( \frac{2.465V}{R_{PROG}} \right) \left( \frac{R_{S2}}{R_{S1}} \right)$$

where  $R_{PROG}$  is the total resistance from PROG pin to ground.

For the sense amplifier CA1 biasing purpose,  $R_{S3}$  should have the same value as  $R_{S2}$  and SPIN should be connected directly to the sense resistor ( $R_{S1}$ ) as shown in the Block Diagram.

For example, 3A charging current is needed. To have low power dissipation on  $R_{S1}$  and enough signal to drive the amplifier CA1, let  $R_{S1} = 100mV/3A = 0.033\Omega$ . This limits  $R_{S1}$  power to 0.3W. Let  $R_{PROG} = 5k$ , then:

$$R_{S2} = R_{S3} = \frac{(I_{BAT})(R_{PROG})(R_{S1})}{2.465V}$$

$$= \frac{(3A)(5k)(0.033)}{2.465V} = 200\Omega$$

Charging current can also be programmed by pulse width modulating  $I_{PROG}$  with a switch Q1 to  $R_{PROG}$  at a frequency higher than a few kHz (Figure 3). Charging current will be proportional to the duty cycle of the switch with full current at 100% duty cycle.

## APPLICATIONS INFORMATION

Figure 3. PWM Current Programming

### Lithium-Ion Charging

The 3A Lithium Battery Charger (Figure 1) charges lithium-ion batteries at a constant 3A until battery voltage reaches a limit set by R3 and R4. The charger will then automatically go into a constant-voltage mode with current decreasing to zero over time as the battery reaches full charge. This is the normal regimen for lithium-ion charging, with the charger holding the battery at “float” voltage indefinitely. In this case no external sensing of full charge is needed.

### Battery Voltage Sense Resistors Selection

To minimize battery drain when the charger is off, current through the R3/R4 divider is set at 15μA. The input current to the OVP pin is 3nA and the error can be neglected.

With divider current set at 15μA,  $R4 = 2.465/15\mu A = 162k$  and,

$$R3 = \frac{(R4)(V_{BAT} - 2.465)}{2.465} = \frac{162k(8.4 - 2.465)}{2.465} = 390k$$

Li-Ion batteries typically require float voltage accuracy of 1% to 2%. Accuracy of the LT1511 OVP voltage is ±0.5% at 25°C and ±1% over full temperature. This leads to the possibility that very accurate (0.1%) resistors might be needed for R3 and R4. Actually, the temperature of the LT1511 will rarely exceed 50°C in float mode because charging currents have tapered off to a low level, so 0.25% resistors will normally provide the required level of overall accuracy.

When power is on, there is about 200μA of current flowing out of the BAT and Sense pins. If the battery is removed during charging, and total load including R3 and R4 is less than the 200μA,  $V_{BAT}$  could float up to  $V_{CC}$  even though the loop has turned switching off. To keep  $V_{BAT}$  regulated to the battery voltage in this condition, R3 and R4 can be chosen to draw 0.5mA and Q3 can be added to disconnect them when power is off (Figure 4). R5 isolates the OVP pin from any high frequency noise on  $V_{IN}$ . An alternative way is to use a Zener diode with a breakdown voltage two or three volts higher than battery voltage to clamp the  $V_{BAT}$  voltage.

Figure 4. Disconnecting Voltage Divider

Some battery manufacturers recommend termination of constant-voltage float mode after charging current has dropped below a specified level (typically around 10% of the full current) and a further time out period of 30 minutes to 90 minutes has elapsed. This may extend the life of the battery, so check with manufacturers for details. The circuit in Figure 5 will detect when charging current has dropped below 400mA. This logic signal is used to initiate a timeout period, after which the LT1511 can be shut down by pulling the  $V_C$  pin low with an open collector or drain. Some external means must be used to detect the need for additional charging or the charger may be turned on periodically to complete a short float-voltage cycle.

Current trip level is determined by the battery voltage, R1 through R3 and the sense resistor ( $R_{S1}$ ). D2 generates hysteresis in the trip level to avoid multiple comparator transitions.

## APPLICATIONS INFORMATION

### Nickel-Cadmium and Nickel-Metal-Hydrate Charging

The circuit in the 3A Lithium Battery Charger (Figure 1) can be modified to charge NiCd or NiMH batteries. For example, 2-level charging is needed; 2A when Q1 is on and 200mA when Q1 is off.

Figure 6. 2-Level Charging

For 2A full current, the current sense resistor ( $R_{S1}$ ) should be increased to  $0.05\Omega$  so that enough signal (10mV) will be across  $R_{S1}$  at 0.2A trickle charge to keep charging current accurate.

For a 2-level charger, R1 and R2 are found from;

$$R1 = \frac{(2.465)(4000)}{I_{LOW}} \quad R2 = \frac{(2.465)(4000)}{I_{HI} - I_{LOW}}$$

All battery chargers with fast charge rates require some means to detect full charge state in the battery to terminate the high charging current. NiCd batteries are typically charged at high current until temperature rise or battery voltage decrease is detected as an indication of near full charge. The charging current is then reduced to a much lower value and maintained as a constant trickle charge. An intermediate "top off" current may be used for a fixed time period to reduce 100% charge time.

NiMH batteries are similar in chemistry to NiCd but have two differences related to charging. First, the inflection characteristic in battery voltage as full charge is approached is not nearly as pronounced. This makes it more difficult to use  $dV/dt$  as an indicator of full charge, and change of temperature is more often used with a temperature sensor in the battery pack. Secondly, constant trickle charge may not be recommended. Instead, a moderate level of current is used on a pulse basis ( $\approx 1\%$  to  $5\%$  duty cycle) with the time-averaged value substituting for a constant low trickle. Please contact the Linear Technology Applications Department about charge termination circuits.

If overvoltage protection is needed, R3 and R4 should be calculated according to the procedure described in Lithium-Ion Charging section. The OVP pin should be grounded if not used.

When a microprocessor DAC output is used to control charging current, it must be capable of sinking current at a compliance up to 2.5V if connected directly to the PROG pin.

### Thermal Calculations

If the LT1511 is used for charging currents above 1.5A, a thermal calculation should be done to ensure that junction temperature will not exceed  $125^\circ\text{C}$ . Power dissipation in the IC is caused by bias and driver current, switch resistance and switch transition losses. The SO wide package, with a thermal resistance of  $30^\circ\text{C/W}$ , can provide a full 3A charging current in many situations. A graph is shown in the Typical Performance Characteristics section.

## APPLICATIONS INFORMATION

$$P_{BIAS} = (3.5\text{mA})(V_{IN}) + 1.5\text{mA}(V_{BAT})$$

$$+ \frac{(V_{BAT})^2}{V_{IN}} [7.5\text{mA} + (0.012)(I_{BAT})]$$

$$P_{DRIVER} = \frac{(I_{BAT})(V_{BAT})^2 \left(1 + \frac{V_{BAT}}{30}\right)}{55(V_{IN})}$$

$$P_{SW} = \frac{(I_{BAT})^2 (R_{SW})(V_{BAT})}{V_{IN}} + (t_{OL})(V_{IN})(I_{BAT})(f)$$

$R_{SW}$  = Switch ON resistance  $\approx 0.16\Omega$   
 $t_{OL}$  = Effective switch overlap time  $\approx 10\text{ns}$   
 $f$  = 200kHz

Example:  $V_{IN} = 15\text{V}$ ,  $V_{BAT} = 8.4\text{V}$ ,  $I_{BAT} = 3\text{A}$ ;

$$P_{BIAS} = (3.5\text{mA})(15) + 1.5\text{mA}(8.4)$$

$$+ \frac{(8.4)^2}{15} [7.5\text{mA} + (0.012)(3)] = 0.27\text{W}$$

$$P_{DRIVER} = \frac{(3)(8.4)^2 \left(1 + \frac{8.4}{30}\right)}{55(15)} = 0.33\text{W}$$

$$P_{SW} = \frac{(3)^2 (0.16)(8.4)}{15} + 10^{-9}(15)(3)(200\text{kHz})$$

$$= 0.81 + 0.09 = 0.9\text{W}$$

Total Power in the IC is:  $0.27 + 0.33 + 0.9 = 1.5\text{W}$

Temperature rise will be  $(1.5\text{W})(30^\circ\text{C/W}) = 45^\circ\text{C}$ . This assumes that the LT1511 is properly heat sunk by connecting the seven fused ground pins to expanded traces and that the PC board has a backside or internal plane for heat spreading.

The  $P_{DRIVER}$  term can be reduced by connecting the boost diode D2 (see Figure 1) to a lower system voltage (lower than  $V_{BAT}$ ) instead of  $V_{BAT}$ .

$$\text{Then } P_{DRIVER} = \frac{(I_{BAT})(V_{BAT})(V_X) \left(1 + \frac{V_X}{30}\right)}{55(V_{IN})}$$

For example,  $V_X = 3.3\text{V}$  then:

Figure 7. Lower  $V_{BOOST}$

$$P_{DRIVER} = \frac{(3\text{A})(8.4\text{V})(3.3\text{V}) \left(1 + \frac{3.3\text{V}}{30}\right)}{55(15\text{V})} = 0.11\text{W}$$

The average  $I_{VX}$  required is:

$$\frac{P_{DRIVER}}{V_X} = \frac{0.11\text{W}}{3.3\text{V}} = 34\text{mA}$$

Fused-lead packages conduct most of their heat out the leads. This makes it very important to provide as much PC board copper around the leads as is practical. Total thermal resistance of the package-board combination is dominated by the characteristics of the board in the immediate area of the package. This means both lateral thermal resistance across the board and vertical thermal resistance through the board to other copper layers. Each layer acts as a thermal heat spreader that increases the heat sinking effectiveness of extended areas of the board.

Total board area becomes an important factor when the area of the board drops below about 20 square inches. The graph in Figure 8 shows thermal resistance vs board area for 2-layer and 4-layer boards with continuous copper planes. Note that 4-layer boards have significantly lower thermal resistance, but both types show a rapid increase for reduced board areas. Figure 9 shows actual measured lead temperatures for chargers operating at full current. Battery voltage and input voltage will affect device power dissipation, so the data sheet power calculations must be used to extrapolate these readings to other situations.

Vias should be used to connect board layers together. Planes under the charger area can be cut away from the rest of the board and connected with vias to form both a

## APPLICATIONS INFORMATION

low thermal resistance system and to act as a ground plane for reduced EMI.

Glue-on, chip-mounted heat sinks are effective only in moderate power applications where the PC board copper cannot be used, or where the board size is small. They offer very little improvement in a properly laid out multi-layer board of reasonable size.

### Higher Duty Cycle for the LT1511 Battery Charger

Maximum duty cycle for the LT1511 is typically 90%, but this may be too low for some applications. For example, if an  $18V \pm 3\%$  adapter is used to charge ten NiMH cells, the charger must put out 15V maximum. A total of 1.6V is lost in the input diode, switch resistance, inductor resistance and parasitics, so the required duty cycle is  $15/16.4 = 91.4\%$ . As it turns out, duty cycle can be extended to 93%

by restricting boost voltage to 5V instead of using  $V_{BAT}$  as is normally done. This lower boost voltage also reduces power dissipation in the LT1511, so it is a win-win decision. Connect an external source of 3V to 6V at  $V_X$  node in Figure 10 with a  $10\mu F$   $C_X$  bypass capacitor.

### Even Lower Dropout

For even lower dropout and/or reducing heat on the board, the input diode D3 should be replaced with a FET (see Figure 11). It is pretty straightforward to connect a P-channel FET across the input diode and connect its gate to the battery so that the FET commutates off when the input goes low. The problem is that the gate must be pumped low so that the FET is fully turned on even when the input is only a volt or two above the battery voltage. Also there is a turn-off speed issue. The FET should turn

Figure 8. LT1511 Thermal Resistance

Figure 10. High Duty Cycle

Figure 11. Replacing the Input Diode

## APPLICATIONS INFORMATION

off instantly when the input is dead shorted to avoid large current surges from the battery back through the charger into the FET. Gate capacitance slows turn-off, so a small P-channel (Q2) is to discharge the gate capacitance quickly in the event of an input short. The body diode of Q2 creates the necessary pumping action to keep the gate of Q1 low during normal operation. Note that Q1 and Q2 have a  $V_{GS}$  spec limit of 20V. This restricts  $V_{IN}$  to a maximum of 20V. For low dropout operation with  $V_{IN} > 20V$  consult factory.

### Optional Connection of Input Diode and Current Sense Resistor

The typical application shown in Figure 1 on the first page of this data sheet shows a single diode to isolate the  $V_{CC}$  pin from the adapter input. This simple connection may be unacceptable in situations where the main system power must be disconnected from both the battery *and* the adapter under some conditions. In particular, if the adapter is disconnected or turned off and it is desired to also

disconnect the system load from the battery, the system will remain powered through the parasitic diode from the SW pin to the  $V_{CC}$  pin.

The circuit in Figure 12b allows system power to go to 0V without drawing battery current by adding an additional diode, D4. To ensure proper operation, the LT1511 current sense amplifier inputs (CLP and CLN) were designed to work above  $V_{CC}$  and not to draw current from  $V_{CC}$  when the inputs are pulled to ground by a powered-down adapter.

### Layout Considerations

Switch rise and fall times are under 10ns for maximum efficiency. To prevent radiation, the catch diode, SW pin and input bypass capacitor leads should be kept as short as possible. A ground plane should be used under the switching circuitry to prevent interplane coupling and to act as a thermal spreading path. All ground pins should be connected to expanded traces for low thermal resistance. The fast-switching high current ground path, including the switch, catch diode and input capacitor, should be kept very short. Catch diode and input capacitor should be close to the chip and terminated to the same point. This path contains nanosecond rise and fall times with several amps of current. The other paths contain only DC and/or 200kHz tri-wave and are less critical. Figure 13 indicates the high speed, high current switching path. Figure 14 shows critical path layout. Contact Linear Technology for an actual LT1511 circuit PCB layout or Gerber file.
