

**Features**

- Integrated Power Control & Band Select
- Single 3.0V to 4.8V Supply Voltage
- +35.0dBm GSM Output Pwr at 3.5V
- +33dBm DCS/PCS Output Pwr at 3.5V
- +29dBm 8PSK Output Pwr
- 53% GSM and 50% DCS/PCS PAE

**Applications**

- 3V Dual/Triple/Quad-Band Mode Handsets
- Portable Battery-Powered Equipment
- GSM850 and GSM900 Products
- Commercial and Consumer Systems
- EDGE and GPRS Class 12 Compatible
- DCS/PCS Products

Functional Block Diagram

**Product Description**

The RF3145 is a high power, high efficiency power amplifier module with integrated power control. This module is self-contained with 50Ω input and output terminals. The device is manufactured on an advance Gallium Arsenide Heterojunction Bipolar Transistor (HBT) process, and has been designed for use as the final dual-mode GMSK/8PSK RF amplifier in GSM, DCS and PCS hand-held cellular equipment and other applications in the 824MHz to 849MHz, 880MHz to 915MHz, and in the 1710MHz to 1910MHz bands. Internal band select provides control to select the GSM850/GSM900 or DCS/PCS band. The device is packaged on ultra-small LCC, minimizing the required board space.

**Ordering Information**

RF3145	Quad-Band GSM/EDGE/GSM850/DCS/PCS Power Amplifier Module
	Power Amplifier Module, 5 Piece Sample Pack
RF3145PCBA-41X	Fully Assembled Evaluation Board

**Optimum Technology Matching® Applied**

## Absolute Maximum Ratings

Parameter	Rating	Unit
Supply Voltage	-0.3 to +6.0	V
Power Control Voltage ( $V_{RAMP}$ )	-0.3 to +1.8	V
Band Select	3.0	V
TX Enable	3.0	V
RF - Input Power	12.0	dBm
Max Duty Cycle	50	%
Output Load VSWR	10:1	
Operating Case Temperature	-30 to +90	°C
Storage Temperature	-55 to +150	°C

**Caution!** ESD sensitive device.

Exceeding any one or a combination of the Absolute Maximum Rating conditions may cause permanent damage to the device. Extended application of Absolute Maximum Rating conditions to the device may reduce device reliability. Specified typical performance or functional operation of the device under Absolute Maximum Rating conditions is not implied.

RoHS status based on EU Directive 2002/95/EC (at time of this document revision).

Note:  $V_{RAMP,MAX} = 3/8 * V_{BATT} + 0.18 \leq 1.6V$

Pin	Function	Description	Interface Schematic
1	<b>DCS/PCS IN</b>	RF input to the DCS/PCS band. This is a 50Ω input.	
2	<b>BAND SELECT</b>	Allows external control to select the GSM or DCS/PCS band with a logic high or low. A logic low enables the GSM band whereas a logic high enables the DCS/PCS band.	
3	<b>TX ENABLE</b>	This signal enables the PA module for operation with a logic high. Once TX Enable is asserted the RF output level will increase to 0dBm.	
4	<b>VBATT</b>	Power supply for the module. This should be connected to the battery.	
5	<b>VMODE</b>	This signal selects 8PSK mode with a logic "high" (1.5V to 3.0V), and selects GMSK mode with a logic "low" (0V to 0.7V). When the VMODE switch is enabled "high", the gain in the GSM band is reduced by bypassing the first stage amplifier. When the VMODE is "low", all stages are active.	
6	<b>VRAMP</b>	Ramping signal from DAC. A simple RC filter may need to be connected between the DAC output and the V <sub>RAMP</sub> input depending on the baseband selected. The ramping profiles shown later in the data sheet are recommended profiles for meeting the GSM specification for burst timing and transient spectrum.	
7	<b>GSM IN</b>	RF input to the GSM band. This is a 50Ω input.	
8	<b>NC</b>	Not connected.	
9	<b>GSM OUT</b>	RF output for the GSM band. This is a 50Ω output. The output load line matching is contained internal to the package.	
10	<b>NC</b>	Not connected.	
11	<b>DCS/PCS OUT</b>	RF output for the DCS/PCS band. This is a 50Ω output. The output load line matching is contained internal to the package.	
12	<b>NC</b>	Not connected.	
<b>Pkg Base</b>	<b>GND</b>		

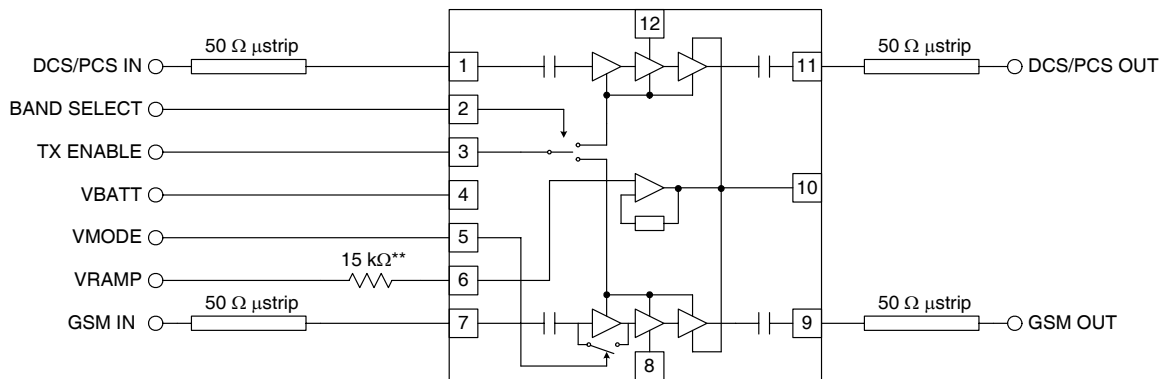

## Package Drawing

## Pin Out

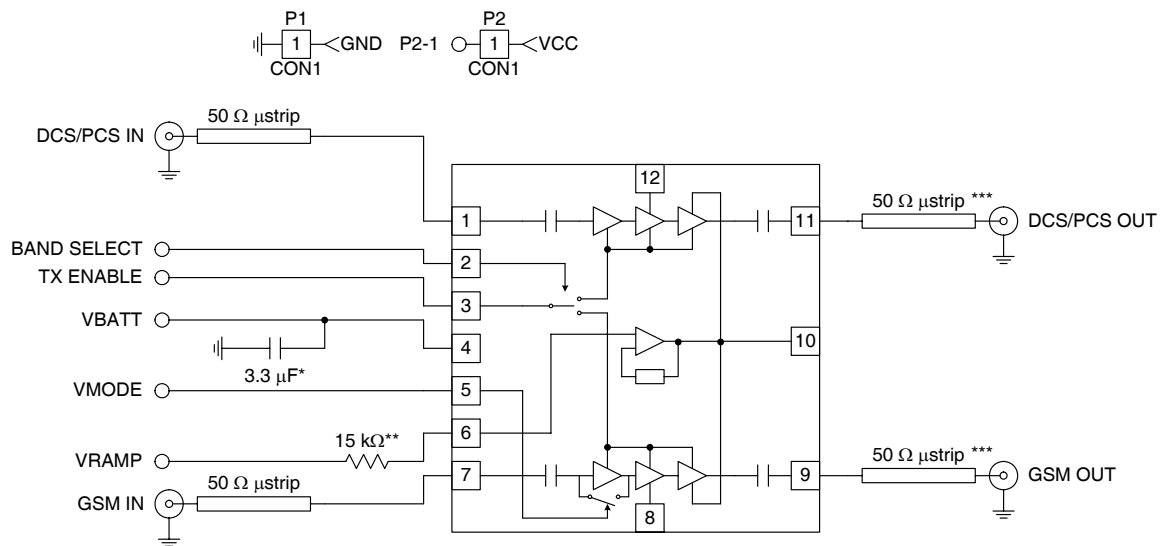

### Application Schematic

\*\* Used to filter noise and spurious from base band.

### Evaluation Board Schematic

(Download [Bill of Materials](http://www.rfmd.com) from [www.rfmd.com](http://www.rfmd.com).)

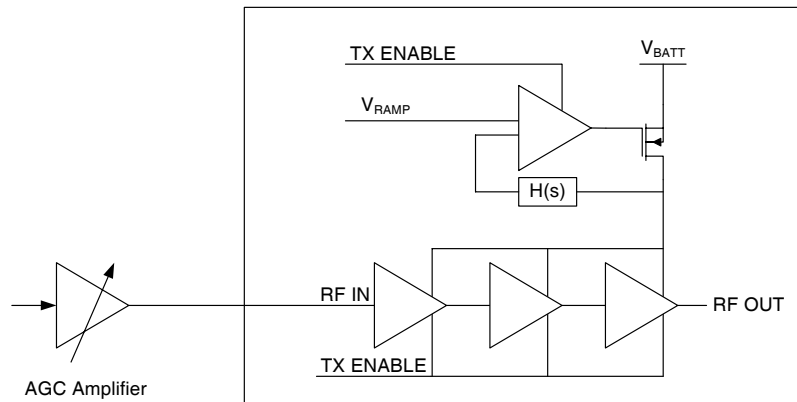

\*Not required in most applications.  
 \*\* Used to filter noise and spurious from baseband.  
 \*\*\* 0.05 dB loss for GSM  
 0.15 dB loss for DCS

## Dual Mode Operation

MODE	RF INPUT	V <sub>RAMP</sub>	TX ENABLE	V <sub>MODE</sub>
GSM	FIXED	Ramp from 0.2V to 1.6V (GSM Burst Ramp Signal)	High (Normal) Low (Isolation)	Low
EDGE	Linear ramp from AGC Amplifier/Source (GSM Burst Ramp Signal)	FIXED	High (Normal) Low (Isolation)	High

## RF3145 Power Amplifier Simplified Block Diagram of a Single Band

## Power On Sequence

## Theory of Operation

### Overview

The RF3145 is a dual-mode, quad-band power amplifier module that is compatible with both GSM and EDGE applications. The device operates in a broad frequency range that includes the GSM850, GSM900, DCS1800, and PCS1900 frequency bands. Integrated band select, mode select, and power control features are also integrated to provide digital control of various features.

Band select provides digital selection of the GSM850/900 or DCS1800/PCS1900 band.  $V_{MODE}$  provides digital control of the gain in the GSM900 band. Due to gain expansion at input powers below the 1dB compression point, low gain mode is provided to maintain the noise power performance in EDGE applications. However, this feature is not required in the DCS1800/PCS1900 bands. Therefore,  $V_{MODE}$  controls only the gain in the GSM850/900 band. (This feature is not provided in the DCS/PCS band.)

The integrated power control feature employs an indirect closed loop method that uses collector control to regulate output power. Collector control design architecture has several advantages, including simplifying the phone design, as well as minimizing gain and linearity variation in EDGE applications. Integrated power control eliminates the need for a complicated control loop design. The indirect closed loop is fully self-contained and does not require loop optimization. It can be driven directly from the DAC output in the baseband circuit.

The RF3145 mode of operation is a function of the input power level and the  $V_{MODE}$  logic level. In GSM applications, the input power is held constant in the range of +2dBm to +5dBm, and the output power is controlled using the  $V_{RAMP}$  input. The required input power for GSM/GPRS applications is typically 3dB to 4dB higher than the 1dB compression point. GSM/GPRS applications use GMSK modulation, which is constant envelope and is not sensitive to amplitude non-linearities. Therefore the power amplifier may be operated in deep class AB which offers high efficiency. However, in EDGE applications, the  $3\pi/8$  rotated 8-PSK constellation shown in Figure 1 contains both phase and amplitude information.

Figure 1. EDGE  $3\pi/8$  Rotated 8-PSK Constellation

Therefore, EDGE applications require a linear power amplifier to transfer EDGE modulation with minimal distortion. Changing  $V_{RAMP}$  in linear applications will cause distortion to the EDGE modulated signal, and is not recommended. If the  $V_{RAMP}$  signal is lowered in EDGE applications, the voltage on the collectors of the power amplifiers will also be lowered (lower than the 1dB compression point). In EDGE applications, the  $V_{RAMP}$  input should be held constant at  $V_{RAMP(MAX)}$ , and the input power is ramped to meet the EDGE burst mask. Typical EDGE systems use a VGA to provide this RF ramp input to the power amplifier.

### Theory of Operation

The indirect closed loop is essentially a closed loop method of power control that is invisible to the user. Most power control systems in GSM sense either forward power or collector/drain current. The RF3145 does not use a power detector. A high-speed control loop is incorporated to regulate the collector voltages of the amplifier while the stages are held at a constant bias. The  $V_{RAMP}$  signal is multiplied and the collector voltages are regulated to the multiplied  $V_{RAMP}$  voltage. The basic circuit is shown in the following diagram.

By regulating the power, the stages are held in saturation across all power levels. As the required output power is decreased from full power down to 0dBm, the collector voltage is also decreased. This regulation of output power is demonstrated in Equation 1 where the relationship between collector voltage and output power is shown. Although load impedance affects output power, supply fluctuations are the dominate mode of power variations. With the RF3145 regulating collector voltage, the dominant mode of power fluctuations is eliminated.

$$P_{dBm} = 10 \cdot \log \left[ \frac{(2 \cdot V_{CC} - V_{SAT})^2}{8 \cdot R_{LOAD} \cdot 10^{-3}} \right] \quad (\text{Eq. 1})$$

There are several key factors to consider in the implementation of a transmitter solution for a mobile phone. Some of them are:

- Effective efficiency ( $\eta_{EFF}$ )
- Current draw and system efficiency
- Power variation due to Supply Voltage
- Power variation due to frequency
- Power variation due to temperature
- Input impedance variation
- Noise power
- Loop stability
- Loop bandwidth variations across power levels
- Burst timing and transient spectrum trade-offs
- Harmonics

Talk time and power management are key concerns in transmitter design since the power amplifier has the highest current draw in a mobile terminal. Considering only the power amplifier's efficiency does not provide a true picture for the total system efficiency. It is important to consider effective efficiency which is represented by  $\eta_{EFF}$ . ( $\eta_{EFF}$  considers the loss between the PA and antenna and is a more accurate measurement to determine how much current will be drawn in the application).  $\eta_{EFF}$  is defined by the following relationship (Equation 2):

$$\eta_{EFF} = \frac{\sum_{n=1}^m P_N - P_{IN}}{P_{DC}} \cdot 100 \quad (\text{Eq. 2})$$

Where  $P_N$  is the sum of all positive and negative RF power,  $P_{IN}$  the input power and  $P_{DC}$  is the delivered DC power. In dB the formula becomes (Equation 3):

$$\eta_{EFF} = \frac{10 \frac{P_{PA} + P_{LOSS}}{10} - 10 \frac{P_{IN}}{10}}{V_{BAT} \cdot I_{BAT} \cdot 10} \tag{Eq. 3}$$

Where  $P_{PA}$  is the output power from the PA,  $P_{LOSS}$  the insertion loss,  $P_{IN}$  the input power to the PA, and  $P_{DC}$  the delivered DC power.

The RF3145 improves the effective efficiency by minimizing the  $P_{LOSS}$  term in the equation. A directional coupler may introduce 0.4dB to 0.5dB loss to the transit path. To demonstrate the improvement in effective efficiency consider the following example:

Conventional PA Solution:

$$\begin{matrix} P_{PA} = +33.5 \text{ dBm} \\ P_{IN} = +3 \text{ dBm} \\ P_{LOSS} = -0.4 \text{ dB} \\ V_{BAT} = 3.5 \text{ V} \\ I_{BAT} = 1.16 \text{ A} \end{matrix} \Rightarrow \eta_{EFF} = 50.3\%$$

RF3145 Solution:

$$\begin{matrix} P_{PA} = +33.5 \text{ dBm} \\ P_{IN} = +3 \text{ dBm} \\ P_{LOSS} = 0 \text{ dB} \\ V_{BAT} = 3.5 \text{ V} \\ I_{BAT} = 1.16 \text{ A} \end{matrix} \Rightarrow \eta_{EFF} = 55.16\%$$

The RF3145 solution improves effective efficiency 5percent.

Output power does not vary due to supply voltage under normal operating conditions if  $V_{RAMP}$  is sufficiently lower than  $V_{BATT}$ . By regulating the collector voltage to the PA, the voltage sensitivity is essentially eliminated. This covers most cases where the PA will be operated. However, as the battery discharges and approaches its lower power range, the maximum output power from the PA will also drop slightly. In this case it is important to also decrease  $V_{RAMP}$  to prevent the power control from inducing switching transients. These transients occur as a result of the control loop slowing down and not regulating power in accordance with  $V_{RAMP}$ .

The switching transients due to low battery conditions are regulated by incorporating the following relationship limiting the maximum  $V_{RAMP}$  voltage (Equation 4). Although no compensation is required for typical battery conditions, the battery compensation required for extreme conditions is covered by the relationship in Equation 4. This should be added to the terminal software.

$$V_{RAMP} \leq \frac{3}{8} \cdot V_{BATT} + 0.18 \tag{Eq. 4}$$

NOTE: Output power is limited by battery voltage. The relationship in Equation 4 does not limit output power. Equation 4 limits the  $V_{RAMP}$  voltage to correspond with the battery voltage.

Due to reactive output matches, there are output power variations across frequency. There are a number of components that can make the effects greater or less.

The components following the power amplifier often have insertion loss variation with respect to frequency. Usually, there is some length of microstrip following the power amplifier. There is also a frequency response found in directional couplers due to variation in the coupling factor over frequency, as well as the sensitivity of the detector diode. Since the RF3145 does not use a directional coupler with a diode detector, these variations do not occur.

Input impedance variation is found in most GSM power amplifiers. This is due to a device phenomena where  $C_{BE}$  and  $C_{CB}$  ( $C_{GS}$  and  $C_{SG}$  for a FET) vary over the bias voltage. The same principle used to make varactors is present in the power amplifiers. The junction capacitance is a function of the bias across the junction. This produces input impedance variations as the  $V_{APC}$  voltage is swept. Although this could present a problem with frequency pulling the transmit  $V_{CO}$  off frequency, most synthesizer designers use very wide loop bandwidths to quickly compensate for frequency variations due to the load variations presented to the  $V_{CO}$ .

The RF3145 presents a very constant load to the  $V_{CO}$ . This is because all stages of the RF3145 are run at constant bias. As a result, there is constant reactance at the base emitter and base collector junction of the input stage to the power amplifier.

Noise power in PA's where output power is controlled by changing the bias voltage is often a problem when backing off of output power. The reason is that the gain is changed in all stages and according to the noise formula (Equation 5),

$$F_{TOT} = F1 + \frac{F2 - 1}{G1} + \frac{F3 - 1}{G1 \cdot G2} \quad (\text{Eq. 5})$$

the noise figure depends on noise factor and gain in all stages. Because the bias point of the RF3145 is kept constant, the gain in the first stage is always high and the overall noise power is not increased when decreasing output power.

Power control loop stability often presents many challenges to transmitter design. Designing a proper power control loop involves trade-offs affecting stability, transient spectrum and burst timing.

In conventional architectures, the PA gain (dB/V) varies across different power levels, and as a result the loop bandwidth also varies. With some power amplifiers it is possible for the PA gain (control slope) to change from 100dB/V to as high as 1000dB/V. The challenge in this scenario is keeping the loop bandwidth wide enough to meet the burst mask at low slope regions which often causes instability at high slope regions.

The RF3145 loop bandwidth is determined by internal bandwidth, and the RF output load and does not change with respect to power levels. This makes it easier to maintain loop stability with a high bandwidth loop since the bias voltage and collector voltage do not vary.

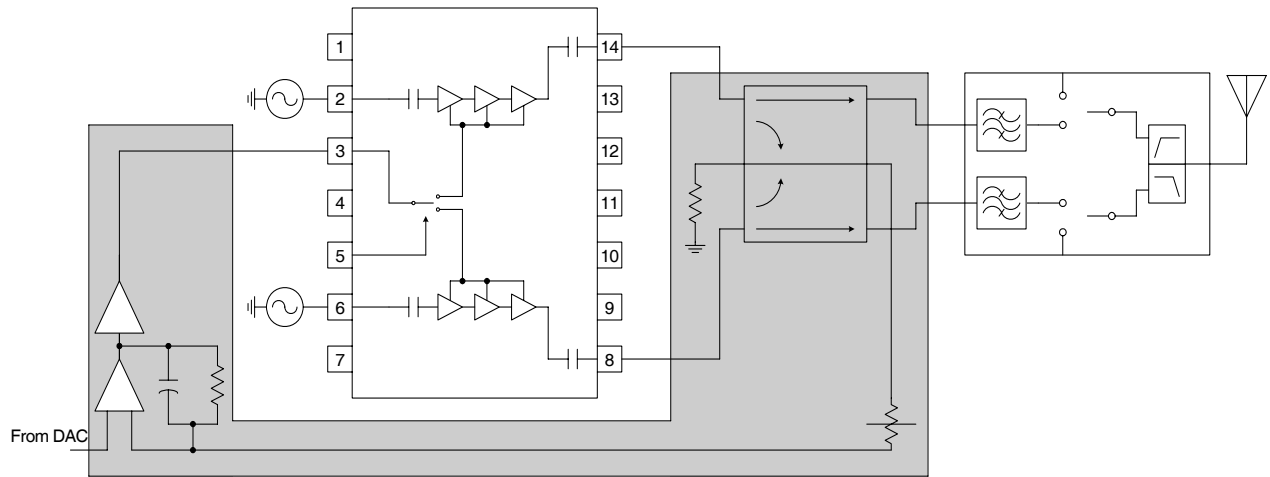

An often overlooked problem in PA control loops is that a delay not only decreases loop stability, it also affects the burst timing (for instance, when the input power from the  $V_{CO}$  decreases (or increases) with respect to temperature or supply voltage). The burst timing then appears to shift to the right, especially at low power levels. The RF3145 is insensitive to a change in input power and the burst timing is constant and requires no software compensation.

Switching transients occur when the up and down ramp of the burst is not smooth enough, or suddenly changes shape. If the control slope of a PA has an inflection point within the output power range, or if the slope is simply too steep, it is difficult to prevent switching transients. Controlling the output power by changing the collector voltage is (as described earlier) based on the physical relationship between voltage swing and output power. Furthermore all stages are kept constantly biased so inflection points are nonexistent.

Harmonics are natural products of high efficiency power amplifier design. An ideal class “E” saturated power amplifier will produce a perfect square wave. Looking at the Fourier transform of a square wave reveals high harmonic content. Although this is common to all power amplifiers, there are other factors that contribute to conducted harmonic content as well. With most power control methods, a peak power diode detector is used to rectify and sense forward power. Through the rectification process, there is additional squaring of the waveform resulting in higher harmonics. The RF3145 addresses this by eliminating the need for the detector diode. Therefore, the harmonics coming out of the PA should represent the maximum power of the harmonics throughout the transmit chain. This is based on proper harmonic termination of the transmit port. The receive port termination on the T/R switch, as well as the harmonic impedance from the switch itself, will have an impact on harmonics. Should a problem arise, these terminations should be explored.

NOTE: Output power is limited by battery voltage. The relationship in Equation 4 does not limit output power. Equation 4 limits  $V_{RAMP}$  to correspond with the battery voltage.

## PCB Design Requirements

### PCB Surface Finish

The PCB surface finish used for RFMD's qualification process is electroless nickel, immersion gold. Typical thickness is 3µinch to 8µinch gold over 180µinch nickel.

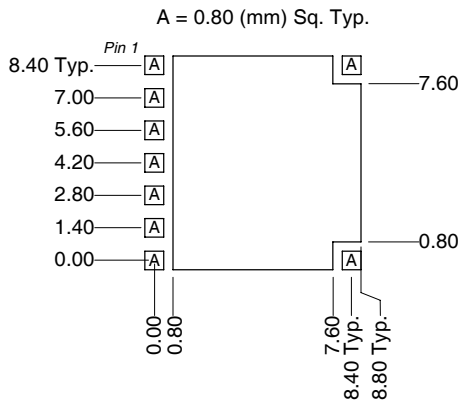

### PCB Land Pattern Recommendation

PCB land patterns are based on IPC-SM-782 standards when possible. The pad pattern shown has been developed and tested for optimized assembly at RFMD; however, it may require some modifications to address company specific assembly processes. The PCB land pattern has been developed to accommodate lead and package tolerances.
